Line 619: `$signed(packed_weight_row[lane*24 +: 24]),` This is continuation line 4 of the 5-line logical statement that begins at source line 616. Its exact fragment is '$signed(packed_weight_row[lane*24 +: 24]),'. The important operands are packed_weight_row: a learned coefficient multiplied by an activation; lane: one parallel arithmetic element within a vector or tensor datapath. Read together, the complete operation is: This condition selects the following hardware branch only when 'errors <= 30) begin $display("ERROR dW tile=%0d row=%0d lane=%0d got=%0d expected=%0d", checked_tiles, row_index, lane, $signed(packed_weight_row[lane*24 +: 24]), expected_weight_gradient[row_index is true. Both branches exist as gates; the condition controls a multiplexer rather than making software jump. The important operands are errors: the value named 'errors' in this block; display: the value named 'display' in this block; ERROR: the value named 'error' in this block. Context: the simulation task run case.

Line 620: `expected_weight_gradient[row_index][lane]);` This is continuation line 5 of the 5-line logical statement that begins at source line 616. Its exact fragment is 'expected_weight_gradient[row_index][lane]);'. The important operands are expected_weight_gradient: a learned coefficient multiplied by an activation; row_index: an integer selecting one tensor element, lane, bank, or state entry; lane: one parallel arithmetic element within a vector or tensor datapath. Read together, the complete operation is: This condition selects the following hardware branch only when 'errors <= 30) begin $display("ERROR dW tile=%0d row=%0d lane=%0d got=%0d expected=%0d", checked_tiles, row_index, lane, $signed(packed_weight_row[lane*24 +: 24]), expected_weight_gradient[row_index][lane]' is true. Both branches exist as gates; the condition controls a multiplexer rather than making software jump. The important operands are errors: the value named 'errors' in this block; display: the value named 'display' in this block; ERROR: the value named 'error' in this block. Context: the simulation task run case.

Line 621: `end` This structural keyword opens or closes the branch/process scope described as the simulation task run case; it has no arithmetic value of its own.

Line 622: `end` This structural keyword opens or closes the branch/process scope described as the simulation task run case; it has no arithmetic value of its own.

Line 623: `end` This structural keyword opens or closes the branch/process scope described as the simulation task run case; it has no arithmetic value of its own.

Line 624: `packed_weight_row = 192'd0;` This makes packed_weight_row, a learned coefficient multiplied by an activation, equal to '192'd0'. It is driven by combinational or procedural logic in the current evaluation. The important operands are d0: the value named 'd0' in this block. Context: the simulation task run case.

Line 625: `end` This structural keyword opens or closes the branch/process scope described as the simulation task run case; it has no arithmetic value of its own.

Line 626: `end` This structural keyword opens or closes the branch/process scope described as the simulation task run case; it has no arithmetic value of its own.

Line 627: `end` This structural keyword opens or closes the branch/process scope described as the simulation task run case; it has no arithmetic value of its own.

Line 629: `timeout = 0;` This makes timeout, the value named 'timeout' in this block, equal to '0'. It is driven by combinational or procedural logic in the current evaluation. The expression is a literal or structural operator and has no hidden software state. Context: the simulation task run case.

Line 630: `while (!done && timeout < 20) begin` Within the simulation task run case, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge linear backward8 RTL block in simulation. The important operands are while: the value named 'while' in this block; done: the value named 'done' in this block; timeout: the value named 'timeout' in this block.

Line 631: `@(negedge clk);` Within the simulation task run case, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge linear backward8 RTL block in simulation. The important operands are negedge: the value named 'negedge' in this block; clk: the clock that makes all registers advance together.

Line 632: `timeout = timeout + 1;` This makes timeout, the value named 'timeout' in this block, equal to 'timeout + 1'. It is driven by combinational or procedural logic in the current evaluation. The important operands are timeout: the value named 'timeout' in this block. Context: the simulation task run case.

Line 633: `end` This structural keyword opens or closes the branch/process scope described as the simulation task run case; it has no arithmetic value of its own.

Line 634: `if (!done) begin` This condition selects the following hardware branch only when '!done' is true. Both branches exist as gates; the condition controls a multiplexer rather than making software jump. The important operands are done: the value named 'done' in this block. Context: the simulation task run case.

Line 635: `errors = errors + 1;` This makes errors, the value named 'errors' in this block, equal to 'errors + 1'. It is driven by combinational or procedural logic in the current evaluation. The important operands are errors: the value named 'errors' in this block. Context: the simulation task run case.

Line 636: `$display("ERROR backward done timeout");` This is a simulation check or diagnostic. It can stop a failing test and print evidence, but it is not part of the synthesized PYNQ circuit.

Line 637: `end` This structural keyword opens or closes the branch/process scope described as the simulation task run case; it has no arithmetic value of its own.

Line 638: `if (config_error !== malformed_tlast) begin` This condition selects the following hardware branch only when ‘config_error !== malformed_tlast‘ is true. Both branches exist as gates; the condition controls a multiplexer rather than making software jump. The important operands are config_error: the value named ’config error’ in this block; malformed_tlast: the AXI-Stream marker for the final beat of a packet or command payload. Context: the simulation task run case.

Line 639: `errors = errors + 1;` This makes errors, the value named ’errors’ in this block, equal to ‘errors + 1‘. It is driven by combinational or procedural logic in the current evaluation. The important operands are errors: the value named ’errors’ in this block. Context: the simulation task run case.

Line 640: `$display("ERROR backward config_error tile=%0d got=%0b expected=%0b",` This is a simulation check or diagnostic. It can stop a failing test and print evidence, but it is not part of the synthesized PYNQ circuit.

Line 641: `checked_tiles, config_error, malformed_tlast);` Within the simulation task run case, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge linear backward8 RTL block in simulation. The important operands are checked_tiles: the value named ’checked tiles’ in this block; config_error: the value named ’config error’ in this block; malformed_tlast: the AXI-Stream marker for the final beat of a packet or command payload.

Line 642: `end` This structural keyword opens or closes the branch/process scope described as the simulation task run case; it has no arithmetic value of its own.

Line 643: `checked_tiles = checked_tiles + 1;` This makes checked_tiles, the value named ’checked tiles’ in this block, equal to ‘checked_tiles + 1‘. It is driven by combinational or procedural logic in the current evaluation. The important operands are checked_tiles: the value named ’checked tiles’ in this block. Context: the simulation task run case.

Line 644: `@(posedge clk);` Within the simulation task run case, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge linear backward8 RTL block in simulation. The important operands are posedge: the value named ’posedge’ in this block; clk: the clock that makes all registers advance together.

Line 645: `@(negedge clk);` Within the simulation task run case, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge linear backward8 RTL block in simulation. The important operands are negedge: the value named ’negedge’ in this block; clk: the clock that makes all registers advance together.

Line 646: `end` This structural keyword opens or closes the branch/process scope described as the simulation task run case; it has no arithmetic value of its own.

Line 647: `endtask` Within the simulation task run case, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge linear backward8 RTL block in simulation. The important operands are endtask: the value named ’endtask’ in this block.

Line 649: `initial begin` This opens simulation initialization. In a testbench it drives starting values and stimulus; project synthesis does not rely on this block as a replacement for explicit reset behavior.

Line 650: `integer case_index;` This declares hardware signal storage or wiring in the module’s structural declarations. Specifically, case_index is an integer selecting one tensor element, lane, bank, or state entry. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 651: `integer rows;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, rows is one output-row position processed by the tensor tile. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 652: `integer inputs;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, inputs is the value named 'inputs' in this block. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 653: `integer outputs;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, outputs is the value named 'outputs' in this block. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 654: `integer dx_shift;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, dx_shift is the value named 'dx shift' in this block. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 655: `integer dw_shift;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, dw_shift is the value named 'dw shift' in this block. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 657: `seed = 32'h17bacc8d;` This makes seed, the value named 'seed' in this block, equal to '32'h17bacc8d'. It is driven by combinational or procedural logic in the current evaluation. The important operands are h17bacc8d: the value named 'h17bacc8d' in this block. Context: the module's structural declarations.

Line 658: `seed = $urandom(seed);` This makes seed, the value named 'seed' in this block, equal to '$urandom(seed)'. It is driven by combinational or procedural logic in the current evaluation. The important operands are urandom: the value named 'urandom' in this block; seed: the value named 'seed' in this block. Context: the module's structural declarations.

Line 659: `repeat (5) @(negedge clk);` Within the module's structural declarations, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge linear backward8 RTL block in simulation. The important operands are repeat: the value named 'repeat' in this block; negedge: the value named 'negedge' in this block; clk: the clock that makes all registers advance together.

Line 660: `rst_n = 1'b1;` This makes rst_n, the active-low synchronous reset, equal to '1'b1'. It is driven by combinational or procedural logic in the current evaluation. The important operands are b1: the value named 'b1' in this block. Context: the module's structural declarations.

Line 662: `run_case(8, 8, 8, 1, 0, 0, 1'b0);` Within the module's structural declarations, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge linear backward8 RTL block in simulation. The important operands are run_case: the value named 'run case' in this block; b0: the value named 'b0' in this block.

Line 663: `run_case(8, 8, 8, 2, 0, 0, 1'b0);` Within the module's structural declarations, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge linear backward8 RTL block in simulation. The important operands are run_case: the value named 'run case' in this block; b0: the value named 'b0' in this block.

Line 664: `run_case(8, 8, 8, 3, 3, 2, 1'b0);` Within the module's structural declarations, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge linear backward8 RTL block in simulation. The important operands are run_case: the value named 'run case' in this block; b0: the value named 'b0' in this block.

Line 665: `run_case(1, 1, 1, 0, 5, 7, 1'b0);` Within the module's structural declarations, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge linear backward8 RTL block in simulation. The important operands are run_case: the value named 'run case' in this block; b0: the value named 'b0' in this block.

Line 666: `for (case_index = 0; case_index < RANDOM_CASES; case_index = case_index + 1) begin` This generate/procedural loop repeats the following operation across lanes or entries. In synthesizable RTL, a fixed loop is expanded into parallel or scheduled hardware rather than executed by a CPU. Context: the module's structural declarations.

Line 667: `rows = $urandom_range(8, 1);` This makes rows, one output-row position processed by the tensor tile, equal to '$urandom_range(8, 1)'. It is driven by combinational or procedural logic in the current evaluation. The important operands are urandom_range: the value named 'urandom range' in this block. Context: the module's structural declarations.

Line 668: `inputs = $urandom_range(8, 1);` This makes inputs, the value named 'inputs' in this block, equal to '$urandom_range(8, 1)'. It is driven by combinational or procedural logic in the current evaluation. The important operands are urandom_range: the value named 'urandom range' in this block. Context: the module's structural declarations.

Line 669: `outputs = $urandom_range(8, 1);` This makes outputs, the value named 'outputs' in this block, equal to '$urandom_range(8, 1)'. It is driven by combinational or procedural logic in the current evaluation. The important operands are urandom_range: the value named 'urandom range' in this block. Context: the module's structural declarations.

Line 670: `dx_shift = $urandom_range(12, 0);` This makes dx_shift, the value named 'dx shift' in this block, equal to '$urandom_range(12, 0)'. It is driven by combinational or procedural logic in the current evaluation. The important operands are urandom_range: the value named 'urandom range' in this block. Context: the module's structural declarations.

Line 671: `dw_shift = $urandom_range(12, 0);` This makes dw_shift, the value named 'dw shift' in this block, equal to '$urandom_range(12, 0)'. It is driven by combinational or procedural logic in the current evaluation. The important operands are urandom_range: the value named 'urandom range' in this block. Context: the module's structural declarations.

Line 672: `run_case(rows, inputs, outputs, 0, dx_shift, dw_shift, 1'b0);` Within the module's structural declarations, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge linear backward8 RTL block in simulation. The important operands are run_case: the value named 'run case' in this block; rows: one output-row position processed by the tensor tile; inputs: the value named 'inputs' in this block.

Line 673: `end` This structural keyword opens or closes the branch/process scope described as the module's structural declarations; it has no arithmetic value of its own.

Line 675: `// A premature TLAST must be reported while arithmetic remains exact.` Design intent: A premature TLAST must be reported while arithmetic remains exact. This comment anchors the surrounding logic in the block that drives, backpressures, and checks the neuraedge linear backward8 RTL block in simulation.

Line 676: `run_case(3, 5, 7, 0, 4, 3, 1'b1);` Within the module's structural declarations, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge linear backward8 RTL block in simulation. The important operands are run_case: the value named 'run case' in this block; b1: the value named 'b1' in this block.

Line 678: `run_exact_accumulation_modes();` Within the module's structural declarations, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge linear backward8 RTL block in simulation. The important operands are run_exact_accumulation_modes: the value named 'run exact accumulation modes' in this block.

Line 680: `// Invalid dimensions and nonzero reserved bits complete without data.` Design intent: Invalid dimensions and nonzero reserved bits complete without data. This comment anchors the surrounding logic in the block that drives, backpressures, and checks the neuraedge linear backward8 RTL block in simulation.

Line 681: `start_tile(0, 1, 1, 0, 0, 1'b0);` Within the module's structural declarations, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge linear backward8 RTL block in simulation. The important operands are start_tile: the value named 'start tile' in this block; b0: the value named 'b0' in this block.

Line 682: `while (!done) @(negedge clk);` Within the module's structural declarations, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge linear backward8 RTL block in simulation. The important operands are while: the value named 'while' in this block; done: the value named 'done' in this block; negedge: the value named 'negedge' in this block.

Line 683: `if (!config_error) begin` This condition selects the following hardware branch only when '!config_error' is true. Both branches exist as gates; the condition controls a multiplexer rather than making software jump. The important operands are config_error: the value named 'config error' in this block. Context: the module's structural declarations.

Line 684: `errors = errors + 1;` This makes errors, the value named 'errors' in this block, equal to 'errors + 1'. It is driven by combinational or procedural logic in the current evaluation. The important operands are errors: the value named 'errors' in this block. Context: the module's structural declarations.

Line 685: `$display("ERROR backward accepted zero rows");` This is a simulation check or diagnostic. It can stop a failing test and print evidence, but it is not part of the synthesized PYNQ circuit.

Line 686: `end` This structural keyword opens or closes the branch/process scope described as the module's structural declarations; it has no arithmetic value of its own.

Line 687: `@(posedge clk);` Within the module's structural declarations, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge linear backward8 RTL block in simulation. The important operands are posedge: the value named 'posedge' in this block; clk: the clock that makes all registers advance together.

Line 688: `@(negedge clk);` Within the module's structural declarations, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge linear backward8 RTL block in simulation. The important operands are negedge: the value named 'negedge' in this block; clk: the clock that makes all registers advance together.

Line 689: `start_tile(1, 1, 1, 0, 0, 1'b1);` Within the module's structural declarations, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge linear backward8 RTL block in simulation. The important operands are start_tile: the value named 'start tile' in this block; b1: the value named 'b1' in this block.

Line 690: `while (!done) @(negedge clk);` Within the module's structural declarations, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge linear backward8 RTL block in simulation. The important operands are while: the value named 'while' in this block; done: the value named 'done' in this block; negedge: the value named 'negedge' in this block.

Line 691: `if (!config_error) begin` This condition selects the following hardware branch only when '!config_error' is true. Both branches exist as gates; the condition controls a multiplexer rather than making software jump. The important operands are config_error: the value named 'config error' in this block. Context: the module's structural declarations.

Line 692: `errors = errors + 1;` This makes errors, the value named 'errors' in this block, equal to 'errors + 1'. It is driven by combinational or procedural logic in the current evaluation. The important operands are errors: the value named 'errors' in this block. Context: the module's structural declarations.

Line 693: `$display("ERROR backward accepted reserved command bits");` This is a simulation check or diagnostic. It can stop a failing test and print evidence, but it is not part of the synthesized PYNQ circuit.

Line 694: `end` This structural keyword opens or closes the branch/process scope described as the module's structural declarations; it has no arithmetic value of its own.

Line 695: `@(posedge clk);` Within the module's structural declarations, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge linear backward8 RTL block in simulation. The important operands are posedge: the value named 'posedge' in this block; clk: the clock that makes all registers advance together.

Line 696: `@(negedge clk);` Within the module's structural declarations, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge linear backward8 RTL block in simulation. The important operands are negedge: the value named 'negedge' in this block; clk: the clock that makes all registers advance together.

Line 698: `if (completed_tiles != checked_tiles || active_cycles == 0) begin` This condition selects the following hardware branch only when 'completed_tiles != checked_tiles || active_cycles == 0' is true. Both branches exist as gates; the condition controls a multiplexer rather than making software jump. The important operands are completed_tiles: the value named 'completed tiles' in this block; checked_tiles: the value named 'checked tiles' in this block; active_cycles: the value named 'active cycles' in this block. Context: the module's structural declarations.

Line 699: `errors = errors + 1;` This makes errors, the value named 'errors' in this block, equal to 'errors + 1'. It is driven by combinational or procedural logic in the current evaluation. The important operands are errors: the value named 'errors' in this block. Context: the module's structural declarations.

Line 700: `$display("ERROR backward counters tiles=%0d/%0d cycles=%0d",` This is a simulation check or diagnostic. It can stop a failing test and print evidence, but it is not part of the synthesized PYNQ circuit.

Line 701: `completed_tiles, checked_tiles, active_cycles);` Within the module's structural declarations, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge linear backward8 RTL block in simulation. The important operands are completed_tiles: the value named 'completed tiles' in this block; checked_tiles: the value named 'checked tiles' in this block; active_cycles: the value named 'active cycles' in this block.

Line 702: `end` This structural keyword opens or closes the branch/process scope described as the module's structural declarations; it has no arithmetic value of its own.

Line 703: `clear_counters = 1'b1;` This makes clear_counters, a hardware telemetry register that accumulates measured events, equal to '1'b1'. It is driven by combinational or procedural logic in the current evaluation. The important operands are b1: the value named 'b1' in this block. Context: the module's structural declarations.

Line 704: `@(posedge clk);` Within the module's structural declarations, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge linear backward8 RTL block in simulation. The important operands are posedge: the value named 'posedge' in this block; clk: the clock that makes all registers advance together.

Line 705: `@(negedge clk);` Within the module's structural declarations, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge linear backward8 RTL block in simulation. The important operands are negedge: the value named 'negedge' in this block; clk: the clock that makes all registers advance together.

Line 706: `clear_counters = 1'b0;` This makes clear_counters, a hardware telemetry register that accumulates measured events, equal to '1'b0'. It is driven by combinational or procedural logic in the current evaluation. The important operands are b0: the value named 'b0' in this block. Context: the module's structural declarations.

Line 707: `if (completed_tiles != 0 || active_cycles != 0) begin` This condition selects the following hardware branch only when 'completed_tiles != 0 || active_cycles != 0' is true. Both branches exist as gates; the condition controls a multiplexer rather than making software jump. The important operands are completed_tiles: the value named 'completed tiles' in this block; active_cycles: the value named 'active cycles' in this block. Context: the module's structural declarations.

Line 708: `errors = errors + 1;` This makes errors, the value named 'errors' in this block, equal to 'errors + 1'. It is driven by combinational or procedural logic in the current evaluation. The important operands are errors: the value named 'errors' in this block. Context: the module's structural declarations.

Line 709: `$display("ERROR backward counters did not clear");` This is a simulation check or diagnostic. It can stop a failing test and print evidence, but it is not part of the synthesized PYNQ circuit.

Line 710: `end` This structural keyword opens or closes the branch/process scope described as the module's structural declarations; it has no arithmetic value of its own.

Line 712: `if (errors != 0) begin` This condition selects the following hardware branch only when 'errors != 0' is true. Both branches exist as gates; the condition controls a multiplexer rather than making software jump. The important operands are errors: the value named 'errors' in this block. Context: the module's structural declarations.

Line 713: `$display("tb_neuraedge_linear_backward8 FAILED errors=%0d tiles=%0d",` This is a simulation check or diagnostic. It can stop a failing test and print evidence, but it is not part of the synthesized PYNQ circuit.

Line 714: `errors, checked_tiles);` Within the module's structural declarations, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge linear backward8 RTL block in simulation. The important operands are errors: the value named 'errors' in this block; checked_tiles: the value named 'checked tiles' in this block.

Line 715: `$finish;` This is a simulation check or diagnostic. It can stop a failing test and print evidence, but it is not part of the synthesized PYNQ circuit.

Line 716: `end` This structural keyword opens or closes the branch/process scope described as the module's structural declarations; it has no arithmetic value of its own.

Line 717: `$display("tb_neuraedge_linear_backward8 PASSED tiles=%0d random=%0d",` This is a simulation check or diagnostic. It can stop a failing test and print evidence, but it is not part of the synthesized PYNQ circuit.

Line 718: `checked_tiles, RANDOM_CASES);` Within the module's structural declarations, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge linear backward8 RTL block in simulation. The important operands are checked_tiles: the value named 'checked tiles' in this block; RANDOM_CASES: the value named 'random cases' in this block.

Line 719: `$finish;` This is a simulation check or diagnostic. It can stop a failing test and print evidence, but it is not part of the synthesized PYNQ circuit.

Line 720: `end` This structural keyword opens or closes the branch/process scope described as the module's structural declarations; it has no arithmetic value of its own.

Line 722: `initial begin` This opens simulation initialization. In a testbench it drives starting values and stimulus; project synthesis does not rely on this block as a replacement for explicit reset behavior.

Line 723: `#10_000_000;` Within the module's structural declarations, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge linear backward8 RTL block in simulation. The expression is a literal or structural operator and has no hidden software state.

Line 724: `$fatal(1, "tb_neuraedge_linear_backward8 watchdog timeout state=%0d", dut.state);` This is a simulation check or diagnostic. It can stop a failing test and print evidence, but it is not part of the synthesized PYNQ circuit.

Line 725: `end` This structural keyword opens or closes the branch/process scope described as the module's structural declarations; it has no arithmetic value of its own.

Line 726: `endmodule` This closes the current hardware definition; no circuit behavior is attached to the keyword itself.

Line 728: `` `default_nettype wire `` This SystemVerilog preprocessor line controls compilation of the block that drives, backpressures, and checks the neuraedge linear backward8 RTL block in simulation.

53 tb/tb_neuraedge_mac2_u8.sv

Role in the complete system: drives, backpressures, and checks the neuraedge mac2 u8 RTL block in simulation.

53.1 Beginner architecture map

Dataflow responsibility This file's end-to-end responsibility is to drives, backpressures, and checks the neuraedge mac2 u8 RTL block in simulation.

Simulation-only status tb_neuraedge_mac2_u8 is not synthesized into the FPGA. It generates clocks, reset, commands, stalls, and expected values around the design under test, then terminates with an explicit result marker.

Evidence produced The file contains approximately 4 explicit assertions, failure diagnostics, or pass/fail markers. Its VCD/WDB trace is useful evidence only when the final pass marker is present; a simulator exit code by itself is insufficient.

```

53.3 Line annotations

Line 1: `` `timescale 1ns / 1ps `` This simulation directive selects nanoseconds as the time unit and picoseconds as the timestamp precision; it does not create FPGA logic.

Line 2: `` `default_nettype none `` This compiler directive forbids accidental implicit one-bit wires, turning misspelled signal names into errors instead of unintended hardware.

Line 4: `module tb_neuraedge_mac2_u8;` This opens tb_neuraedge_mac2_u8;, an independently compiled hardware definition. Its ports and statements collectively describe circuitry that drives, backpressures, and checks the neuraedge mac2 u8 RTL block in simulation.

Line 5: `logic clk;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, clk is the clock that makes all registers advance together. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 6: `logic rst_n = 1'b0;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, rst_n is the active-low synchronous reset. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 7: `logic enable = 1'b0;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, enable is the value named 'enable' in this block. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 8: `logic [7:0] activation = '0;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, activation is an input feature value consumed by a neuron or multiply-accumulate operation. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 9: `logic [7:0] weight_lo = '0;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, weight_lo is a learned coefficient multiplied by an activation. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 10: `logic [7:0] weight_hi = '0;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, weight_hi is a learned coefficient multiplied by an activation. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 11: `logic product_valid;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, product_valid is the producer's statement that its current payload is meaningful. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 12: `logic [15:0] product_lo;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, product_lo is the value named 'product lo' in this block. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 13: `logic [15:0] product_hi;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, product_hi is the value named 'product hi' in this block. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 15: `int errors = 0;` Within the module's structural declarations, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge mac2 u8 RTL block in simulation. The important operands are errors: the value named 'errors' in this block.

Line 16: `int checks = 0;` Within the module's structural declarations, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge mac2 u8 RTL block in simulation. The important operands are checks: the value named 'checks' in this block.

Line 18: `neuraedge_mac2_u8 dut (` This instantiates module neuraedge_mac2_u8 as dut. Synthesis creates that subordinate circuit and connects its ports in the lines that follow.

Line 19: `.clk(clk),` This connects the child instance's named port 'clk' to parent expression 'clk'. The connection is a physical net bundle after synthesis; direction is declared in the child module, and the clock that makes all registers advance together.

Line 20: `.rst_n(rst_n),` This connects the child instance's named port 'rst_n' to parent expression 'rst_n'. The connection is a physical net bundle after synthesis; direction is declared in the child module, and the active-low synchronous reset.

Line 21: `.enable(enable),` This connects the child instance's named port 'enable' to parent expression 'enable'. The connection is a physical net bundle after synthesis; direction is declared in the child module, and the value named 'enable' in this block.

Line 22: `.activation(activation),` This connects the child instance's named port 'activation' to parent expression 'activation'. The connection is a physical net bundle after synthesis; direction is declared in the child module, and an input feature value consumed by a neuron or multiply-accumulate operation.

Line 23: `.weight_lo(weight_lo),` This connects the child instance's named port 'weight_lo' to parent expression 'weight_lo'. The connection is a physical net bundle after synthesis; direction is declared in the child module, and a learned coefficient multiplied by an activation.

Line 24: `.weight_hi(weight_hi),` This connects the child instance's named port 'weight_hi' to parent expression 'weight_hi'. The connection is a physical net bundle after synthesis; direction is declared in the child module, and a learned coefficient multiplied by an activation.

Line 25: `.product_valid(product_valid),` This connects the child instance's named port 'product_valid' to parent expression 'product_valid'. The connection is a physical net bundle after synthesis; direction is declared in the child module, and the producer's statement that its current payload is meaningful.

Line 26: `.product_lo(product_lo),` This connects the child instance's named port 'product_lo' to parent expression 'product_lo'. The connection is a physical net bundle after synthesis; direction is declared in the child module, and the value named 'product lo' in this block.

Line 27: `.product_hi(product_hi)` This connects the child instance's named port 'product_hi' to parent expression 'product_hi'. The connection is a physical net bundle after synthesis; direction is declared in the child module, and the value named 'product hi' in this block.

Line 28: `);` Within the module's structural declarations, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge mac2 u8 RTL block in simulation. The expression is a literal or structural operator and has no hidden software state.

Line 30: `initial clk = 1'b0;` This opens simulation initialization. In a testbench it drives starting values and stimulus; project synthesis does not rely on this block as a replacement for explicit reset behavior.

Line 31: `always #5 clk = ~clk;` Within the module's structural declarations, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge mac2 u8 RTL block in simulation. The important operands are always: the value named 'always' in this block; clk: the clock that makes all registers advance together.

Line 33: `task automatic apply_and_check(` Within the simulation task apply and check, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge mac2 u8 RTL block in simulation. The important operands are task: the value named 'task' in this block; automatic: the value named 'automatic' in this block; apply_and_check: the value named 'apply and check' in this block.

Line 34: `input logic [7:0] a,` This declares a as a input port with width [7:0]. It carries the value named 'a' in this block across the module boundary; a port is a bundle of physical FPGA nets, not a software argument.

Line 35: `input logic [7:0] w0,` This declares w0 as a input port with width [7:0]. It carries the value named 'w0' in this block across the module boundary; a port is a bundle of physical FPGA nets, not a software argument.

Line 36: `input logic [7:0] w1` This declares w1 as a input port with width [7:0]. It carries the value named 'w1' in this block across the module boundary; a port is a bundle of physical FPGA nets, not a software argument.

Line 37: `);` Within the simulation task apply and check, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge mac2 u8 RTL block in simulation. The expression is a literal or structural operator and has no hidden software state.

Line 38: `logic [15:0] expected_lo;` This declares hardware signal storage or wiring in the simulation task apply and check. Specifically, expected_lo is the value named 'expected lo' in this block. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 39: `logic [15:0] expected_hi;` This declares hardware signal storage or wiring in the simulation task apply and check. Specifically, expected_hi is the value named 'expected hi' in this block. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 40: `begin` This structural keyword opens or closes the branch/process scope described as the simulation task apply and check; it has no arithmetic value of its own.

Line 41: `expected_lo = a * w0;` This makes expected_lo, the value named 'expected lo' in this block, equal to 'a * w0'. It is driven by combinational or procedural logic in the current evaluation. The important operands are a: the value named 'a' in this block; w0: the value named 'w0' in this block. Context: the simulation task apply and check.

Line 42: `expected_hi = a * w1;` This makes expected_hi, the value named 'expected hi' in this block, equal to 'a * w1'. It is driven by combinational or procedural logic in the current evaluation. The important operands are a: the value named 'a' in this block; w1: the value named 'w1' in this block. Context: the simulation task apply and check.

Line 43: `@(negedge clk);` Within the simulation task apply and check, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge mac2 u8 RTL block in simulation. The important operands are negedge: the value named 'negedge' in this block; clk: the clock that makes all registers advance together.

Line 44: `enable = 1'b1;` This makes enable, the value named 'enable' in this block, equal to '1'b1'. It is driven by combinational or procedural logic in the current evaluation. The important operands are b1: the value named 'b1' in this block. Context: the simulation task apply and check.

Line 45: `activation = a;` This makes activation, an input feature value consumed by a neuron or multiply-accumulate operation, equal to 'a'. It is driven by combinational or procedural logic in the current evaluation. The important operands are a: the value named 'a' in this block. Context: the simulation task apply and check.

Line 46: `weight_lo = w0;` This makes weight_lo, a learned coefficient multiplied by an activation, equal to 'w0'. It is driven by combinational or procedural logic in the current evaluation. The important operands are w0: the value named 'w0' in this block. Context: the simulation task apply and check.

Line 47: `weight_hi = w1;` This makes weight_hi, a learned coefficient multiplied by an activation, equal to 'w1'. It is driven by combinational or procedural logic in the current evaluation. The important operands are w1: the value named 'w1' in this block. Context: the simulation task apply and check.

Line 48: `@(posedge clk);` Within the simulation task apply and check, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge mac2 u8 RTL block in simulation. The important operands are posedge: the value named 'posedge' in this block; clk: the clock that makes all registers advance together.

Line 49: `@(posedge clk);` Within the simulation task apply and check, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge mac2 u8 RTL block in simulation. The important operands are posedge: the value named 'posedge' in this block; clk: the clock that makes all registers advance together.

Line 50: `@(posedge clk);` Within the simulation task apply and check, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge mac2 u8 RTL block in simulation. The important operands are posedge: the value named 'posedge' in this block; clk: the clock that makes all registers advance together.

Line 51: `#1;` Within the simulation task apply and check, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge mac2 u8 RTL block in simulation. The expression is a literal or structural operator and has no hidden software state.

Line 52: `checks++;` Within the simulation task apply and check, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge mac2 u8 RTL block in simulation. The important operands are checks: the value named 'checks' in this block.

Line 53: `if (!product_valid || product_lo !== expected_lo || product_hi !== expected_hi) begin` This condition selects the following hardware branch only when ‘!product_valid || product_lo !== expected_lo || product_hi !== expected_hi‘ is true. Both branches exist as gates; the condition controls a multiplexer rather than making software jump. The important operands are product_valid: the producer’s statement that its current payload is meaningful; product_lo: the value named ’product lo’ in this block; expected_lo: the value named ’expected lo’ in this block. Context: the simulation task apply and check.

Line 54: `errors++;` Within the simulation task apply and check, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge mac2 u8 RTL block in simulation. The important operands are errors: the value named ’errors’ in this block.

Line 55: `if (errors <= 20) begin` This statement continues through source line 57; the explanation uses the complete expression rather than only the first visual fragment. This condition selects the following hardware branch only when ‘errors <= 20) begin $display("ERROR a=%0d w0=%0d w1=%0d got=(%0d,%0d) expected=(%0d,%0d)", a, w0, w1, product_lo, product_hi, expected_lo, expected_hi‘ is true. Both branches exist as gates; the condition controls a multiplexer rather than making software jump. The important operands are errors: the value named ’errors’ in this block; display: the value named ’display’ in this block; ERROR: the value named ’error’ in this block. Context: the simulation task apply and check.

Line 56: `$display("ERROR a=%0d w0=%0d w1=%0d got=(%0d,%0d) expected=(%0d,%0d)",` This is continuation line 2 of the 3-line logical statement that begins at source line 55. Its exact fragment is ‘$display("ERROR a=%0d w0=%0d w1=%0d got=(%0d,%0d) expected=(%0d,%0d)",‘. The important operands are display: the value named ’display’ in this block; ERROR: the value named ’error’ in this block; a: the value named ’a’ in this block. Read together, the complete operation is: This condition selects the following hardware branch only when ‘errors <= 20) begin $display("ERROR a=%0d w0=%0d w1=%0d got=(%0d,%0d) expected=(%0d,%0d)", a, w0, w1, product_lo, product_hi, expected_lo, expected_hi‘ is true. Both branches exist as gates; the condition controls a multiplexer rather than making software jump. The important operands are errors: the value named ’errors’ in this block; display: the value named ’display’ in this block; ERROR: the value named ’error’ in this block. Context: the simulation task apply and check.

Line 57: `a, w0, w1, product_lo, product_hi, expected_lo, expected_hi);` This is continuation line 3 of the 3-line logical statement that begins at source line 55. Its exact fragment is ‘a, w0, w1, product_lo, product_hi, expected_lo, expected_hi);‘. The important operands are a: the value named ’a’ in this block; w0: the value named ’w0’ in this block; w1: the value named ’w1’ in this block. Read together, the complete operation is: This condition selects the following hardware branch only when ‘errors <= 20) begin $display("ERROR a=%0d w0=%0d w1=%0d got=(%0d,%0d) expected=(%0d,%0d)", a, w0, w1, product_lo, product_hi, expected_lo, expected_hi‘ is true. Both branches exist as gates; the condition controls a multiplexer rather than making software jump. The important operands are errors: the value named ’errors’ in this block; display: the value named ’display’ in this block; ERROR: the value named ’error’ in this block. Context: the simulation task apply and check.

Line 58: `end` This structural keyword opens or closes the branch/process scope described as the simulation task apply and check; it has no arithmetic value of its own.

Line 59: `end` This structural keyword opens or closes the branch/process scope described as the simulation task apply and check; it has no arithmetic value of its own.

Line 60: `end` This structural keyword opens or closes the branch/process scope described as the simulation task apply and check; it has no arithmetic value of its own.

Line 61: `endtask` Within the simulation task apply and check, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge mac2 u8 RTL block in simulation. The important operands are endtask: the value named ’endtask’ in this block.

Line 63: `initial begin` This opens simulation initialization. In a testbench it drives starting values and stimulus; project synthesis does not rely on this block as a replacement for explicit reset behavior.

Line 64: `repeat (3) @(negedge clk);` Within the module's structural declarations, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge mac2 u8 RTL block in simulation. The important operands are repeat: the value named 'repeat' in this block; negedge: the value named 'negedge' in this block; clk: the clock that makes all registers advance together.

Line 65: `rst_n = 1'b1;` This makes rst_n, the active-low synchronous reset, equal to '1'b1'. It is driven by combinational or procedural logic in the current evaluation. The important operands are b1: the value named 'b1' in this block. Context: the module's structural declarations.

Line 67: `// Exhaust every activation/low-weight combination while sweeping the` Design intent: Exhaust every activation/low-weight combination while sweeping the This comment anchors the surrounding logic in the block that drives, backpressures, and checks the neuraedge mac2 u8 RTL block in simulation.

Line 68: `// upper field through a deterministic permutation of all byte values.` Design intent: upper field through a deterministic permutation of all byte values. This comment anchors the surrounding logic in the block that drives, backpressures, and checks the neuraedge mac2 u8 RTL block in simulation.

Line 69: `for (int a = 0; a < 256; a++) begin` This generate/procedural loop repeats the following operation across lanes or entries. In synthesizable RTL, a fixed loop is expanded into parallel or scheduled hardware rather than executed by a CPU. Context: the module's structural declarations.

Line 70: `for (int w0 = 0; w0 < 256; w0++) begin` This generate/procedural loop repeats the following operation across lanes or entries. In synthesizable RTL, a fixed loop is expanded into parallel or scheduled hardware rather than executed by a CPU. Context: the module's structural declarations.

Line 71: `apply_and_check(8'(a), 8'(w0), 8'((w0 * 73 + a * 29 + 17) & 255));` Within the module's structural declarations, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge mac2 u8 RTL block in simulation. The important operands are apply_and_check: the value named 'apply and check' in this block; a: the value named 'a' in this block; w0: the value named 'w0' in this block.

Line 72: `end` This structural keyword opens or closes the branch/process scope described as the module's structural declarations; it has no arithmetic value of its own.

Line 73: `end` This structural keyword opens or closes the branch/process scope described as the module's structural declarations; it has no arithmetic value of its own.

Line 75: `// Exhaust every activation/high-weight combination independently.` Design intent: Exhaust every activation/high-weight combination independently. This comment anchors the surrounding logic in the block that drives, backpressures, and checks the neuraedge mac2 u8 RTL block in simulation.

Line 76: `for (int a = 0; a < 256; a++) begin` This generate/procedural loop repeats the following operation across lanes or entries. In synthesizable RTL, a fixed loop is expanded into parallel or scheduled hardware rather than executed by a CPU. Context: the module's structural declarations.

Line 77: `for (int w1 = 0; w1 < 256; w1++) begin` This generate/procedural loop repeats the following operation across lanes or entries. In synthesizable RTL, a fixed loop is expanded into parallel or scheduled hardware rather than executed by a CPU. Context: the module's structural declarations.

Line 78: `apply_and_check(8'(a), 8'((w1 * 151 + a * 11 + 3) & 255), 8'(w1));` Within the module's structural declarations, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge mac2 u8 RTL block in simulation. The important operands are apply_and_check: the value named 'apply and check' in this block; a: the value named 'a' in this block; w1: the value named 'w1' in this block.

Line 79: `end` This structural keyword opens or closes the branch/process scope described as the module's structural declarations; it has no arithmetic value of its own.

Line 80: `end` This structural keyword opens or closes the branch/process scope described as the module's structural declarations; it has no arithmetic value of its own.

Line 82: `@(negedge clk);` Within the module's structural declarations, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge mac2 u8 RTL block in simulation. The important operands are negedge: the value named 'negedge' in this block; clk: the clock that makes all registers advance together.

Line 83: `enable = 1'b0;` This makes enable, the value named 'enable' in this block, equal to '1'b0'. It is driven by combinational or procedural logic in the current evaluation. The important operands are b0: the value named 'b0' in this block. Context: the module's structural declarations.

Line 84: `@(posedge clk);` Within the module's structural declarations, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge mac2 u8 RTL block in simulation. The important operands are posedge: the value named 'posedge' in this block; clk: the clock that makes all registers advance together.

Line 85: `@(posedge clk);` Within the module's structural declarations, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge mac2 u8 RTL block in simulation. The important operands are posedge: the value named 'posedge' in this block; clk: the clock that makes all registers advance together.

Line 86: `@(posedge clk);` Within the module's structural declarations, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge mac2 u8 RTL block in simulation. The important operands are posedge: the value named 'posedge' in this block; clk: the clock that makes all registers advance together.

Line 87: `#1;` Within the module's structural declarations, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge mac2 u8 RTL block in simulation. The expression is a literal or structural operator and has no hidden software state.

Line 88: `if (product_valid) begin` This condition selects the following hardware branch only when 'product_valid' is true. Both branches exist as gates; the condition controls a multiplexer rather than making software jump. The important operands are product_valid: the producer's statement that its current payload is meaningful. Context: the module's structural declarations.

Line 89: `errors++;` Within the module's structural declarations, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge mac2 u8 RTL block in simulation. The important operands are errors: the value named 'errors' in this block.

Line 90: `$display("ERROR product_valid did not follow enable low");` This is a simulation check or diagnostic. It can stop a failing test and print evidence, but it is not part of the synthesized PYNQ circuit.

Line 91: `end` This structural keyword opens or closes the branch/process scope described as the module's structural declarations; it has no arithmetic value of its own.

Line 93: `if (errors != 0) begin` This condition selects the following hardware branch only when 'errors != 0' is true. Both branches exist as gates; the condition controls a multiplexer rather than making software jump. The important operands are errors: the value named 'errors' in this block. Context: the module's structural declarations.

Line 94: `$display("tb_neuraedge_mac2_u8 FAILED checks=%0d errors=%0d", checks, errors);` This is a simulation check or diagnostic. It can stop a failing test and print evidence, but it is not part of the synthesized PYNQ circuit.

Line 95: `$fatal(1);` This is a simulation check or diagnostic. It can stop a failing test and print evidence, but it is not part of the synthesized PYNQ circuit.

Line 96: `end` This structural keyword opens or closes the branch/process scope described as the module's structural declarations; it has no arithmetic value of its own.

Line 97: `$display("tb_neuraedge_mac2_u8 PASSED checks=%0d errors=0", checks);` This is a simulation check or diagnostic. It can stop a failing test and print evidence, but it is not part of the synthesized PYNQ circuit.

Line 98: `$finish;` This is a simulation check or diagnostic. It can stop a failing test and print evidence, but it is not part of the synthesized PYNQ circuit.

Line 99: `end` This structural keyword opens or closes the branch/process scope described as the module's structural declarations; it has no arithmetic value of its own.

Line 101: `initial begin` This opens simulation initialization. In a testbench it drives starting values and stimulus; project synthesis does not rely on this block as a replacement for explicit reset behavior.

Line 102: `#6_000_000;` Within the module's structural declarations, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge mac2 u8 RTL block in simulation. The expression is a literal or structural operator and has no hidden software state.

Line 103: `$display("ERROR tb_neuraedge_mac2_u8 watchdog timeout");` This is a simulation check or diagnostic. It can stop a failing test and print evidence, but it is not part of the synthesized PYNQ circuit.

Line 104: `$fatal(1);` This is a simulation check or diagnostic. It can stop a failing test and print evidence, but it is not part of the synthesized PYNQ circuit.

Line 105: `end` This structural keyword opens or closes the branch/process scope described as the module's structural declarations; it has no arithmetic value of its own.

Line 106: `endmodule` This closes the current hardware definition; no circuit behavior is attached to the keyword itself.

Line 108: `` `default_nettype wire `` This SystemVerilog preprocessor line controls compilation of the block that drives, backpressures, and checks the neuraedge mac2 u8 RTL block in simulation.

54 tb/tb_neuraedge_normalization_units.sv

Role in the complete system: drives, backpressures, and checks the neuraedge normalization units RTL block in simulation.

54.1 Beginner architecture map

Dataflow responsibility This file's end-to-end responsibility is to drives, backpressures, and checks the neuraedge normalization units RTL block in simulation.

Simulation-only status tb_neuraedge_normalization_units is not synthesized into the FPGA. It generates clocks, reset, commands, stalls, and expected values around the design under test, then terminates with an explicit result marker.

Evidence produced The file contains approximately 3 explicit assertions, failure diagnostics, or pass/fail markers. Its VCD/WDB trace is useful evidence only when the final pass marker is present; a simulator exit code by itself is insufficient.

54.3 Line annotations

Line 1: `` `timescale 1ns / 1ps `` This simulation directive selects nanoseconds as the time unit and picoseconds as the timestamp precision; it does not create FPGA logic.

Line 2: `` `default_nettype none `` This compiler directive forbids accidental implicit one-bit wires, turning misspelled signal names into errors instead of unintended hardware.

Line 3: `` `include "tb/fixtures/operator_fixture_params.svh" `` This SystemVerilog preprocessor line controls compilation of the block that drives, backpressures, and checks the neuraedge normalization units RTL block in simulation.

Line 5: `module tb_neuraedge_normalization_units;` This opens tb_neuraedge_normalization_units;, an independently compiled hardware definition. Its ports and statements collectively describe circuitry that drives, backpressures, and checks the neuraedge normalization units RTL block in simulation.

Line 6: `localparam int LN_CASES = ‘NEURAEDGE_LAYERNORM_CASES;` This fixes LN_CASES to ‘NEURAEDGE_LAYERNOR during elaboration. Vivado uses that constant to shape or simplify the generated circuit; LN_CASES denotes the value named ’ln cases’ in this block.

Line 7: `localparam int LN_SAMPLES = ‘NEURAEDGE_LAYERNORM_SAMPLES;` This fixes LN_SAMPLES to ‘NEURAEDGE_LAY during elaboration. Vivado uses that constant to shape or simplify the generated circuit; LN_SAMPLES denotes the value named ’ln samples’ in this block.

Line 8: `localparam int SM_CASES = ‘NEURAEDGE_SOFTMAX_CASES;` This fixes SM_CASES to ‘NEURAEDGE_SOFTMAX_C during elaboration. Vivado uses that constant to shape or simplify the generated circuit; SM_CASES denotes the value named ’sm cases’ in this block.

Line 9: `localparam int SM_SAMPLES = ‘NEURAEDGE_SOFTMAX_SAMPLES;` This fixes SM_SAMPLES to ‘NEURAEDGE_SOFTM during elaboration. Vivado uses that constant to shape or simplify the generated circuit; SM_SAMPLES denotes the value named ’sm samples’ in this block.

Line 11: `logic clk = 1’b0;` This declares hardware signal storage or wiring in the module’s structural declarations. Specifically, clk is the clock that makes all registers advance together. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 12: `logic rst_n = 1’b0;` This declares hardware signal storage or wiring in the module’s structural declarations. Specifically, rst_n is the active-low synchronous reset. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 14: `logic ln_start_valid = 1’b0;` This declares hardware signal storage or wiring in the module’s structural declarations. Specifically, ln_start_valid is the producer’s statement that its current payload is meaningful. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 15: `logic ln_start_ready;` This declares hardware signal storage or wiring in the module’s structural declarations. Specifically, ln_start_ready is the consumer’s statement that it can accept a payload this cycle. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 16: `logic [11:0] ln_feature_count = 12’d0;` This declares hardware signal storage or wiring in the module’s structural declarations. Specifically, ln_feature_count is an integer count retained for control or measurable telemetry. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 17: `logic [31:0] ln_epsilon = 32’d1;` This declares hardware signal storage or wiring in the module’s structural declarations. Specifically, ln_epsilon is the value named ’ln epsilon’ in this block. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 18: `logic ln_sample_valid = 1’b0;` This declares hardware signal storage or wiring in the module’s structural declarations. Specifically, ln_sample_valid is the producer’s statement that its current payload is meaningful. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 19: `logic ln_sample_ready;` This declares hardware signal storage or wiring in the module’s structural declarations. Specifically, ln_sample_ready is the consumer’s statement that it can accept a payload this cycle. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 20: `logic signed [23:0] ln_sample_value = 24’sd0;` This declares hardware signal storage or wiring in the module’s structural declarations. Specifically, ln_sample_value is the value named ’ln sample value’ in this block. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 21: `logic signed [23:0] ln_sample_gamma = 24'sd0;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, ln_sample_gamma is the learned multiplicative LayerNorm parameter. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 22: `logic signed [23:0] ln_sample_beta = 24'sd0;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, ln_sample_beta is the learned additive LayerNorm parameter. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 23: `logic ln_sample_last = 1'b0;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, ln_sample_last is the AXI-Stream marker for the final beat of a packet or command payload. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 24: `logic ln_result_valid;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, ln_result_valid is the producer's statement that its current payload is meaningful. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 25: `logic ln_result_ready = 1'b0;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, ln_result_ready is the consumer's statement that it can accept a payload this cycle. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 26: `logic signed [31:0] ln_result_value;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, ln_result_value is the value named 'ln result value' in this block. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 27: `logic [11:0] ln_result_index;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, ln_result_index is an integer selecting one tensor element, lane, bank, or state entry. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 28: `logic ln_result_last;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, ln_result_last is the AXI-Stream marker for the final beat of a packet or command payload. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 29: `logic ln_config_error;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, ln_config_error is the value named 'ln config error' in this block. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 30: `logic [31:0] ln_cycle_count;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, ln_cycle_count is an integer count retained for control or measurable telemetry. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 31: `logic signed [31:0] ln_debug_mean;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, ln_debug_mean is the arithmetic average used by normalization. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 32: `logic [31:0] ln_debug_variance;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, ln_debug_variance is the average squared distance from the mean. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 33: `logic [31:0] ln_debug_sigma;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, ln_debug_sigma is the value named 'ln debug sigma' in this block. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 34: `logic [31:0] ln_debug_reciprocal;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, ln_debug_reciprocal is the value named 'ln debug reciprocal' in this block. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 36: `logic sm_start_valid = 1'b0;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, sm_start_valid is the producer's statement that its current payload is meaningful. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 37: `logic sm_start_ready;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, sm_start_ready is the consumer's statement that it can accept a payload this cycle. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 38: `logic [8:0] sm_item_count = 9'd0;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, sm_item_count is an integer count retained for control or measurable telemetry. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 39: `logic [4:0] sm_difference_shift = 5'd0;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, sm_difference_shift is the value named 'sm difference shift' in this block. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 40: `logic sm_score_valid = 1'b0;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, sm_score_valid is the producer's statement that its current payload is meaningful. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 41: `logic sm_score_ready;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, sm_score_ready is the consumer's statement that it can accept a payload this cycle. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 42: `logic signed [23:0] sm_score_value = 24'sd0;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, sm_score_value is the value named 'sm score value' in this block. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 43: `logic sm_score_last = 1'b0;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, sm_score_last is the AXI-Stream marker for the final beat of a packet or command payload. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 44: `logic sm_probability_valid;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, sm_probability_valid is the producer's statement that its current payload is meaningful. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 45: `logic sm_probability_ready = 1'b0;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, sm_probability_ready is the consumer's statement that it can accept a payload this cycle. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 46: `logic [15:0] sm_probability;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, sm_probability is the value named 'sm probability' in this block. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 47: `logic [8:0] sm_probability_index;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, sm_probability_index is an integer selecting one tensor element, lane, bank, or state entry. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 48: `logic sm_probability_last;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, sm_probability_last is the AXI-Stream marker for the final beat of a packet or command payload. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 49: `logic sm_config_error;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, sm_config_error is the value named 'sm config error' in this block. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 50: `logic [31:0] sm_cycle_count;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, sm_cycle_count is an integer count retained for control or measurable telemetry. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 51: `logic signed [23:0] sm_debug_maximum;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, sm_debug_maximum is the value named 'sm debug maximum' in this block. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 52: `logic [23:0] sm_debug_denominator;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, sm_debug_denominator is the value named 'sm debug denominator' in this block. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 53: `logic [31:0] sm_debug_reciprocal;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, sm_debug_reciprocal is the value named 'sm debug reciprocal' in this block. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 55: `logic [63:0] ln_case_mem [0:LN_CASES-1];` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, ln_case_mem is local FPGA storage addressed by surrounding index logic. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 56: `logic signed [23:0] ln_value_mem [0:LN_SAMPLES-1];` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, ln_value_mem is local FPGA storage addressed by surrounding index logic. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 57: `logic signed [23:0] ln_gamma_mem [0:LN_SAMPLES-1];` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, ln_gamma_mem is the learned multiplicative LayerNorm parameter. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 58: `logic signed [23:0] ln_beta_mem [0:LN_SAMPLES-1];` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, ln_beta_mem is the learned additive LayerNorm parameter. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 59: `logic signed [31:0] ln_expected_mem [0:LN_SAMPLES-1];` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, ln_expected_mem is local FPGA storage addressed by surrounding index logic. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 60: `logic [127:0] ln_debug_mem [0:LN_CASES-1];` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, ln_debug_mem is local FPGA storage addressed by surrounding index logic. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 61: `logic [31:0] sm_case_mem [0:SM_CASES-1];` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, sm_case_mem is local FPGA storage addressed by surrounding index logic. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 62: `logic signed [23:0] sm_score_mem [0:SM_SAMPLES-1];` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, sm_score_mem is local FPGA storage addressed by surrounding index logic. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 63: `logic [15:0] sm_expected_mem [0:SM_SAMPLES-1];` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, sm_expected_mem is local FPGA storage addressed by surrounding index logic. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 64: `logic [79:0] sm_debug_mem [0:SM_CASES-1];` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, sm_debug_mem is local FPGA storage addressed by surrounding index logic. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 66: `int ln_pointer = 0;` Within the module's structural declarations, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge normalization units RTL block in simulation. The important operands are ln_pointer: the value named 'ln pointer' in this block.

Line 67: `int sm_pointer = 0;` Within the module's structural declarations, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge normalization units RTL block in simulation. The important operands are sm_pointer: the value named 'sm pointer' in this block.

Line 68: `int errors = 0;` Within the module's structural declarations, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge normalization units RTL block in simulation. The important operands are errors: the value named 'errors' in this block.

Line 69: `int ln_checked = 0;` Within the module's structural declarations, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge normalization units RTL block in simulation. The important operands are ln_checked: the value named 'ln checked' in this block.

Line 70: `int sm_checked = 0;` Within the module's structural declarations, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge normalization units RTL block in simulation. The important operands are sm_checked: the value named 'sm checked' in this block.

Line 72: `neuraedge_integer_layernorm u_layernorm (` This instantiates module neuraedge_integer_layernorm as u_layernorm. Synthesis creates that subordinate circuit and connects its ports in the lines that follow.

Line 73: `.clk(clk), .rst_n(rst_n),` This connects the child instance's named port 'clk' to parent expression 'clk), .rst_n(rst_n'. The connection is a physical net bundle after synthesis; direction is declared in the child module, and the clock that makes all registers advance together.

Line 74: `.start_valid(ln_start_valid), .start_ready(ln_start_ready),` This connects the child instance's named port 'start_valid' to parent expression 'ln_start_valid), .start_ready(ln_start_ready'. The connection is a physical net bundle after synthesis; direction is declared in the child module, and the producer's statement that its current payload is meaningful.

Line 75: `.feature_count(ln_feature_count), .epsilon(ln_epsilon),` This connects the child instance's named port 'feature_count' to parent expression 'ln_feature_count), .epsilon(ln_epsilon'. The connection is a physical net bundle after synthesis; direction is declared in the child module, and the value named 'ln feature count), .epsilon(ln epsilon' in this block.

Line 76: `.sample_valid(ln_sample_valid), .sample_ready(ln_sample_ready),` This connects the child instance's named port 'sample_valid' to parent expression 'ln_sample_valid), .sample_ready(ln_sample_ready'. The connection is a physical net bundle after synthesis; direction is declared in the child module, and the producer's statement that its current payload is meaningful.

Line 77: `.sample_value(ln_sample_value), .sample_gamma_q15(ln_sample_gamma),` This connects the child instance's named port 'sample_value' to parent expression 'ln_sample_value), .sample_gamma_q15(ln_sample_gamma'. The connection is a physical net bundle after synthesis; direction is declared in the child module, and the learned multiplicative LayerNorm parameter.

Line 78: `.sample_beta(ln_sample_beta), .sample_last(ln_sample_last),` This connects the child instance's named port 'sample_beta' to parent expression 'ln_sample_beta), .sample_last(ln_sample_last'. The connection is a physical net bundle after synthesis; direction is declared in the child module, and the AXI-Stream marker for the final beat of a packet or command payload.

Line 79: `.result_valid(ln_result_valid), .result_ready(ln_result_ready),` This connects the child instance's named port 'result_valid' to parent expression 'ln_result_valid), .result_ready(ln_result_ready'. The connection is a physical net bundle after synthesis; direction is declared in the child module, and the producer's statement that its current payload is meaningful.

Line 80: `.result_value(ln_result_value), .result_index(ln_result_index),` This connects the child instance's named port 'result_value' to parent expression 'ln_result_value), .result_index(ln_result_index'. The connection is a physical net bundle after synthesis; direction is declared in the child module, and an integer selecting one tensor element, lane, bank, or state entry.

Line 81: `.result_last(ln_result_last), .config_error(ln_config_error),` This connects the child instance's named port 'result_last' to parent expression 'ln_result_last), .config_error(ln_config_error'. The connection is a physical net bundle after synthesis; direction is declared in the child module, and the AXI-Stream marker for the final beat of a packet or command payload.

Line 82: `.cycle_count(ln_cycle_count), .debug_mean(ln_debug_mean),` This connects the child instance's named port 'cycle_count' to parent expression 'ln_cycle_count), .debug_mean(ln_debug_mean'. The connection is a physical net bundle after synthesis; direction is declared in the child module, and the arithmetic average used by normalization.

Line 83: `.debug_variance(ln_debug_variance), .debug_sigma(ln_debug_sigma),` This connects the child instance's named port 'debug_variance' to parent expression 'ln_debug_variance), .debug_sigma(ln_debug_sigma'. The connection is a physical net bundle after synthesis; direction is declared in the child module, and the average squared distance from the mean.

Line 84: `.debug_reciprocal_q31(ln_debug_reciprocal)` This connects the child instance's named port 'debug_reciprocal_q31 to parent expression 'ln_debug_reciprocal'. The connection is a physical net bundle after synthesis; direction is declared in the child module, and the value named 'ln debug reciprocal' in this block.

Line 85: `);` Within the module's structural declarations, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge normalization units RTL block in simulation. The expression is a literal or structural operator and has no hidden software state.

Line 87: `neuraedge_log_softmax u_softmax (` This instantiates module neuraedge_log_softmax as u_softmax. Synthesis creates that subordinate circuit and connects its ports in the lines that follow.

Line 88: `.clk(clk), .rst_n(rst_n),` This connects the child instance's named port 'clk' to parent expression 'clk), .rst_n(rst_n'. The connection is a physical net bundle after synthesis; direction is declared in the child module, and the clock that makes all registers advance together.

Line 89: `.start_valid(sm_start_valid), .start_ready(sm_start_ready),` This connects the child instance's named port 'start_valid' to parent expression 'sm_start_valid), .start_ready(sm_start_ready'. The connection is a physical net bundle after synthesis; direction is declared in the child module, and the producer's statement that its current payload is meaningful.

Line 90: `.item_count(sm_item_count), .difference_shift(sm_difference_shift),` This connects the child instance's named port ‘item_count‘ to parent expression ‘sm_item_count), .difference_shift(sm_difference_shift‘. The connection is a physical net bundle after synthesis; direction is declared in the child module, and the value named ’sm item count), .difference shift(sm difference shift’ in this block.

Line 91: `.score_valid(sm_score_valid), .score_ready(sm_score_ready),` This connects the child instance's named port ‘score_valid‘ to parent expression ‘sm_score_valid), .score_ready(sm_score_ready‘. The connection is a physical net bundle after synthesis; direction is declared in the child module, and the producer's statement that its current payload is meaningful.

Line 92: `.score_value(sm_score_value), .score_last(sm_score_last),` This connects the child instance's named port ‘score_value‘ to parent expression ‘sm_score_value), .score_last(sm_score_last‘. The connection is a physical net bundle after synthesis; direction is declared in the child module, and the AXI-Stream marker for the final beat of a packet or command payload.

Line 93: `.probability_valid(sm_probability_valid), .probability_ready(sm_probability_ready),` This connects the child instance's named port ‘probability_valid‘ to parent expression ‘sm_probability_valid), .probability_ready(sm_proba The connection is a physical net bundle after synthesis; direction is declared in the child module, and the producer's statement that its current payload is meaningful.

Line 94: `.probability_q15(sm_probability), .probability_index(sm_probability_index),` This connects the child instance's named port ‘probability_q15‘ to parent expression ‘sm_probability), .probability_index(sm_probability_index‘. The connection is a physical net bundle after synthesis; direction is declared in the child module, and an integer selecting one tensor element, lane, bank, or state entry.

Line 95: `.probability_last(sm_probability_last), .config_error(sm_config_error),` This connects the child instance's named port ‘probability_last‘ to parent expression ‘sm_probability_last), .config_error(sm_config_error‘. The connection is a physical net bundle after synthesis; direction is declared in the child module, and the AXI-Stream marker for the final beat of a packet or command payload.

Line 96: `.cycle_count(sm_cycle_count), .debug_maximum_score(sm_debug_maximum),` This connects the child instance's named port ‘cycle_count‘ to parent expression ‘sm_cycle_count), .debug_maximum_score(sm_debug_maximum‘. The connection is a physical net bundle after synthesis; direction is declared in the child module, and the value named ’sm cycle count), .debug maximum score(sm debug maximum’ in this block.

Line 97: `.debug_denominator(sm_debug_denominator),` This connects the child instance's named port ‘debug_denominator‘ to parent expression ‘sm_debug_denominator‘. The connection is a physical net bundle after synthesis; direction is declared in the child module, and the value named ’sm debug denominator’ in this block.

Line 98: `.debug_reciprocal_q31(sm_debug_reciprocal)` This connects the child instance's named port ‘debug_reciprocal_q31 to parent expression ‘sm_debug_reciprocal‘. The connection is a physical net bundle after synthesis; direction is declared in the child module, and the value named ’sm debug reciprocal’ in this block.

Line 99: `);` Within the module's structural declarations, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge normalization units RTL block in simulation. The expression is a literal or structural operator and has no hidden software state.

Line 101: `always #2.5 clk = ~clk;` Within the module's structural declarations, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge normalization units RTL block in simulation. The important operands are always: the value named ’always’ in this block; clk: the clock that makes all registers advance together.

Line 103: `task automatic run_layernorm_case(input int case_index);` Within the simulation task run layernorm case, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge normalization units RTL block in simulation. The important operands are task: the value named 'task' in this block; automatic: the value named 'automatic' in this block; run_layernorm_case: the value named 'run layernorm case' in this block.

Line 104: `int count;` Within the simulation task run layernorm case, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge normalization units RTL block in simulation. The important operands are count: the value named 'count' in this block.

Line 105: `int epsilon_value;` Within the simulation task run layernorm case, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge normalization units RTL block in simulation. The important operands are epsilon_value: the value named 'epsilon value' in this block.

Line 106: `int received;` Within the simulation task run layernorm case, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge normalization units RTL block in simulation. The important operands are received: the value named 'received' in this block.

Line 107: `int output_cycle;` Within the simulation task run layernorm case, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge normalization units RTL block in simulation. The important operands are output_cycle: the value named 'output cycle' in this block.

Line 108: `int first_sample;` Within the simulation task run layernorm case, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge normalization units RTL block in simulation. The important operands are first_sample: the value named 'first sample' in this block.

Line 109: `begin` This structural keyword opens or closes the branch/process scope described as the simulation task run layernorm case; it has no arithmetic value of its own.

Line 110: `count = ln_case_mem[case_index][11:0];` This makes count, the value named 'count' in this block, equal to 'ln_case_mem[case_index][11:0]'. It is driven by combinational or procedural logic in the current evaluation. The important operands are ln_case_mem: local FPGA storage addressed by surrounding index logic; case_index: an integer selecting one tensor element, lane, bank, or state entry. Context: the simulation task run layernorm case.

Line 111: `epsilon_value = ln_case_mem[case_index][43:12];` This makes epsilon_value, the value named 'epsilon value' in this block, equal to 'ln_case_mem[case_index][43:12]'. It is driven by combinational or procedural logic in the current evaluation. The important operands are ln_case_mem: local FPGA storage addressed by surrounding index logic; case_index: an integer selecting one tensor element, lane, bank, or state entry. Context: the simulation task run layernorm case.

Line 112: `first_sample = ln_pointer;` This makes first_sample, the value named 'first sample' in this block, equal to 'ln_pointer'. It is driven by combinational or procedural logic in the current evaluation. The important operands are ln_pointer: the value named 'ln pointer' in this block. Context: the simulation task run layernorm case.

Line 113: `while (!ln_start_ready) @(negedge clk);` Within the simulation task run layernorm case, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge normalization units RTL block in simulation. The important operands are while: the value named 'while' in this block; ln_start_ready: the consumer's statement that it can accept a payload this cycle; negedge: the value named 'negedge' in this block.

Line 114: `@(negedge clk);` Within the simulation task run layernorm case, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge normalization units RTL block in simulation. The important operands are negedge: the value named 'negedge' in this block; clk: the clock that makes all registers advance together.

Line 115: `ln_feature_count = 12'(count);` This makes ln_feature_count, an integer count retained for control or measurable telemetry, equal to ‘12’(count)‘. It is driven by combinational or procedural logic in the current evaluation. The important operands are count: the value named ’count’ in this block. Context: the simulation task run layernorm case.

Line 116: `ln_epsilon = epsilon_value;` This makes ln_epsilon, the value named ’ln epsilon’ in this block, equal to ‘epsilon_value‘. It is driven by combinational or procedural logic in the current evaluation. The important operands are epsilon_value: the value named ’epsilon value’ in this block. Context: the simulation task run layernorm case.

Line 117: `ln_start_valid = 1'b1;` This makes ln_start_valid, the producer’s statement that its current payload is meaningful, equal to ‘1’b1‘. It is driven by combinational or procedural logic in the current evaluation. The important operands are b1: the value named ’b1’ in this block. Context: the simulation task run layernorm case.

Line 118: `@(posedge clk);` Within the simulation task run layernorm case, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge normalization units RTL block in simulation. The important operands are posedge: the value named ’posedge’ in this block; clk: the clock that makes all registers advance together.

Line 119: `@(negedge clk);` Within the simulation task run layernorm case, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge normalization units RTL block in simulation. The important operands are negedge: the value named ’negedge’ in this block; clk: the clock that makes all registers advance together.

Line 120: `ln_start_valid = 1'b0;` This makes ln_start_valid, the producer’s statement that its current payload is meaningful, equal to ‘1’b0‘. It is driven by combinational or procedural logic in the current evaluation. The important operands are b0: the value named ’b0’ in this block. Context: the simulation task run layernorm case.

Line 122: `for (int sample = 0; sample < count; sample++) begin` This generate/procedural loop repeats the following operation across lanes or entries. In synthesizable RTL, a fixed loop is expanded into parallel or scheduled hardware rather than executed by a CPU. Context: the simulation task run layernorm case.

Line 123: `if (!ln_sample_ready) begin` This condition selects the following hardware branch only when ‘!ln_sample_ready‘ is true. Both branches exist as gates; the condition controls a multiplexer rather than making software jump. The important operands are ln_sample_ready: the consumer’s statement that it can accept a payload this cycle. Context: the simulation task run layernorm case.

Line 124: `errors++;` Within the simulation task run layernorm case, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge normalization units RTL block in simulation. The important operands are errors: the value named ’errors’ in this block.

Line 125: `$display("ERROR LayerNorm sample ready case=%0d sample=%0d", case_index, sample);` This is a simulation check or diagnostic. It can stop a failing test and print evidence, but it is not part of the synthesized PYNQ circuit.

Line 126: `end` This structural keyword opens or closes the branch/process scope described as the simulation task run layernorm case; it has no arithmetic value of its own.

Line 127: `ln_sample_value = ln_value_mem[first_sample + sample];` This makes ln_sample_value, the value named ’ln sample value’ in this block, equal to ‘ln_value_mem[first_sample + sample]‘. It is driven by combinational or procedural logic in the current evaluation. The important operands are ln_value_mem: local FPGA storage addressed by surrounding index logic; first_sample: the value named ’first sample’ in this block; sample: the value named ’sample’ in this block. Context: the simulation task run layernorm case.

Line 128: `ln_sample_gamma = ln_gamma_mem[first_sample + sample];` This makes ln_sample_gamma, the learned multiplicative LayerNorm parameter, equal to ‘ln_gamma_mem[first_sample + sample]‘. It is driven by combinational or procedural logic in the current evaluation. The important operands are ln_gamma_mem: the learned multiplicative LayerNorm parameter; first_sample: the value named ’first sample’ in this block; sample: the value named ’sample’ in this block. Context: the simulation task run layernorm case.

Line 129: `ln_sample_beta = ln_beta_mem[first_sample + sample];` This makes ln_sample_beta, the learned additive LayerNorm parameter, equal to ‘ln_beta_mem[first_sample + sample]‘. It is driven by combinational or procedural logic in the current evaluation. The important operands are ln_beta_mem: the learned additive LayerNorm parameter; first_sample: the value named ’first sample’ in this block; sample: the value named ’sample’ in this block. Context: the simulation task run layernorm case.

Line 130: `ln_sample_last = sample == count - 1;` This makes ln_sample_last, the AXI-Stream marker for the final beat of a packet or command payload, equal to ‘sample == count - 1‘. It is driven by combinational or procedural logic in the current evaluation. The important operands are sample: the value named ’sample’ in this block; count: the value named ’count’ in this block. Context: the simulation task run layernorm case.

Line 131: `ln_sample_valid = 1'b1;` This makes ln_sample_valid, the producer’s statement that its current payload is meaningful, equal to ‘1’b1‘. It is driven by combinational or procedural logic in the current evaluation. The important operands are b1: the value named ’b1’ in this block. Context: the simulation task run layernorm case.

Line 132: `@(posedge clk);` Within the simulation task run layernorm case, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge normalization units RTL block in simulation. The important operands are posedge: the value named ’posedge’ in this block; clk: the clock that makes all registers advance together.

Line 133: `@(negedge clk);` Within the simulation task run layernorm case, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge normalization units RTL block in simulation. The important operands are negedge: the value named ’negedge’ in this block; clk: the clock that makes all registers advance together.

Line 134: `end` This structural keyword opens or closes the branch/process scope described as the simulation task run layernorm case; it has no arithmetic value of its own.

Line 135: `ln_sample_valid = 1'b0;` This makes ln_sample_valid, the producer’s statement that its current payload is meaningful, equal to ‘1’b0‘. It is driven by combinational or procedural logic in the current evaluation. The important operands are b0: the value named ’b0’ in this block. Context: the simulation task run layernorm case.

Line 136: `ln_sample_last = 1'b0;` This makes ln_sample_last, the AXI-Stream marker for the final beat of a packet or command payload, equal to ‘1’b0‘. It is driven by combinational or procedural logic in the current evaluation. The important operands are b0: the value named ’b0’ in this block. Context: the simulation task run layernorm case.

Line 138: `received = 0;` This makes received, the value named ’received’ in this block, equal to ‘0‘. It is driven by combinational or procedural logic in the current evaluation. The expression is a literal or structural operator and has no hidden software state. Context: the simulation task run layernorm case.

Line 139: `output_cycle = 0;` This makes output_cycle, the value named ’output cycle’ in this block, equal to ‘0‘. It is driven by combinational or procedural logic in the current evaluation. The expression is a literal or structural operator and has no hidden software state. Context: the simulation task run layernorm case.

Line 140: `while (received < count && output_cycle < 100000) begin` Within the simulation task run layernorm case, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge normalization units RTL block in simulation. The important operands are while: the value named ’while’ in this block; received: the value named ’received’ in this block; count: the value named ’count’ in this block.

Line 141: `ln_result_ready = ((output_cycle + case_index) % 6 != 1);` This makes ln_result_ready, the consumer's statement that it can accept a payload this cycle, equal to '((output_cycle + case_index) % 6 != 1)'. It is driven by combinational or procedural logic in the current evaluation. The important operands are output_cycle: the value named 'output cycle' in this block; case_index: an integer selecting one tensor element, lane, bank, or state entry. Context: the simulation task run layernorm case.

Line 142: `@(posedge clk);` Within the simulation task run layernorm case, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge normalization units RTL block in simulation. The important operands are posedge: the value named 'posedge' in this block; clk: the clock that makes all registers advance together.

Line 143: `if (ln_result_valid && ln_result_ready) begin` This condition selects the following hardware branch only when 'ln_result_valid && ln_result_ready' is true. Both branches exist as gates; the condition controls a multiplexer rather than making software jump. The important operands are ln_result_valid: the producer's statement that its current payload is meaningful; ln_result_ready: the consumer's statement that it can accept a payload this cycle. Context: the simulation task run layernorm case.

Line 144: `if (ln_result_value !== ln_expected_mem[first_sample + received]` Within the simulation task run layernorm case, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge normalization units RTL block in simulation. The important operands are ln_result_value: the value named 'ln result value' in this block; ln_expected_mem: local FPGA storage addressed by surrounding index logic; first_sample: the value named 'first sample' in this block.

Line 145: `|| ln_result_index !== received` Within the simulation task run layernorm case, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge normalization units RTL block in simulation. The important operands are ln_result_index: an integer selecting one tensor element, lane, bank, or state entry; received: the value named 'received' in this block.

Line 146: `|| ln_result_last !== (received == count - 1)) begin` Within the simulation task run layernorm case, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge normalization units RTL block in simulation. The important operands are ln_result_last: the AXI-Stream marker for the final beat of a packet or command payload; received: the value named 'received' in this block; count: the value named 'count' in this block.

Line 147: `errors++;` Within the simulation task run layernorm case, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge normalization units RTL block in simulation. The important operands are errors: the value named 'errors' in this block.

Line 148: `if (errors <= 20) begin` This statement continues through source line 151; the explanation uses the complete expression rather than only the first visual fragment. This condition selects the following hardware branch only when 'errors <= 20) begin $display("ERROR LayerNorm case=%0d index=%0d got=%0d expected=%0d rtl_index=%0d last=%0d", case_index, received, ln_result_value, ln_expected_mem[first_sample + received], ln_result_index, ln_result_last' is true. Both branches exist as gates; the condition controls a multiplexer rather than making software jump. The important operands are errors: the value named 'errors' in this block; display: the value named 'display' in this block; ERROR: the value named 'error' in this block. Context: the simulation task run layernorm case.

Line 149: `$display("ERROR LayerNorm case=%0d index=%0d got=%0d expected=%0d rtl_index=%0d last=%0d",` This is continuation line 2 of the 4-line logical statement that begins at source line 148. Its exact fragment is '$display("ERROR LayerNorm case=%0d index=%0d got=%0d expected=%0d rtl_index=%0d last=%0d",'. The important operands are display: the value named 'display' in this block; ERROR: the value named 'error' in this block; LayerNorm: the value named 'layer norm' in this block. Read together, the complete operation is: This condition selects the following hardware branch only when 'errors <= 20) begin $display("ERROR LayerNorm case=%0d index=%0d got=%0d expected=%0d rtl_index=%0d last=%0d", case_index, received, ln_result_value, ln_expected_mem[first_sample + received], ln_result_index, ln_result_last' is true. Both branches exist as gates; the condition controls a multiplexer rather than making software jump. The important operands are errors: the value named 'errors' in this block; display: the value named 'display' in this block; ERROR: the value named 'error' in this block. Context: the simulation task run layernorm case.

Line 150: `case_index, received, ln_result_value,` This is continuation line 3 of the 4-line logical statement that begins at source line 148. Its exact fragment is ‘case_index, received, ln_result_value,‘. The important operands are case_index: an integer selecting one tensor element, lane, bank, or state entry; received: the value named ’received’ in this block; ln_result_value: the value named ’ln result value’ in this block. Read together, the complete operation is: This condition selects the following hardware branch only when ‘errors <= 20) begin $display("ERROR LayerNorm case=%0d index=%0d got=%0d expected=%0d rtl_index=%0d last=%0d", case_index, received, ln_result_value, ln_expected_mem[first_sample + received], ln_result_index, ln_result_last‘ is true. Both branches exist as gates; the condition controls a multiplexer rather than making software jump. The important operands are errors: the value named ’errors’ in this block; display: the value named ’display’ in this block; ERROR: the value named ’error’ in this block. Context: the simulation task run layernorm case.

Line 151: `ln_expected_mem[first_sample + received], ln_result_index, ln_result_last);` This is continuation line 4 of the 4-line logical statement that begins at source line 148. Its exact fragment is ‘ln_expected_mem[first_sample + received], ln_result_index, ln_result_last);‘. The important operands are ln_expected_mem: local FPGA storage addressed by surrounding index logic; first_sample: the value named ’first sample’ in this block; received: the value named ’received’ in this block. Read together, the complete operation is: This condition selects the following hardware branch only when ‘errors <= 20) begin $display("ERROR LayerNorm case=%0d index=%0d got=%0d expected=%0d rtl_index=%0d last=%0d", case_index, received, ln_result_value, ln_expected_mem[first_sample + received], ln_result_index, ln_result_last‘ is true. Both branches exist as gates; the condition controls a multiplexer rather than making software jump. The important operands are errors: the value named ’errors’ in this block; display: the value named ’display’ in this block; ERROR: the value named ’error’ in this block. Context: the simulation task run layernorm case.

Line 152: `end` This structural keyword opens or closes the branch/process scope described as the simulation task run layernorm case; it has no arithmetic value of its own.

Line 153: `end` This structural keyword opens or closes the branch/process scope described as the simulation task run layernorm case; it has no arithmetic value of its own.

Line 154: `received++;` Within the simulation task run layernorm case, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge normalization units RTL block in simulation. The important operands are received: the value named ’received’ in this block.

Line 155: `ln_checked++;` Within the simulation task run layernorm case, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge normalization units RTL block in simulation. The important operands are ln_checked: the value named ’ln checked’ in this block.

Line 156: `end` This structural keyword opens or closes the branch/process scope described as the simulation task run layernorm case; it has no arithmetic value of its own.

Line 157: `@(negedge clk);` Within the simulation task run layernorm case, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge normalization units RTL block in simulation. The important operands are negedge: the value named ’negedge’ in this block; clk: the clock that makes all registers advance together.

Line 158: `output_cycle++;` Within the simulation task run layernorm case, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge normalization units RTL block in simulation. The important operands are output_cycle: the value named ’output cycle’ in this block.

Line 159: `end` This structural keyword opens or closes the branch/process scope described as the simulation task run layernorm case; it has no arithmetic value of its own.

Line 160: `ln_result_ready = 1'b0;` This makes ln_result_ready, the consumer’s statement that it can accept a payload this cycle, equal to ‘1’b0‘. It is driven by combinational or procedural logic in the current evaluation. The important operands are b0: the value named ’b0’ in this block. Context: the simulation task run layernorm case.

Line 161: `if (received != count || ln_config_error` Within the simulation task run layernorm case, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge normalization units RTL block in simulation. The important operands are received: the value named 'received' in this block; count: the value named 'count' in this block; ln_config_error: the value named 'ln config error' in this block.

Line 162: `|| ln_debug_mean !== ln_debug_mem[case_index][31:0]` Within the simulation task run layernorm case, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge normalization units RTL block in simulation. The important operands are ln_debug_mean: the arithmetic average used by normalization; ln_debug_mem: local FPGA storage addressed by surrounding index logic; case_index: an integer selecting one tensor element, lane, bank, or state entry.

Line 163: `|| ln_debug_variance !== ln_debug_mem[case_index][63:32]` Within the simulation task run layernorm case, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge normalization units RTL block in simulation. The important operands are ln_debug_variance: the average squared distance from the mean; ln_debug_mem: local FPGA storage addressed by surrounding index logic; case_index: an integer selecting one tensor element, lane, bank, or state entry.

Line 164: `|| ln_debug_sigma !== ln_debug_mem[case_index][95:64]` Within the simulation task run layernorm case, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge normalization units RTL block in simulation. The important operands are ln_debug_sigma: the value named 'ln debug sigma' in this block; ln_debug_mem: local FPGA storage addressed by surrounding index logic; case_index: an integer selecting one tensor element, lane, bank, or state entry.

Line 165: `|| ln_debug_reciprocal !== ln_debug_mem[case_index][127:96]) begin` Within the simulation task run layernorm case, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge normalization units RTL block in simulation. The important operands are ln_debug_reciprocal: the value named 'ln debug reciprocal' in this block; ln_debug_mem: local FPGA storage addressed by surrounding index logic; case_index: an integer selecting one tensor element, lane, bank, or state entry.

Line 166: `errors++;` Within the simulation task run layernorm case, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge normalization units RTL block in simulation. The important operands are errors: the value named 'errors' in this block.

Line 167: `$display("ERROR LayerNorm completion case=%0d received=%0d/%0d error=%0d debug=(%0d,%0d,%0d,%0d) expected=(...` This is a simulation check or diagnostic. It can stop a failing test and print evidence, but it is not part of the synthesized PYNQ circuit.

Line 168: `case_index, received, count, ln_config_error,` Within the simulation task run layernorm case, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge normalization units RTL block in simulation. The important operands are case_index: an integer selecting one tensor element, lane, bank, or state entry; received: the value named 'received' in this block; count: the value named 'count' in this block.

Line 169: `ln_debug_mean, ln_debug_variance, ln_debug_sigma, ln_debug_reciprocal,` Within the simulation task run layernorm case, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge normalization units RTL block in simulation. The important operands are ln_debug_mean: the arithmetic average used by normalization; ln_debug_variance: the average squared distance from the mean; ln_debug_sigma: the value named 'ln debug sigma' in this block.

Line 170: `$signed(ln_debug_mem[case_index][31:0]), ln_debug_mem[case_index][63:32],` Within the simulation task run layernorm case, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge normalization units RTL block in simulation. The important operands are ln_debug_mem: local FPGA storage addressed by surrounding index logic; case_index: an integer selecting one tensor element, lane, bank, or state entry.

Line 171: `ln_debug_mem[case_index][95:64], ln_debug_mem[case_index][127:96]);` Within the simulation task run layernorm case, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge normalization units RTL block in simulation. The important operands are ln_debug_mem: local FPGA storage addressed by surrounding index logic; case_index: an integer selecting one tensor element, lane, bank, or state entry.

Line 172: `end` This structural keyword opens or closes the branch/process scope described as the simulation task run layernorm case; it has no arithmetic value of its own.

Line 173: `$display("layernorm_case=%0d features=%0d cycles=%0d", case_index, count, ln_cycle_count);` This is a simulation check or diagnostic. It can stop a failing test and print evidence, but it is not part of the synthesized PYNQ circuit.

Line 174: `ln_pointer += count;` Within the simulation task run layernorm case, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge normalization units RTL block in simulation. The important operands are ln_pointer: the value named 'ln pointer' in this block; count: the value named 'count' in this block.

Line 175: `end` This structural keyword opens or closes the branch/process scope described as the simulation task run layernorm case; it has no arithmetic value of its own.

Line 176: `endtask` Within the simulation task run layernorm case, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge normalization units RTL block in simulation. The important operands are endtask: the value named 'endtask' in this block.

Line 178: `task automatic run_softmax_case(input int case_index);` Within the simulation task run softmax case, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge normalization units RTL block in simulation. The important operands are task: the value named 'task' in this block; automatic: the value named 'automatic' in this block; run_softmax_case: the value named 'run softmax case' in this block.

Line 179: `int count;` Within the simulation task run softmax case, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge normalization units RTL block in simulation. The important operands are count: the value named 'count' in this block.

Line 180: `int shift_value;` Within the simulation task run softmax case, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge normalization units RTL block in simulation. The important operands are shift_value: the value named 'shift value' in this block.

Line 181: `int received;` Within the simulation task run softmax case, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge normalization units RTL block in simulation. The important operands are received: the value named 'received' in this block.

Line 182: `int output_cycle;` Within the simulation task run softmax case, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge normalization units RTL block in simulation. The important operands are output_cycle: the value named 'output cycle' in this block.

Line 183: `int first_sample;` Within the simulation task run softmax case, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge normalization units RTL block in simulation. The important operands are first_sample: the value named 'first sample' in this block.

Line 184: `begin` This structural keyword opens or closes the branch/process scope described as the simulation task run softmax case; it has no arithmetic value of its own.

Line 185: `count = sm_case_mem[case_index][8:0];` This makes count, the value named 'count' in this block, equal to 'sm_case_mem[case_index][8:0]'. It is driven by combinational or procedural logic in the current evaluation. The important operands are sm_case_mem: local FPGA storage addressed by surrounding index logic; case_index: an integer selecting one tensor element, lane, bank, or state entry. Context: the simulation task run softmax case.

Line 186: `shift_value = sm_case_mem[case_index][13:9];` This makes shift_value, the value named 'shift value' in this block, equal to 'sm_case_mem[case_index][13:9]'. It is driven by combinational or procedural logic in the current evaluation. The important operands are sm_case_mem: local FPGA storage addressed by surrounding index logic; case_index: an integer selecting one tensor element, lane, bank, or state entry. Context: the simulation task run softmax case.

Line 187: `first_sample = sm_pointer;` This makes first_sample, the value named 'first sample' in this block, equal to 'sm_pointer'. It is driven by combinational or procedural logic in the current evaluation. The important operands are sm_pointer: the value named 'sm pointer' in this block. Context: the simulation task run softmax case.

Line 188: `while (!sm_start_ready) @(negedge clk);` Within the simulation task run softmax case, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge normalization units RTL block in simulation. The important operands are while: the value named 'while' in this block; sm_start_ready: the consumer's statement that it can accept a payload this cycle; negedge: the value named 'negedge' in this block.

Line 189: `@(negedge clk);` Within the simulation task run softmax case, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge normalization units RTL block in simulation. The important operands are negedge: the value named 'negedge' in this block; clk: the clock that makes all registers advance together.

Line 190: `sm_item_count = 9'(count);` This makes sm_item_count, an integer count retained for control or measurable telemetry, equal to '9'(count)'. It is driven by combinational or procedural logic in the current evaluation. The important operands are count: the value named 'count' in this block. Context: the simulation task run softmax case.

Line 191: `sm_difference_shift = 5'(shift_value);` This makes sm_difference_shift, the value named 'sm difference shift' in this block, equal to '5'(shift_value)'. It is driven by combinational or procedural logic in the current evaluation. The important operands are shift_value: the value named 'shift value' in this block. Context: the simulation task run softmax case.

Line 192: `sm_start_valid = 1'b1;` This makes sm_start_valid, the producer's statement that its current payload is meaningful, equal to '1'b1'. It is driven by combinational or procedural logic in the current evaluation. The important operands are b1: the value named 'b1' in this block. Context: the simulation task run softmax case.

Line 193: `@(posedge clk);` Within the simulation task run softmax case, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge normalization units RTL block in simulation. The important operands are posedge: the value named 'posedge' in this block; clk: the clock that makes all registers advance together.

Line 194: `@(negedge clk);` Within the simulation task run softmax case, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge normalization units RTL block in simulation. The important operands are negedge: the value named 'negedge' in this block; clk: the clock that makes all registers advance together.

Line 195: `sm_start_valid = 1'b0;` This makes sm_start_valid, the producer's statement that its current payload is meaningful, equal to '1'b0'. It is driven by combinational or procedural logic in the current evaluation. The important operands are b0: the value named 'b0' in this block. Context: the simulation task run softmax case.

Line 197: `for (int sample = 0; sample < count; sample++) begin` This generate/procedural loop repeats the following operation across lanes or entries. In synthesizable RTL, a fixed loop is expanded into parallel or scheduled hardware rather than executed by a CPU. Context: the simulation task run softmax case.

Line 198: `if (!sm_score_ready) begin` This condition selects the following hardware branch only when ‘!sm_score_ready‘ is true. Both branches exist as gates; the condition controls a multiplexer rather than making software jump. The important operands are sm_score_ready: the consumer’s statement that it can accept a payload this cycle. Context: the simulation task run softmax case.

Line 199: `errors++;` Within the simulation task run softmax case, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge normalization units RTL block in simulation. The important operands are errors: the value named ’errors’ in this block.

Line 200: `$display("ERROR softmax score ready case=%0d sample=%0d", case_index, sample);` This is a simulation check or diagnostic. It can stop a failing test and print evidence, but it is not part of the synthesized PYNQ circuit.

Line 201: `end` This structural keyword opens or closes the branch/process scope described as the simulation task run softmax case; it has no arithmetic value of its own.

Line 202: `sm_score_value = sm_score_mem[first_sample + sample];` This makes sm_score_value, the value named ’sm score value’ in this block, equal to ‘sm_score_mem[first_sample + sample]‘. It is driven by combinational or procedural logic in the current evaluation. The important operands are sm_score_mem: local FPGA storage addressed by surrounding index logic; first_sample: the value named ’first sample’ in this block; sample: the value named ’sample’ in this block. Context: the simulation task run softmax case.

Line 203: `sm_score_last = sample == count - 1;` This makes sm_score_last, the AXI-Stream marker for the final beat of a packet or command payload, equal to ‘sample == count - 1‘. It is driven by combinational or procedural logic in the current evaluation. The important operands are sample: the value named ’sample’ in this block; count: the value named ’count’ in this block. Context: the simulation task run softmax case.

Line 204: `sm_score_valid = 1'b1;` This makes sm_score_valid, the producer’s statement that its current payload is meaningful, equal to ‘1’b1‘. It is driven by combinational or procedural logic in the current evaluation. The important operands are b1: the value named ’b1’ in this block. Context: the simulation task run softmax case.

Line 205: `@(posedge clk);` Within the simulation task run softmax case, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge normalization units RTL block in simulation. The important operands are posedge: the value named ’posedge’ in this block; clk: the clock that makes all registers advance together.

Line 206: `@(negedge clk);` Within the simulation task run softmax case, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge normalization units RTL block in simulation. The important operands are negedge: the value named ’negedge’ in this block; clk: the clock that makes all registers advance together.

Line 207: `end` This structural keyword opens or closes the branch/process scope described as the simulation task run softmax case; it has no arithmetic value of its own.

Line 208: `sm_score_valid = 1'b0;` This makes sm_score_valid, the producer’s statement that its current payload is meaningful, equal to ‘1’b0‘. It is driven by combinational or procedural logic in the current evaluation. The important operands are b0: the value named ’b0’ in this block. Context: the simulation task run softmax case.

Line 209: `sm_score_last = 1'b0;` This makes sm_score_last, the AXI-Stream marker for the final beat of a packet or command payload, equal to ‘1’b0‘. It is driven by combinational or procedural logic in the current evaluation. The important operands are b0: the value named ’b0’ in this block. Context: the simulation task run softmax case.

Line 211: `received = 0;` This makes received, the value named ’received’ in this block, equal to ‘0‘. It is driven by combinational or procedural logic in the current evaluation. The expression is a literal or structural operator and has no hidden software state. Context: the simulation task run softmax case.

Line 212: `output_cycle = 0;` This makes output_cycle, the value named 'output cycle' in this block, equal to '0'. It is driven by combinational or procedural logic in the current evaluation. The expression is a literal or structural operator and has no hidden software state. Context: the simulation task run softmax case.

Line 213: `while (received < count && output_cycle < 100000) begin` Within the simulation task run softmax case, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge normalization units RTL block in simulation. The important operands are while: the value named 'while' in this block; received: the value named 'received' in this block; count: the value named 'count' in this block.

Line 214: `sm_probability_ready = ((output_cycle + case_index) % 5 != 2);` This makes sm_probability_ready, the consumer's statement that it can accept a payload this cycle, equal to '((output_cycle + case_index) % 5 != 2)'. It is driven by combinational or procedural logic in the current evaluation. The important operands are output_cycle: the value named 'output cycle' in this block; case_index: an integer selecting one tensor element, lane, bank, or state entry. Context: the simulation task run softmax case.

Line 215: `@(posedge clk);` Within the simulation task run softmax case, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge normalization units RTL block in simulation. The important operands are posedge: the value named 'posedge' in this block; clk: the clock that makes all registers advance together.

Line 216: `if (sm_probability_valid && sm_probability_ready) begin` This condition selects the following hardware branch only when 'sm_probability_valid && sm_probability_ready' is true. Both branches exist as gates; the condition controls a multiplexer rather than making software jump. The important operands are sm_probability_valid: the producer's statement that its current payload is meaningful; sm_probability_ready: the consumer's statement that it can accept a payload this cycle. Context: the simulation task run softmax case.

Line 217: `if (sm_probability !== sm_expected_mem[first_sample + received]` Within the simulation task run softmax case, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge normalization units RTL block in simulation. The important operands are sm_probability: the value named 'sm probability' in this block; sm_expected_mem: local FPGA storage addressed by surrounding index logic; first_sample: the value named 'first sample' in this block.

Line 218: `|| sm_probability_index !== received` Within the simulation task run softmax case, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge normalization units RTL block in simulation. The important operands are sm_probability_index: an integer selecting one tensor element, lane, bank, or state entry; received: the value named 'received' in this block.

Line 219: `|| sm_probability_last !== (received == count - 1)) begin` Within the simulation task run softmax case, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge normalization units RTL block in simulation. The important operands are sm_probability_last: the AXI-Stream marker for the final beat of a packet or command payload; received: the value named 'received' in this block; count: the value named 'count' in this block.

Line 220: `errors++;` Within the simulation task run softmax case, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge normalization units RTL block in simulation. The important operands are errors: the value named 'errors' in this block.

Line 221: `if (errors <= 20) begin` This statement continues through source line 224; the explanation uses the complete expression rather than only the first visual fragment. This condition selects the following hardware branch only when 'errors <= 20) begin $display("ERROR softmax case=%0d index=%0d got=%0d expected=%0d", case_index, received, sm_probability, sm_expected_mem[first_sample + received]' is true. Both branches exist as gates; the condition controls a multiplexer rather than making software jump. The important operands are errors: the value named 'errors' in this block; display: the value named 'display' in this block; ERROR: the value named 'error' in this block. Context: the simulation task run softmax case.

Line 222: `$display("ERROR softmax case=%0d index=%0d got=%0d expected=%0d",` This is continuation line 2 of the 4-line logical statement that begins at source line 221. Its exact fragment is '$display("ERROR softmax case=%0d index=%0d got=%0d expected=%0d",'. The important operands are display: the value named 'display' in this block; ERROR: the value named 'error' in this block; softmax: the value named 'softmax' in this block. Read together, the complete operation is: This condition selects the following hardware branch only when 'errors <= 20) begin $display("ERROR softmax case=%0d index=%0d got=%0d expected=%0d", case_index, received, sm_probability, sm_expected_mem[first_sample + received]' is true. Both branches exist as gates; the condition controls a multiplexer rather than making software jump. The important operands are errors: the value named 'errors' in this block; display: the value named 'display' in this block; ERROR: the value named 'error' in this block. Context: the simulation task run softmax case.

Line 223: `case_index, received, sm_probability,` This is continuation line 3 of the 4-line logical statement that begins at source line 221. Its exact fragment is 'case_index, received, sm_probability,'. The important operands are case_index: an integer selecting one tensor element, lane, bank, or state entry; received: the value named 'received' in this block; sm_probability: the value named 'sm probability' in this block. Read together, the complete operation is: This condition selects the following hardware branch only when 'errors <= 20) begin $display("ERROR softmax case=%0d index=%0d got=%0d expected=%0d", case_index, received, sm_probability, sm_expected_mem[first_sample + received]' is true. Both branches exist as gates; the condition controls a multiplexer rather than making software jump. The important operands are errors: the value named 'errors' in this block; display: the value named 'display' in this block; ERROR: the value named 'error' in this block. Context: the simulation task run softmax case.

Line 224: `sm_expected_mem[first_sample + received]);` This is continuation line 4 of the 4-line logical statement that begins at source line 221. Its exact fragment is 'sm_expected_mem[first_sample + received]);'. The important operands are sm_expected_mem: local FPGA storage addressed by surrounding index logic; first_sample: the value named 'first sample' in this block; received: the value named 'received' in this block. Read together, the complete operation is: This condition selects the following hardware branch only when 'errors <= 20) begin $display("ERROR softmax case=%0d index=%0d got=%0d expected=%0d", case_index, received, sm_probability, sm_expected_mem[first_sample + received]' is true. Both branches exist as gates; the condition controls a multiplexer rather than making software jump. The important operands are errors: the value named 'errors' in this block; display: the value named 'display' in this block; ERROR: the value named 'error' in this block. Context: the simulation task run softmax case.

Line 225: `end` This structural keyword opens or closes the branch/process scope described as the simulation task run softmax case; it has no arithmetic value of its own.

Line 226: `end` This structural keyword opens or closes the branch/process scope described as the simulation task run softmax case; it has no arithmetic value of its own.

Line 227: `received++;` Within the simulation task run softmax case, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge normalization units RTL block in simulation. The important operands are received: the value named 'received' in this block.

Line 228: `sm_checked++;` Within the simulation task run softmax case, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge normalization units RTL block in simulation. The important operands are sm_checked: the value named 'sm checked' in this block.

Line 229: `end` This structural keyword opens or closes the branch/process scope described as the simulation task run softmax case; it has no arithmetic value of its own.

Line 230: `@(negedge clk);` Within the simulation task run softmax case, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge normalization units RTL block in simulation. The important operands are negedge: the value named 'negedge' in this block; clk: the clock that makes all registers advance together.

Line 231: `output_cycle++;` Within the simulation task run softmax case, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge normalization units RTL block in simulation. The important operands are output_cycle: the value named 'output cycle' in this block.

Line 232: `end` This structural keyword opens or closes the branch/process scope described as the simulation task run softmax case; it has no arithmetic value of its own.

Line 233: `sm_probability_ready = 1'b0;` This makes sm_probability_ready, the consumer's statement that it can accept a payload this cycle, equal to `1'b0`. It is driven by combinational or procedural logic in the current evaluation. The important operands are b0: the value named 'b0' in this block. Context: the simulation task run softmax case.

Line 234: `if (received != count || sm_config_error` Within the simulation task run softmax case, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge normalization units RTL block in simulation. The important operands are received: the value named 'received' in this block; count: the value named 'count' in this block; sm_config_error: the value named 'sm config error' in this block.

Line 235: `|| sm_debug_maximum !== sm_debug_mem[case_index][23:0]` Within the simulation task run softmax case, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge normalization units RTL block in simulation. The important operands are sm_debug_maximum: the value named 'sm debug maximum' in this block; sm_debug_mem: local FPGA storage addressed by surrounding index logic; case_index: an integer selecting one tensor element, lane, bank, or state entry.

Line 236: `|| sm_debug_denominator !== sm_debug_mem[case_index][47:24]` Within the simulation task run softmax case, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge normalization units RTL block in simulation. The important operands are sm_debug_denominator: the value named 'sm debug denominator' in this block; sm_debug_mem: local FPGA storage addressed by surrounding index logic; case_index: an integer selecting one tensor element, lane, bank, or state entry.

Line 237: `|| sm_debug_reciprocal !== sm_debug_mem[case_index][79:48]) begin` Within the simulation task run softmax case, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge normalization units RTL block in simulation. The important operands are sm_debug_reciprocal: the value named 'sm debug reciprocal' in this block; sm_debug_mem: local FPGA storage addressed by surrounding index logic; case_index: an integer selecting one tensor element, lane, bank, or state entry.

Line 238: `errors++;` Within the simulation task run softmax case, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge normalization units RTL block in simulation. The important operands are errors: the value named 'errors' in this block.

Line 239: `$display("ERROR softmax completion case=%0d received=%0d/%0d error=%0d", case_index,` This is a simulation check or diagnostic. It can stop a failing test and print evidence, but it is not part of the synthesized PYNQ circuit.

Line 240: `received, count, sm_config_error);` Within the simulation task run softmax case, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge normalization units RTL block in simulation. The important operands are received: the value named 'received' in this block; count: the value named 'count' in this block; sm_config_error: the value named 'sm config error' in this block.

Line 241: `end` This structural keyword opens or closes the branch/process scope described as the simulation task run softmax case; it has no arithmetic value of its own.

Line 242: `$display("softmax_case=%0d items=%0d cycles=%0d", case_index, count, sm_cycle_count);` This is a simulation check or diagnostic. It can stop a failing test and print evidence, but it is not part of the synthesized PYNQ circuit.

Line 243: `sm_pointer += count;` Within the simulation task run softmax case, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge normalization units RTL block in simulation. The important operands are sm_pointer: the value named 'sm pointer' in this block; count: the value named 'count' in this block.

Line 244: `end` This structural keyword opens or closes the branch/process scope described as the simulation task run softmax case; it has no arithmetic value of its own.

Line 245: `endtask` Within the simulation task run softmax case, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge normalization units RTL block in simulation. The important operands are endtask: the value named 'endtask' in this block.

Line 247: `initial begin` This opens simulation initialization. In a testbench it drives starting values and stimulus; project synthesis does not rely on this block as a replacement for explicit reset behavior.

Line 248: `$readmemh("tb/fixtures/layernorm_cases.mem", ln_case_mem);` Within the module's structural declarations, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge normalization units RTL block in simulation. The important operands are readmemh: the value named 'readmemh' in this block; tb: the value named 'tb' in this block; fixtures: the value named 'fixtures' in this block.

Line 249: `$readmemh("tb/fixtures/layernorm_values.mem", ln_value_mem);` Within the module's structural declarations, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge normalization units RTL block in simulation. The important operands are readmemh: the value named 'readmemh' in this block; tb: the value named 'tb' in this block; fixtures: the value named 'fixtures' in this block.

Line 250: `$readmemh("tb/fixtures/layernorm_gammas.mem", ln_gamma_mem);` Within the module's structural declarations, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge normalization units RTL block in simulation. The important operands are readmemh: the value named 'readmemh' in this block; tb: the value named 'tb' in this block; fixtures: the value named 'fixtures' in this block.

Line 251: `$readmemh("tb/fixtures/layernorm_betas.mem", ln_beta_mem);` Within the module's structural declarations, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge normalization units RTL block in simulation. The important operands are readmemh: the value named 'readmemh' in this block; tb: the value named 'tb' in this block; fixtures: the value named 'fixtures' in this block.

Line 252: `$readmemh("tb/fixtures/layernorm_expected.mem", ln_expected_mem);` Within the module's structural declarations, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge normalization units RTL block in simulation. The important operands are readmemh: the value named 'readmemh' in this block; tb: the value named 'tb' in this block; fixtures: the value named 'fixtures' in this block.

Line 253: `$readmemh("tb/fixtures/layernorm_debug.mem", ln_debug_mem);` Within the module's structural declarations, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge normalization units RTL block in simulation. The important operands are readmemh: the value named 'readmemh' in this block; tb: the value named 'tb' in this block; fixtures: the value named 'fixtures' in this block.

Line 254: `$readmemh("tb/fixtures/softmax_cases.mem", sm_case_mem);` Within the module's structural declarations, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge normalization units RTL block in simulation. The important operands are readmemh: the value named 'readmemh' in this block; tb: the value named 'tb' in this block; fixtures: the value named 'fixtures' in this block.

Line 255: `$readmemh("tb/fixtures/softmax_scores.mem", sm_score_mem);` Within the module's structural declarations, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge normalization units RTL block in simulation. The important operands are readmemh: the value named 'readmemh' in this block; tb: the value named 'tb' in this block; fixtures: the value named 'fixtures' in this block.

Line 256: `$readmemh("tb/fixtures/softmax_expected.mem", sm_expected_mem);` Within the module's structural declarations, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge normalization units RTL block in simulation. The important operands are readmemh: the value named 'readmemh' in this block; tb: the value named 'tb' in this block; fixtures: the value named 'fixtures' in this block.

Line 257: `$readmemh("tb/fixtures/softmax_debug.mem", sm_debug_mem);` Within the module's structural declarations, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge normalization units RTL block in simulation. The important operands are readmemh: the value named 'readmemh' in this block; tb: the value named 'tb' in this block; fixtures: the value named 'fixtures' in this block.

Line 259: `repeat (5) @(negedge clk);` Within the module's structural declarations, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge normalization units RTL block in simulation. The important operands are repeat: the value named 'repeat' in this block; negedge: the value named 'negedge' in this block; clk: the clock that makes all registers advance together.

Line 260: `rst_n = 1'b1;` This makes rst_n, the active-low synchronous reset, equal to '1'b1'. It is driven by combinational or procedural logic in the current evaluation. The important operands are b1: the value named 'b1' in this block. Context: the module's structural declarations.

Line 262: `for (int case_index = 0; case_index < LN_CASES; case_index++) begin` This generate/procedural loop repeats the following operation across lanes or entries. In synthesizable RTL, a fixed loop is expanded into parallel or scheduled hardware rather than executed by a CPU. Context: the module's structural declarations.

Line 263: `run_layernorm_case(case_index);` Within the module's structural declarations, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge normalization units RTL block in simulation. The important operands are run_layernorm_case: the value named 'run layernorm case' in this block; case_index: an integer selecting one tensor element, lane, bank, or state entry.

Line 264: `end` This structural keyword opens or closes the branch/process scope described as the module's structural declarations; it has no arithmetic value of its own.

Line 265: `for (int case_index = 0; case_index < SM_CASES; case_index++) begin` This generate/procedural loop repeats the following operation across lanes or entries. In synthesizable RTL, a fixed loop is expanded into parallel or scheduled hardware rather than executed by a CPU. Context: the module's structural declarations.

Line 266: `run_softmax_case(case_index);` Within the module's structural declarations, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge normalization units RTL block in simulation. The important operands are run_softmax_case: the value named 'run softmax case' in this block; case_index: an integer selecting one tensor element, lane, bank, or state entry.

Line 267: `end` This structural keyword opens or closes the branch/process scope described as the module's structural declarations; it has no arithmetic value of its own.

Line 269: `if (ln_pointer != LN_SAMPLES || sm_pointer != SM_SAMPLES` Within the module's structural declarations, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge normalization units RTL block in simulation. The important operands are ln_pointer: the value named 'ln pointer' in this block; LN_SAMPLES: the value named 'ln samples' in this block; sm_pointer: the value named 'sm pointer' in this block.

Line 270: `|| ln_checked != LN_SAMPLES || sm_checked != SM_SAMPLES) begin` Within the module's structural declarations, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge normalization units RTL block in simulation. The important operands are ln_checked: the value named 'ln checked' in this block; LN_SAMPLES: the value named 'ln samples' in this block; sm_checked: the value named 'sm checked' in this block.

Line 271: `errors++;` Within the module's structural declarations, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge normalization units RTL block in simulation. The important operands are errors: the value named 'errors' in this block.

Line 272: `$display("ERROR normalization accounting ln=%0d/%0d checked=%0d sm=%0d/%0d checked=%0d",` This is a simulation check or diagnostic. It can stop a failing test and print evidence, but it is not part of the synthesized PYNQ circuit.

Line 273: `ln_pointer, LN_SAMPLES, ln_checked, sm_pointer, SM_SAMPLES, sm_checked);` Within the module's structural declarations, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge normalization units RTL block in simulation. The important operands are ln_pointer: the value named 'ln pointer' in this block; LN_SAMPLES: the value named 'ln samples' in this block; ln_checked: the value named 'ln checked' in this block.

Line 274: `end` This structural keyword opens or closes the branch/process scope described as the module's structural declarations; it has no arithmetic value of its own.

Line 275: `if (errors != 0) begin` This condition selects the following hardware branch only when 'errors != 0' is true. Both branches exist as gates; the condition controls a multiplexer rather than making software jump. The important operands are errors: the value named 'errors' in this block. Context: the module's structural declarations.

Line 276: `$display("tb_neuraedge_normalization_units FAILED errors=%0d", errors);` This is a simulation check or diagnostic. It can stop a failing test and print evidence, but it is not part of the synthesized PYNQ circuit.

Line 277: `$finish;` This is a simulation check or diagnostic. It can stop a failing test and print evidence, but it is not part of the synthesized PYNQ circuit.

Line 278: `end else begin` This structural keyword opens or closes the branch/process scope described as the module's structural declarations; it has no arithmetic value of its own.

Line 279: `$display("tb_neuraedge_normalization_units PASSED layernorm=%0d softmax=%0d",` This is a simulation check or diagnostic. It can stop a failing test and print evidence, but it is not part of the synthesized PYNQ circuit.

Line 280: `ln_checked, sm_checked);` Within the module's structural declarations, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge normalization units RTL block in simulation. The important operands are ln_checked: the value named 'ln checked' in this block; sm_checked: the value named 'sm checked' in this block.

Line 281: `$finish;` This is a simulation check or diagnostic. It can stop a failing test and print evidence, but it is not part of the synthesized PYNQ circuit.

Line 282: `end` This structural keyword opens or closes the branch/process scope described as the module's structural declarations; it has no arithmetic value of its own.

Line 283: `end` This structural keyword opens or closes the branch/process scope described as the module's structural declarations; it has no arithmetic value of its own.

Line 285: `initial begin` This opens simulation initialization. In a testbench it drives starting values and stimulus; project synthesis does not rely on this block as a replacement for explicit reset behavior.

Line 286: `#2_000_000;` Within the module's structural declarations, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge normalization units RTL block in simulation. The expression is a literal or structural operator and has no hidden software state.

Line 287: `$fatal(1, "tb_neuraedge_normalization_units watchdog timeout");` This is a simulation check or diagnostic. It can stop a failing test and print evidence, but it is not part of the synthesized PYNQ circuit.

Line 288: `end` This structural keyword opens or closes the branch/process scope described as the module's structural declarations; it has no arithmetic value of its own.

Line 289: `endmodule` This closes the current hardware definition; no circuit behavior is attached to the keyword itself.

Line 291: `` `default_nettype wire `` This SystemVerilog preprocessor line controls compilation of the block that drives, backpressures, and checks the neuraedge normalization units RTL block in simulation.

55 tb/tb_neuraedge_pynq_axi_top.sv

Role in the complete system: drives, backpressures, and checks the neuraedge pynq axi top RTL block in simulation.

55.1 Beginner architecture map

Dataflow responsibility This file's end-to-end responsibility is to drives, backpressures, and checks the neuraedge pynq axi top RTL block in simulation.

Simulation-only status tb_neuraedge_pynq_axi_top is not synthesized into the FPGA. It generates clocks, reset, commands, stalls, and expected values around the design under test, then terminates with an explicit result marker.

Evidence produced The file contains approximately 3 explicit assertions, failure diagnostics, or pass/fail markers. Its VCD/WDB trace is useful evidence only when the final pass marker is present; a simulator exit code by itself is insufficient.

55.3 Line annotations

Line 1: `` `timescale 1ns / 1ps `` This simulation directive selects nanoseconds as the time unit and picoseconds as the timestamp precision; it does not create FPGA logic.

Line 2: `` `default_nettype none `` This compiler directive forbids accidental implicit one-bit wires, turning misspelled signal names into errors instead of unintended hardware.

Line 4: `module tb_neuraedge_pynq_axi_top;` This opens tb_neuraedge_pynq_axi_top;, an independently compiled hardware definition. Its ports and statements collectively describe circuitry that drives, backpressures, and checks the neuraedge pynq axi top RTL block in simulation.

Line 5: `logic aclk = 1'b0;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, aclk is the AXI and accelerator clock. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 6: `logic aresetn = 1'b0;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, aresetn is the active-low AXI reset. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 7: `logic [7:0] s_axi_awaddr = 8'd0;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, s_axi_awaddr is the value named 's axi awaddr' in this block. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 8: `logic s_axi_awvalid = 1'b0;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, s_axi_awvalid is the producer's statement that its current payload is meaningful. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 9: `logic s_axi_awready;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, s_axi_awready is the consumer's statement that it can accept a payload this cycle. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 10: `logic [31:0] s_axi_wdata = 32'd0;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, s_axi_wdata is the value named 's axi wdata' in this block. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 11: `logic [3:0] s_axi_wstrb = 4'd0;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, s_axi_wstrb is the value named 's axi wstrb' in this block. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 12: `logic s_axi_wvalid = 1'b0;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, s_axi_wvalid is the producer's statement that its current payload is meaningful. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 13: `logic s_axi_wready;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, s_axi_wready is the consumer's statement that it can accept a payload this cycle. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 14: `logic [1:0] s_axi_bresp;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, s_axi_bresp is the value named 's axi bresp' in this block. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 15: `logic s_axi_bvalid;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, s_axi_bvalid is the producer's statement that its current payload is meaningful. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 16: `logic s_axi_bready = 1'b0;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, s_axi_bready is the consumer's statement that it can accept a payload this cycle. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 17: `logic [7:0] s_axi_araddr = 8'd0;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, s_axi_araddr is the value named 's axi araddr' in this block. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 18: `logic s_axi_arvalid = 1'b0;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, s_axi_arvalid is the producer's statement that its current payload is meaningful. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 19: `logic s_axi_arready;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, s_axi_arready is the consumer's statement that it can accept a payload this cycle. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 20: `logic [31:0] s_axi_rdata;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, s_axi_rdata is the value named 's axi rdata' in this block. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 21: `logic [1:0] s_axi_rresp;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, s_axi_rresp is the value named 's axi rresp' in this block. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 22: `logic s_axi_rvalid;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, s_axi_rvalid is the producer's statement that its current payload is meaningful. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 23: `logic s_axi_rready = 1'b0;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, s_axi_rready is the consumer's statement that it can accept a payload this cycle. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 24: `logic s_axis_tvalid = 1'b0;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, s_axis_tvalid is the producer's statement that its current payload is meaningful. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 25: `logic s_axis_tready;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, s_axis_tready is the consumer's statement that it can accept a payload this cycle. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 26: `logic [63:0] s_axis_tdata = 64'd0;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, s_axis_tdata is the value named 's axis tdata' in this block. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 27: `logic [7:0] s_axis_tkeep = 8'hff;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, s_axis_tkeep is the value named 's axis tkeep' in this block. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 28: `logic s_axis_tlast = 1'b0;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, s_axis_tlast is the AXI-Stream marker for the final beat of a packet or command payload. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 29: `logic m_axis_tvalid;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, m_axis_tvalid is the producer's statement that its current payload is meaningful. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 30: `logic m_axis_tready = 1'b0;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, m_axis_tready is the consumer's statement that it can accept a payload this cycle. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 31: `logic [63:0] m_axis_tdata;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, m_axis_tdata is the value named 'm axis tdata' in this block. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 32: `logic [7:0] m_axis_tkeep;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, m_axis_tkeep is the value named 'm axis tkeep' in this block. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 33: `logic m_axis_tlast;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, m_axis_tlast is the AXI-Stream marker for the final beat of a packet or command payload. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 34: `logic interrupt;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, interrupt is the hardware notification that wakes software after completion or error. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 35: `int errors = 0;` Within the module's structural declarations, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge pynq axi top RTL block in simulation. The important operands are errors: the value named 'errors' in this block.

Line 37: `neuraedge_pynq_axi_top dut (` This instantiates module neuraedge_pynq_axi_top as dut. Synthesis creates that subordinate circuit and connects its ports in the lines that follow.

Line 38: `.aclk(aclk), .aresetn(aresetn),` This connects the child instance's named port ‘aclk‘ to parent expression ‘aclk), .aresetn(aresetn‘. The connection is a physical net bundle after synthesis; direction is declared in the child module, and the clock that makes all registers advance together.

Line 39: `.s_axi_awaddr(s_axi_awaddr), .s_axi_awvalid(s_axi_awvalid),` This connects the child instance's named port ‘s_axi_awaddr‘ to parent expression ‘s_axi_awaddr), .s_axi_awvalid(s_axi_awvalid‘. The connection is a physical net bundle after synthesis; direction is declared in the child module, and the producer's statement that its current payload is meaningful.

Line 40: `.s_axi_awready(s_axi_awready), .s_axi_wdata(s_axi_wdata),` This connects the child instance's named port ‘s_axi_awready‘ to parent expression ‘s_axi_awready), .s_axi_wdata(s_axi_wdata‘. The connection is a physical net bundle after synthesis; direction is declared in the child module, and the consumer's statement that it can accept a payload this cycle.

Line 41: `.s_axi_wstrb(s_axi_wstrb), .s_axi_wvalid(s_axi_wvalid),` This connects the child instance's named port ‘s_axi_wstrb‘ to parent expression ‘s_axi_wstrb), .s_axi_wvalid(s_axi_wvalid‘. The connection is a physical net bundle after synthesis; direction is declared in the child module, and the producer's statement that its current payload is meaningful.

Line 42: `.s_axi_wready(s_axi_wready), .s_axi_bresp(s_axi_bresp),` This connects the child instance's named port ‘s_axi_wready‘ to parent expression ‘s_axi_wready), .s_axi_bresp(s_axi_bresp‘. The connection is a physical net bundle after synthesis; direction is declared in the child module, and the consumer's statement that it can accept a payload this cycle.

Line 43: `.s_axi_bvalid(s_axi_bvalid), .s_axi_bready(s_axi_bready),` This connects the child instance's named port ‘s_axi_bvalid‘ to parent expression ‘s_axi_bvalid), .s_axi_bready(s_axi_bready‘. The connection is a physical net bundle after synthesis; direction is declared in the child module, and the producer's statement that its current payload is meaningful.

Line 44: `.s_axi_araddr(s_axi_araddr), .s_axi_arvalid(s_axi_arvalid),` This connects the child instance's named port ‘s_axi_araddr‘ to parent expression ‘s_axi_araddr), .s_axi_arvalid(s_axi_arvalid‘. The connection is a physical net bundle after synthesis; direction is declared in the child module, and the producer's statement that its current payload is meaningful.

Line 45: `.s_axi_arready(s_axi_arready), .s_axi_rdata(s_axi_rdata),` This connects the child instance's named port ‘s_axi_arready‘ to parent expression ‘s_axi_arready), .s_axi_rdata(s_axi_rdata‘. The connection is a physical net bundle after synthesis; direction is declared in the child module, and the consumer's statement that it can accept a payload this cycle.

Line 46: `.s_axi_rresp(s_axi_rresp), .s_axi_rvalid(s_axi_rvalid),` This connects the child instance's named port ‘s_axi_rresp‘ to parent expression ‘s_axi_rresp), .s_axi_rvalid(s_axi_rvalid‘. The connection is a physical net bundle after synthesis; direction is declared in the child module, and the producer's statement that its current payload is meaningful.

Line 47: `.s_axi_rready(s_axi_rready),` This connects the child instance's named port ‘s_axi_rready‘ to parent expression ‘s_axi_rready‘. The connection is a physical net bundle after synthesis; direction is declared in the child module, and the consumer's statement that it can accept a payload this cycle.

Line 48: `.s_axis_tvalid(s_axis_tvalid), .s_axis_tready(s_axis_tready),` This connects the child instance's named port ‘s_axis_tvalid‘ to parent expression ‘s_axis_tvalid), .s_axis_tready(s_axis_tready‘. The connection is a physical net bundle after synthesis; direction is declared in the child module, and the producer's statement that its current payload is meaningful.

Line 49: `.s_axis_tdata(s_axis_tdata), .s_axis_tkeep(s_axis_tkeep),` This connects the child instance's named port ‘s_axis_tdata‘ to parent expression ‘s_axis_tdata), .s_axis_tkeep(s_axis_tkeep‘. The connection is a physical net bundle after synthesis; direction is declared in the child module, and the value named 's axis tdata), .s axis tkeep(s axis tkeep' in this block.

Line 50: `.s_axis_tlast(s_axis_tlast), .m_axis_tvalid(m_axis_tvalid),` This connects the child instance's named port ‘s_axis_tlast‘ to parent expression ‘s_axis_tlast), .m_axis_tvalid(m_axis_tvalid‘. The connection is a physical net bundle after synthesis; direction is declared in the child module, and the producer's statement that its current payload is meaningful.

Line 51: `.m_axis_tready(m_axis_tready), .m_axis_tdata(m_axis_tdata),` This connects the child instance's named port ‘m_axis_tready‘ to parent expression ‘m_axis_tready), .m_axis_tdata(m_axis_tdata‘. The connection is a physical net bundle after synthesis; direction is declared in the child module, and the consumer's statement that it can accept a payload this cycle.

Line 52: `.m_axis_tkeep(m_axis_tkeep), .m_axis_tlast(m_axis_tlast),` This connects the child instance's named port ‘m_axis_tkeep‘ to parent expression ‘m_axis_tkeep), .m_axis_tlast(m_axis_tlast‘. The connection is a physical net bundle after synthesis; direction is declared in the child module, and the AXI-Stream marker for the final beat of a packet or command payload.

Line 53: `.interrupt(interrupt)` This connects the child instance's named port 'interrupt' to parent expression 'interrupt'. The connection is a physical net bundle after synthesis; direction is declared in the child module, and the hardware notification that wakes software after completion or error.

Line 54: `);` Within the module's structural declarations, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge pynq axi top RTL block in simulation. The expression is a literal or structural operator and has no hidden software state.

Line 56: `always #2.5 aclk = ~aclk;` Within the module's structural declarations, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge pynq axi top RTL block in simulation. The important operands are always: the value named 'always' in this block; aclk: the AXI and accelerator clock.

Line 58: `task automatic send_aw(input logic [7:0] address);` Within the simulation task send aw, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge pynq axi top RTL block in simulation. The important operands are task: the value named 'task' in this block; automatic: the value named 'automatic' in this block; send_aw: the value named 'send aw' in this block.

Line 59: `begin` This structural keyword opens or closes the branch/process scope described as the simulation task send aw; it has no arithmetic value of its own.

Line 60: `@(negedge aclk);` Within the simulation task send aw, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge pynq axi top RTL block in simulation. The important operands are negedge: the value named 'negedge' in this block; aclk: the AXI and accelerator clock.

Line 61: `s_axi_awaddr = address;` This makes s_axi_awaddr, the value named 's axi awaddr' in this block, equal to 'address'. It is driven by combinational or procedural logic in the current evaluation. The important operands are address: the value named 'address' in this block. Context: the simulation task send aw.

Line 62: `s_axi_awvalid = 1'b1;` This makes s_axi_awvalid, the producer's statement that its current payload is meaningful, equal to '1'b1'. It is driven by combinational or procedural logic in the current evaluation. The important operands are b1: the value named 'b1' in this block. Context: the simulation task send aw.

Line 63: `while (!s_axi_awready) @(negedge aclk);` Within the simulation task send aw, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge pynq axi top RTL block in simulation. The important operands are while: the value named 'while' in this block; s_axi_awready: the consumer's statement that it can accept a payload this cycle; negedge: the value named 'negedge' in this block.

Line 64: `@(posedge aclk);` Within the simulation task send aw, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge pynq axi top RTL block in simulation. The important operands are posedge: the value named 'posedge' in this block; aclk: the AXI and accelerator clock.

Line 65: `@(negedge aclk);` Within the simulation task send aw, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge pynq axi top RTL block in simulation. The important operands are negedge: the value named 'negedge' in this block; aclk: the AXI and accelerator clock.

Line 66: `s_axi_awvalid = 1'b0;` This makes s_axi_awvalid, the producer's statement that its current payload is meaningful, equal to '1'b0'. It is driven by combinational or procedural logic in the current evaluation. The important operands are b0: the value named 'b0' in this block. Context: the simulation task send aw.

Line 67: `end` This structural keyword opens or closes the branch/process scope described as the simulation task send aw; it has no arithmetic value of its own.

Line 68: `endtask` Within the simulation task send aw, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge pynq axi top RTL block in simulation. The important operands are endtask: the value named 'endtask' in this block.

Line 70: `task automatic send_w(input logic [31:0] value, input logic [3:0] strobes);` Within the simulation task send w, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge pynq axi top RTL block in simulation. The important operands are task: the value named 'task' in this block; automatic: the value named 'automatic' in this block; send_w: the value named 'send w' in this block.

Line 71: `begin` This structural keyword opens or closes the branch/process scope described as the simulation task send w; it has no arithmetic value of its own.

Line 72: `@(negedge aclk);` Within the simulation task send w, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge pynq axi top RTL block in simulation. The important operands are negedge: the value named 'negedge' in this block; aclk: the AXI and accelerator clock.

Line 73: `s_axi_wdata = value;` This makes s_axi_wdata, the value named 's axi wdata' in this block, equal to ‘value‘. It is driven by combinational or procedural logic in the current evaluation. The important operands are value: the value named 'value' in this block. Context: the simulation task send w.

Line 74: `s_axi_wstrb = strobes;` This makes s_axi_wstrb, the value named 's axi wstrb' in this block, equal to ‘strobes‘. It is driven by combinational or procedural logic in the current evaluation. The important operands are strobes: the value named 'strobes' in this block. Context: the simulation task send w.

Line 75: `s_axi_wvalid = 1'b1;` This makes s_axi_wvalid, the producer's statement that its current payload is meaningful, equal to ‘1'b1‘. It is driven by combinational or procedural logic in the current evaluation. The important operands are b1: the value named 'b1' in this block. Context: the simulation task send w.

Line 76: `while (!s_axi_wready) @(negedge aclk);` Within the simulation task send w, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge pynq axi top RTL block in simulation. The important operands are while: the value named 'while' in this block; s_axi_wready: the consumer's statement that it can accept a payload this cycle; negedge: the value named 'negedge' in this block.

Line 77: `@(posedge aclk);` Within the simulation task send w, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge pynq axi top RTL block in simulation. The important operands are posedge: the value named 'posedge' in this block; aclk: the AXI and accelerator clock.

Line 78: `@(negedge aclk);` Within the simulation task send w, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge pynq axi top RTL block in simulation. The important operands are negedge: the value named 'negedge' in this block; aclk: the AXI and accelerator clock.

Line 79: `s_axi_wvalid = 1'b0;` This makes s_axi_wvalid, the producer's statement that its current payload is meaningful, equal to ‘1'b0‘. It is driven by combinational or procedural logic in the current evaluation. The important operands are b0: the value named 'b0' in this block. Context: the simulation task send w.

Line 80: `end` This structural keyword opens or closes the branch/process scope described as the simulation task send w; it has no arithmetic value of its own.

Line 81: `endtask` Within the simulation task send w, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge pynq axi top RTL block in simulation. The important operands are endtask: the value named 'endtask' in this block.

Line 83: `task automatic axi_write(` Within the simulation task axi write, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge pynq axi top RTL block in simulation. The important operands are task: the value named 'task' in this block; automatic: the value named 'automatic' in this block; axi_write: the value named 'axi write' in this block.

Line 84: `input logic [7:0] address,` This declares address as a input port with width [7:0]. It carries the value named 'address' in this block across the module boundary; a port is a bundle of physical FPGA nets, not a software argument.

Line 85: `input logic [31:0] value,` This declares value as a input port with width [31:0]. It carries the value named 'value' in this block across the module boundary; a port is a bundle of physical FPGA nets, not a software argument.

Line 86: `input logic [3:0] strobes,` This declares strobes as a input port with width [3:0]. It carries the value named 'strobes' in this block across the module boundary; a port is a bundle of physical FPGA nets, not a software argument.

Line 87: `input logic address_first` This declares address_first as a input port with width one bit. It carries the value named 'address first' in this block across the module boundary; a port is a bundle of physical FPGA nets, not a software argument.

Line 88: `);` Within the simulation task axi write, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge pynq axi top RTL block in simulation. The expression is a literal or structural operator and has no hidden software state.

Line 89: `begin` This structural keyword opens or closes the branch/process scope described as the simulation task axi write; it has no arithmetic value of its own.

Line 90: `if (address_first) begin` This condition selects the following hardware branch only when ‘address_first‘ is true. Both branches exist as gates; the condition controls a multiplexer rather than making software jump. The important operands are address_first: the value named 'address first' in this block. Context: the simulation task axi write.

Line 91: `send_aw(address);` Within the simulation task axi write, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge pynq axi top RTL block in simulation. The important operands are send_aw: the value named 'send aw' in this block; address: the value named 'address' in this block.

Line 92: `repeat (2) @(negedge aclk);` Within the simulation task axi write, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge pynq axi top RTL block in simulation. The important operands are repeat: the value named 'repeat' in this block; negedge: the value named 'negedge' in this block; aclk: the AXI and accelerator clock.

Line 93: `send_w(value, strobes);` Within the simulation task axi write, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge pynq axi top RTL block in simulation. The important operands are send_w: the value named 'send w' in this block; value: the value named 'value' in this block; strobes: the value named 'strobes' in this block.

Line 94: `end else begin` This structural keyword opens or closes the branch/process scope described as the simulation task axi write; it has no arithmetic value of its own.

Line 95: `send_w(value, strobes);` Within the simulation task axi write, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge pynq axi top RTL block in simulation. The important operands are send_w: the value named 'send w' in this block; value: the value named 'value' in this block; strobes: the value named 'strobes' in this block.

Line 96: `repeat (3) @(negedge aclk);` Within the simulation task axi write, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge pynq axi top RTL block in simulation. The important operands are repeat: the value named 'repeat' in this block; negedge: the value named 'negedge' in this block; aclk: the AXI and accelerator clock.

Line 97: `send_aw(address);` Within the simulation task axi write, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge pynq axi top RTL block in simulation. The important operands are send_aw: the value named 'send aw' in this block; address: the value named 'address' in this block.

Line 98: `end` This structural keyword opens or closes the branch/process scope described as the simulation task axi write; it has no arithmetic value of its own.

Line 99: `while (!s_axi_bvalid) @(negedge aclk);` Within the simulation task axi write, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge pynq axi top RTL block in simulation. The important operands are while: the value named 'while' in this block; s_axi_bvalid: the producer's statement that its current payload is meaningful; negedge: the value named 'negedge' in this block.

Line 100: `if (s_axi_bresp != 2'b00) begin` This condition selects the following hardware branch only when ‘s_axi_bresp != 2'b00‘ is true. Both branches exist as gates; the condition controls a multiplexer rather than making software jump. The important operands are s_axi_bresp: the value named 's axi bresp' in this block; b00: the value named 'b00' in this block. Context: the simulation task axi write.

Line 101: `errors++;` Within the simulation task axi write, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge pynq axi top RTL block in simulation. The important operands are errors: the value named 'errors' in this block.

Line 102: `$display("ERROR AXI write response address=%h response=%b", address, s_axi_bresp);` This is a simulation check or diagnostic. It can stop a failing test and print evidence, but it is not part of the synthesized PYNQ circuit.

Line 103: `end` This structural keyword opens or closes the branch/process scope described as the simulation task axi write; it has no arithmetic value of its own.

Line 104: `s_axi_bready = 1'b1;` This makes s_axi_bready, the consumer's statement that it can accept a payload this cycle, equal to ‘1'b1‘. It is driven by combinational or procedural logic in the current evaluation. The important operands are b1: the value named 'b1' in this block. Context: the simulation task axi write.

Line 105: `@(posedge aclk);` Within the simulation task axi write, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge pynq axi top RTL block in simulation. The important operands are posedge: the value named 'posedge' in this block; aclk: the AXI and accelerator clock.

Line 106: `@(negedge aclk);` Within the simulation task axi write, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge pynq axi top RTL block in simulation. The important operands are negedge: the value named 'negedge' in this block; aclk: the AXI and accelerator clock.

Line 107: `s_axi_bready = 1'b0;` This makes s_axi_bready, the consumer's statement that it can accept a payload this cycle, equal to ‘1'b0‘. It is driven by combinational or procedural logic in the current evaluation. The important operands are b0: the value named 'b0' in this block. Context: the simulation task axi write.

Line 108: `end` This structural keyword opens or closes the branch/process scope described as the simulation task axi write; it has no arithmetic value of its own.

Line 109: `endtask` Within the simulation task axi write, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge pynq axi top RTL block in simulation. The important operands are endtask: the value named 'endtask' in this block.

Line 111: `task automatic axi_read(input logic [7:0] address, output logic [31:0] value);` Within the simulation task axi read, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge pynq axi top RTL block in simulation. The important operands are task: the value named 'task' in this block; automatic: the value named 'automatic' in this block; axi_read: the value named 'axi read' in this block.

Line 112: `begin` This structural keyword opens or closes the branch/process scope described as the simulation task axi read; it has no arithmetic value of its own.

Line 113: `@(negedge aclk);` Within the simulation task axi read, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge pynq axi top RTL block in simulation. The important operands are negedge: the value named 'negedge' in this block; aclk: the AXI and accelerator clock.

Line 114: `s_axi_araddr = address;` This makes s_axi_araddr, the value named 's axi araddr' in this block, equal to ‘address‘. It is driven by combinational or procedural logic in the current evaluation. The important operands are address: the value named 'address' in this block. Context: the simulation task axi read.

Line 115: `s_axi_arvalid = 1'b1;` This makes s_axi_arvalid, the producer's statement that its current payload is meaningful, equal to ‘1'b1‘. It is driven by combinational or procedural logic in the current evaluation. The important operands are b1: the value named 'b1' in this block. Context: the simulation task axi read.

Line 116: `while (!s_axi_arready) @(negedge aclk);` Within the simulation task axi read, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge pynq axi top RTL block in simulation. The important operands are while: the value named 'while' in this block; s_axi_arready: the consumer's statement that it can accept a payload this cycle; negedge: the value named 'negedge' in this block.

Line 117: `@(posedge aclk);` Within the simulation task axi read, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge pynq axi top RTL block in simulation. The important operands are posedge: the value named 'posedge' in this block; aclk: the AXI and accelerator clock.

Line 118: `@(negedge aclk);` Within the simulation task axi read, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge pynq axi top RTL block in simulation. The important operands are negedge: the value named 'negedge' in this block; aclk: the AXI and accelerator clock.

Line 119: `s_axi_arvalid = 1'b0;` This makes s_axi_arvalid, the producer's statement that its current payload is meaningful, equal to ‘1'b0‘. It is driven by combinational or procedural logic in the current evaluation. The important operands are b0: the value named 'b0' in this block. Context: the simulation task axi read.

Line 120: `while (!s_axi_rvalid) @(negedge aclk);` Within the simulation task axi read, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge pynq axi top RTL block in simulation. The important operands are while: the value named 'while' in this block; s_axi_rvalid: the producer's statement that its current payload is meaningful; negedge: the value named 'negedge' in this block.

Line 121: `value = s_axi_rdata;` This makes value, the value named 'value' in this block, equal to ‘s_axi_rdata‘. It is driven by combinational or procedural logic in the current evaluation. The important operands are s_axi_rdata: the value named 's axi rdata' in this block. Context: the simulation task axi read.

Line 122: `if (s_axi_rresp != 2'b00) begin` This condition selects the following hardware branch only when ‘s_axi_rresp != 2'b00‘ is true. Both branches exist as gates; the condition controls a multiplexer rather than making software jump. The important operands are s_axi_rresp: the value named 's axi rresp' in this block; b00: the value named 'b00' in this block. Context: the simulation task axi read.

Line 123: `errors++;` Within the simulation task axi read, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge pynq axi top RTL block in simulation. The important operands are errors: the value named 'errors' in this block.

Line 124: `$display("ERROR AXI read response address=%h response=%b", address, s_axi_rresp);` This is a simulation check or diagnostic. It can stop a failing test and print evidence, but it is not part of the synthesized PYNQ circuit.

Line 125: `end` This structural keyword opens or closes the branch/process scope described as the simulation task axi read; it has no arithmetic value of its own.

Line 126: `repeat (2) @(negedge aclk);` Within the simulation task axi read, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge pynq axi top RTL block in simulation. The important operands are repeat: the value named 'repeat' in this block; negedge: the value named 'negedge' in this block; aclk: the AXI and accelerator clock.

Line 127: `if (!s_axi_rvalid || s_axi_rdata !== value) begin` This condition selects the following hardware branch only when ‘!s_axi_rvalid || s_axi_rdata !== value‘ is true. Both branches exist as gates; the condition controls a multiplexer rather than making software jump. The important operands are s_axi_rvalid: the producer's statement that its current payload is meaningful; s_axi_rdata: the value named 's axi rdata' in this block; value: the value named 'value' in this block. Context: the simulation task axi read.

Line 128: `errors++;` Within the simulation task axi read, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge pynq axi top RTL block in simulation. The important operands are errors: the value named 'errors' in this block.

Line 129: `$display("ERROR AXI read data did not remain stable under backpressure");` This is a simulation check or diagnostic. It can stop a failing test and print evidence, but it is not part of the synthesized PYNQ circuit.

Line 130: `end` This structural keyword opens or closes the branch/process scope described as the simulation task axi read; it has no arithmetic value of its own.

Line 131: `s_axi_rready = 1'b1;` This makes s_axi_rready, the consumer's statement that it can accept a payload this cycle, equal to ‘1'b1‘. It is driven by combinational or procedural logic in the current evaluation. The important operands are b1: the value named 'b1' in this block. Context: the simulation task axi read.

Line 132: `@(posedge aclk);` Within the simulation task axi read, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge pynq axi top RTL block in simulation. The important operands are posedge: the value named 'posedge' in this block; aclk: the AXI and accelerator clock.

Line 133: `@(negedge aclk);` Within the simulation task axi read, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge pynq axi top RTL block in simulation. The important operands are negedge: the value named 'negedge' in this block; aclk: the AXI and accelerator clock.

Line 134: `s_axi_rready = 1'b0;` This makes s_axi_rready, the consumer's statement that it can accept a payload this cycle, equal to ‘1'b0‘. It is driven by combinational or procedural logic in the current evaluation. The important operands are b0: the value named 'b0' in this block. Context: the simulation task axi read.

Line 135: `end` This structural keyword opens or closes the branch/process scope described as the simulation task axi read; it has no arithmetic value of its own.

Line 136: `endtask` Within the simulation task axi read, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge pynq axi top RTL block in simulation. The important operands are endtask: the value named 'endtask' in this block.

Line 138: `task automatic wait_interrupt;` Within the simulation task task, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge pynq axi top RTL block in simulation. The important operands are task: the value named 'task' in this block; automatic: the value named 'automatic' in this block; wait_interrupt: the hardware notification that wakes software after completion or error.

Line 139: `int timeout;` Within the simulation task task, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge pynq axi top RTL block in simulation. The important operands are timeout: the value named 'timeout' in this block.

Line 140: `begin` This structural keyword opens or closes the branch/process scope described as the simulation task task; it has no arithmetic value of its own.

Line 141: `timeout = 0;` This makes timeout, the value named 'timeout' in this block, equal to '0'. It is driven by combinational or procedural logic in the current evaluation. The expression is a literal or structural operator and has no hidden software state. Context: the simulation task task.

Line 142: `while (!interrupt && timeout < 10000) begin` Within the simulation task task, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge pynq axi top RTL block in simulation. The important operands are while: the value named 'while' in this block; interrupt: the hardware notification that wakes software after completion or error; timeout: the value named 'timeout' in this block.

Line 143: `@(negedge aclk);` Within the simulation task task, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge pynq axi top RTL block in simulation. The important operands are negedge: the value named 'negedge' in this block; aclk: the AXI and accelerator clock.

Line 144: `timeout++;` Within the simulation task task, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge pynq axi top RTL block in simulation. The important operands are timeout: the value named 'timeout' in this block.

Line 145: `end` This structural keyword opens or closes the branch/process scope described as the simulation task task; it has no arithmetic value of its own.

Line 146: `if (!interrupt) begin` This condition selects the following hardware branch only when '!interrupt' is true. Both branches exist as gates; the condition controls a multiplexer rather than making software jump. The important operands are interrupt: the hardware notification that wakes software after completion or error. Context: the simulation task task.

Line 147: `errors++;` Within the simulation task task, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge pynq axi top RTL block in simulation. The important operands are errors: the value named 'errors' in this block.

Line 148: `$display("ERROR AXI interrupt timeout");` This is a simulation check or diagnostic. It can stop a failing test and print evidence, but it is not part of the synthesized PYNQ circuit.

Line 149: `end` This structural keyword opens or closes the branch/process scope described as the simulation task task; it has no arithmetic value of its own.

Line 150: `end` This structural keyword opens or closes the branch/process scope described as the simulation task task; it has no arithmetic value of its own.

Line 151: `endtask` Within the simulation task task, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge pynq axi top RTL block in simulation. The important operands are endtask: the value named 'endtask' in this block.

Line 153: `task automatic send_axis_word(` Within the simulation task send axis word, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge pynq axi top RTL block in simulation. The important operands are task: the value named 'task' in this block; automatic: the value named 'automatic' in this block; send_axis_word: the value named 'send axis word' in this block.

Line 154: `input logic [63:0] value,` This declares value as a input port with width [63:0]. It carries the value named 'value' in this block across the module boundary; a port is a bundle of physical FPGA nets, not a software argument.

Line 155: `input logic last_value` This declares last_value as a input port with width one bit. It carries the AXI-Stream marker for the final beat of a packet or command payload across the module boundary; a port is a bundle of physical FPGA nets, not a software argument.

Line 156: `);` Within the simulation task send axis word, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge pynq axi top RTL block in simulation. The expression is a literal or structural operator and has no hidden software state.

Line 157: `begin` This structural keyword opens or closes the branch/process scope described as the simulation task send axis word; it has no arithmetic value of its own.

Line 158: `@(negedge aclk);` Within the simulation task send axis word, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge pynq axi top RTL block in simulation. The important operands are negedge: the value named 'negedge' in this block; aclk: the AXI and accelerator clock.

Line 159: `s_axis_tdata = value;` This makes s_axis_tdata, the value named 's axis tdata' in this block, equal to ‘value‘. It is driven by combinational or procedural logic in the current evaluation. The important operands are value: the value named 'value' in this block. Context: the simulation task send axis word.

Line 160: `s_axis_tlast = last_value;` This makes s_axis_tlast, the AXI-Stream marker for the final beat of a packet or command payload, equal to ‘last_value‘. It is driven by combinational or procedural logic in the current evaluation. The important operands are last_value: the AXI-Stream marker for the final beat of a packet or command payload. Context: the simulation task send axis word.

Line 161: `s_axis_tvalid = 1'b1;` This makes s_axis_tvalid, the producer's statement that its current payload is meaningful, equal to ‘1'b1‘. It is driven by combinational or procedural logic in the current evaluation. The important operands are b1: the value named 'b1' in this block. Context: the simulation task send axis word.

Line 162: `while (!s_axis_tready) @(negedge aclk);` Within the simulation task send axis word, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge pynq axi top RTL block in simulation. The important operands are while: the value named 'while' in this block; s_axis_tready: the consumer's statement that it can accept a payload this cycle; negedge: the value named 'negedge' in this block.

Line 163: `@(posedge aclk);` Within the simulation task send axis word, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge pynq axi top RTL block in simulation. The important operands are posedge: the value named 'posedge' in this block; aclk: the AXI and accelerator clock.

Line 164: `@(negedge aclk);` Within the simulation task send axis word, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge pynq axi top RTL block in simulation. The important operands are negedge: the value named 'negedge' in this block; aclk: the AXI and accelerator clock.

Line 165: `s_axis_tvalid = 1'b0;` This makes s_axis_tvalid, the producer's statement that its current payload is meaningful, equal to '1'b0'. It is driven by combinational or procedural logic in the current evaluation. The important operands are b0: the value named 'b0' in this block. Context: the simulation task send axis word.

Line 166: `s_axis_tlast = 1'b0;` This makes s_axis_tlast, the AXI-Stream marker for the final beat of a packet or command payload, equal to '1'b0'. It is driven by combinational or procedural logic in the current evaluation. The important operands are b0: the value named 'b0' in this block. Context: the simulation task send axis word.

Line 167: `s_axis_tdata = 64'd0;` This makes s_axis_tdata, the value named 's axis tdata' in this block, equal to '64'd0'. It is driven by combinational or procedural logic in the current evaluation. The important operands are d0: the value named 'd0' in this block. Context: the simulation task send axis word.

Line 168: `end` This structural keyword opens or closes the branch/process scope described as the simulation task send axis word; it has no arithmetic value of its own.

Line 169: `endtask` Within the simulation task send axis word, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge pynq axi top RTL block in simulation. The important operands are endtask: the value named 'endtask' in this block.

Line 171: `initial begin` This opens simulation initialization. In a testbench it drives starting values and stimulus; project synthesis does not rely on this block as a replacement for explicit reset behavior.

Line 172: `logic [31:0] read_value;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, read_value is the value named 'read value' in this block. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 173: `repeat (5) @(negedge aclk);` Within the module's structural declarations, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge pynq axi top RTL block in simulation. The important operands are repeat: the value named 'repeat' in this block; negedge: the value named 'negedge' in this block; aclk: the AXI and accelerator clock.

Line 174: `aresetn = 1'b1;` This makes aresetn, the active-low AXI reset, equal to '1'b1'. It is driven by combinational or procedural logic in the current evaluation. The important operands are b1: the value named 'b1' in this block. Context: the module's structural declarations.

Line 176: `axi_read(8'h34, read_value);` Within the module's structural declarations, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge pynq axi top RTL block in simulation. The important operands are axi_read: the value named 'axi read' in this block; h34: the value named 'h34' in this block; read_value: the value named 'read value' in this block.

Line 177: `if (read_value != 32'h4e455552) begin` This condition selects the following hardware branch only when 'read_value != 32'h4e455552' is true. Both branches exist as gates; the condition controls a multiplexer rather than making software jump. The important operands are read_value: the value named 'read value' in this block; h4e455552: the value named 'h4e455552' in this block. Context: the module's structural declarations.

Line 178: `errors++;` Within the module's structural declarations, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge pynq axi top RTL block in simulation. The important operands are errors: the value named 'errors' in this block.

Line 179: `$display("ERROR AXI identity got=%h", read_value);` This is a simulation check or diagnostic. It can stop a failing test and print evidence, but it is not part of the synthesized PYNQ circuit.

Line 180: `end` This structural keyword opens or closes the branch/process scope described as the module's structural declarations; it has no arithmetic value of its own.

Line 181: `axi_read(8'h2c, read_value);` Within the module's structural declarations, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge pynq axi top RTL block in simulation. The important operands are axi_read: the value named 'axi read' in this block; h2c: the value named 'h2c' in this block; read_value: the value named 'read value' in this block.

Line 182: `if (read_value != 32'h1ff) errors++;` This condition selects the following hardware branch only when 'read_value != 32'h1ff' is true. Both branches exist as gates; the condition controls a multiplexer rather than making software jump. The important operands are read_value: the value named 'read value' in this block; h1ff: the value named 'h1ff' in this block. Context: the module's structural declarations.

Line 183: `axi_read(8'h30, read_value);` Within the module's structural declarations, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge pynq axi top RTL block in simulation. The important operands are axi_read: the value named 'axi read' in this block; h30: the value named 'h30' in this block; read_value: the value named 'read value' in this block.

Line 184: `if (read_value != 32'h00010007) errors++;` This condition selects the following hardware branch only when 'read_value != 32'h00010007' is true. Both branches exist as gates; the condition controls a multiplexer rather than making software jump. The important operands are read_value: the value named 'read value' in this block; h00010007: the value named 'h00010007' in this block. Context: the module's structural declarations.

Line 185: `axi_read(8'h28, read_value);` Within the module's structural declarations, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge pynq axi top RTL block in simulation. The important operands are axi_read: the value named 'axi read' in this block; h28: the value named 'h28' in this block; read_value: the value named 'read value' in this block.

Line 186: `if (read_value != 32'd200000000) errors++;` This condition selects the following hardware branch only when 'read_value != 32'd200000000' is true. Both branches exist as gates; the condition controls a multiplexer rather than making software jump. The important operands are read_value: the value named 'read value' in this block; d200000000: the value named 'd200000000' in this block. Context: the module's structural declarations.

Line 187: `axi_read(8'h48, read_value);` Within the module's structural declarations, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge pynq axi top RTL block in simulation. The important operands are axi_read: the value named 'axi read' in this block; h48: the value named 'h48' in this block; read_value: the value named 'read value' in this block.

Line 188: `if (read_value != 0) errors++;` This condition selects the following hardware branch only when 'read_value != 0' is true. Both branches exist as gates; the condition controls a multiplexer rather than making software jump. The important operands are read_value: the value named 'read value' in this block. Context: the module's structural declarations.

Line 189: `axi_read(8'h74, read_value);` Within the module's structural declarations, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge pynq axi top RTL block in simulation. The important operands are axi_read: the value named 'axi read' in this block; h74: the value named 'h74' in this block; read_value: the value named 'read value' in this block.

Line 190: `if (read_value != 0) errors++;` This condition selects the following hardware branch only when 'read_value != 0' is true. Both branches exist as gates; the condition controls a multiplexer rather than making software jump. The important operands are read_value: the value named 'read value' in this block. Context: the module's structural declarations.

Line 191: `axi_read(8'h80, read_value);` Within the module's structural declarations, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge pynq axi top RTL block in simulation. The important operands are axi_read: the value named 'axi read' in this block; h80: the value named 'h80' in this block; read_value: the value named 'read value' in this block.

Line 192: `if (read_value != 0) errors++;` This condition selects the following hardware branch only when ‘read_value != 0‘ is true. Both branches exist as gates; the condition controls a multiplexer rather than making software jump. The important operands are read_value: the value named ’read value’ in this block. Context: the module’s structural declarations.

Line 193: `axi_read(8’h94, read_value);` Within the module’s structural declarations, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge pynq axi top RTL block in simulation. The important operands are axi_read: the value named ’axi read’ in this block; h94: the value named ’h94’ in this block; read_value: the value named ’read value’ in this block.

Line 194: `if (read_value != 0) errors++;` This condition selects the following hardware branch only when ‘read_value != 0‘ is true. Both branches exist as gates; the condition controls a multiplexer rather than making software jump. The important operands are read_value: the value named ’read value’ in this block. Context: the module’s structural declarations.

Line 195: `axi_read(8’h98, read_value);` Within the module’s structural declarations, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge pynq axi top RTL block in simulation. The important operands are axi_read: the value named ’axi read’ in this block; h98: the value named ’h98’ in this block; read_value: the value named ’read value’ in this block.

Line 196: `if (read_value != 0) errors++;` This condition selects the following hardware branch only when ‘read_value != 0‘ is true. Both branches exist as gates; the condition controls a multiplexer rather than making software jump. The important operands are read_value: the value named ’read value’ in this block. Context: the module’s structural declarations.

Line 198: `// Write address and data channels in both legal arrival orders.` Design intent: Write address and data channels in both legal arrival orders. This comment anchors the surrounding logic in the block that drives, backpressures, and checks the neuraedge pynq axi top RTL block in simulation.

Line 199: `axi_write(8’h10, 32’h0000000f, 4’hf, 1’b1);` Within the module’s structural declarations, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge pynq axi top RTL block in simulation. The important operands are axi_write: the value named ’axi write’ in this block; h10: the value named ’h10’ in this block; h0000000f: the value named ’h0000000f’ in this block.

Line 200: `axi_write(8’h14, 32’h00000000, 4’hf, 1’b0);` Within the module’s structural declarations, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge pynq axi top RTL block in simulation. The important operands are axi_write: the value named ’axi write’ in this block; h14: the value named ’h14’ in this block; h00000000: the value named ’h00000000’ in this block.

Line 201: `axi_write(8’h18, 32’h00000000, 4’hf, 1’b1);` Within the module’s structural declarations, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge pynq axi top RTL block in simulation. The important operands are axi_write: the value named ’axi write’ in this block; h18: the value named ’h18’ in this block; h00000000: the value named ’h00000000’ in this block.

Line 202: `axi_write(8’h1c, 32’h00000000, 4’hf, 1’b0);` Within the module’s structural declarations, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge pynq axi top RTL block in simulation. The important operands are axi_write: the value named ’axi write’ in this block; h1c: the value named ’h1c’ in this block; h00000000: the value named ’h00000000’ in this block.

Line 203: `axi_write(8’h00, 32’h00000101, 4’hf, 1’b1);` Within the module’s structural declarations, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge pynq axi top RTL block in simulation. The important operands are axi_write: the value named ’axi write’ in this block; h00: the value named ’h00’ in this block; h00000101: the value named ’h00000101’ in this block.

Line 204: `wait_interrupt();` Within the module's structural declarations, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge pynq axi top RTL block in simulation. The important operands are wait_interrupt: the hardware notification that wakes software after completion or error.

Line 205: `axi_read(8'h04, read_value);` Within the module's structural declarations, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge pynq axi top RTL block in simulation. The important operands are axi_read: the value named 'axi read' in this block; h04: the value named 'h04' in this block; read_value: the value named 'read value' in this block.

Line 206: `if (!read_value[4] || !read_value[2] || read_value[1] || read_value[0]) begin` This condition selects the following hardware branch only when '!read_value[4] || !read_value[2] || read_value[1] || read_value[0]' is true. Both branches exist as gates; the condition controls a multiplexer rather than making software jump. The important operands are read_value: the value named 'read value' in this block. Context: the module's structural declarations.

Line 207: `errors++;` Within the module's structural declarations, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge pynq axi top RTL block in simulation. The important operands are errors: the value named 'errors' in this block.

Line 208: `$display("ERROR AXI successful status=%h", read_value);` This is a simulation check or diagnostic. It can stop a failing test and print evidence, but it is not part of the synthesized PYNQ circuit.

Line 209: `end` This structural keyword opens or closes the branch/process scope described as the module's structural declarations; it has no arithmetic value of its own.

Line 210: `axi_read(8'h0c, read_value);` Within the module's structural declarations, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge pynq axi top RTL block in simulation. The important operands are axi_read: the value named 'axi read' in this block; h0c: the value named 'h0c' in this block; read_value: the value named 'read value' in this block.

Line 211: `if (read_value != 1) begin` This condition selects the following hardware branch only when 'read_value != 1' is true. Both branches exist as gates; the condition controls a multiplexer rather than making software jump. The important operands are read_value: the value named 'read value' in this block. Context: the module's structural declarations.

Line 212: `errors++;` Within the module's structural declarations, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge pynq axi top RTL block in simulation. The important operands are errors: the value named 'errors' in this block.

Line 213: `$display("ERROR AXI command count=%0d", read_value);` This is a simulation check or diagnostic. It can stop a failing test and print evidence, but it is not part of the synthesized PYNQ circuit.

Line 214: `end` This structural keyword opens or closes the branch/process scope described as the module's structural declarations; it has no arithmetic value of its own.

Line 216: `// Four output words fill the wrapper's two-entry FIFO plus capture` Design intent: Four output words fill the wrapper's two-entry FIFO plus capture This comment anchors the surrounding logic in the block that drives, backpressures, and checks the neuraedge pynq axi top RTL block in simulation.

Line 217: `// register. Hold the external sink stalled long enough to prove that` Design intent: register. Hold the external sink stalled long enough to prove that This comment anchors the surrounding logic in the block that drives, backpressures, and checks the neuraedge pynq axi top RTL block in simulation.

Line 218: `// registered credit stops the core without dropping or changing data.` Design intent: registered credit stops the core without dropping or changing data. This comment anchors the surrounding logic in the block that drives, backpressures, and checks the neuraedge pynq axi top RTL block in simulation.

Line 219: `axi_write(8'h10, 32'h00000009, 4'hf, 1'b1);` Within the module's structural declarations, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge pynq axi top RTL block in simulation. The important operands are axi_write: the value named 'axi write' in this block; h10: the value named 'h10' in this block; h00000009: the value named 'h00000009' in this block.

Line 220: `axi_write(8'h14, 32'h00000000, 4'hf, 1'b0);` Within the module's structural declarations, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge pynq axi top RTL block in simulation. The important operands are axi_write: the value named 'axi write' in this block; h14: the value named 'h14' in this block; h00000000: the value named 'h00000000' in this block.

Line 221: `axi_write(8'h18, 32'h00000000, 4'hf, 1'b1);` Within the module's structural declarations, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge pynq axi top RTL block in simulation. The important operands are axi_write: the value named 'axi write' in this block; h18: the value named 'h18' in this block; h00000000: the value named 'h00000000' in this block.

Line 222: `axi_write(8'h1c, 32'h00000000, 4'hf, 1'b0);` Within the module's structural declarations, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge pynq axi top RTL block in simulation. The important operands are axi_write: the value named 'axi write' in this block; h1c: the value named 'h1c' in this block; h00000000: the value named 'h00000000' in this block.

Line 223: `axi_write(8'h00, 32'h00000101, 4'hf, 1'b1);` Within the module's structural declarations, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge pynq axi top RTL block in simulation. The important operands are axi_write: the value named 'axi write' in this block; h00: the value named 'h00' in this block; h00000101: the value named 'h00000101' in this block.

Line 224: `send_axis_word(64'h7fffffff80000000, 1'b0);` Within the module's structural declarations, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge pynq axi top RTL block in simulation. The important operands are send_axis_word: the value named 'send axis word' in this block; h7fffffff80000000: the value named 'h7fffffff80000000' in this block; b0: the value named 'b0' in this block.

Line 225: `for (int beat = 0; beat < 4; beat++) begin` This generate/procedural loop repeats the following operation across lanes or entries. In synthesizable RTL, a fixed loop is expanded into parallel or scheduled hardware rather than executed by a CPU. Context: the module's structural declarations.

Line 226: `send_axis_word({32'(11 + 2*beat), 32'(10 + 2*beat)}, 1'b0);` Within the module's structural declarations, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge pynq axi top RTL block in simulation. The important operands are send_axis_word: the value named 'send axis word' in this block; beat: the value named 'beat' in this block; b0: the value named 'b0' in this block.

Line 227: `end` This structural keyword opens or closes the branch/process scope described as the module's structural declarations; it has no arithmetic value of its own.

Line 228: `for (int beat = 0; beat < 4; beat++) begin` This generate/procedural loop repeats the following operation across lanes or entries. In synthesizable RTL, a fixed loop is expanded into parallel or scheduled hardware rather than executed by a CPU. Context: the module's structural declarations.

Line 229: `send_axis_word({32'(3 * (2*beat + 1)), 32'(3 * (2*beat))}, beat == 3);` Within the module's structural declarations, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge pynq axi top RTL block in simulation. The important operands are send_axis_word: the value named 'send axis word' in this block; beat: the value named 'beat' in this block.

Line 230: `end` This structural keyword opens or closes the branch/process scope described as the module's structural declarations; it has no arithmetic value of its own.

Line 231: `while (!m_axis_tvalid) @(negedge aclk);` Within the module's structural declarations, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge pynq axi top RTL block in simulation. The important operands are while: the value named 'while' in this block; m_axis_tvalid: the producer's statement that its current payload is meaningful; negedge: the value named 'negedge' in this block.

Line 232: `begin` This structural keyword opens or closes the branch/process scope described as the module's structural declarations; it has no arithmetic value of its own.

Line 233: `logic [63:0] stalled_data;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, stalled_data is the payload carried with the surrounding valid/ready handshake. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 234: `logic stalled_last;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, stalled_last is the AXI-Stream marker for the final beat of a packet or command payload. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 235: `stalled_data = m_axis_tdata;` This makes stalled_data, the payload carried with the surrounding valid/ready handshake, equal to 'm_axis_tdata'. It is driven by combinational or procedural logic in the current evaluation. The important operands are m_axis_tdata: the value named 'm axis tdata' in this block. Context: the module's structural declarations.

Line 236: `stalled_last = m_axis_tlast;` This makes stalled_last, the AXI-Stream marker for the final beat of a packet or command payload, equal to 'm_axis_tlast'. It is driven by combinational or procedural logic in the current evaluation. The important operands are m_axis_tlast: the AXI-Stream marker for the final beat of a packet or command payload. Context: the module's structural declarations.

Line 237: `repeat (12) begin` Within the module's structural declarations, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge pynq axi top RTL block in simulation. The important operands are repeat: the value named 'repeat' in this block.

Line 238: `@(negedge aclk);` Within the module's structural declarations, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge pynq axi top RTL block in simulation. The important operands are negedge: the value named 'negedge' in this block; aclk: the AXI and accelerator clock.

Line 239: `if (!m_axis_tvalid || m_axis_tdata !== stalled_data` Within the module's structural declarations, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge pynq axi top RTL block in simulation. The important operands are m_axis_tvalid: the producer's statement that its current payload is meaningful; m_axis_tdata: the value named 'm axis tdata' in this block; stalled_data: the payload carried with the surrounding valid/ready handshake.

Line 240: `|| m_axis_tlast !== stalled_last) begin` Within the module's structural declarations, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge pynq axi top RTL block in simulation. The important operands are m_axis_tlast: the AXI-Stream marker for the final beat of a packet or command payload; stalled_last: the AXI-Stream marker for the final beat of a packet or command payload.

Line 241: `errors++;` Within the module's structural declarations, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge pynq axi top RTL block in simulation. The important operands are errors: the value named 'errors' in this block.

Line 242: `$display("ERROR AXI output changed while backpressured");` This is a simulation check or diagnostic. It can stop a failing test and print evidence, but it is not part of the synthesized PYNQ circuit.

Line 243: `end` This structural keyword opens or closes the branch/process scope described as the module's structural declarations; it has no arithmetic value of its own.

Line 244: `end` This structural keyword opens or closes the branch/process scope described as the module's structural declarations; it has no arithmetic value of its own.

Line 245: `end` This structural keyword opens or closes the branch/process scope described as the module's structural declarations; it has no arithmetic value of its own.

Line 246: `for (int beat = 0; beat < 4; beat++) begin` This generate/procedural loop repeats the following operation across lanes or entries. In synthesizable RTL, a fixed loop is expanded into parallel or scheduled hardware rather than executed by a CPU. Context: the module's structural declarations.

Line 247: `logic [63:0] expected_word;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, expected_word is the value named 'expected word' in this block. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 248: `expected_word = {32'(14 + 8*beat), 32'(10 + 8*beat)};` This makes expected_word, the value named 'expected word' in this block, equal to '{32'(14 + 8*beat), 32'(10 + 8*beat)}'. It is driven by combinational or procedural logic in the current evaluation. The important operands are beat: the value named 'beat' in this block. Context: the module's structural declarations.

Line 249: `while (!m_axis_tvalid) @(negedge aclk);` Within the module's structural declarations, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge pynq axi top RTL block in simulation. The important operands are while: the value named 'while' in this block; m_axis_tvalid: the producer's statement that its current payload is meaningful; negedge: the value named 'negedge' in this block.

Line 250: `if (m_axis_tdata !== expected_word || m_axis_tlast != (beat == 3)` This condition selects the following hardware branch only when 'm_axis_tdata !== expected_word || m_axis_tlast != (beat == 3' is true. Both branches exist as gates; the condition controls a multiplexer rather than making software jump. The important operands are m_axis_tdata: the value named 'm axis tdata' in this block; expected_word: the value named 'expected word' in this block; m_axis_tlast: the AXI-Stream marker for the final beat of a packet or command payload. Context: the module's structural declarations.

Line 251: `|| m_axis_tkeep != 8'hff) begin` Within the module's structural declarations, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge pynq axi top RTL block in simulation. The important operands are m_axis_tkeep: the value named 'm axis tkeep' in this block; hff: the value named 'hff' in this block.

Line 252: `errors++;` Within the module's structural declarations, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge pynq axi top RTL block in simulation. The important operands are errors: the value named 'errors' in this block.

Line 253: `$display("ERROR AXI vector beat=%0d got=%h last=%0d expected=%h",` This is a simulation check or diagnostic. It can stop a failing test and print evidence, but it is not part of the synthesized PYNQ circuit.

Line 254: `beat, m_axis_tdata, m_axis_tlast, expected_word);` Within the module's structural declarations, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge pynq axi top RTL block in simulation. The important operands are beat: the value named 'beat' in this block; m_axis_tdata: the value named 'm axis tdata' in this block; m_axis_tlast: the AXI-Stream marker for the final beat of a packet or command payload.

Line 255: `end` This structural keyword opens or closes the branch/process scope described as the module's structural declarations; it has no arithmetic value of its own.

Line 256: `m_axis_tready = 1'b1;` This makes m_axis_tready, the consumer's statement that it can accept a payload this cycle, equal to '1'b1'. It is driven by combinational or procedural logic in the current evaluation. The important operands are b1: the value named 'b1' in this block. Context: the module's structural declarations.

Line 257: `@(posedge aclk);` Within the module's structural declarations, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge pynq axi top RTL block in simulation. The important operands are posedge: the value named 'posedge' in this block; aclk: the AXI and accelerator clock.

Line 258: `@(negedge aclk);` Within the module's structural declarations, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge pynq axi top RTL block in simulation. The important operands are negedge: the value named 'negedge' in this block; aclk: the AXI and accelerator clock.

Line 259: `m_axis_tready = 1'b0;` This makes m_axis_tready, the consumer's statement that it can accept a payload this cycle, equal to '1'b0'. It is driven by combinational or procedural logic in the current evaluation. The important operands are b0: the value named 'b0' in this block. Context: the module's structural declarations.

Line 260: `end` This structural keyword opens or closes the branch/process scope described as the module's structural declarations; it has no arithmetic value of its own.

Line 261: `wait_interrupt();` Within the module's structural declarations, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge pynq axi top RTL block in simulation. The important operands are wait_interrupt: the hardware notification that wakes software after completion or error.

Line 262: `axi_read(8'h20, read_value);` Within the module's structural declarations, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge pynq axi top RTL block in simulation. The important operands are axi_read: the value named 'axi read' in this block; h20: the value named 'h20' in this block; read_value: the value named 'read value' in this block.

Line 263: `if (read_value != 9) begin` This condition selects the following hardware branch only when 'read_value != 9' is true. Both branches exist as gates; the condition controls a multiplexer rather than making software jump. The important operands are read_value: the value named 'read value' in this block. Context: the module's structural declarations.

Line 264: `errors++;` Within the module's structural declarations, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge pynq axi top RTL block in simulation. The important operands are errors: the value named 'errors' in this block.

Line 265: `$display("ERROR AXI vector input-beat count=%0d", read_value);` This is a simulation check or diagnostic. It can stop a failing test and print evidence, but it is not part of the synthesized PYNQ circuit.

Line 266: `end` This structural keyword opens or closes the branch/process scope described as the module's structural declarations; it has no arithmetic value of its own.

Line 267: `axi_read(8'h24, read_value);` Within the module's structural declarations, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge pynq axi top RTL block in simulation. The important operands are axi_read: the value named 'axi read' in this block; h24: the value named 'h24' in this block; read_value: the value named 'read value' in this block.

Line 268: `if (read_value != 4) begin` This condition selects the following hardware branch only when 'read_value != 4' is true. Both branches exist as gates; the condition controls a multiplexer rather than making software jump. The important operands are read_value: the value named 'read value' in this block. Context: the module's structural declarations.

Line 269: `errors++;` Within the module's structural declarations, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge pynq axi top RTL block in simulation. The important operands are errors: the value named 'errors' in this block.

Line 270: `$display("ERROR AXI vector output-beat count=%0d", read_value);` This is a simulation check or diagnostic. It can stop a failing test and print evidence, but it is not part of the synthesized PYNQ circuit.

Line 271: `end` This structural keyword opens or closes the branch/process scope described as the module's structural declarations; it has no arithmetic value of its own.

Line 273: `// Byte strobes update only the selected command byte.` Design intent: Byte strobes update only the selected command byte. This comment anchors the surrounding logic in the block that drives, backpressures, and checks the neuraedge pynq axi top RTL block in simulation.

Line 274: `axi_write(8'h10, 32'hdeadbe00, 4'b0001, 1'b0);` Within the module's structural declarations, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge pynq axi top RTL block in simulation. The important operands are axi_write: the value named 'axi write' in this block; h10: the value named 'h10' in this block; hdeadbe00: the value named 'hdeadbe00' in this block.

Line 275: `axi_read(8'h10, read_value);` Within the module's structural declarations, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge pynq axi top RTL block in simulation. The important operands are axi_read: the value named 'axi read' in this block; h10: the value named 'h10' in this block; read_value: the value named 'read value' in this block.

Line 276: `if (read_value != 32'h00000000) begin` This condition selects the following hardware branch only when 'read_value != 32'h00000000' is true. Both branches exist as gates; the condition controls a multiplexer rather than making software jump. The important operands are read_value: the value named 'read value' in this block; h00000000: the value named 'h00000000' in this block. Context: the module's structural declarations.

Line 277: `errors++;` Within the module's structural declarations, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge pynq axi top RTL block in simulation. The important operands are errors: the value named 'errors' in this block.

Line 278: `$display("ERROR AXI write strobe result=%h", read_value);` This is a simulation check or diagnostic. It can stop a failing test and print evidence, but it is not part of the synthesized PYNQ circuit.

Line 279: `end` This structural keyword opens or closes the branch/process scope described as the module's structural declarations; it has no arithmetic value of its own.

Line 281: `// Opcode zero is illegal and must set the core error bit.` Design intent: Opcode zero is illegal and must set the core error bit. This comment anchors the surrounding logic in the block that drives, backpressures, and checks the neuraedge pynq axi top RTL block in simulation.

Line 282: `axi_write(8'h00, 32'h00000102, 4'hf, 1'b1);` Within the module's structural declarations, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge pynq axi top RTL block in simulation. The important operands are axi_write: the value named 'axi write' in this block; h00: the value named 'h00' in this block; h00000102: the value named 'h00000102' in this block.

Line 283: `axi_write(8'h00, 32'h00000101, 4'hf, 1'b0);` Within the module's structural declarations, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge pynq axi top RTL block in simulation. The important operands are axi_write: the value named 'axi write' in this block; h00: the value named 'h00' in this block; h00000101: the value named 'h00000101' in this block.

Line 284: `wait_interrupt();` Within the module's structural declarations, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge pynq axi top RTL block in simulation. The important operands are wait_interrupt: the hardware notification that wakes software after completion or error.

Line 285: `axi_read(8'h04, read_value);` Within the module's structural declarations, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge pynq axi top RTL block in simulation. The important operands are axi_read: the value named 'axi read' in this block; h04: the value named 'h04' in this block; read_value: the value named 'read value' in this block.

Line 286: `if (!read_value[1] || !read_value[2]) begin` This condition selects the following hardware branch only when '!read_value[1] || !read_value[2]' is true. Both branches exist as gates; the condition controls a multiplexer rather than making software jump. The important operands are read_value: the value named 'read value' in this block. Context: the module's structural declarations.

Line 287: `errors++;` Within the module's structural declarations, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge pynq axi top RTL block in simulation. The important operands are errors: the value named 'errors' in this block.

Line 288: `$display("ERROR AXI invalid-command status=%h", read_value);` This is a simulation check or diagnostic. It can stop a failing test and print evidence, but it is not part of the synthesized PYNQ circuit.

Line 289: `end` This structural keyword opens or closes the branch/process scope described as the module's structural declarations; it has no arithmetic value of its own.

Line 291: `// Restore opcode F and clear all nested sticky errors once more.` Design intent: Restore opcode F and clear all nested sticky errors once more. This comment anchors the surrounding logic in the block that drives, backpressures, and checks the neuraedge pynq axi top RTL block in simulation.

Line 292: `axi_write(8'h10, 32'h0000000f, 4'b0001, 1'b1);` Within the module's structural declarations, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge pynq axi top RTL block in simulation. The important operands are axi_write: the value named 'axi write' in this block; h10: the value named 'h10' in this block; h0000000f: the value named 'h0000000f' in this block.

Line 293: `axi_write(8'h00, 32'h00000102, 4'hf, 1'b0);` Within the module's structural declarations, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge pynq axi top RTL block in simulation. The important operands are axi_write: the value named 'axi write' in this block; h00: the value named 'h00' in this block; h00000102: the value named 'h00000102' in this block.

Line 294: `axi_write(8'h00, 32'h00000101, 4'hf, 1'b1);` Within the module's structural declarations, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge pynq axi top RTL block in simulation. The important operands are axi_write: the value named 'axi write' in this block; h00: the value named 'h00' in this block; h00000101: the value named 'h00000101' in this block.

Line 295: `wait_interrupt();` Within the module's structural declarations, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge pynq axi top RTL block in simulation. The important operands are wait_interrupt: the hardware notification that wakes software after completion or error.

Line 296: `axi_read(8'h04, read_value);` Within the module's structural declarations, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge pynq axi top RTL block in simulation. The important operands are axi_read: the value named 'axi read' in this block; h04: the value named 'h04' in this block; read_value: the value named 'read value' in this block.

Line 297: `if (read_value[1] || !read_value[2]) begin` This condition selects the following hardware branch only when ‘read_value[1] || !read_value[2]‘ is true. Both branches exist as gates; the condition controls a multiplexer rather than making software jump. The important operands are read_value: the value named ’read value’ in this block. Context: the module’s structural declarations.

Line 298: `errors++;` Within the module’s structural declarations, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge pynq axi top RTL block in simulation. The important operands are errors: the value named ’errors’ in this block.

Line 299: `$display("ERROR AXI final clear status=%h", read_value);` This is a simulation check or diagnostic. It can stop a failing test and print evidence, but it is not part of the synthesized PYNQ circuit.

Line 300: `end` This structural keyword opens or closes the branch/process scope described as the module’s structural declarations; it has no arithmetic value of its own.

Line 301: `axi_read(8'h0c, read_value);` Within the module’s structural declarations, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge pynq axi top RTL block in simulation. The important operands are axi_read: the value named ’axi read’ in this block; h0c: the value named ’h0c’ in this block; read_value: the value named ’read value’ in this block.

Line 302: `if (read_value != 4) begin` This condition selects the following hardware branch only when ‘read_value != 4‘ is true. Both branches exist as gates; the condition controls a multiplexer rather than making software jump. The important operands are read_value: the value named ’read value’ in this block. Context: the module’s structural declarations.

Line 303: `errors++;` Within the module’s structural declarations, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge pynq axi top RTL block in simulation. The important operands are errors: the value named ’errors’ in this block.

Line 304: `$display("ERROR AXI final command count=%0d", read_value);` This is a simulation check or diagnostic. It can stop a failing test and print evidence, but it is not part of the synthesized PYNQ circuit.

Line 305: `end` This structural keyword opens or closes the branch/process scope described as the module’s structural declarations; it has no arithmetic value of its own.

Line 307: `if (errors != 0) begin` This condition selects the following hardware branch only when ‘errors != 0‘ is true. Both branches exist as gates; the condition controls a multiplexer rather than making software jump. The important operands are errors: the value named ’errors’ in this block. Context: the module’s structural declarations.

Line 308: `$display("tb_neuraedge_pynq_axi_top FAILED errors=%0d", errors);` This is a simulation check or diagnostic. It can stop a failing test and print evidence, but it is not part of the synthesized PYNQ circuit.

Line 309: `$finish;` This is a simulation check or diagnostic. It can stop a failing test and print evidence, but it is not part of the synthesized PYNQ circuit.

Line 310: `end else begin` This structural keyword opens or closes the branch/process scope described as the module’s structural declarations; it has no arithmetic value of its own.

Line 311: `$display("tb_neuraedge_pynq_axi_top PASSED commands=%0d", read_value);` This is a simulation check or diagnostic. It can stop a failing test and print evidence, but it is not part of the synthesized PYNQ circuit.

Line 312: `$finish;` This is a simulation check or diagnostic. It can stop a failing test and print evidence, but it is not part of the synthesized PYNQ circuit.

Line 313: `end` This structural keyword opens or closes the branch/process scope described as the module's structural declarations; it has no arithmetic value of its own.

Line 314: `end` This structural keyword opens or closes the branch/process scope described as the module's structural declarations; it has no arithmetic value of its own.

Line 316: `initial begin` This opens simulation initialization. In a testbench it drives starting values and stimulus; project synthesis does not rely on this block as a replacement for explicit reset behavior.

Line 317: `#20_000;` Within the module's structural declarations, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge pynq axi top RTL block in simulation. The expression is a literal or structural operator and has no hidden software state.

Line 318: `$fatal(1, "tb_neuraedge_pynq_axi_top watchdog timeout");` This is a simulation check or diagnostic. It can stop a failing test and print evidence, but it is not part of the synthesized PYNQ circuit.

Line 319: `end` This structural keyword opens or closes the branch/process scope described as the module's structural declarations; it has no arithmetic value of its own.

Line 320: `endmodule` This closes the current hardware definition; no circuit behavior is attached to the keyword itself.

Line 322: `` `default_nettype wire `` This SystemVerilog preprocessor line controls compilation of the block that drives, backpressures, and checks the neuraedge pynq axi top RTL block in simulation.

56 tb/tb_neuraedge_pynq_descriptor.sv

Role in the complete system: drives, backpressures, and checks the neuraedge pynq descriptor RTL block in simulation.

56.1 Beginner architecture map

Dataflow responsibility This file's end-to-end responsibility is to drives, backpressures, and checks the neuraedge pynq descriptor RTL block in simulation.

Simulation-only status tb_neuraedge_pynq_descriptor is not synthesized into the FPGA. It generates clocks, reset, commands, stalls, and expected values around the design under test, then terminates with an explicit result marker.

Evidence produced The file contains approximately 3 explicit assertions, failure diagnostics, or pass/fail markers. Its VCD/WDB trace is useful evidence only when the final pass marker is present; a simulator exit code by itself is insufficient.

56.3 Line annotations

Line 1: `` `timescale 1ns / 1ps `` This simulation directive selects nanoseconds as the time unit and picoseconds as the timestamp precision; it does not create FPGA logic.

Line 2: `` `default_nettype none `` This compiler directive forbids accidental implicit one-bit wires, turning misspelled signal names into errors instead of unintended hardware.

Line 4: `module tb_neuraedge_pynq_descriptor;` This opens tb_neuraedge_pynq_descriptor;, an independently compiled hardware definition. Its ports and statements collectively describe circuitry that drives, backpressures, and checks the neuraedge pynq descriptor RTL block in simulation.

Line 5: `logic clk = 1'b0;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, clk is the clock that makes all registers advance together. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 6: `logic rst_n = 1'b0;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, rst_n is the active-low synchronous reset. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 7: `logic [7:0] awaddr = 8'd0;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, awaddr is the value named 'awaddr' in this block. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 8: `logic awvalid = 1'b0;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, awvalid is the producer's statement that its current payload is meaningful. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 9: `wire awready;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, awready is the consumer's statement that it can accept a payload this cycle. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 10: `logic [31:0] wdata = 32'd0;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, wdata is the value named 'wdata' in this block. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 11: `logic [3:0] wstrb = 4'hf;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, wstrb is the value named 'wstrb' in this block. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 12: `logic wvalid = 1'b0;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, wvalid is the producer's statement that its current payload is meaningful. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 13: `wire wready;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, wready is the consumer's statement that it can accept a payload this cycle. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 14: `wire [1:0] bresp;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, bresp is the value named 'bresp' in this block. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 15: `wire bvalid;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, bvalid is the producer's statement that its current payload is meaningful. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 16: `logic bready = 1'b0;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, bready is the consumer's statement that it can accept a payload this cycle. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 17: `logic [7:0] araddr = 8'd0;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, araddr is the value named 'araddr' in this block. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 18: `logic arvalid = 1'b0;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, arvalid is the producer's statement that its current payload is meaningful. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 19: `wire arready;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, arready is the consumer's statement that it can accept a payload this cycle. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 20: `wire [31:0] rdata;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, rdata is the value named 'rdata' in this block. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 21: `wire [1:0] rresp;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, rresp is the value named 'rresp' in this block. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 22: `wire rvalid;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, rvalid is the producer's statement that its current payload is meaningful. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 23: `logic rready = 1'b0;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, rready is the consumer's statement that it can accept a payload this cycle. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 24: `logic s_valid = 1'b0;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, s_valid is the producer's statement that its current payload is meaningful. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 25: `wire s_ready;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, s_ready is the consumer's statement that it can accept a payload this cycle. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 26: `logic [63:0] s_data = 64'd0;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, s_data is the payload carried with the surrounding valid/ready handshake. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 27: `logic [7:0] s_keep = 8'hff;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, s_keep is the value named 's keep' in this block. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 28: `logic s_last = 1'b0;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, s_last is the AXI-Stream marker for the final beat of a packet or command payload. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 29: `wire m_valid;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, m_valid is the producer's statement that its current payload is meaningful. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 30: `logic m_ready = 1'b0;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, m_ready is the consumer's statement that it can accept a payload this cycle. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 31: `wire [63:0] m_data;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, m_data is the payload carried with the surrounding valid/ready handshake. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 32: `wire [7:0] m_keep;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, m_keep is the value named 'm keep' in this block. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 33: `wire m_last;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, m_last is the AXI-Stream marker for the final beat of a packet or command payload. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 34: `wire interrupt;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, interrupt is the hardware notification that wakes software after completion or error. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 35: `int errors = 0;` Within the module's structural declarations, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge pynq descriptor RTL block in simulation. The important operands are errors: the value named 'errors' in this block.

Line 37: `neuraedge_pynq_axi_top dut (` This instantiates module neuraedge_pynq_axi_top as dut. Synthesis creates that subordinate circuit and connects its ports in the lines that follow.

Line 38: `.aclk(clk), .aresetn(rst_n),` This connects the child instance's named port 'aclk' to parent expression 'clk), .aresetn(rst_n'. The connection is a physical net bundle after synthesis; direction is declared in the child module, and the clock that makes all registers advance together.

Line 39: `.s_axi_awaddr(awaddr), .s_axi_awvalid(awvalid), .s_axi_awready(awready),` This connects the child instance's named port 's_axi_awaddr' to parent expression 'awaddr), .s_axi_awvalid(awvalid), .s_axi_awready(awready'. The connection is a physical net bundle after synthesis; direction is declared in the child module, and the producer's statement that its current payload is meaningful.

Line 40: `.s_axi_wdata(wdata), .s_axi_wstrb(wstrb), .s_axi_wvalid(wvalid),` This connects the child instance's named port 's_axi_wdata' to parent expression 'wdata), .s_axi_wstrb(wstrb), .s_axi_wvalid(wvalid'. The connection is a physical net bundle after synthesis; direction is declared in the child module, and the producer's statement that its current payload is meaningful.

Line 41: `.s_axi_wready(wready), .s_axi_bresp(bresp), .s_axi_bvalid(bvalid),` This connects the child instance's named port 's_axi_wready' to parent expression 'wready), .s_axi_bresp(bresp), .s_axi_bvalid(bvalid'. The connection is a physical net bundle after synthesis; direction is declared in the child module, and the producer's statement that its current payload is meaningful.

Line 42: `.s_axi_bready(bready), .s_axi_araddr(araddr), .s_axi_arvalid(arvalid),` This connects the child instance's named port 's_axi_bready' to parent expression 'bready), .s_axi_araddr(araddr), .s_axi_arvalid(arvalid'. The connection is a physical net bundle after synthesis; direction is declared in the child module, and the producer's statement that its current payload is meaningful.

Line 43: `.s_axi_arready(arready), .s_axi_rdata(rdata), .s_axi_rresp(rresp),` This connects the child instance's named port 's_axi_arready' to parent expression 'arready), .s_axi_rdata(rdata), .s_axi_rresp(rresp'. The connection is a physical net bundle after synthesis; direction is declared in the child module, and the consumer's statement that it can accept a payload this cycle.

Line 44: `.s_axi_rvalid(rvalid), .s_axi_rready(rready),` This connects the child instance's named port 's_axi_rvalid' to parent expression 'rvalid), .s_axi_rready(rready'. The connection is a physical net bundle after synthesis; direction is declared in the child module, and the producer's statement that its current payload is meaningful.

Line 45: `.s_axis_tvalid(s_valid), .s_axis_tready(s_ready), .s_axis_tdata(s_data),` This connects the child instance's named port 's_axis_tvalid' to parent expression 's_valid), .s_axis_tready(s_ready), .s_axis_tdata(s_data'. The connection is a physical net bundle after synthesis; direction is declared in the child module, and the producer's statement that its current payload is meaningful.

Line 46: `.s_axis_tkeep(s_keep), .s_axis_tlast(s_last),` This connects the child instance's named port 's_axis_tkeep' to parent expression 's_keep), .s_axis_tlast(s_last'. The connection is a physical net bundle after synthesis; direction is declared in the child module, and the AXI-Stream marker for the final beat of a packet or command payload.

Line 47: `.m_axis_tvalid(m_valid), .m_axis_tready(m_ready), .m_axis_tdata(m_data),` This connects the child instance's named port 'm_axis_tvalid' to parent expression 'm_valid), .m_axis_tready(m_ready), .m_axis_tdata(m_data'. The connection is a physical net bundle after synthesis; direction is declared in the child module, and the producer's statement that its current payload is meaningful.

Line 48: `.m_axis_tkeep(m_keep), .m_axis_tlast(m_last), .interrupt(interrupt)` This connects the child instance's named port 'm_axis_tkeep' to parent expression 'm_keep), .m_axis_tlast(m_last), .interrupt(interrupt'. The connection is a physical net bundle after synthesis; direction is declared in the child module, and the AXI-Stream marker for the final beat of a packet or command payload.

Line 49: `);` Within the module's structural declarations, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge pynq descriptor RTL block in simulation. The expression is a literal or structural operator and has no hidden software state.

Line 51: `always #2.5 clk = ~clk;` Within the module's structural declarations, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge pynq descriptor RTL block in simulation. The important operands are always: the value named 'always' in this block; clk: the clock that makes all registers advance together.

Line 53: `task automatic axi_write(input logic [7:0] address, input logic [31:0] value);` Within the simulation task axi write, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge pynq descriptor RTL block in simulation. The important operands are task: the value named 'task' in this block; automatic: the value named 'automatic' in this block; axi_write: the value named 'axi write' in this block.

Line 54: `begin` This structural keyword opens or closes the branch/process scope described as the simulation task axi write; it has no arithmetic value of its own.

Line 55: `@(negedge clk);` Within the simulation task axi write, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge pynq descriptor RTL block in simulation. The important operands are negedge: the value named 'negedge' in this block; clk: the clock that makes all registers advance together.

Line 56: `awaddr = address;` This makes awaddr, the value named 'awaddr' in this block, equal to 'address'. It is driven by combinational or procedural logic in the current evaluation. The important operands are address: the value named 'address' in this block. Context: the simulation task axi write.

Line 57: `wdata = value;` This makes wdata, the value named 'wdata' in this block, equal to 'value'. It is driven by combinational or procedural logic in the current evaluation. The important operands are value: the value named 'value' in this block. Context: the simulation task axi write.

Line 58: `awvalid = 1'b1;` This makes awvalid, the producer's statement that its current payload is meaningful, equal to '1'b1'. It is driven by combinational or procedural logic in the current evaluation. The important operands are b1: the value named 'b1' in this block. Context: the simulation task axi write.

Line 59: `wvalid = 1'b1;` This makes wvalid, the producer's statement that its current payload is meaningful, equal to '1'b1'. It is driven by combinational or procedural logic in the current evaluation. The important operands are b1: the value named 'b1' in this block. Context: the simulation task axi write.

Line 60: `while (!(awready && wready)) @(negedge clk);` Within the simulation task axi write, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge pynq descriptor RTL block in simulation. The important operands are while: the value named 'while' in this block; awready: the consumer's statement that it can accept a payload this cycle; wready: the consumer's statement that it can accept a payload this cycle.

Line 61: `@(posedge clk);` Within the simulation task axi write, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge pynq descriptor RTL block in simulation. The important operands are posedge: the value named 'posedge' in this block; clk: the clock that makes all registers advance together.

Line 62: `@(negedge clk);` Within the simulation task axi write, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge pynq descriptor RTL block in simulation. The important operands are negedge: the value named 'negedge' in this block; clk: the clock that makes all registers advance together.

Line 63: `awvalid = 1'b0;` This makes awvalid, the producer's statement that its current payload is meaningful, equal to '1'b0'. It is driven by combinational or procedural logic in the current evaluation. The important operands are b0: the value named 'b0' in this block. Context: the simulation task axi write.

Line 64: `wvalid = 1'b0;` This makes wvalid, the producer's statement that its current payload is meaningful, equal to '1'b0'. It is driven by combinational or procedural logic in the current evaluation. The important operands are b0: the value named 'b0' in this block. Context: the simulation task axi write.

Line 65: `while (!bvalid) @(negedge clk);` Within the simulation task axi write, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge pynq descriptor RTL block in simulation. The important operands are while: the value named 'while' in this block; bvalid: the producer's statement that its current payload is meaningful; negedge: the value named 'negedge' in this block.

Line 66: `if (bresp != 0) errors++;` This condition selects the following hardware branch only when 'bresp != 0' is true. Both branches exist as gates; the condition controls a multiplexer rather than making software jump. The important operands are bresp: the value named 'bresp' in this block. Context: the simulation task axi write.

Line 67: `bready = 1'b1;` This makes bready, the consumer's statement that it can accept a payload this cycle, equal to '1'b1'. It is driven by combinational or procedural logic in the current evaluation. The important operands are b1: the value named 'b1' in this block. Context: the simulation task axi write.

Line 68: `@(posedge clk);` Within the simulation task axi write, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge pynq descriptor RTL block in simulation. The important operands are posedge: the value named 'posedge' in this block; clk: the clock that makes all registers advance together.

Line 69: `@(negedge clk);` Within the simulation task axi write, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge pynq descriptor RTL block in simulation. The important operands are negedge: the value named 'negedge' in this block; clk: the clock that makes all registers advance together.

Line 70: `bready = 1'b0;` This makes bready, the consumer's statement that it can accept a payload this cycle, equal to '1'b0'. It is driven by combinational or procedural logic in the current evaluation. The important operands are b0: the value named 'b0' in this block. Context: the simulation task axi write.

Line 71: `end` This structural keyword opens or closes the branch/process scope described as the simulation task axi write; it has no arithmetic value of its own.

Line 72: `endtask` Within the simulation task axi write, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge pynq descriptor RTL block in simulation. The important operands are endtask: the value named 'endtask' in this block.

Line 74: `task automatic axi_read(input logic [7:0] address, output logic [31:0] value);` Within the simulation task axi read, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge pynq descriptor RTL block in simulation. The important operands are task: the value named 'task' in this block; automatic: the value named 'automatic' in this block; axi_read: the value named 'axi read' in this block.

Line 75: `begin` This structural keyword opens or closes the branch/process scope described as the simulation task axi read; it has no arithmetic value of its own.

Line 76: `@(negedge clk);` Within the simulation task axi read, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge pynq descriptor RTL block in simulation. The important operands are negedge: the value named 'negedge' in this block; clk: the clock that makes all registers advance together.

Line 77: `araddr = address;` This makes araddr, the value named 'araddr' in this block, equal to 'address'. It is driven by combinational or procedural logic in the current evaluation. The important operands are address: the value named 'address' in this block. Context: the simulation task axi read.

Line 78: `arvalid = 1'b1;` This makes arvalid, the producer's statement that its current payload is meaningful, equal to '1'b1'. It is driven by combinational or procedural logic in the current evaluation. The important operands are b1: the value named 'b1' in this block. Context: the simulation task axi read.

Line 79: `while (!aready) @(negedge clk);` Within the simulation task axi read, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge pynq descriptor RTL block in simulation. The important operands are while: the value named 'while' in this block; aready: the consumer's statement that it can accept a payload this cycle; negedge: the value named 'negedge' in this block.

Line 80: `@(posedge clk);` Within the simulation task axi read, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge pynq descriptor RTL block in simulation. The important operands are posedge: the value named 'posedge' in this block; clk: the clock that makes all registers advance together.

Line 81: `@(negedge clk);` Within the simulation task axi read, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge pynq descriptor RTL block in simulation. The important operands are negedge: the value named 'negedge' in this block; clk: the clock that makes all registers advance together.

Line 82: `arvalid = 1'b0;` This makes arvalid, the producer's statement that its current payload is meaningful, equal to '1'b0'. It is driven by combinational or procedural logic in the current evaluation. The important operands are b0: the value named 'b0' in this block. Context: the simulation task axi read.

Line 83: `while (!rvalid) @(negedge clk);` Within the simulation task axi read, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge pynq descriptor RTL block in simulation. The important operands are while: the value named 'while' in this block; rvalid: the producer's statement that its current payload is meaningful; negedge: the value named 'negedge' in this block.

Line 84: `value = rdata;` This makes value, the value named 'value' in this block, equal to 'rdata'. It is driven by combinational or procedural logic in the current evaluation. The important operands are rdata: the value named 'rdata' in this block. Context: the simulation task axi read.

Line 85: `if (rresp != 0) errors++;` This condition selects the following hardware branch only when 'rresp != 0' is true. Both branches exist as gates; the condition controls a multiplexer rather than making software jump. The important operands are rresp: the value named 'rresp' in this block. Context: the simulation task axi read.

Line 86: `rready = 1'b1;` This makes rready, the consumer's statement that it can accept a payload this cycle, equal to '1'b1'. It is driven by combinational or procedural logic in the current evaluation. The important operands are b1: the value named 'b1' in this block. Context: the simulation task axi read.

Line 87: `@(posedge clk);` Within the simulation task axi read, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge pynq descriptor RTL block in simulation. The important operands are posedge: the value named 'posedge' in this block; clk: the clock that makes all registers advance together.

Line 88: `@(negedge clk);` Within the simulation task axi read, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge pynq descriptor RTL block in simulation. The important operands are negedge: the value named 'negedge' in this block; clk: the clock that makes all registers advance together.

Line 89: `rready = 1'b0;` This makes rready, the consumer's statement that it can accept a payload this cycle, equal to '1'b0'. It is driven by combinational or procedural logic in the current evaluation. The important operands are b0: the value named 'b0' in this block. Context: the simulation task axi read.

Line 90: `end` This structural keyword opens or closes the branch/process scope described as the simulation task axi read; it has no arithmetic value of its own.

Line 91: `endtask` Within the simulation task axi read, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge pynq descriptor RTL block in simulation. The important operands are endtask: the value named 'endtask' in this block.

Line 93: `task automatic send_word(input logic [63:0] value, input logic last);` Within the simulation task send word, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge pynq descriptor RTL block in simulation. The important operands are task: the value named 'task' in this block; automatic: the value named 'automatic' in this block; send_word: the value named 'send word' in this block.

Line 94: `begin` This structural keyword opens or closes the branch/process scope described as the simulation task send word; it has no arithmetic value of its own.

Line 95: `@(negedge clk);` Within the simulation task send word, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge pynq descriptor RTL block in simulation. The important operands are negedge: the value named 'negedge' in this block; clk: the clock that makes all registers advance together.

Line 96: `s_data = value;` This makes s_data, the payload carried with the surrounding valid/ready handshake, equal to 'value'. It is driven by combinational or procedural logic in the current evaluation. The important operands are value: the value named 'value' in this block. Context: the simulation task send word.

Line 97: `s_last = last;` This makes s_last, the AXI-Stream marker for the final beat of a packet or command payload, equal to 'last'. It is driven by combinational or procedural logic in the current evaluation. The important operands are last: the AXI-Stream marker for the final beat of a packet or command payload. Context: the simulation task send word.

Line 98: `s_valid = 1'b1;` This makes s_valid, the producer's statement that its current payload is meaningful, equal to '1'b1'. It is driven by combinational or procedural logic in the current evaluation. The important operands are b1: the value named 'b1' in this block. Context: the simulation task send word.

Line 99: `while (!s_ready) @(negedge clk);` Within the simulation task send word, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge pynq descriptor RTL block in simulation. The important operands are while: the value named 'while' in this block; s_ready: the consumer's statement that it can accept a payload this cycle; negedge: the value named 'negedge' in this block.

Line 100: `@(posedge clk);` Within the simulation task send word, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge pynq descriptor RTL block in simulation. The important operands are posedge: the value named 'posedge' in this block; clk: the clock that makes all registers advance together.

Line 101: `@(negedge clk);` Within the simulation task send word, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge pynq descriptor RTL block in simulation. The important operands are negedge: the value named 'negedge' in this block; clk: the clock that makes all registers advance together.

Line 102: `s_valid = 1'b0;` This makes s_valid, the producer's statement that its current payload is meaningful, equal to '1'b0'. It is driven by combinational or procedural logic in the current evaluation. The important operands are b0: the value named 'b0' in this block. Context: the simulation task send word.

Line 103: `s_last = 1'b0;` This makes s_last, the AXI-Stream marker for the final beat of a packet or command payload, equal to '1'b0'. It is driven by combinational or procedural logic in the current evaluation. The important operands are b0: the value named 'b0' in this block. Context: the simulation task send word.

Line 104: `end` This structural keyword opens or closes the branch/process scope described as the simulation task send word; it has no arithmetic value of its own.

Line 105: `endtask` Within the simulation task send word, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge pynq descriptor RTL block in simulation. The important operands are endtask: the value named 'endtask' in this block.

Line 107: `initial begin` This opens simulation initialization. In a testbench it drives starting values and stimulus; project synthesis does not rely on this block as a replacement for explicit reset behavior.

Line 108: `logic [31:0] value;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, value is the value named 'value' in this block. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 109: `repeat (5) @(negedge clk);` Within the module's structural declarations, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge pynq descriptor RTL block in simulation. The important operands are repeat: the value named 'repeat' in this block; negedge: the value named 'negedge' in this block; clk: the clock that makes all registers advance together.

Line 110: `rst_n = 1'b1;` This makes rst_n, the active-low synchronous reset, equal to '1'b1'. It is driven by combinational or procedural logic in the current evaluation. The important operands are b1: the value named 'b1' in this block. Context: the module's structural declarations.

Line 111: `axi_read(8'h2c, value);` Within the module's structural declarations, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge pynq descriptor RTL block in simulation. The important operands are axi_read: the value named 'axi read' in this block; h2c: the value named 'h2c' in this block; value: the value named 'value' in this block.

Line 112: `if (value != 32'h1ff) errors++;` This condition selects the following hardware branch only when 'value != 32'h1ff' is true. Both branches exist as gates; the condition controls a multiplexer rather than making software jump. The important operands are value: the value named 'value' in this block; h1ff: the value named 'h1ff' in this block. Context: the module's structural declarations.

Line 113: `axi_read(8'h30, value);` Within the module's structural declarations, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge pynq descriptor RTL block in simulation. The important operands are axi_read: the value named 'axi read' in this block; h30: the value named 'h30' in this block; value: the value named 'value' in this block.

Line 114: `if (value != 32'h00010007) errors++;` This condition selects the following hardware branch only when 'value != 32'h00010007' is true. Both branches exist as gates; the condition controls a multiplexer rather than making software jump. The important operands are value: the value named 'value' in this block; h00010007: the value named 'h00010007' in this block. Context: the module's structural declarations.

Line 115: `axi_read(8'h94, value);` Within the module's structural declarations, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge pynq descriptor RTL block in simulation. The important operands are axi_read: the value named 'axi read' in this block; h94: the value named 'h94' in this block; value: the value named 'value' in this block.

Line 116: `if (value != 0) errors++;` This condition selects the following hardware branch only when 'value != 0' is true. Both branches exist as gates; the condition controls a multiplexer rather than making software jump. The important operands are value: the value named 'value' in this block. Context: the module's structural declarations.

Line 117: `axi_read(8'h98, value);` Within the module's structural declarations, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge pynq descriptor RTL block in simulation. The important operands are axi_read: the value named 'axi read' in this block; h98: the value named 'h98' in this block; value: the value named 'value' in this block.

Line 118: `if (value != 0) errors++;` This condition selects the following hardware branch only when 'value != 0' is true. Both branches exist as gates; the condition controls a multiplexer rather than making software jump. The important operands are value: the value named 'value' in this block. Context: the module's structural declarations.

Line 120: `axi_write(8'h90, 32'd0);` Within the module's structural declarations, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge pynq descriptor RTL block in simulation. The important operands are axi_write: the value named 'axi write' in this block; h90: the value named 'h90' in this block; d0: the value named 'd0' in this block.

Line 121: `axi_write(8'h00, 32'h00000104);` Within the module's structural declarations, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge pynq descriptor RTL block in simulation. The important operands are axi_write: the value named 'axi write' in this block; h00: the value named 'h00' in this block; h00000104: the value named 'h00000104' in this block.

Line 122: `send_word({1'b1, 31'd0, 32'd0}, 1'b0);` Within the module's structural declarations, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge pynq descriptor RTL block in simulation. The important operands are send_word: the value named 'send word' in this block; b1: the value named 'b1' in this block; d0: the value named 'd0' in this block.

Line 123: `send_word(64'h000000000000000f, 1'b0);` Within the module's structural declarations, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge pynq descriptor RTL block in simulation. The important operands are send_word: the value named 'send word' in this block; h000000000000000f: the value named 'h000000000000000f' in this block; b0: the value named 'b0' in this block.

Line 124: `send_word(64'd0, 1'b1);` Within the module's structural declarations, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge pynq descriptor RTL block in simulation. The important operands are send_word: the value named 'send word' in this block; d0: the value named 'd0' in this block; b1: the value named 'b1' in this block.

Line 126: `wait (interrupt);` Within the module's structural declarations, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge pynq descriptor RTL block in simulation. The important operands are wait: the value named 'wait' in this block; interrupt: the hardware notification that wakes software after completion or error.

Line 127: `axi_read(8'h04, value);` Within the module's structural declarations, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge pynq descriptor RTL block in simulation. The important operands are axi_read: the value named 'axi read' in this block; h04: the value named 'h04' in this block; value: the value named 'value' in this block.

Line 128: `if (!value[2] || value[5] || value[1] || value[0]) begin` This condition selects the following hardware branch only when '!value[2] || value[5] || value[1] || value[0]' is true. Both branches exist as gates; the condition controls a multiplexer rather than making software jump. The important operands are value: the value named 'value' in this block. Context: the module's structural declarations.

Line 129: `errors++;` Within the module's structural declarations, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge pynq descriptor RTL block in simulation. The important operands are errors: the value named 'errors' in this block.

Line 130: `$display("ERROR descriptor status=%h", value);` This is a simulation check or diagnostic. It can stop a failing test and print evidence, but it is not part of the synthesized PYNQ circuit.

Line 131: `end` This structural keyword opens or closes the branch/process scope described as the module's structural declarations; it has no arithmetic value of its own.

Line 132: `axi_read(8'h8c, value);` Within the module's structural declarations, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge pynq descriptor RTL block in simulation. The important operands are axi_read: the value named 'axi read' in this block; h8c: the value named 'h8c' in this block; value: the value named 'value' in this block.

Line 133: `if (value != 1) begin` This condition selects the following hardware branch only when 'value != 1' is true. Both branches exist as gates; the condition controls a multiplexer rather than making software jump. The important operands are value: the value named 'value' in this block. Context: the module's structural declarations.

Line 134: `errors++;` Within the module's structural declarations, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge pynq descriptor RTL block in simulation. The important operands are errors: the value named 'errors' in this block.

Line 135: `$display("ERROR descriptor records=%0d", value);` This is a simulation check or diagnostic. It can stop a failing test and print evidence, but it is not part of the synthesized PYNQ circuit.

Line 136: `end` This structural keyword opens or closes the branch/process scope described as the module's structural declarations; it has no arithmetic value of its own.

Line 137: `axi_read(8'h0c, value);` Within the module's structural declarations, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge pynq descriptor RTL block in simulation. The important operands are axi_read: the value named 'axi read' in this block; h0c: the value named 'h0c' in this block; value: the value named 'value' in this block.

Line 138: `if (value != 1) begin` This condition selects the following hardware branch only when 'value != 1' is true. Both branches exist as gates; the condition controls a multiplexer rather than making software jump. The important operands are value: the value named 'value' in this block. Context: the module's structural declarations.

Line 139: `errors++;` Within the module's structural declarations, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge pynq descriptor RTL block in simulation. The important operands are errors: the value named 'errors' in this block.

Line 140: `$display("ERROR descriptor commands=%0d", value);` This is a simulation check or diagnostic. It can stop a failing test and print evidence, but it is not part of the synthesized PYNQ circuit.

Line 141: `end` This structural keyword opens or closes the branch/process scope described as the module's structural declarations; it has no arithmetic value of its own.

Line 142: `if (errors != 0) begin` This condition selects the following hardware branch only when 'errors != 0' is true. Both branches exist as gates; the condition controls a multiplexer rather than making software jump. The important operands are errors: the value named 'errors' in this block. Context: the module's structural declarations.

Line 143: `$display("tb_neuraedge_pynq_descriptor FAILED errors=%0d", errors);` This is a simulation check or diagnostic. It can stop a failing test and print evidence, but it is not part of the synthesized PYNQ circuit.

Line 144: `end else begin` This structural keyword opens or closes the branch/process scope described as the module's structural declarations; it has no arithmetic value of its own.

Line 145: `$display("tb_neuraedge_pynq_descriptor PASSED records=1");` This is a simulation check or diagnostic. It can stop a failing test and print evidence, but it is not part of the synthesized PYNQ circuit.

Line 146: `end` This structural keyword opens or closes the branch/process scope described as the module's structural declarations; it has no arithmetic value of its own.

Line 147: `$finish;` This is a simulation check or diagnostic. It can stop a failing test and print evidence, but it is not part of the synthesized PYNQ circuit.

Line 148: `end` This structural keyword opens or closes the branch/process scope described as the module's structural declarations; it has no arithmetic value of its own.

Line 150: `initial begin` This opens simulation initialization. In a testbench it drives starting values and stimulus; project synthesis does not rely on this block as a replacement for explicit reset behavior.

Line 151: `#20_000;` Within the module's structural declarations, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge pynq descriptor RTL block in simulation. The expression is a literal or structural operator and has no hidden software state.

Line 152: `$fatal(1, "PYNQ descriptor watchdog timeout");` This is a simulation check or diagnostic. It can stop a failing test and print evidence, but it is not part of the synthesized PYNQ circuit.

Line 153: `end` This structural keyword opens or closes the branch/process scope described as the module's structural declarations; it has no arithmetic value of its own.

Line 154: `endmodule` This closes the current hardware definition; no circuit behavior is attached to the keyword itself.

Line 156: `` `default_nettype wire `` This SystemVerilog preprocessor line controls compilation of the block that drives, backpressures, and checks the neuraedge pynq descriptor RTL block in simulation.

57 tb/tb_neuraedge_sgd_optimizer8.sv

Role in the complete system: drives, backpressures, and checks the neuraedge sgd optimizer8 RTL block in simulation.

57.1 Beginner architecture map

Dataflow responsibility This file's end-to-end responsibility is to drives, backpressures, and checks the neuraedge sgd optimizer8 RTL block in simulation.

Simulation-only status tb_neuraedge_sgd_optimizer8 is not synthesized into the FPGA. It generates clocks, reset, commands, stalls, and expected values around the design under test, then terminates with an explicit result marker.

Evidence produced The file contains approximately 3 explicit assertions, failure diagnostics, or pass/fail markers. Its VCD/WDB trace is useful evidence only when the final pass marker is present; a simulator exit code by itself is insufficient.

57.3 Line annotations

Line 1: `` `timescale 1ns / 1ps `` This simulation directive selects nanoseconds as the time unit and picoseconds as the timestamp precision; it does not create FPGA logic.

Line 2: `` `default_nettype none `` This compiler directive forbids accidental implicit one-bit wires, turning misspelled signal names into errors instead of unintended hardware.

Line 3: `` `include "tb/fixtures/operator_fixture_params.svh" `` This SystemVerilog preprocessor line controls compilation of the block that drives, backpressures, and checks the neuraedge sgd optimizer8 RTL block in simulation.

Line 5: `module tb_neuraedge_sgd_optimizer8;` This opens tb_neuraedge_sgd_optimizer8;, an independently compiled hardware definition. Its ports and statements collectively describe circuitry that drives, backpressures, and checks the neuraedge sgd optimizer8 RTL block in simulation.

**Line 6: `localparam int CASES = `NEURAEDGE_OPTIMIZER_CASES;`** This fixes CASES to `NEURAEDGE_OPTIMIZER_CASES during elaboration. Vivado uses that constant to shape or simplify the generated circuit; CASES denotes the value named 'cases' in this block.

Line 8: `logic clk = 1'b0;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, clk is the clock that makes all registers advance together. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 9: `logic rst_n = 1'b0;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, rst_n is the active-low synchronous reset. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 10: `logic clear_counters = 1'b0;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, clear_counters is a hardware telemetry register that accumulates measured events. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 11: `logic input_valid = 1'b0;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, input_valid is the producer's statement that its current payload is meaningful. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 12: `logic input_ready;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, input_ready is the consumer's statement that it can accept a payload this cycle. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 13: `logic [127:0] weight_vector = '0;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, weight_vector is a learned coefficient multiplied by an activation. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 14: `logic [191:0] gradient_vector = '0;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, gradient_vector is the signed loss derivative used to update a learned parameter. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 15: `logic [191:0] velocity_vector = '0;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, velocity_vector is the momentum history retained by the SGD optimizer. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 16: `logic [17:0] learning_rate_q16 = 18'd0;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, learning_rate_q16 is the fixed-point multiplier controlling update magnitude. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 17: `logic [16:0] momentum_q16 = 17'd0;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, momentum_q16 is the value named 'momentum q16' in this block. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 18: `logic [16:0] weight_decay_q16 = 17'd0;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, weight_decay_q16 is a learned coefficient multiplied by an activation. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 19: `logic [4:0] update_right_shift = 5'd16;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, update_right_shift is the value named 'update right shift' in this block. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 20: `logic output_valid;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, output_valid is the producer's statement that its current payload is meaningful. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 21: `logic output_ready = 1'b0;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, output_ready is the consumer's statement that it can accept a payload this cycle. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 22: `logic [127:0] updated_weight_vector;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, updated_weight_vector is a learned coefficient multiplied by an activation. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 23: `logic [191:0] updated_velocity_vector;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, updated_velocity_vector is the momentum history retained by the SGD optimizer. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 24: `logic config_error;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, config_error is the value named 'config error' in this block. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 25: `logic [31:0] update_count;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, update_count is an integer count retained for control or measurable telemetry. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 27: `logic [63:0] parameter_mem [0:CASES-1];` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, parameter_mem is local FPGA storage addressed by surrounding index logic. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 28: `logic [127:0] weight_mem [0:CASES-1];` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, weight_mem is a learned coefficient multiplied by an activation. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 29: `logic [191:0] gradient_mem [0:CASES-1];` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, gradient_mem is the signed loss derivative used to update a learned parameter. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 30: `logic [191:0] velocity_mem [0:CASES-1];` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, velocity_mem is the momentum history retained by the SGD optimizer. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 31: `logic [127:0] expected_weight_mem [0:CASES-1];` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, expected_weight_mem is a learned coefficient multiplied by an activation. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 32: `logic [191:0] expected_velocity_mem [0:CASES-1];` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, expected_velocity_mem is the momentum history retained by the SGD optimizer. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 33: `int errors = 0;` Within the module's structural declarations, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge sgd optimizer8 RTL block in simulation. The important operands are errors: the value named 'errors' in this block.

Line 34: `int checked = 0;` Within the module's structural declarations, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge sgd optimizer8 RTL block in simulation. The important operands are checked: the value named 'checked' in this block.

Line 35: `logic held_valid = 1'b0;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, held_valid is the producer's statement that its current payload is meaningful. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 36: `logic [127:0] held_weight;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, held_weight is a learned coefficient multiplied by an activation. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 37: `logic [191:0] held_velocity;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, held_velocity is the momentum history retained by the SGD optimizer. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 39: `neuraedge_sgd_optimizer8 dut (` This instantiates module neuraedge_sgd_optimizer8 as dut. Synthesis creates that subordinate circuit and connects its ports in the lines that follow.

Line 40: `.clk(clk),` This connects the child instance's named port 'clk' to parent expression 'clk'. The connection is a physical net bundle after synthesis; direction is declared in the child module, and the clock that makes all registers advance together.

Line 41: `.rst_n(rst_n),` This connects the child instance's named port 'rst_n' to parent expression 'rst_n'. The connection is a physical net bundle after synthesis; direction is declared in the child module, and the active-low synchronous reset.

Line 42: `.clear_counters(clear_counters),` This connects the child instance's named port 'clear_counters' to parent expression 'clear_counters'. The connection is a physical net bundle after synthesis; direction is declared in the child module, and a hardware telemetry register that accumulates measured events.

Line 43: `.input_valid(input_valid),` This connects the child instance's named port 'input_valid' to parent expression 'input_valid'. The connection is a physical net bundle after synthesis; direction is declared in the child module, and the producer's statement that its current payload is meaningful.

Line 44: `.input_ready(input_ready),` This connects the child instance's named port 'input_ready' to parent expression 'input_ready'. The connection is a physical net bundle after synthesis; direction is declared in the child module, and the consumer's statement that it can accept a payload this cycle.

Line 45: `.weight_vector(weight_vector),` This connects the child instance's named port 'weight_vector' to parent expression 'weight_vector'. The connection is a physical net bundle after synthesis; direction is declared in the child module, and a learned coefficient multiplied by an activation.

Line 46: `.gradient_vector(gradient_vector),` This connects the child instance's named port 'gradient_vector' to parent expression 'gradient_vector'. The connection is a physical net bundle after synthesis; direction is declared in the child module, and the signed loss derivative used to update a learned parameter.

Line 47: `.velocity_vector(velocity_vector),` This connects the child instance's named port 'velocity_vector' to parent expression 'velocity_vector'. The connection is a physical net bundle after synthesis; direction is declared in the child module, and the momentum history retained by the SGD optimizer.

Line 48: `.learning_rate_q16(learning_rate_q16),` This connects the child instance's named port 'learning_rate_q16' to parent expression 'learning_rate_q16'. The connection is a physical net bundle after synthesis; direction is declared in the child module, and the fixed-point multiplier controlling update magnitude.

Line 49: `.momentum_q16(momentum_q16),` This connects the child instance's named port 'momentum_q16' to parent expression 'momentum_q16'. The connection is a physical net bundle after synthesis; direction is declared in the child module, and the value named 'momentum q16' in this block.

Line 50: `.weight_decay_q16(weight_decay_q16),` This connects the child instance's named port 'weight_decay_q16' to parent expression 'weight_decay_q16'. The connection is a physical net bundle after synthesis; direction is declared in the child module, and a learned coefficient multiplied by an activation.

Line 51: `.update_right_shift(update_right_shift),` This connects the child instance's named port 'update_right_shift' to parent expression 'update_right_shift'. The connection is a physical net bundle after synthesis; direction is declared in the child module, and the value named 'update right shift' in this block.

Line 52: `.output_valid(output_valid),` This connects the child instance's named port 'output_valid' to parent expression 'output_valid'. The connection is a physical net bundle after synthesis; direction is declared in the child module, and the producer's statement that its current payload is meaningful.

Line 53: `.output_ready(output_ready),` This connects the child instance's named port 'output_ready' to parent expression 'output_ready'. The connection is a physical net bundle after synthesis; direction is declared in the child module, and the consumer's statement that it can accept a payload this cycle.

Line 54: `.updated_weight_vector(updated_weight_vector),` This connects the child instance's named port 'updated_weight_vector' to parent expression 'updated_weight_vector'. The connection is a physical net bundle after synthesis; direction is declared in the child module, and a learned coefficient multiplied by an activation.

Line 55: `.updated_velocity_vector(updated_velocity_vector),` This connects the child instance's named port 'updated_velocity_vector' to parent expression 'updated_velocity_vector'. The connection is a physical net bundle after synthesis; direction is declared in the child module, and the momentum history retained by the SGD optimizer.

Line 56: `.config_error(config_error),` This connects the child instance's named port 'config_error' to parent expression 'config_error'. The connection is a physical net bundle after synthesis; direction is declared in the child module, and the value named 'config error' in this block.

Line 57: `.update_count(update_count)` This connects the child instance's named port 'update_count' to parent expression 'update_count'. The connection is a physical net bundle after synthesis; direction is declared in the child module, and an integer count retained for control or measurable telemetry.

Line 58: `);` Within the module's structural declarations, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge sgd optimizer8 RTL block in simulation. The expression is a literal or structural operator and has no hidden software state.

Line 60: `always #2.5 clk = ~clk;` Within the module's structural declarations, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge sgd optimizer8 RTL block in simulation. The important operands are always: the value named 'always' in this block; clk: the clock that makes all registers advance together.

Line 62: `always @(posedge clk) begin` Within the module's structural declarations, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge sgd optimizer8 RTL block in simulation. The important operands are always: the value named 'always' in this block; posedge: the value named 'posedge' in this block; clk: the clock that makes all registers advance together.

Line 63: `if (held_valid && (!output_valid || updated_weight_vector !== held_weight` Within the module's structural declarations, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge sgd optimizer8 RTL block in simulation. The important operands are held_valid: the producer's statement that its current payload is meaningful; output_valid: the producer's statement that its current payload is meaningful; updated_weight_vector: a learned coefficient multiplied by an activation.

Line 64: `|| updated_velocity_vector !== held_velocity)) begin` Within the module's structural declarations, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge sgd optimizer8 RTL block in simulation. The important operands are updated_velocity_vector: the momentum history retained by the SGD optimizer; held_velocity: the momentum history retained by the SGD optimizer.

Line 65: `errors++;` Within the module's structural declarations, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge sgd optimizer8 RTL block in simulation. The important operands are errors: the value named 'errors' in this block.

Line 66: `$display("ERROR optimizer output changed while stalled");` This is a simulation check or diagnostic. It can stop a failing test and print evidence, but it is not part of the synthesized PYNQ circuit.

Line 67: `end` This structural keyword opens or closes the branch/process scope described as the module's structural declarations; it has no arithmetic value of its own.

Line 68: `held_valid <= output_valid && !output_ready;` This makes held_valid, the producer's statement that its current payload is meaningful, equal to 'output_valid && !output_ready'. It updates after the active clock edge together with other nonblocking assignments. The important operands are output_valid: the producer's statement that its current payload is meaningful; output_ready: the consumer's statement that it can accept a payload this cycle. Context: the module's structural declarations.

Line 69: `held_weight <= updated_weight_vector;` This makes held_weight, a learned coefficient multiplied by an activation, equal to 'updated_weight_vector'. It updates after the active clock edge together with other nonblocking assignments. The important operands are updated_weight_vector: a learned coefficient multiplied by an activation. Context: the module's structural declarations.

Line 70: `held_velocity <= updated_velocity_vector;` This makes held_velocity, the momentum history retained by the SGD optimizer, equal to 'updated_velocity_vector'. It updates after the active clock edge together with other nonblocking assignments. The important operands are updated_velocity_vector: the momentum history retained by the SGD optimizer. Context: the module's structural declarations.

Line 71: `end` This structural keyword opens or closes the branch/process scope described as the module's structural declarations; it has no arithmetic value of its own.

Line 73: `initial begin` This opens simulation initialization. In a testbench it drives starting values and stimulus; project synthesis does not rely on this block as a replacement for explicit reset behavior.

Line 74: `$readmemh("tb/fixtures/optimizer_parameters.mem", parameter_mem);` Within the module's structural declarations, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge sgd optimizer8 RTL block in simulation. The important operands are readmemh: the value named 'readmemh' in this block; tb: the value named 'tb' in this block; fixtures: the value named 'fixtures' in this block.

Line 75: `$readmemh("tb/fixtures/optimizer_weights.mem", weight_mem);` Within the module's structural declarations, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge sgd optimizer8 RTL block in simulation. The important operands are readmemh: the value named 'readmemh' in this block; tb: the value named 'tb' in this block; fixtures: the value named 'fixtures' in this block.

Line 76: `$readmemh("tb/fixtures/optimizer_gradients.mem", gradient_mem);` Within the module's structural declarations, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge sgd optimizer8 RTL block in simulation. The important operands are readmemh: the value named 'readmemh' in this block; tb: the value named 'tb' in this block; fixtures: the value named 'fixtures' in this block.

Line 77: `$readmemh("tb/fixtures/optimizer_velocities.mem", velocity_mem);` Within the module's structural declarations, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge sgd optimizer8 RTL block in simulation. The important operands are readmemh: the value named 'readmemh' in this block; tb: the value named 'tb' in this block; fixtures: the value named 'fixtures' in this block.

Line 78: `$readmemh("tb/fixtures/optimizer_expected_weights.mem", expected_weight_mem);` Within the module's structural declarations, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge sgd optimizer8 RTL block in simulation. The important operands are readmemh: the value named 'readmemh' in this block; tb: the value named 'tb' in this block; fixtures: the value named 'fixtures' in this block.

Line 79: `$readmemh("tb/fixtures/optimizer_expected_velocities.mem", expected_velocity_mem);` Within the module's structural declarations, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge sgd optimizer8 RTL block in simulation. The important operands are readmemh: the value named 'readmemh' in this block; tb: the value named 'tb' in this block; fixtures: the value named 'fixtures' in this block.

Line 81: `repeat (5) @(negedge clk);` Within the module's structural declarations, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge sgd optimizer8 RTL block in simulation. The important operands are repeat: the value named 'repeat' in this block; negedge: the value named 'negedge' in this block; clk: the clock that makes all registers advance together.

Line 82: `rst_n = 1'b1;` This makes rst_n, the active-low synchronous reset, equal to '1'b1'. It is driven by combinational or procedural logic in the current evaluation. The important operands are b1: the value named 'b1' in this block. Context: the module's structural declarations.

Line 84: `for (int case_index = 0; case_index < CASES; case_index++) begin` This generate/procedural loop repeats the following operation across lanes or entries. In synthesizable RTL, a fixed loop is expanded into parallel or scheduled hardware rather than executed by a CPU. Context: the module's structural declarations.

Line 85: `while (!input_ready) @(negedge clk);` Within the module's structural declarations, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge sgd optimizer8 RTL block in simulation. The important operands are while: the value named 'while' in this block; input_ready: the consumer's statement that it can accept a payload this cycle; negedge: the value named 'negedge' in this block.

Line 86: `@(negedge clk);` Within the module's structural declarations, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge sgd optimizer8 RTL block in simulation. The important operands are negedge: the value named 'negedge' in this block; clk: the clock that makes all registers advance together.

Line 87: `learning_rate_q16 = parameter_mem[case_index][17:0];` This makes learning_rate_q16, the fixed-point multiplier controlling update magnitude, equal to 'parameter_mem[case_index][17:0]'. It is driven by combinational or procedural logic in the current evaluation. The important operands are parameter_mem: local FPGA storage addressed by surrounding index logic; case_index: an integer selecting one tensor element, lane, bank, or state entry. Context: the module's structural declarations.

Line 88: `momentum_q16 = parameter_mem[case_index][34:18];` This makes momentum_q16, the value named 'momentum q16' in this block, equal to 'parameter_mem[case_index][34:18]'. It is driven by combinational or procedural logic in the current evaluation. The important operands are parameter_mem: local FPGA storage addressed by surrounding index logic; case_index: an integer selecting one tensor element, lane, bank, or state entry. Context: the module's structural declarations.

Line 89: `weight_decay_q16 = parameter_mem[case_index][51:35];` This makes weight_decay_q16, a learned coefficient multiplied by an activation, equal to 'parameter_mem[case_index][51:35]'. It is driven by combinational or procedural logic in the current evaluation. The important operands are parameter_mem: local FPGA storage addressed by surrounding index logic; case_index: an integer selecting one tensor element, lane, bank, or state entry. Context: the module's structural declarations.

Line 90: `update_right_shift = parameter_mem[case_index][56:52];` This makes update_right_shift, the value named 'update right shift' in this block, equal to 'parameter_mem[case_index][56:52]'. It is driven by combinational or procedural logic in the current evaluation. The important operands are parameter_mem: local FPGA storage addressed by surrounding index logic; case_index: an integer selecting one tensor element, lane, bank, or state entry. Context: the module's structural declarations.

Line 91: `weight_vector = weight_mem[case_index];` This makes weight_vector, a learned coefficient multiplied by an activation, equal to 'weight_mem[case_index]'. It is driven by combinational or procedural logic in the current evaluation. The important operands are weight_mem: a learned coefficient multiplied by an activation; case_index: an integer selecting one tensor element, lane, bank, or state entry. Context: the module's structural declarations.

Line 92: `gradient_vector = gradient_mem[case_index];` This makes gradient_vector, the signed loss derivative used to update a learned parameter, equal to 'gradient_mem[case_index]'. It is driven by combinational or procedural logic in the current evaluation. The important operands are gradient_mem: the signed loss derivative used to update a learned parameter; case_index: an integer selecting one tensor element, lane, bank, or state entry. Context: the module's structural declarations.

Line 93: `velocity_vector = velocity_mem[case_index];` This makes velocity_vector, the momentum history retained by the SGD optimizer, equal to 'velocity_mem[case_index]'. It is driven by combinational or procedural logic in the current evaluation. The important operands are velocity_mem: the momentum history retained by the SGD optimizer; case_index: an integer selecting one tensor element, lane, bank, or state entry. Context: the module's structural declarations.

Line 94: `input_valid = 1'b1;` This makes input_valid, the producer's statement that its current payload is meaningful, equal to '1'b1'. It is driven by combinational or procedural logic in the current evaluation. The important operands are b1: the value named 'b1' in this block. Context: the module's structural declarations.

Line 95: `@(posedge clk);` Within the module's structural declarations, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge sgd optimizer8 RTL block in simulation. The important operands are posedge: the value named 'posedge' in this block; clk: the clock that makes all registers advance together.

Line 96: `@(negedge clk);` Within the module's structural declarations, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge sgd optimizer8 RTL block in simulation. The important operands are negedge: the value named 'negedge' in this block; clk: the clock that makes all registers advance together.

Line 97: `input_valid = 1'b0;` This makes input_valid, the producer's statement that its current payload is meaningful, equal to '1'b0'. It is driven by combinational or procedural logic in the current evaluation. The important operands are b0: the value named 'b0' in this block. Context: the module's structural declarations.

Line 99: `while (!output_valid) @(negedge clk);` Within the module's structural declarations, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge sgd optimizer8 RTL block in simulation. The important operands are while: the value named 'while' in this block; output_valid: the producer's statement that its current payload is meaningful; negedge: the value named 'negedge' in this block.

Line 100: `repeat (case_index % 4) @(negedge clk);` Within the module's structural declarations, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge sgd optimizer8 RTL block in simulation. The important operands are repeat: the value named 'repeat' in this block; case_index: an integer selecting one tensor element, lane, bank, or state entry; negedge: the value named 'negedge' in this block.

Line 101: `if (config_error || updated_weight_vector !== expected_weight_mem[case_index]` Within the module's structural declarations, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge sgd optimizer8 RTL block in simulation. The important operands are config_error: the value named 'config error' in this block; updated_weight_vector: a learned coefficient multiplied by an activation; expected_weight_mem: a learned coefficient multiplied by an activation.

Line 102: `|| updated_velocity_vector !== expected_velocity_mem[case_index]) begin` Within the module's structural declarations, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge sgd optimizer8 RTL block in simulation. The important operands are updated_velocity_vector: the momentum history retained by the SGD optimizer; expected_velocity_mem: the momentum history retained by the SGD optimizer; case_index: an integer selecting one tensor element, lane, bank, or state entry.

Line 103: `errors++;` Within the module's structural declarations, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge sgd optimizer8 RTL block in simulation. The important operands are errors: the value named 'errors' in this block.

Line 104: `if (errors <= 20) begin` This statement continues through source line 105; the explanation uses the complete expression rather than only the first visual fragment. This condition selects the following hardware branch only when 'errors <= 20) begin $display("ERROR optimizer case=%0d config=%0d", case_index, config_error' is true. Both branches exist as gates; the condition controls a multiplexer rather than making software jump. The important operands are errors: the value named 'errors' in this block; display: the value named 'display' in this block; ERROR: the value named 'error' in this block. Context: the module's structural declarations.

Line 105: `$display("ERROR optimizer case=%0d config=%0d", case_index, config_error);` This is continuation line 2 of the 2-line logical statement that begins at source line 104. Its exact fragment is '$display("ERROR optimizer case=%0d config=%0d", case_index, config_error);'. The important operands are display: the value named 'display' in this block; ERROR: the value named 'error' in this block; optimizer: the value named 'optimizer' in this block. Read together, the complete operation is: This condition selects the following hardware branch only when 'errors <= 20) begin $display("ERROR optimizer case=%0d config=%0d", case_index, config_error' is true. Both branches exist as gates; the condition controls a multiplexer rather than making software jump. The important operands are errors: the value named 'errors' in this block; display: the value named 'display' in this block; ERROR: the value named 'error' in this block. Context: the module's structural declarations.

Line 106: `for (int lane = 0; lane < 8; lane++) begin` This generate/procedural loop repeats the following operation across lanes or entries. In synthesizable RTL, a fixed loop is expanded into parallel or scheduled hardware rather than executed by a CPU. Context: the module's structural declarations.

Line 107: `if (updated_weight_vector[lane*16 +: 16]` Within the module's structural declarations, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge sgd optimizer8 RTL block in simulation. The important operands are updated_weight_vector: a learned coefficient multiplied by an activation; lane: one parallel arithmetic element within a vector or tensor datapath.

Line 108: `!== expected_weight_mem[case_index][lane*16 +: 16]) begin` Within the module's structural declarations, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge sgd optimizer8 RTL block in simulation. The important operands are expected_weight_mem: a learned coefficient multiplied by an activation; case_index: an integer selecting one tensor element, lane, bank, or state entry; lane: one parallel arithmetic element within a vector or tensor datapath.

Line 109: `$display(" weight lane=%0d got=%0d expected=%0d", lane,` This is a simulation check or diagnostic. It can stop a failing test and print evidence, but it is not part of the synthesized PYNQ circuit.

Line 110: `$signed(updated_weight_vector[lane*16 +: 16]),` Within the module's structural declarations, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge sgd optimizer8 RTL block in simulation. The important operands are updated_weight_vector: a learned coefficient multiplied by an activation; lane: one parallel arithmetic element within a vector or tensor datapath.

Line 111: `$signed(expected_weight_mem[case_index][lane*16 +: 16]));` Within the module's structural declarations, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge sgd optimizer8 RTL block in simulation. The important operands are expected_weight_mem: a learned coefficient multiplied by an activation; case_index: an integer selecting one tensor element, lane, bank, or state entry; lane: one parallel arithmetic element within a vector or tensor datapath.

Line 112: `end` This structural keyword opens or closes the branch/process scope described as the module's structural declarations; it has no arithmetic value of its own.

Line 113: `if (updated_velocity_vector[lane*24 +: 24]` Within the module's structural declarations, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge sgd optimizer8 RTL block in simulation. The important operands are updated_velocity_vector: the momentum history retained by the SGD optimizer; lane: one parallel arithmetic element within a vector or tensor datapath.

Line 114: `!== expected_velocity_mem[case_index][lane*24 +: 24]) begin` Within the module's structural declarations, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge sgd optimizer8 RTL block in simulation. The important operands are expected_velocity_mem: the momentum history retained by the SGD optimizer; case_index: an integer selecting one tensor element, lane, bank, or state entry; lane: one parallel arithmetic element within a vector or tensor datapath.

Line 115: `$display(" velocity lane=%0d got=%0d expected=%0d", lane,` This is a simulation check or diagnostic. It can stop a failing test and print evidence, but it is not part of the synthesized PYNQ circuit.

Line 116: `$signed(updated_velocity_vector[lane*24 +: 24]),` Within the module's structural declarations, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge sgd optimizer8 RTL block in simulation. The important operands are updated_velocity_vector: the momentum history retained by the SGD optimizer; lane: one parallel arithmetic element within a vector or tensor datapath.

Line 117: `$signed(expected_velocity_mem[case_index][lane*24 +: 24]));` Within the module's structural declarations, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge sgd optimizer8 RTL block in simulation. The important operands are expected_velocity_mem: the momentum history retained by the SGD optimizer; case_index: an integer selecting one tensor element, lane, bank, or state entry; lane: one parallel arithmetic element within a vector or tensor datapath.

Line 118: `end` This structural keyword opens or closes the branch/process scope described as the module's structural declarations; it has no arithmetic value of its own.

Line 119: `end` This structural keyword opens or closes the branch/process scope described as the module's structural declarations; it has no arithmetic value of its own.

Line 120: `end` This structural keyword opens or closes the branch/process scope described as the module's structural declarations; it has no arithmetic value of its own.

Line 121: `end` This structural keyword opens or closes the branch/process scope described as the module's structural declarations; it has no arithmetic value of its own.

Line 122: `checked++;` Within the module's structural declarations, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge sgd optimizer8 RTL block in simulation. The important operands are checked: the value named 'checked' in this block.

Line 123: `output_ready = 1'b1;` This makes output_ready, the consumer's statement that it can accept a payload this cycle, equal to '1'b1'. It is driven by combinational or procedural logic in the current evaluation. The important operands are b1: the value named 'b1' in this block. Context: the module's structural declarations.

Line 124: `@(posedge clk);` Within the module's structural declarations, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge sgd optimizer8 RTL block in simulation. The important operands are posedge: the value named 'posedge' in this block; clk: the clock that makes all registers advance together.

Line 125: `@(negedge clk);` Within the module's structural declarations, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge sgd optimizer8 RTL block in simulation. The important operands are negedge: the value named 'negedge' in this block; clk: the clock that makes all registers advance together.

Line 126: `output_ready = 1'b0;` This makes output_ready, the consumer's statement that it can accept a payload this cycle, equal to '1'b0'. It is driven by combinational or procedural logic in the current evaluation. The important operands are b0: the value named 'b0' in this block. Context: the module's structural declarations.

Line 127: `end` This structural keyword opens or closes the branch/process scope described as the module's structural declarations; it has no arithmetic value of its own.

Line 129: `if (update_count != CASES * 8) begin` This condition selects the following hardware branch only when 'update_count != CASES * 8' is true. Both branches exist as gates; the condition controls a multiplexer rather than making software jump. The important operands are update_count: an integer count retained for control or measurable telemetry; CASES: the value named 'cases' in this block. Context: the module's structural declarations.

Line 130: `errors++;` Within the module's structural declarations, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge sgd optimizer8 RTL block in simulation. The important operands are errors: the value named 'errors' in this block.

Line 131: `$display("ERROR optimizer update count got=%0d expected=%0d", update_count, CASES * 8);` This is a simulation check or diagnostic. It can stop a failing test and print evidence, but it is not part of the synthesized PYNQ circuit.

Line 132: `end` This structural keyword opens or closes the branch/process scope described as the module's structural declarations; it has no arithmetic value of its own.

Line 134: `@(negedge clk);` Within the module's structural declarations, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge sgd optimizer8 RTL block in simulation. The important operands are negedge: the value named 'negedge' in this block; clk: the clock that makes all registers advance together.

Line 135: `clear_counters = 1'b1;` This makes clear_counters, a hardware telemetry register that accumulates measured events, equal to '1'b1'. It is driven by combinational or procedural logic in the current evaluation. The important operands are b1: the value named 'b1' in this block. Context: the module's structural declarations.

Line 136: `@(posedge clk);` Within the module's structural declarations, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge sgd optimizer8 RTL block in simulation. The important operands are posedge: the value named 'posedge' in this block; clk: the clock that makes all registers advance together.

Line 137: `@(negedge clk);` Within the module's structural declarations, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge sgd optimizer8 RTL block in simulation. The important operands are negedge: the value named 'negedge' in this block; clk: the clock that makes all registers advance together.

Line 138: `clear_counters = 1'b0;` This makes clear_counters, a hardware telemetry register that accumulates measured events, equal to '1'b0'. It is driven by combinational or procedural logic in the current evaluation. The important operands are b0: the value named 'b0' in this block. Context: the module's structural declarations.

Line 139: `if (update_count != 0) begin` This condition selects the following hardware branch only when 'update_count != 0' is true. Both branches exist as gates; the condition controls a multiplexer rather than making software jump. The important operands are update_count: an integer count retained for control or measurable telemetry. Context: the module's structural declarations.

Line 140: `errors++;` Within the module's structural declarations, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge sgd optimizer8 RTL block in simulation. The important operands are errors: the value named 'errors' in this block.

Line 141: `$display("ERROR optimizer update counter did not clear independently");` This is a simulation check or diagnostic. It can stop a failing test and print evidence, but it is not part of the synthesized PYNQ circuit.

Line 142: `end` This structural keyword opens or closes the branch/process scope described as the module's structural declarations; it has no arithmetic value of its own.

Line 144: `if (errors != 0) begin` This condition selects the following hardware branch only when 'errors != 0' is true. Both branches exist as gates; the condition controls a multiplexer rather than making software jump. The important operands are errors: the value named 'errors' in this block. Context: the module's structural declarations.

Line 145: `$display("tb_neuraedge_sgd_optimizer8 FAILED errors=%0d checked=%0d", errors, checked);` This is a simulation check or diagnostic. It can stop a failing test and print evidence, but it is not part of the synthesized PYNQ circuit.

Line 146: `$finish;` This is a simulation check or diagnostic. It can stop a failing test and print evidence, but it is not part of the synthesized PYNQ circuit.

Line 147: `end else begin` This structural keyword opens or closes the branch/process scope described as the module's structural declarations; it has no arithmetic value of its own.

Line 148: `$display("tb_neuraedge_sgd_optimizer8 PASSED checked=%0d updates=%0d", checked, update_count);` This is a simulation check or diagnostic. It can stop a failing test and print evidence, but it is not part of the synthesized PYNQ circuit.

Line 149: `$finish;` This is a simulation check or diagnostic. It can stop a failing test and print evidence, but it is not part of the synthesized PYNQ circuit.

Line 150: `end` This structural keyword opens or closes the branch/process scope described as the module's structural declarations; it has no arithmetic value of its own.

Line 151: `end` This structural keyword opens or closes the branch/process scope described as the module's structural declarations; it has no arithmetic value of its own.

Line 153: `initial begin` This opens simulation initialization. In a testbench it drives starting values and stimulus; project synthesis does not rely on this block as a replacement for explicit reset behavior.

Line 154: `#200_000;` Within the module's structural declarations, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge sgd optimizer8 RTL block in simulation. The expression is a literal or structural operator and has no hidden software state.

Line 155: `$fatal(1, "tb_neuraedge_sgd_optimizer8 watchdog timeout");` This is a simulation check or diagnostic. It can stop a failing test and print evidence, but it is not part of the synthesized PYNQ circuit.

Line 156: `end` This structural keyword opens or closes the branch/process scope described as the module's structural declarations; it has no arithmetic value of its own.

Line 157: `endmodule` This closes the current hardware definition; no circuit behavior is attached to the keyword itself.

Line 159: `` `default_nettype wire `` This SystemVerilog preprocessor line controls compilation of the block that drives, backpressures, and checks the neuraedge sgd optimizer8 RTL block in simulation.

58 tb/tb_neuraedge_tensor_tile.sv

Role in the complete system: drives, backpressures, and checks the neuraedge tensor tile RTL block in simulation.

58.1 Beginner architecture map

Dataflow responsibility This file's end-to-end responsibility is to drives, backpressures, and checks the neuraedge tensor tile RTL block in simulation.

Simulation-only status tb_neuraedge_tensor_tile is not synthesized into the FPGA. It generates clocks, reset, commands, stalls, and expected values around the design under test, then terminates with an explicit result marker.

Evidence produced The file contains approximately 4 explicit assertions, failure diagnostics, or pass/fail markers. Its VCD/WDB trace is useful evidence only when the final pass marker is present; a simulator exit code by itself is insufficient.

`default_nettype wire
```

58.3 Line annotations

Line 1: `‘timescale 1ns / 1ps` This simulation directive selects nanoseconds as the time unit and picoseconds as the timestamp precision; it does not create FPGA logic.

Line 2: `‘default_nettype none` This compiler directive forbids accidental implicit one-bit wires, turning misspelled signal names into errors instead of unintended hardware.

Line 3: `‘include "tb/fixtures/tensor_tile_params.svh"` This SystemVerilog preprocessor line controls compilation of the block that drives, backpressures, and checks the neuraedge tensor tile RTL block in simulation.

Line 5: `module tb_neuraedge_tensor_tile;` This opens tb_neuraedge_tensor_tile;, an independently compiled hardware definition. Its ports and statements collectively describe circuitry that drives, backpressures, and checks the neuraedge tensor tile RTL block in simulation.

Line 6: `localparam int CASES = ‘NEURAEDGE_TENSOR_CASES;` This fixes CASES to ‘NEURAEDGE_TENSOR_CASES during elaboration. Vivado uses that constant to shape or simplify the generated circuit; CASES denotes the value named 'cases' in this block.

Line 7: `localparam int ISSUES = ‘NEURAEDGE_TENSOR_ISSUES;` This fixes ISSUES to ‘NEURAEDGE_TENSOR_ISSUES during elaboration. Vivado uses that constant to shape or simplify the generated circuit; ISSUES denotes the value named 'issues' in this block.

Line 8: `localparam int RESULTS = ‘NEURAEDGE_TENSOR_RESULTS;` This fixes RESULTS to ‘NEURAEDGE_TENSOR_RESU during elaboration. Vivado uses that constant to shape or simplify the generated circuit; RESULTS denotes the value named 'results' in this block.

Line 9: `localparam int ROW_LANES = 8;` This fixes ROW_LANES to 8 during elaboration. Vivado uses that constant to shape or simplify the generated circuit; ROW_LANES denotes one parallel arithmetic element within a vector or tensor datapath.

Line 10: `localparam int COLUMN_LANES = ‘NEURAEDGE_COLUMN_LANES;` This fixes COLUMN_LANES to ‘NEURAEDGE_COLUMN_LANES during elaboration. Vivado uses that constant to shape or simplify the generated circuit; COLUMN_LANES denotes one parallel arithmetic element within a vector or tensor datapath.

Line 12: `logic clk;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, clk is the clock that makes all registers advance together. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 13: `logic rst_n = 1’b0;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, rst_n is the active-low synchronous reset. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 14: `logic start = 1’b0;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, start is the value named 'start' in this block. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 15: `logic [1:0] compute_mode = 2’d0;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, compute_mode is the value named 'compute mode' in this block. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 16: `logic [3:0] active_rows = 4’d1;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, active_rows is one output-row position processed by the tensor tile. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 17: `logic [5:0] active_columns = 6'd1;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, active_columns is one output-feature position processed in parallel. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 18: `logic [7:0] activation_zero_point = 8'd0;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, activation_zero_point is an input feature value consumed by a neuron or multiply-accumulate operation. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 19: `logic [7:0] weight_zero_point = 8'd0;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, weight_zero_point is a learned coefficient multiplied by an activation. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 20: `logic config_error;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, config_error is the value named 'config error' in this block. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 21: `logic issue_valid = 1'b0;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, issue_valid is the producer's statement that its current payload is meaningful. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 22: `logic issue_ready;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, issue_ready is the consumer's statement that it can accept a payload this cycle. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 23: `logic [63:0] activation_vector = 64'd0;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, activation_vector is an input feature value consumed by a neuron or multiply-accumulate operation. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 24: `logic [COLUMN_LANES*8-1:0] outer_weight_vector = '0;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, outer_weight_vector is a learned coefficient multiplied by an activation. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 25: `logic [COLUMN_LANES*8*8-1:0] dot_weight_vector = '0;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, dot_weight_vector is a learned coefficient multiplied by an activation. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 26: `logic issue_last = 1'b0;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, issue_last is the AXI-Stream marker for the final beat of a packet or command payload. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 27: `logic busy;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, busy is the value named 'busy' in this block. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 28: `logic result_valid;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, result_valid is the producer's statement that its current payload is meaningful. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 29: `logic result_ready = 1'b0;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, result_ready is the consumer's statement that it can accept a payload this cycle. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 30: `logic signed [47:0] result_value;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, result_value is the value named 'result value' in this block. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 31: `logic [3:0] result_row;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, result_row is one output-row position processed by the tensor tile. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 32: `logic [5:0] result_column;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, result_column is one output-feature position processed in parallel. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 33: `logic result_last;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, result_last is the AXI-Stream marker for the final beat of a packet or command payload. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 34: `logic [31:0] debug_accepted_issues;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, debug_accepted_issues is the value named 'debug accepted issues' in this block. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 35: `logic [31:0] debug_skipped_issues;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, debug_skipped_issues is the value named 'debug skipped issues' in this block. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 36: `logic [31:0] debug_retired_issues;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, debug_retired_issues is the value named 'debug retired issues' in this block. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 37: `logic [63:0] debug_dense_macs;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, debug_dense_macs is a count of ordinary activation-times-weight operations actually issued. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 38: `logic [63:0] debug_spike_adds;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, debug_spike_adds is a binary event produced when a neuron crosses its threshold. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 40: `logic [63:0] case_mem [0:CASES-1];` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, case_mem is local FPGA storage addressed by surrounding index logic. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 41: `logic [63:0] activation_mem [0:ISSUES-1];` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, activation_mem is an input feature value consumed by a neuron or multiply-accumulate operation. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 42: `logic [COLUMN_LANES*8*8-1:0] weight_mem [0:ISSUES-1];` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, weight_mem is a learned coefficient multiplied by an activation. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 43: `logic signed [63:0] expected_mem [0:RESULTS-1];` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, expected_mem is local FPGA storage addressed by surrounding index logic. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 45: `int issue_pointer = 0;` Within the module's structural declarations, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge tensor tile RTL block in simulation. The important operands are issue_pointer: the value named 'issue pointer' in this block.

Line 46: `int expected_pointer = 0;` Within the module's structural declarations, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge tensor tile RTL block in simulation. The important operands are expected_pointer: the value named 'expected pointer' in this block.

Line 47: `int errors = 0;` Within the module's structural declarations, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge tensor tile RTL block in simulation. The important operands are errors: the value named 'errors' in this block.

Line 48: `int checked = 0;` Within the module's structural declarations, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge tensor tile RTL block in simulation. The important operands are checked: the value named 'checked' in this block.

Line 49: `int cycle = 0;` Within the module's structural declarations, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge tensor tile RTL block in simulation. The important operands are cycle: the value named 'cycle' in this block.

Line 50: `logic stalled_valid = 1'b0;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, stalled_valid is the producer's statement that its current payload is meaningful. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 51: `logic signed [47:0] stalled_value;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, stalled_value is the value named 'stalled value' in this block. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 52: `logic [3:0] stalled_row;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, stalled_row is one output-row position processed by the tensor tile. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 53: `logic [5:0] stalled_column;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, stalled_column is one output-feature position processed in parallel. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 54: `logic stalled_last;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, stalled_last is the AXI-Stream marker for the final beat of a packet or command payload. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 56: `neuraedge_tensor_tile dut (` This instantiates module neuraedge_tensor_tile as dut. Synthesis creates that subordinate circuit and connects its ports in the lines that follow.

Line 57: `.clk(clk),` This connects the child instance's named port 'clk' to parent expression 'clk'. The connection is a physical net bundle after synthesis; direction is declared in the child module, and the clock that makes all registers advance together.

Line 58: `.rst_n(rst_n),` This connects the child instance's named port 'rst_n' to parent expression 'rst_n'. The connection is a physical net bundle after synthesis; direction is declared in the child module, and the active-low synchronous reset.

Line 59: `.start(start),` This connects the child instance's named port 'start' to parent expression 'start'. The connection is a physical net bundle after synthesis; direction is declared in the child module, and the value named 'start' in this block.

Line 60: `.compute_mode(compute_mode),` This connects the child instance's named port ‘compute_mode‘ to parent expression ‘compute_mode‘. The connection is a physical net bundle after synthesis; direction is declared in the child module, and the value named 'compute mode' in this block.

Line 61: `.active_rows(active_rows),` This connects the child instance's named port ‘active_rows‘ to parent expression ‘active_rows‘. The connection is a physical net bundle after synthesis; direction is declared in the child module, and one output-row position processed by the tensor tile.

Line 62: `.active_columns(active_columns),` This connects the child instance's named port ‘active_columns‘ to parent expression ‘active_columns‘. The connection is a physical net bundle after synthesis; direction is declared in the child module, and one output-feature position processed in parallel.

Line 63: `.activation_zero_point(activation_zero_point),` This connects the child instance's named port ‘activation_zero_point‘ to parent expression ‘activation_zero_point‘. The connection is a physical net bundle after synthesis; direction is declared in the child module, and an input feature value consumed by a neuron or multiply-accumulate operation.

Line 64: `.weight_zero_point(weight_zero_point),` This connects the child instance's named port ‘weight_zero_point‘ to parent expression ‘weight_zero_point‘. The connection is a physical net bundle after synthesis; direction is declared in the child module, and a learned coefficient multiplied by an activation.

Line 65: `.config_error(config_error),` This connects the child instance's named port ‘config_error‘ to parent expression ‘config_error‘. The connection is a physical net bundle after synthesis; direction is declared in the child module, and the value named 'config error' in this block.

Line 66: `.issue_valid(issue_valid),` This connects the child instance's named port ‘issue_valid‘ to parent expression ‘issue_valid‘. The connection is a physical net bundle after synthesis; direction is declared in the child module, and the producer's statement that its current payload is meaningful.

Line 67: `.issue_ready(issue_ready),` This connects the child instance's named port ‘issue_ready‘ to parent expression ‘issue_ready‘. The connection is a physical net bundle after synthesis; direction is declared in the child module, and the consumer's statement that it can accept a payload this cycle.

Line 68: `.activation_vector(activation_vector),` This connects the child instance's named port ‘activation_vector‘ to parent expression ‘activation_vector‘. The connection is a physical net bundle after synthesis; direction is declared in the child module, and an input feature value consumed by a neuron or multiply-accumulate operation.

Line 69: `.outer_weight_vector(outer_weight_vector),` This connects the child instance's named port ‘outer_weight_vector‘ to parent expression ‘outer_weight_vector‘. The connection is a physical net bundle after synthesis; direction is declared in the child module, and a learned coefficient multiplied by an activation.

Line 70: `.dot_weight_vector(dot_weight_vector),` This connects the child instance's named port ‘dot_weight_vector‘ to parent expression ‘dot_weight_vector‘. The connection is a physical net bundle after synthesis; direction is declared in the child module, and a learned coefficient multiplied by an activation.

Line 71: `.issue_last(issue_last),` This connects the child instance's named port ‘issue_last‘ to parent expression ‘issue_last‘. The connection is a physical net bundle after synthesis; direction is declared in the child module, and the AXI-Stream marker for the final beat of a packet or command payload.

Line 72: `.busy(busy),` This connects the child instance's named port ‘busy‘ to parent expression ‘busy‘. The connection is a physical net bundle after synthesis; direction is declared in the child module, and the value named 'busy' in this block.

Line 73: `.result_valid(result_valid),` This connects the child instance's named port 'result_valid' to parent expression 'result_valid'. The connection is a physical net bundle after synthesis; direction is declared in the child module, and the producer's statement that its current payload is meaningful.

Line 74: `.result_ready(result_ready),` This connects the child instance's named port 'result_ready' to parent expression 'result_ready'. The connection is a physical net bundle after synthesis; direction is declared in the child module, and the consumer's statement that it can accept a payload this cycle.

Line 75: `.result_value(result_value),` This connects the child instance's named port 'result_value' to parent expression 'result_value'. The connection is a physical net bundle after synthesis; direction is declared in the child module, and the value named 'result value' in this block.

Line 76: `.result_row(result_row),` This connects the child instance's named port 'result_row' to parent expression 'result_row'. The connection is a physical net bundle after synthesis; direction is declared in the child module, and one output-row position processed by the tensor tile.

Line 77: `.result_column(result_column),` This connects the child instance's named port 'result_column' to parent expression 'result_column'. The connection is a physical net bundle after synthesis; direction is declared in the child module, and one output-feature position processed in parallel.

Line 78: `.result_last(result_last),` This connects the child instance's named port 'result_last' to parent expression 'result_last'. The connection is a physical net bundle after synthesis; direction is declared in the child module, and the AXI-Stream marker for the final beat of a packet or command payload.

Line 79: `.debug_accepted_issues(debug_accepted_issues),` This connects the child instance's named port 'debug_accepted_issues' to parent expression 'debug_accepted_issues'. The connection is a physical net bundle after synthesis; direction is declared in the child module, and the value named 'debug accepted issues' in this block.

Line 80: `.debug_skipped_issues(debug_skipped_issues),` This connects the child instance's named port 'debug_skipped_issues' to parent expression 'debug_skipped_issues'. The connection is a physical net bundle after synthesis; direction is declared in the child module, and the value named 'debug skipped issues' in this block.

Line 81: `.debug_retired_issues(debug_retired_issues),` This connects the child instance's named port 'debug_retired_issues' to parent expression 'debug_retired_issues'. The connection is a physical net bundle after synthesis; direction is declared in the child module, and the value named 'debug retired issues' in this block.

Line 82: `.debug_dense_macs(debug_dense_macs),` This connects the child instance's named port 'debug_dense_macs' to parent expression 'debug_dense_macs'. The connection is a physical net bundle after synthesis; direction is declared in the child module, and a count of ordinary activation-times-weight operations actually issued.

Line 83: `.debug_spike_adds(debug_spike_adds)` This connects the child instance's named port 'debug_spike_adds' to parent expression 'debug_spike_adds'. The connection is a physical net bundle after synthesis; direction is declared in the child module, and a binary event produced when a neuron crosses its threshold.

Line 84: `);` Within the module's structural declarations, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge tensor tile RTL block in simulation. The expression is a literal or structural operator and has no hidden software state.

Line 86: `initial clk = 1'b0;` This opens simulation initialization. In a testbench it drives starting values and stimulus; project synthesis does not rely on this block as a replacement for explicit reset behavior.

Line 87: `always #2.5 clk = ~clk;` Within the module's structural declarations, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge tensor tile RTL block in simulation. The important operands are always: the value named 'always' in this block; clk: the clock that makes all registers advance together.

Line 89: `task automatic run_case(input int case_index);` Within the simulation task run case, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge tensor tile RTL block in simulation. The important operands are task: the value named 'task' in this block; automatic: the value named 'automatic' in this block; run_case: the value named 'run case' in this block.

Line 90: `logic [63:0] command;` This declares hardware signal storage or wiring in the simulation task run case. Specifically, command is the 128-bit instruction selecting an engine, shape, mode, and numeric parameters. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 91: `int case_issues;` Within the simulation task run case, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge tensor tile RTL block in simulation. The important operands are case_issues: the value named 'case issues' in this block.

Line 92: `int case_results;` Within the simulation task run case, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge tensor tile RTL block in simulation. The important operands are case_results: the value named 'case results' in this block.

Line 93: `int received;` Within the simulation task run case, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge tensor tile RTL block in simulation. The important operands are received: the value named 'received' in this block.

Line 94: `int watchdog;` Within the simulation task run case, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge tensor tile RTL block in simulation. The important operands are watchdog: the value named 'watchdog' in this block.

Line 95: `int output_cycle;` Within the simulation task run case, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge tensor tile RTL block in simulation. The important operands are output_cycle: the value named 'output cycle' in this block.

Line 96: `longint unsigned expected_dense_macs;` Within the simulation task run case, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge tensor tile RTL block in simulation. The important operands are longint: the value named 'longint' in this block; expected_dense_macs: a count of ordinary activation-times-weight operations actually issued.

Line 97: `longint unsigned expected_spike_adds;` Within the simulation task run case, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge tensor tile RTL block in simulation. The important operands are longint: the value named 'longint' in this block; expected_spike_adds: a binary event produced when a neuron crosses its threshold.

Line 98: `logic signed [63:0] result_extended;` This declares hardware signal storage or wiring in the simulation task run case. Specifically, result_extended is the value named 'result extended' in this block. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 99: `begin` This structural keyword opens or closes the branch/process scope described as the simulation task run case; it has no arithmetic value of its own.

Line 100: `command = case_mem[case_index];` This makes command, the 128-bit instruction selecting an engine, shape, mode, and numeric parameters, equal to ‘case_mem[case_index]‘. It is driven by combinational or procedural logic in the current evaluation. The important operands are case_mem: local FPGA storage addressed by surrounding index logic; case_index: an integer selecting one tensor element, lane, bank, or state entry. Context: the simulation task run case.

Line 101: `compute_mode = command[1:0];` This makes compute_mode, the value named 'compute mode' in this block, equal to 'command[1:0]'. It is driven by combinational or procedural logic in the current evaluation. The important operands are command: the 128-bit instruction selecting an engine, shape, mode, and numeric parameters. Context: the simulation task run case.

Line 102: `active_rows = command[7:4];` This makes active_rows, one output-row position processed by the tensor tile, equal to 'command[7:4]'. It is driven by combinational or procedural logic in the current evaluation. The important operands are command: the 128-bit instruction selecting an engine, shape, mode, and numeric parameters. Context: the simulation task run case.

Line 103: `active_columns = command[13:8];` This makes active_columns, one output-feature position processed in parallel, equal to 'command[13:8]'. It is driven by combinational or procedural logic in the current evaluation. The important operands are command: the 128-bit instruction selecting an engine, shape, mode, and numeric parameters. Context: the simulation task run case.

Line 104: `case_issues = command[25:14];` This makes case_issues, the value named 'case issues' in this block, equal to 'command[25:14]'. It is driven by combinational or procedural logic in the current evaluation. The important operands are command: the 128-bit instruction selecting an engine, shape, mode, and numeric parameters. Context: the simulation task run case.

Line 105: `activation_zero_point = command[33:26];` This makes activation_zero_point, an input feature value consumed by a neuron or multiply-accumulate operation, equal to 'command[33:26]'. It is driven by combinational or procedural logic in the current evaluation. The important operands are command: the 128-bit instruction selecting an engine, shape, mode, and numeric parameters. Context: the simulation task run case.

Line 106: `weight_zero_point = command[41:34];` This makes weight_zero_point, a learned coefficient multiplied by an activation, equal to 'command[41:34]'. It is driven by combinational or procedural logic in the current evaluation. The important operands are command: the 128-bit instruction selecting an engine, shape, mode, and numeric parameters. Context: the simulation task run case.

Line 107: `// Cast before multiplying. Without these casts, SystemVerilog keeps` Design intent: Cast before multiplying. Without these casts, SystemVerilog keeps This comment anchors the surrounding logic in the block that drives, backpressures, and checks the neuraedge tensor tile RTL block in simulation.

Line 108: `// a full tile product can wrap before assignment to an integer.` Design intent: a full tile product can wrap before assignment to an integer. This comment anchors the surrounding logic in the block that drives, backpressures, and checks the neuraedge tensor tile RTL block in simulation.

Line 109: `case_results = int'(active_rows) * int'(active_columns);` This makes case_results, the value named 'case results' in this block, equal to 'int'(active_rows) * int'(active_columns)'. It is driven by combinational or procedural logic in the current evaluation. The important operands are active_rows: one output-row position processed by the tensor tile; active_columns: one output-feature position processed in parallel. Context: the simulation task run case.

Line 110: `expected_dense_macs = 0;` This makes expected_dense_macs, a count of ordinary activation-times-weight operations actually issued, equal to '0'. It is driven by combinational or procedural logic in the current evaluation. The expression is a literal or structural operator and has no hidden software state. Context: the simulation task run case.

Line 111: `expected_spike_adds = 0;` This makes expected_spike_adds, a binary event produced when a neuron crosses its threshold, equal to '0'. It is driven by combinational or procedural logic in the current evaluation. The expression is a literal or structural operator and has no hidden software state. Context: the simulation task run case.

Line 113: `@(negedge clk);` Within the simulation task run case, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge tensor tile RTL block in simulation. The important operands are negedge: the value named 'negedge' in this block; clk: the clock that makes all registers advance together.

Line 114: `start = 1'b1;` This makes start, the value named 'start' in this block, equal to '1'b1'. It is driven by combinational or procedural logic in the current evaluation. The important operands are b1: the value named 'b1' in this block. Context: the simulation task run case.

Line 115: `@(negedge clk);` Within the simulation task run case, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge tensor tile RTL block in simulation. The important operands are negedge: the value named 'negedge' in this block; clk: the clock that makes all registers advance together.

Line 116: `start = 1'b0;` This makes start, the value named 'start' in this block, equal to '1'b0'. It is driven by combinational or procedural logic in the current evaluation. The important operands are b0: the value named 'b0' in this block. Context: the simulation task run case.

Line 117: `if (config_error) begin` This condition selects the following hardware branch only when 'config_error' is true. Both branches exist as gates; the condition controls a multiplexer rather than making software jump. The important operands are config_error: the value named 'config error' in this block. Context: the simulation task run case.

Line 118: `errors++;` Within the simulation task run case, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge tensor tile RTL block in simulation. The important operands are errors: the value named 'errors' in this block.

Line 119: `$display("ERROR case=%0d unexpectedly reported config_error", case_index);` This is a simulation check or diagnostic. It can stop a failing test and print evidence, but it is not part of the synthesized PYNQ circuit.

Line 120: `end` This structural keyword opens or closes the branch/process scope described as the simulation task run case; it has no arithmetic value of its own.

Line 122: `for (int issue = 0; issue < case_issues; issue++) begin` This generate/procedural loop repeats the following operation across lanes or entries. In synthesizable RTL, a fixed loop is expanded into parallel or scheduled hardware rather than executed by a CPU. Context: the simulation task run case.

Line 123: `while (!issue_ready) @(negedge clk);` Within the simulation task run case, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge tensor tile RTL block in simulation. The important operands are while: the value named 'while' in this block; issue_ready: the consumer's statement that it can accept a payload this cycle; negedge: the value named 'negedge' in this block.

Line 124: `activation_vector = activation_mem[issue_pointer];` This makes activation_vector, an input feature value consumed by a neuron or multiply-accumulate operation, equal to 'activation_mem[issue_pointer]'. It is driven by combinational or procedural logic in the current evaluation. The important operands are activation_mem: an input feature value consumed by a neuron or multiply-accumulate operation; issue_pointer: the value named 'issue pointer' in this block. Context: the simulation task run case.

Line 125: `if (compute_mode == 2'd0 || compute_mode == 2'd1) begin` This condition selects the following hardware branch only when 'compute_mode == 2'd0 || compute_mode == 2'd1' is true. Both branches exist as gates; the condition controls a multiplexer rather than making software jump. The important operands are compute_mode: the value named 'compute mode' in this block; d0: the value named 'd0' in this block; d1: the value named 'd1' in this block. Context: the simulation task run case.

Line 126: `logic issue_nonzero;` This declares hardware signal storage or wiring in the simulation task run case. Specifically, issue_nonzero is the value named 'issue nonzero' in this block. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 127: `issue_nonzero = 1'b0;` This makes issue_nonzero, the value named 'issue nonzero' in this block, equal to '1'b0'. It is driven by combinational or procedural logic in the current evaluation. The important operands are b0: the value named 'b0' in this block. Context: the simulation task run case.

Line 128: `for (int row = 0; row < ROW_LANES; row++) begin` This generate/procedural loop repeats the following operation across lanes or entries. In synthesizable RTL, a fixed loop is expanded into parallel or scheduled hardware rather than executed by a CPU. Context: the simulation task run case.

Line 129: `issue_nonzero = issue_nonzero` This statement continues through source line 131; the explanation uses the complete expression rather than only the first visual fragment. This makes issue_nonzero, the value named 'issue nonzero' in this block, equal to 'issue_nonzero || activation_mem[issue_pointer][row*8 +: 8] != activation_zero_point'. It is driven by combinational or procedural logic in the current evaluation. The important operands are issue_nonzero: the value named 'issue nonzero' in this block; activation_mem: an input feature value consumed by a neuron or multiply-accumulate operation; issue_pointer: the value named 'issue pointer' in this block. Context: the simulation task run case.

Line 130: `|| activation_mem[issue_pointer][row*8 +: 8]` This is continuation line 2 of the 3-line logical statement that begins at source line 129. Its exact fragment is '|| activation_mem[issue_pointer][row*8 +: 8]'. The important operands are activation_mem: an input feature value consumed by a neuron or multiply-accumulate operation; issue_pointer: the value named 'issue pointer' in this block; row: one output-row position processed by the tensor tile. Read together, the complete operation is: This makes issue_nonzero, the value named 'issue nonzero' in this block, equal to 'issue_nonzero || activation_mem[issue_pointer][row*8 +: 8] != activation_zero_point'. It is driven by combinational or procedural logic in the current evaluation. The important operands are issue_nonzero: the value named 'issue nonzero' in this block; activation_mem: an input feature value consumed by a neuron or multiply-accumulate operation; issue_pointer: the value named 'issue pointer' in this block. Context: the simulation task run case.

Line 131: `!= activation_zero_point;` This is continuation line 3 of the 3-line logical statement that begins at source line 129. Its exact fragment is '!= activation_zero_point;'. The important operands are activation_zero_point: an input feature value consumed by a neuron or multiply-accumulate operation. Read together, the complete operation is: This makes issue_nonzero, the value named 'issue nonzero' in this block, equal to 'issue_nonzero || activation_mem[issue_pointer][row*8 +: 8] != activation_zero_point'. It is driven by combinational or procedural logic in the current evaluation. The important operands are issue_nonzero: the value named 'issue nonzero' in this block; activation_mem: an input feature value consumed by a neuron or multiply-accumulate operation; issue_pointer: the value named 'issue pointer' in this block. Context: the simulation task run case.

Line 132: `end` This structural keyword opens or closes the branch/process scope described as the simulation task run case; it has no arithmetic value of its own.

Line 133: `if (issue_nonzero) begin` This condition selects the following hardware branch only when 'issue_nonzero' is true. Both branches exist as gates; the condition controls a multiplexer rather than making software jump. The important operands are issue_nonzero: the value named 'issue nonzero' in this block. Context: the simulation task run case.

Line 134: `expected_dense_macs += compute_mode == 2'd0` This statement continues through source line 136; the explanation uses the complete expression rather than only the first visual fragment. Within the simulation task run case, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge tensor tile RTL block in simulation. The important operands are expected_dense_macs: a count of ordinary activation-times-weight operations actually issued; compute_mode: the value named 'compute mode' in this block; d0: the value named 'd0' in this block.

Line 135: `? int'(active_rows) * int'(active_columns)` This is continuation line 2 of the 3-line logical statement that begins at source line 134. Its exact fragment is '? int'(active_rows) * int'(active_columns)'. The important operands are active_rows: one output-row position processed by the tensor tile; active_columns: one output-feature position processed in parallel. Read together, the complete operation is: Within the simulation task run case, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge tensor tile RTL block in

simulation. The important operands are expected_dense_macs: a count of ordinary activation-times-weight operations actually issued; compute_mode: the value named 'compute mode' in this block; d0: the value named 'd0' in this block.

Line 136: `: ROW_LANES * int'(active_columns);` This is continuation line 3 of the 3-line logical statement that begins at source line 134. Its exact fragment is ': ROW_LANES * int'(active_columns);'. The important operands are ROW_LANES: one parallel arithmetic element within a vector or tensor datapath; active_columns: one output-feature position processed in parallel. Read together, the complete operation is: Within the simulation task run case, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge tensor tile RTL block in simulation. The important operands are expected_dense_macs: a count of ordinary activation-times-weight operations actually issued; compute_mode: the value named 'compute mode' in this block; d0: the value named 'd0' in this block.

Line 137: `end` This structural keyword opens or closes the branch/process scope described as the simulation task run case; it has no arithmetic value of its own.

Line 138: `end else begin` This structural keyword opens or closes the branch/process scope described as the simulation task run case; it has no arithmetic value of its own.

Line 139: `int active_spikes;` Within the simulation task run case, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge tensor tile RTL block in simulation. The important operands are active_spikes: a binary event produced when a neuron crosses its threshold.

Line 140: `active_spikes = 0;` This makes active_spikes, a binary event produced when a neuron crosses its threshold, equal to '0'. It is driven by combinational or procedural logic in the current evaluation. The expression is a literal or structural operator and has no hidden software state. Context: the simulation task run case.

Line 141: `for (int row = 0; row < ROW_LANES; row++) begin` This generate/procedural loop repeats the following operation across lanes or entries. In synthesizable RTL, a fixed loop is expanded into parallel or scheduled hardware rather than executed by a CPU. Context: the simulation task run case.

Line 142: `if (row < active_rows` Within the simulation task run case, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge tensor tile RTL block in simulation. The important operands are row: one output-row position processed by the tensor tile; active_rows: one output-row position processed by the tensor tile.

Line 143: `&& activation_mem[issue_pointer][row*8 +: 8] != 0) begin` Within the simulation task run case, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge tensor tile RTL block in simulation. The important operands are activation_mem: an input feature value consumed by a neuron or multiply-accumulate operation; issue_pointer: the value named 'issue pointer' in this block; row: one output-row position processed by the tensor tile.

Line 144: `active_spikes++;` Within the simulation task run case, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge tensor tile RTL block in simulation. The important operands are active_spikes: a binary event produced when a neuron crosses its threshold.

Line 145: `end` This structural keyword opens or closes the branch/process scope described as the simulation task run case; it has no arithmetic value of its own.

Line 146: `end` This structural keyword opens or closes the branch/process scope described as the simulation task run case; it has no arithmetic value of its own.

Line 147: `expected_spike_adds += active_spikes * int'(active_columns);` Within the simulation task run case, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge tensor tile RTL block in simulation. The important operands are expected_spike_adds: a binary event produced when a neuron crosses its threshold; active_spikes: a binary event produced when a neuron crosses its threshold; active_columns: one output-feature position processed in parallel.

Line 148: `end` This structural keyword opens or closes the branch/process scope described as the simulation task run case; it has no arithmetic value of its own.

Line 149: `dot_weight_vector = weight_mem[issue_pointer];` This makes dot_weight_vector, a learned coefficient multiplied by an activation, equal to 'weight_mem[issue_pointer]'. It is driven by combinational or procedural logic in the current evaluation. The important operands are weight_mem: a learned coefficient multiplied by an activation; issue_pointer: the value named 'issue pointer' in this block. Context: the simulation task run case.

Line 150: `outer_weight_vector = weight_mem[issue_pointer][COLUMN_LANES*8-1:0];` This makes outer_weight_vector, a learned coefficient multiplied by an activation, equal to 'weight_mem[issue_pointer][COLUMN_LANES*8-1:0]'. It is driven by combinational or procedural logic in the current evaluation. The important operands are weight_mem: a learned coefficient multiplied by an activation; issue_pointer: the value named 'issue pointer' in this block; COLUMN_LANES: one parallel arithmetic element within a vector or tensor datapath. Context: the simulation task run case.

Line 151: `issue_last = (issue == case_issues - 1);` This makes issue_last, the AXI-Stream marker for the final beat of a packet or command payload, equal to '(issue == case_issues - 1)'. It is driven by combinational or procedural logic in the current evaluation. The important operands are issue: the value named 'issue' in this block; case_issues: the value named 'case issues' in this block. Context: the simulation task run case.

Line 152: `issue_valid = 1'b1;` This makes issue_valid, the producer's statement that its current payload is meaningful, equal to '1'b1'. It is driven by combinational or procedural logic in the current evaluation. The important operands are b1: the value named 'b1' in this block. Context: the simulation task run case.

Line 153: `@(posedge clk);` Within the simulation task run case, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge tensor tile RTL block in simulation. The important operands are posedge: the value named 'posedge' in this block; clk: the clock that makes all registers advance together.

Line 154: `@(negedge clk);` Within the simulation task run case, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge tensor tile RTL block in simulation. The important operands are negedge: the value named 'negedge' in this block; clk: the clock that makes all registers advance together.

Line 155: `issue_valid = 1'b0;` This makes issue_valid, the producer's statement that its current payload is meaningful, equal to '1'b0'. It is driven by combinational or procedural logic in the current evaluation. The important operands are b0: the value named 'b0' in this block. Context: the simulation task run case.

Line 156: `issue_last = 1'b0;` This makes issue_last, the AXI-Stream marker for the final beat of a packet or command payload, equal to '1'b0'. It is driven by combinational or procedural logic in the current evaluation. The important operands are b0: the value named 'b0' in this block. Context: the simulation task run case.

Line 157: `issue_pointer++;` Within the simulation task run case, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge tensor tile RTL block in simulation. The important operands are issue_pointer: the value named 'issue pointer' in this block.

Line 158: `end` This structural keyword opens or closes the branch/process scope described as the simulation task run case; it has no arithmetic value of its own.

Line 160: `received = 0;` This makes received, the value named 'received' in this block, equal to '0'. It is driven by combinational or procedural logic in the current evaluation. The expression is a literal or structural operator and has no hidden software state. Context: the simulation task run case.

Line 161: `watchdog = 0;` This makes watchdog, the value named 'watchdog' in this block, equal to '0'. It is driven by combinational or procedural logic in the current evaluation. The expression is a literal or structural operator and has no hidden software state. Context: the simulation task run case.

Line 162: `output_cycle = 0;` This makes output_cycle, the value named 'output cycle' in this block, equal to '0'. It is driven by combinational or procedural logic in the current evaluation. The expression is a literal or structural operator and has no hidden software state. Context: the simulation task run case.

Line 163: `if (case_index == 0) begin` This condition selects the following hardware branch only when 'case_index == 0' is true. Both branches exist as gates; the condition controls a multiplexer rather than making software jump. The important operands are case_index: an integer selecting one tensor element, lane, bank, or state entry. Context: the simulation task run case.

Line 164: `// The first fixture is the maximum 8x16 tile. Keep READY low` Design intent: The first fixture is the maximum 8x16 tile. Keep READY low This comment anchors the surrounding logic in the block that drives, backpressures, and checks the neuraedge tensor tile RTL block in simulation.

Line 165: `// until all 128 records are resident, proving that compute can` Design intent: until all 128 records are resident, proving that compute can This comment anchors the surrounding logic in the block that drives, backpressures, and checks the neuraedge tensor tile RTL block in simulation.

Line 166: `// finish without a downstream consumer and without overflow.` Design intent: finish without a downstream consumer and without overflow. This comment anchors the surrounding logic in the block that drives, backpressures, and checks the neuraedge tensor tile RTL block in simulation.

Line 167: `result_ready = 1'b0;` This makes result_ready, the consumer's statement that it can accept a payload this cycle, equal to '1'b0'. It is driven by combinational or procedural logic in the current evaluation. The important operands are b0: the value named 'b0' in this block. Context: the simulation task run case.

Line 168: `while (int'(dut.result_fifo_count_r)` Within the simulation task run case, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge tensor tile RTL block in simulation. The important operands are while: the value named 'while' in this block; dut: the value named 'dut' in this block; result_fifo_count_r: an integer count retained for control or measurable telemetry.

Line 169: `+ int'(dut.result_stage_valid_r) < case_results` Within the simulation task run case, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge tensor tile RTL block in simulation. The important operands are dut: the value named 'dut' in this block; result_stage_valid_r: the producer's statement that its current payload is meaningful; case_results: the value named 'case results' in this block.

Line 170: `&& watchdog < 2000) begin` Within the simulation task run case, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge tensor tile RTL block in simulation. The important operands are watchdog: the value named 'watchdog' in this block.

Line 171: `@(negedge clk);` Within the simulation task run case, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge tensor tile RTL block in simulation. The important operands are negedge: the value named 'negedge' in this block; clk: the clock that makes all registers advance together.

Line 172: `watchdog++;` Within the simulation task run case, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge tensor tile RTL block in simulation. The important operands are watchdog: the value named 'watchdog' in this block.

Line 173: `end` This structural keyword opens or closes the branch/process scope described as the simulation task run case; it has no arithmetic value of its own.

Line 174: `if (int'(dut.result_fifo_count_r)` This condition selects the following hardware branch only when 'int'(dut.result_fifo_count_r' is true. Both branches exist as gates; the condition controls a multiplexer rather than making software jump. The important operands are dut: the value named 'dut' in this block; result_fifo_count_r: an integer count retained for control or measurable telemetry. Context: the simulation task run case.

Line 175: `+ int'(dut.result_stage_valid_r) != case_results` Within the simulation task run case, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge tensor tile RTL block in simulation. The important operands are dut: the value named 'dut' in this block; result_stage_valid_r: the producer's statement that its current payload is meaningful; case_results: the value named 'case results' in this block.

Line 176: `|| !dut.result_fifo_nonempty_r` Within the simulation task run case, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge tensor tile RTL block in simulation. The important operands are dut: the value named 'dut' in this block; result_fifo_nonempty_r: the value named 'result fifo nonempty r' in this block.

Line 177: `|| !dut.result_fifo_has_space_r` Within the simulation task run case, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge tensor tile RTL block in simulation. The important operands are dut: the value named 'dut' in this block; result_fifo_has_space_r: the value named 'result fifo has space r' in this block.

Line 178: `|| !dut.result_stage_valid_r` Within the simulation task run case, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge tensor tile RTL block in simulation. The important operands are dut: the value named 'dut' in this block; result_stage_valid_r: the producer's statement that its current payload is meaningful.

Line 179: `|| dut.p5_valid_r) begin` Within the simulation task run case, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge tensor tile RTL block in simulation. The important operands are dut: the value named 'dut' in this block; p5_valid_r: the producer's statement that its current payload is meaningful.

Line 180: `errors++;` Within the simulation task run case, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge tensor tile RTL block in simulation. The important operands are errors: the value named 'errors' in this block.

Line 181: `$display("ERROR maximum result buffer did not fill exactly memory_count=%0d stage_valid=%0d nonempty=%0d sp...` This is a simulation check or diagnostic. It can stop a failing test and print evidence, but it is not part of the synthesized PYNQ circuit.

Line 182: `dut.result_fifo_count_r, dut.result_stage_valid_r,` Within the simulation task run case, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge tensor tile RTL block in simulation. The important operands are dut: the value named 'dut' in this block; result_fifo_count_r: an integer count retained for control or measurable telemetry; result_stage_valid_r: the producer's statement that its current payload is meaningful.

Line 183: `dut.result_fifo_nonempty_r,` Within the simulation task run case, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge tensor tile RTL block in simulation. The important operands are dut: the value named 'dut' in this block; result_fifo_nonempty_r: the value named 'result fifo nonempty r' in this block.

Line 184: `dut.result_fifo_has_space_r, dut.p5_valid_r);` Within the simulation task run case, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge tensor tile RTL block in simulation. The important operands are dut: the value named 'dut' in this block; result_fifo_has_space_r: the value named 'result fifo has space r' in this block; p5_valid_r: the producer's statement that its current payload is meaningful.

Line 185: `end` This structural keyword opens or closes the branch/process scope described as the simulation task run case; it has no arithmetic value of its own.

Line 186: `watchdog = 0;` This makes watchdog, the value named 'watchdog' in this block, equal to '0'. It is driven by combinational or procedural logic in the current evaluation. The expression is a literal or structural operator and has no hidden software state. Context: the simulation task run case.

Line 187: `end` This structural keyword opens or closes the branch/process scope described as the simulation task run case; it has no arithmetic value of its own.

Line 188: `while (received < case_results && watchdog < 20000) begin` Within the simulation task run case, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge tensor tile RTL block in simulation. The important operands are while: the value named 'while' in this block; received: the value named 'received' in this block; case_results: the value named 'case results' in this block.

Line 189: `@(negedge clk);` Within the simulation task run case, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge tensor tile RTL block in simulation. The important operands are negedge: the value named 'negedge' in this block; clk: the clock that makes all registers advance together.

Line 190: `// Drive READY independently of the result count. Tying stalls to` Design intent: Drive READY independently of the result count. Tying stalls to This comment anchors the surrounding logic in the block that drives, backpressures, and checks the neuraedge tensor tile RTL block in simulation.

Line 191: `// 'received' can deadlock a ready/valid test when a stalled count` Design intent: 'received' can deadlock a ready/valid test when a stalled count This comment anchors the surrounding logic in the block that drives, backpressures, and checks the neuraedge tensor tile RTL block in simulation.

Line 192: `// selects the same false value forever.` Design intent: selects the same false value forever. This comment anchors the surrounding logic in the block that drives, backpressures, and checks the neuraedge tensor tile RTL block in simulation.

Line 193: `result_ready = ((output_cycle + case_index) % 5 != 1);` This makes result_ready, the consumer's statement that it can accept a payload this cycle, equal to '((output_cycle + case_index) % 5 != 1)'. It is driven by combinational or procedural logic in the current evaluation. The important operands are output_cycle: the value named 'output cycle' in this block; case_index: an integer selecting one tensor element, lane, bank, or state entry. Context: the simulation task run case.

Line 194: `// READY is now stable before the active edge. Sample the result` Design intent: READY is now stable before the active edge. Sample the result This comment anchors the surrounding logic in the block that drives, backpressures, and checks the neuraedge tensor tile RTL block in simulation.

Line 195: `// on the same rising edge on which the DUT commits the transfer.` Design intent: on the same rising edge on which the DUT commits the transfer. This comment anchors the surrounding logic in the block that drives, backpressures, and checks the neuraedge tensor tile RTL block in simulation.

Line 196: `@(posedge clk);` Within the simulation task run case, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge tensor tile RTL block in simulation. The important operands are posedge: the value named 'posedge' in this block; clk: the clock that makes all registers advance together.

Line 197: `if (result_valid && result_ready) begin` This condition selects the following hardware branch only when 'result_valid && result_ready' is true. Both branches exist as gates; the condition controls a multiplexer rather than making software jump. The important operands are result_valid: the producer's statement that its current payload is meaningful; result_ready: the consumer's statement that it can accept a payload this cycle. Context: the simulation task run case.

Line 198: `result_extended = {{16{result_value[47]}}, result_value};` This makes result_extended, the value named 'result extended' in this block, equal to '{{16{result_value[47]}}, result_value}'. It is driven by combinational or procedural logic in the current evaluation. The important operands are result_value: the value named 'result value' in this block. Context: the simulation task run case.

Line 199: `if (result_extended !== expected_mem[expected_pointer]) begin` This condition selects the following hardware branch only when 'result_extended !== expected_mem[expected_pointer]' is true. Both branches exist as gates; the condition controls a multiplexer rather than making software jump. The important operands are result_extended: the value named 'result extended' in this block; expected_mem: local FPGA storage addressed by surrounding index logic; expected_pointer: the value named 'expected pointer' in this block. Context: the simulation task run case.

Line 200: `errors++;` Within the simulation task run case, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge tensor tile RTL block in simulation. The important operands are errors: the value named 'errors' in this block.

Line 201: `if (errors <= 30) begin` This statement continues through source line 204; the explanation uses the complete expression rather than only the first visual fragment. This condition selects the following hardware branch only when 'errors <= 30) begin $display("ERROR case=%0d row=%0d col=%0d got=%0d expected=%0d", case_index, result_row, result_column, result_extended, expected_mem[expected_pointer]' is true. Both branches exist as gates; the condition controls a multiplexer rather than making software jump. The important operands are errors: the value named 'errors' in this block; display: the value named 'display' in this block; ERROR: the value named 'error' in this block. Context: the simulation task run case.

Line 202: `$display("ERROR case=%0d row=%0d col=%0d got=%0d expected=%0d",` This is continuation line 2 of the 4-line logical statement that begins at source line 201. Its exact fragment is '$display("ERROR case=%0d row=%0d col=%0d got=%0d expected=%0d",'. The important operands are display: the value named 'display' in this block; ERROR: the value named 'error' in this block; case: the value named 'case' in this block. Read together, the complete operation is: This condition selects the following hardware branch only when 'errors <= 30) begin $display("ERROR case=%0d row=%0d col=%0d got=%0d expected=%0d", case_index, result_row, result_column, result_extended, expected_mem[expected_pointer]' is true. Both branches exist as gates; the condition controls a multiplexer rather than making software jump. The important operands are errors: the value named 'errors' in this block; display: the value named 'display' in this block; ERROR: the value named 'error' in this block. Context: the simulation task run case.

Line 203: `case_index, result_row, result_column,` This is continuation line 3 of the 4-line logical statement that begins at source line 201. Its exact fragment is 'case_index, result_row, result_column,'. The important operands are case_index: an integer selecting one tensor element, lane, bank, or state entry; result_row: one output-row position processed by the tensor tile; result_column: one output-feature position processed in parallel. Read together, the complete operation is: This condition selects the following hardware branch only when 'errors <= 30) begin $display("ERROR case=%0d row=%0d col=%0d got=%0d expected=%0d", case_index, result_row, result_column, result_extended, expected_mem[expected_pointer]' is true. Both branches exist as gates; the condition controls a multiplexer rather than making software jump. The important operands are errors: the value named 'errors' in this block; display: the value named 'display' in this block; ERROR: the value named 'error' in this block. Context: the simulation task run case.

Line 204: `result_extended, expected_mem[expected_pointer]);` This is continuation line 4 of the 4-line logical statement that begins at source line 201. Its exact fragment is 'result_extended, expected_mem[expected_pointer]);'. The important operands are result_extended: the value named 'result extended' in this block; expected_mem: local FPGA storage addressed by surrounding index logic; expected_pointer: the value named 'expected pointer' in this block. Read together, the complete operation is: This condition selects the following hardware branch only when 'errors <= 30) begin $display("ERROR case=%0d row=%0d col=%0d got=%0d expected=%0d", case_index, result_row, result_column, result_extended, expected_mem[expected_pointer]' is true. Both branches exist as gates; the condition controls a multiplexer rather than making software jump. The important operands are errors: the value named 'errors' in this block; display: the value named 'display' in this block; ERROR: the value named 'error' in this block. Context: the simulation task run case.

Line 205: `end` This structural keyword opens or closes the branch/process scope described as the simulation task run case; it has no arithmetic value of its own.

Line 206: `end` This structural keyword opens or closes the branch/process scope described as the simulation task run case; it has no arithmetic value of its own.

Line 207: `if (result_last !== (received == case_results - 1)) begin` This condition selects the following hardware branch only when ‘result_last !== (received == case_results - 1)‘ is true. Both branches exist as gates; the condition controls a multiplexer rather than making software jump. The important operands are result_last: the AXI-Stream marker for the final beat of a packet or command payload; received: the value named ’received’ in this block; case_results: the value named ’case results’ in this block. Context: the simulation task run case.

Line 208: `errors++;` Within the simulation task run case, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge tensor tile RTL block in simulation. The important operands are errors: the value named ’errors’ in this block.

Line 209: `$display("ERROR case=%0d result_last mismatch at result=%0d", case_index, received);` This is a simulation check or diagnostic. It can stop a failing test and print evidence, but it is not part of the synthesized PYNQ circuit.

Line 210: `end` This structural keyword opens or closes the branch/process scope described as the simulation task run case; it has no arithmetic value of its own.

Line 211: `expected_pointer++;` Within the simulation task run case, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge tensor tile RTL block in simulation. The important operands are expected_pointer: the value named ’expected pointer’ in this block.

Line 212: `received++;` Within the simulation task run case, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge tensor tile RTL block in simulation. The important operands are received: the value named ’received’ in this block.

Line 213: `checked++;` Within the simulation task run case, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge tensor tile RTL block in simulation. The important operands are checked: the value named ’checked’ in this block.

Line 214: `end` This structural keyword opens or closes the branch/process scope described as the simulation task run case; it has no arithmetic value of its own.

Line 215: `output_cycle++;` Within the simulation task run case, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge tensor tile RTL block in simulation. The important operands are output_cycle: the value named ’output cycle’ in this block.

Line 216: `watchdog++;` Within the simulation task run case, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge tensor tile RTL block in simulation. The important operands are watchdog: the value named ’watchdog’ in this block.

Line 217: `end` This structural keyword opens or closes the branch/process scope described as the simulation task run case; it has no arithmetic value of its own.

Line 218: `@(negedge clk);` Within the simulation task run case, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge tensor tile RTL block in simulation. The important operands are negedge: the value named ’negedge’ in this block; clk: the clock that makes all registers advance together.

Line 219: `result_ready = 1'b0;` This makes result_ready, the consumer's statement that it can accept a payload this cycle, equal to '1'b0'. It is driven by combinational or procedural logic in the current evaluation. The important operands are b0: the value named 'b0' in this block. Context: the simulation task run case.

Line 220: `if (received != case_results) begin` This condition selects the following hardware branch only when 'received != case_results' is true. Both branches exist as gates; the condition controls a multiplexer rather than making software jump. The important operands are received: the value named 'received' in this block; case_results: the value named 'case results' in this block. Context: the simulation task run case.

Line 221: `errors++;` Within the simulation task run case, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge tensor tile RTL block in simulation. The important operands are errors: the value named 'errors' in this block.

Line 222: `$display("ERROR case=%0d output timeout received=%0d expected=%0d", case_index, received, case_results);` This is a simulation check or diagnostic. It can stop a failing test and print evidence, but it is not part of the synthesized PYNQ circuit.

Line 223: `end` This structural keyword opens or closes the branch/process scope described as the simulation task run case; it has no arithmetic value of its own.

Line 224: `while (busy) @(negedge clk);` Within the simulation task run case, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge tensor tile RTL block in simulation. The important operands are while: the value named 'while' in this block; busy: the value named 'busy' in this block; negedge: the value named 'negedge' in this block.

Line 225: `if (debug_dense_macs !== expected_dense_macs` Within the simulation task run case, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge tensor tile RTL block in simulation. The important operands are debug_dense_macs: a count of ordinary activation-times-weight operations actually issued; expected_dense_macs: a count of ordinary activation-times-weight operations actually issued.

Line 226: `|| debug_spike_adds !== expected_spike_adds) begin` Within the simulation task run case, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge tensor tile RTL block in simulation. The important operands are debug_spike_adds: a binary event produced when a neuron crosses its threshold; expected_spike_adds: a binary event produced when a neuron crosses its threshold.

Line 227: `errors++;` Within the simulation task run case, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge tensor tile RTL block in simulation. The important operands are errors: the value named 'errors' in this block.

Line 228: `$display("ERROR case=%0d counter mismatch dense=%0d/%0d spike=%0d/%0d",` This is a simulation check or diagnostic. It can stop a failing test and print evidence, but it is not part of the synthesized PYNQ circuit.

Line 229: `case_index, debug_dense_macs, expected_dense_macs,` Within the simulation task run case, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge tensor tile RTL block in simulation. The important operands are case_index: an integer selecting one tensor element, lane, bank, or state entry; debug_dense_macs: a count of ordinary activation-times-weight operations actually issued; expected_dense_macs: a count of ordinary activation-times-weight operations actually issued.

Line 230: `debug_spike_adds, expected_spike_adds);` Within the simulation task run case, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge tensor tile RTL block in simulation. The important operands are debug_spike_adds: a binary event produced when a neuron crosses its threshold; expected_spike_adds: a binary event produced when a neuron crosses its threshold.

Line 231: `end` This structural keyword opens or closes the branch/process scope described as the simulation task run case; it has no arithmetic value of its own.

Line 232: `$display("case=%0d mode=%0d rows=%0d columns=%0d issues=%0d skips=%0d dense_macs=%0d spike_adds=%0d` This is a simulation check or diagnostic. It can stop a failing test and print evidence, but it is not part of the synthesized PYNQ circuit.

Line 233: `case_index, compute_mode, active_rows, active_columns, case_issues,` Within the simulation task run case, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge tensor tile RTL block in simulation. The important operands are case_index: an integer selecting one tensor element, lane, bank, or state entry; compute_mode: the value named 'compute mode' in this block; active_rows: one output-row position processed by the tensor tile.

Line 234: `debug_skipped_issues, debug_dense_macs, debug_spike_adds);` Within the simulation task run case, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge tensor tile RTL block in simulation. The important operands are debug_skipped_issues: the value named 'debug skipped issues' in this block; debug_dense_macs: a count of ordinary activation-times-weight operations actually issued; debug_spike_adds: a binary event produced when a neuron crosses its threshold.

Line 235: `end` This structural keyword opens or closes the branch/process scope described as the simulation task run case; it has no arithmetic value of its own.

Line 236: `endtask` Within the simulation task run case, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge tensor tile RTL block in simulation. The important operands are endtask: the value named 'endtask' in this block.

Line 238: `always @(posedge clk) begin` Within the module's structural declarations, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge tensor tile RTL block in simulation. The important operands are always: the value named 'always' in this block; posedge: the value named 'posedge' in this block; clk: the clock that makes all registers advance together.

Line 239: `cycle <= cycle + 1;` This makes cycle, the value named 'cycle' in this block, equal to 'cycle + 1'. It updates after the active clock edge together with other nonblocking assignments. The important operands are cycle: the value named 'cycle' in this block. Context: the module's structural declarations.

Line 240: `if (stalled_valid) begin` This condition selects the following hardware branch only when 'stalled_valid' is true. Both branches exist as gates; the condition controls a multiplexer rather than making software jump. The important operands are stalled_valid: the producer's statement that its current payload is meaningful. Context: the module's structural declarations.

Line 241: `if (!result_valid || result_value !== stalled_value || result_row !== stalled_row` Within the module's structural declarations, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge tensor tile RTL block in simulation. The important operands are result_valid: the producer's statement that its current payload is meaningful; result_value: the value named 'result value' in this block; stalled_value: the value named 'stalled value' in this block.

Line 242: `|| result_column !== stalled_column || result_last !== stalled_last) begin` Within the module's structural declarations, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge tensor tile RTL block in simulation. The important operands are result_column: one output-feature position processed in parallel; stalled_column: one output-feature position processed in parallel; result_last: the AXI-Stream marker for the final beat of a packet or command payload.

Line 243: `errors++;` Within the module's structural declarations, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge tensor tile RTL block in simulation. The important operands are errors: the value named 'errors' in this block.

Line 244: `$display("ERROR result changed while backpressured");` This is a simulation check or diagnostic. It can stop a failing test and print evidence, but it is not part of the synthesized PYNQ circuit.

Line 245: `end` This structural keyword opens or closes the branch/process scope described as the module's structural declarations; it has no arithmetic value of its own.

Line 246: `end` This structural keyword opens or closes the branch/process scope described as the module's structural declarations; it has no arithmetic value of its own.

Line 247: `stalled_valid <= result_valid && !result_ready;` This makes stalled_valid, the producer's statement that its current payload is meaningful, equal to 'result_valid && !result_ready'. It updates after the active clock edge together with other nonblocking assignments. The important operands are result_valid: the producer's statement that its current payload is meaningful; result_ready: the consumer's statement that it can accept a payload this cycle. Context: the module's structural declarations.

Line 248: `stalled_value <= result_value;` This makes stalled_value, the value named 'stalled value' in this block, equal to 'result_value'. It updates after the active clock edge together with other nonblocking assignments. The important operands are result_value: the value named 'result value' in this block. Context: the module's structural declarations.

Line 249: `stalled_row <= result_row;` This makes stalled_row, one output-row position processed by the tensor tile, equal to 'result_row'. It updates after the active clock edge together with other nonblocking assignments. The important operands are result_row: one output-row position processed by the tensor tile. Context: the module's structural declarations.

Line 250: `stalled_column <= result_column;` This makes stalled_column, one output-feature position processed in parallel, equal to 'result_column'. It updates after the active clock edge together with other nonblocking assignments. The important operands are result_column: one output-feature position processed in parallel. Context: the module's structural declarations.

Line 251: `stalled_last <= result_last;` This makes stalled_last, the AXI-Stream marker for the final beat of a packet or command payload, equal to 'result_last'. It updates after the active clock edge together with other nonblocking assignments. The important operands are result_last: the AXI-Stream marker for the final beat of a packet or command payload. Context: the module's structural declarations.

Line 252: `end` This structural keyword opens or closes the branch/process scope described as the module's structural declarations; it has no arithmetic value of its own.

Line 254: `initial begin` This opens simulation initialization. In a testbench it drives starting values and stimulus; project synthesis does not rely on this block as a replacement for explicit reset behavior.

Line 255: `$readmemh("tb/fixtures/tensor_cases.mem", case_mem);` Within the module's structural declarations, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge tensor tile RTL block in simulation. The important operands are readmemh: the value named 'readmemh' in this block; tb: the value named 'tb' in this block; fixtures: the value named 'fixtures' in this block.

Line 256: `$readmemh("tb/fixtures/tensor_activations.mem", activation_mem);` Within the module's structural declarations, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge tensor tile RTL block in simulation. The important operands are readmemh: the value named 'readmemh' in this block; tb: the value named 'tb' in this block; fixtures: the value named 'fixtures' in this block.

Line 257: `$readmemh("tb/fixtures/tensor_weights.mem", weight_mem);` Within the module's structural declarations, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge tensor tile RTL block in simulation. The important operands are readmemh: the value named 'readmemh' in this block; tb: the value named 'tb' in this block; fixtures: the value named 'fixtures' in this block.

Line 258: `$readmemh("tb/fixtures/tensor_expected.mem", expected_mem);` Within the module's structural declarations, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge tensor tile RTL block in simulation. The important operands are readmemh: the value named 'readmemh' in this block; tb: the value named 'tb' in this block; fixtures: the value named 'fixtures' in this block.

Line 259: `// The complete numerical regression deliberately runs without a VCD:` Design intent: The complete numerical regression deliberately runs without a VCD: This comment anchors the surrounding logic in the block that drives, backpressures, and checks the neuraedge tensor tile RTL block in simulation.

Line 260: `// 128 MAC instances make an unrestricted trace needlessly enormous.` Design intent: 128 MAC instances make an unrestricted trace needlessly enormous. This comment anchors the surrounding logic in the block that drives, backpressures, and checks the neuraedge tensor tile RTL block in simulation.

Line 261: `// A bounded, purpose-built waveform test generates the review VCD.` Design intent: A bounded, purpose-built waveform test generates the review VCD. This comment anchors the surrounding logic in the block that drives, backpressures, and checks the neuraedge tensor tile RTL block in simulation.

Line 263: `repeat (5) @(negedge clk);` Within the module's structural declarations, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge tensor tile RTL block in simulation. The important operands are repeat: the value named 'repeat' in this block; negedge: the value named 'negedge' in this block; clk: the clock that makes all registers advance together.

Line 264: `rst_n = 1'b1;` This makes rst_n, the active-low synchronous reset, equal to '1'b1'. It is driven by combinational or procedural logic in the current evaluation. The important operands are b1: the value named 'b1' in this block. Context: the module's structural declarations.

Line 265: `repeat (2) @(negedge clk);` Within the module's structural declarations, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge tensor tile RTL block in simulation. The important operands are repeat: the value named 'repeat' in this block; negedge: the value named 'negedge' in this block; clk: the clock that makes all registers advance together.

Line 267: `for (int case_index = 0; case_index < CASES; case_index++) begin` This generate/procedural loop repeats the following operation across lanes or entries. In synthesizable RTL, a fixed loop is expanded into parallel or scheduled hardware rather than executed by a CPU. Context: the module's structural declarations.

Line 268: `run_case(case_index);` Within the module's structural declarations, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge tensor tile RTL block in simulation. The important operands are run_case: the value named 'run case' in this block; case_index: an integer selecting one tensor element, lane, bank, or state entry.

Line 269: `end` This structural keyword opens or closes the branch/process scope described as the module's structural declarations; it has no arithmetic value of its own.

Line 271: `// Synchronous reset recovery is checked after all numerical cases so it cannot` Design intent: Synchronous reset recovery is checked after all numerical cases so it cannot This comment anchors the surrounding logic in the block that drives, backpressures, and checks the neuraedge tensor tile RTL block in simulation.

Line 272: `// conceal a fixture mismatch.` Design intent: conceal a fixture mismatch. This comment anchors the surrounding logic in the block that drives, backpressures, and checks the neuraedge tensor tile RTL block in simulation.

Line 273: `compute_mode = 2'd0;` This makes compute_mode, the value named 'compute mode' in this block, equal to '2'd0'. It is driven by combinational or procedural logic in the current evaluation. The important operands are d0: the value named 'd0' in this block. Context: the module's structural declarations.

Line 274: `active_rows = 4'd1;` This makes active_rows, one output-row position processed by the tensor tile, equal to '4'd1'. It is driven by combinational or procedural logic in the current evaluation. The important operands are d1: the value named 'd1' in this block. Context: the module's structural declarations.

Line 275: `active_columns = 6'd1;` This makes active_columns, one output-feature position processed in parallel, equal to '6'd1'. It is driven by combinational or procedural logic in the current evaluation. The important operands are d1: the value named 'd1' in this block. Context: the module's structural declarations.

Line 276: `@(negedge clk);` Within the module's structural declarations, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge tensor tile RTL block in simulation. The important operands are negedge: the value named 'negedge' in this block; clk: the clock that makes all registers advance together.

Line 277: `start = 1'b1;` This makes start, the value named 'start' in this block, equal to '1'b1'. It is driven by combinational or procedural logic in the current evaluation. The important operands are b1: the value named 'b1' in this block. Context: the module's structural declarations.

Line 278: `@(negedge clk);` Within the module's structural declarations, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge tensor tile RTL block in simulation. The important operands are negedge: the value named 'negedge' in this block; clk: the clock that makes all registers advance together.

Line 279: `start = 1'b0;` This makes start, the value named 'start' in this block, equal to '1'b0'. It is driven by combinational or procedural logic in the current evaluation. The important operands are b0: the value named 'b0' in this block. Context: the module's structural declarations.

Line 280: `if (!busy) begin` This condition selects the following hardware branch only when '!busy' is true. Both branches exist as gates; the condition controls a multiplexer rather than making software jump. The important operands are busy: the value named 'busy' in this block. Context: the module's structural declarations.

Line 281: `errors++;` Within the module's structural declarations, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge tensor tile RTL block in simulation. The important operands are errors: the value named 'errors' in this block.

Line 282: `$display("ERROR reset-recovery setup did not enter busy state");` This is a simulation check or diagnostic. It can stop a failing test and print evidence, but it is not part of the synthesized PYNQ circuit.

Line 283: `end` This structural keyword opens or closes the branch/process scope described as the module's structural declarations; it has no arithmetic value of its own.

Line 284: `rst_n = 1'b0;` This makes rst_n, the active-low synchronous reset, equal to '1'b0'. It is driven by combinational or procedural logic in the current evaluation. The important operands are b0: the value named 'b0' in this block. Context: the module's structural declarations.

Line 285: `repeat (2) @(negedge clk);` Within the module's structural declarations, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge tensor tile RTL block in simulation. The important operands are repeat: the value named 'repeat' in this block; negedge: the value named 'negedge' in this block; clk: the clock that makes all registers advance together.

Line 286: `if (busy || result_valid || issue_ready) begin` This condition selects the following hardware branch only when 'busy || result_valid || issue_ready' is true. Both branches exist as gates; the condition controls a multiplexer rather than making software jump. The important operands are busy: the value named 'busy' in this block; result_valid: the producer's statement that its current payload is meaningful; issue_ready: the consumer's statement that it can accept a payload this cycle. Context: the module's structural declarations.

Line 287: `errors++;` Within the module's structural declarations, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge tensor tile RTL block in simulation. The important operands are errors: the value named 'errors' in this block.

Line 288: `$display("ERROR external reset did not return tile to idle outputs");` This is a simulation check or diagnostic. It can stop a failing test and print evidence, but it is not part of the synthesized PYNQ circuit.

Line 289: `end` This structural keyword opens or closes the branch/process scope described as the module's structural declarations; it has no arithmetic value of its own.

Line 290: `rst_n = 1'b1;` This makes rst_n, the active-low synchronous reset, equal to '1'b1'. It is driven by combinational or procedural logic in the current evaluation. The important operands are b1: the value named 'b1' in this block. Context: the module's structural declarations.

Line 292: `if (issue_pointer != ISSUES || expected_pointer != RESULTS || checked != RESULTS) begin` This condition selects the following hardware branch only when 'issue_pointer != ISSUES || expected_pointer != RESULTS || checked != RESULTS' is true. Both branches exist as gates; the condition controls a multiplexer rather than making software jump. The important operands are issue_pointer: the value named 'issue pointer' in this block; ISSUES: the value named 'issues' in this block; expected_pointer: the value named 'expected pointer' in this block. Context: the module's structural declarations.

Line 293: `errors++;` Within the module's structural declarations, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge tensor tile RTL block in simulation. The important operands are errors: the value named 'errors' in this block.

Line 294: `$display("ERROR fixture accounting issue_ptr=%0d/%0d result_ptr=%0d/%0d checked=%0d",` This is a simulation check or diagnostic. It can stop a failing test and print evidence, but it is not part of the synthesized PYNQ circuit.

Line 295: `issue_pointer, ISSUES, expected_pointer, RESULTS, checked);` Within the module's structural declarations, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge tensor tile RTL block in simulation. The important operands are issue_pointer: the value named 'issue pointer' in this block; ISSUES: the value named 'issues' in this block; expected_pointer: the value named 'expected pointer' in this block.

Line 296: `end` This structural keyword opens or closes the branch/process scope described as the module's structural declarations; it has no arithmetic value of its own.

Line 297: `if (errors != 0) begin` This condition selects the following hardware branch only when 'errors != 0' is true. Both branches exist as gates; the condition controls a multiplexer rather than making software jump. The important operands are errors: the value named 'errors' in this block. Context: the module's structural declarations.

Line 298: `$display("tb_neuraedge_tensor_tile FAILED errors=%0d checked=%0d", errors, checked);` This is a simulation check or diagnostic. It can stop a failing test and print evidence, but it is not part of the synthesized PYNQ circuit.

Line 299: `$fatal(1);` This is a simulation check or diagnostic. It can stop a failing test and print evidence, but it is not part of the synthesized PYNQ circuit.

Line 300: `end` This structural keyword opens or closes the branch/process scope described as the module's structural declarations; it has no arithmetic value of its own.

Line 301: `$display("tb_neuraedge_tensor_tile PASSED cases=%0d checked=%0d", CASES, checked);` This is a simulation check or diagnostic. It can stop a failing test and print evidence, but it is not part of the synthesized PYNQ circuit.

Line 302: `$finish;` This is a simulation check or diagnostic. It can stop a failing test and print evidence, but it is not part of the synthesized PYNQ circuit.

Line 303: `end` This structural keyword opens or closes the branch/process scope described as the module's structural declarations; it has no arithmetic value of its own.

Line 305: `initial begin` This opens simulation initialization. In a testbench it drives starting values and stimulus; project synthesis does not rely on this block as a replacement for explicit reset behavior.

Line 306: `#100_000;` Within the module's structural declarations, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge tensor tile RTL block in simulation. The expression is a literal or structural operator and has no hidden software state.

Line 307: `$display("ERROR tb_neuraedge_tensor_tile watchdog timeout state=%0d busy=%0d issue_ready=%0d result_valid=%...` This is a simulation check or diagnostic. It can stop a failing test and print evidence, but it is not part of the synthesized PYNQ circuit.

Line 308: `dut.state, busy, issue_ready, result_valid, result_ready,` Within the module's structural declarations, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge tensor tile RTL block in simulation. The important operands are dut: the value named 'dut' in this block; state: the finite-state-machine phase retained in flip-flops; busy: the value named 'busy' in this block.

Line 309: `debug_accepted_issues, debug_retired_issues,` Within the module's structural declarations, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge tensor tile RTL block in simulation. The important operands are debug_accepted_issues: the value named 'debug accepted issues' in this block; debug_retired_issues: the value named 'debug retired issues' in this block.

Line 310: `dut.mac_issue_count, dut.mac_retire_count, dut.target_mac_retires);` Within the module's structural declarations, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge tensor tile RTL block in simulation. The important operands are dut: the value named 'dut' in this block; mac_issue_count: an integer count retained for control or measurable telemetry; mac_retire_count: an integer count retained for control or measurable telemetry.

Line 311: `$fatal(1);` This is a simulation check or diagnostic. It can stop a failing test and print evidence, but it is not part of the synthesized PYNQ circuit.

Line 312: `end` This structural keyword opens or closes the branch/process scope described as the module's structural declarations; it has no arithmetic value of its own.

Line 313: `endmodule` This closes the current hardware definition; no circuit behavior is attached to the keyword itself.

Line 315: `` `default_nettype wire `` This SystemVerilog preprocessor line controls compilation of the block that drives, backpressures, and checks the neuraedge tensor tile RTL block in simulation.

59 tb/tb_neuraedge_universal_core.sv

Role in the complete system: drives, backpressures, and checks the neuraedge universal core RTL block in simulation.

59.1 Beginner architecture map

Dataflow responsibility This file's end-to-end responsibility is to drives, backpressures, and checks the neuraedge universal core RTL block in simulation.

Simulation-only status tb_neuraedge_universal_core is not synthesized into the FPGA. It generates clocks, reset, commands, stalls, and expected values around the design under test, then terminates with an explicit result marker.

Evidence produced The file contains approximately 3 explicit assertions, failure diagnostics, or pass/fail markers. Its VCD/WDB trace is useful evidence only when the final pass marker is present; a simulator exit code by itself is insufficient.

59.3 Line annotations

Line 1: `` `timescale 1ns / 1ps `` This simulation directive selects nanoseconds as the time unit and picoseconds as the timestamp precision; it does not create FPGA logic.

Line 2: `` `default_nettype none `` This compiler directive forbids accidental implicit one-bit wires, turning misspelled signal names into errors instead of unintended hardware.

Line 3: `` `include "tb/fixtures/operator_fixture_params.svh" `` This SystemVerilog preprocessor line controls compilation of the block that drives, backpressures, and checks the neuraedge universal core RTL block in simulation.

Line 5: `module tb_neuraedge_universal_core;` This opens tb_neuraedge_universal_core;, an independently compiled hardware definition. Its ports and statements collectively describe circuitry that drives, backpressures, and checks the neuraedge universal core RTL block in simulation.

Line 6: `import neuraedge_command_pkg::*;` This imports shared package names into the current module so opcodes and mode constants have exactly one definition. The import changes compile-time name visibility; it does not create registers or consume a clock cycle.

Line 8: `logic clk = 1'b0;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, clk is the clock that makes all registers advance together. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 9: `logic rst_n = 1'b0;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, rst_n is the active-low synchronous reset. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 10: `logic command_valid = 1'b0;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, command_valid is the producer's statement that its current payload is meaningful. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 11: `logic command_ready;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, command_ready is the consumer's statement that it can accept a payload this cycle. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 12: `logic [127:0] command_data = 128'd0;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, command_data is the 128-bit instruction selecting an engine, shape, mode, and numeric parameters. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 13: `logic command_done;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, command_done is the 128-bit instruction selecting an engine, shape, mode, and numeric parameters. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 14: `logic status_busy;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, status_busy is the value named 'status busy' in this block. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 15: `logic status_error;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, status_error is the value named 'status error' in this block. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 16: `logic [3:0] status_active_opcode;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, status_active_opcode is the value named 'status active opcode' in this block. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 17: `logic [31:0] status_command_count;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, status_command_count is the 128-bit instruction selecting an engine, shape, mode, and numeric parameters. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 18: `logic [31:0] status_input_beats;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, status_input_beats is the value named 'status input beats' in this block. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 19: `logic [31:0] status_output_beats;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, status_output_beats is the value named 'status output beats' in this block. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 20: `logic s_axis_tvalid = 1'b0;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, s_axis_tvalid is the producer's statement that its current payload is meaningful. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 21: `logic s_axis_tready;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, s_axis_tready is the consumer's statement that it can accept a payload this cycle. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 22: `logic [63:0] s_axis_tdata = 64'd0;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, s_axis_tdata is the value named 's axis tdata' in this block. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 23: `logic s_axis_tlast = 1'b0;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, s_axis_tlast is the AXI-Stream marker for the final beat of a packet or command payload. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 24: `logic m_axis_tvalid;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, m_axis_tvalid is the producer's statement that its current payload is meaningful. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 25: `logic m_axis_tready = 1'b0;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, m_axis_tready is the consumer's statement that it can accept a payload this cycle. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 26: `logic [63:0] m_axis_tdata;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, m_axis_tdata is the value named 'm axis tdata' in this block. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 27: `logic m_axis_tlast;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, m_axis_tlast is the AXI-Stream marker for the final beat of a packet or command payload. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 29: `logic [191:0] vector_command_mem [0:‘NEURAEDGE_VECTOR_CASES-1];` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, vector_command_mem is the 128-bit instruction selecting an engine, shape, mode, and numeric parameters. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 30: `logic [255:0] vector_a_mem [0:‘NEURAEDGE_VECTOR_CASES-1];` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, vector_a_mem is local FPGA storage addressed by surrounding index logic. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 31: `logic [255:0] vector_b_mem [0:‘NEURAEDGE_VECTOR_CASES-1];` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, vector_b_mem is local FPGA storage addressed by surrounding index logic. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 32: `logic [255:0] vector_expected_mem [0:‘NEURAEDGE_VECTOR_CASES-1];` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, vector_expected_mem is local FPGA storage addressed by surrounding index logic. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 33: `logic [63:0] optimizer_parameter_mem [0:‘NEURAEDGE_OPTIMIZER_CASES-1];` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, optimizer_parameter_mem is local FPGA storage addressed by surrounding index logic. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 34: `logic [127:0] optimizer_weight_mem [0:‘NEURAEDGE_OPTIMIZER_CASES-1];` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, optimizer_weight_mem is a learned coefficient multiplied by an activation. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 35: `logic [191:0] optimizer_gradient_mem [0:‘NEURAEDGE_OPTIMIZER_CASES-1];` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, optimizer_gradient_mem is the signed loss derivative used to update a learned parameter. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 36: `logic [191:0] optimizer_velocity_mem [0:‘NEURAEDGE_OPTIMIZER_CASES-1];` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, optimizer_velocity_mem is the momentum history retained by the SGD optimizer. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 37: `logic [127:0] optimizer_expected_weight_mem [0:‘NEURAEDGE_OPTIMIZER_CASES-1];` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, optimizer_expected_weight_mem is a learned coefficient multiplied by an activation. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 38: `logic [191:0] optimizer_expected_velocity_mem [0:‘NEURAEDGE_OPTIMIZER_CASES-1];` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, optimizer_expected_velocity_mem is the momentum history retained by the SGD optimizer. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 39: `logic signed [23:0] ln_value_mem [0:‘NEURAEDGE_LAYERNORM_SAMPLES-1];` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, ln_value_mem is local FPGA storage addressed by surrounding index logic. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 40: `logic signed [23:0] ln_gamma_mem [0:‘NEURAEDGE_LAYERNORM_SAMPLES-1];` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, ln_gamma_mem is the learned multiplicative LayerNorm parameter. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 41: `logic signed [23:0] ln_beta_mem [0:‘NEURAEDGE_LAYERNORM_SAMPLES-1];` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, ln_beta_mem is the learned additive LayerNorm parameter. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 42: `logic signed [31:0] ln_expected_mem [0:‘NEURAEDGE_LAYERNORM_SAMPLES-1];` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, ln_expected_mem is local FPGA storage addressed by surrounding index logic. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 43: `logic signed [23:0] sm_score_mem [0:‘NEURAEDGE_SOFTMAX_SAMPLES-1];` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, sm_score_mem is local FPGA storage addressed by surrounding index logic. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 44: `logic [15:0] sm_expected_mem [0:‘NEURAEDGE_SOFTMAX_SAMPLES-1];` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, sm_expected_mem is local FPGA storage addressed by surrounding index logic. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 45: `integer train_expected_dx [0:1][0:7];` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, train_expected_dx is the value named 'train expected dx' in this block. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 46: `integer train_expected_dw [0:2][0:7];` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, train_expected_dw is the value named 'train expected dw' in this block. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 47: `logic [31:0] debug_training_tiles;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, debug_training_tiles is the value named 'debug training tiles' in this block. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 48: `logic [31:0] debug_training_cycles;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, debug_training_cycles is the value named 'debug training cycles' in this block. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 50: `int errors = 0;` Within the module's structural declarations, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge universal core RTL block in simulation. The important operands are errors: the value named 'errors' in this block.

Line 51: `int commands_expected = 0;` Within the module's structural declarations, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge universal core RTL block in simulation. The important operands are commands_expected: the 128-bit instruction selecting an engine, shape, mode, and numeric parameters.

Line 53: `neuraedge_universal_core dut (` This instantiates module neuraedge_universal_core as dut. Synthesis creates that subordinate circuit and connects its ports in the lines that follow.

Line 54: `.clk(clk), .rst_n(rst_n),` This connects the child instance's named port 'clk' to parent expression 'clk), .rst_n(rst_n'. The connection is a physical net bundle after synthesis; direction is declared in the child module, and the clock that makes all registers advance together.

Line 55: `.command_valid(command_valid), .command_ready(command_ready),` This connects the child instance's named port 'command_valid' to parent expression 'command_valid), .command_ready(command_ready'. The connection is a physical net bundle after synthesis; direction is declared in the child module, and the producer's statement that its current payload is meaningful.

Line 56: `.command_data(command_data), .command_done(command_done),` This connects the child instance's named port 'command_data' to parent expression 'command_data), .command_done(command_done'. The connection is a physical net bundle after synthesis; direction is declared in the child module, and the 128-bit instruction selecting an engine, shape, mode, and numeric parameters.

Line 57: `.status_busy(status_busy), .status_error(status_error),` This connects the child instance's named port 'status_busy' to parent expression 'status_busy), .status_error(status_error'. The connection is a physical net bundle after synthesis; direction is declared in the child module, and the value named 'status busy), .status error(status error' in this block.

Line 58: `.status_active_opcode(status_active_opcode),` This connects the child instance's named port 'status_active_opcode' to parent expression 'status_active_opcode'. The connection is a physical net bundle after synthesis; direction is declared in the child module, and the value named 'status active opcode' in this block.

Line 59: `.status_command_count(status_command_count),` This connects the child instance's named port 'status_command_count' to parent expression 'status_command_count'. The connection is a physical net bundle after synthesis; direction is declared in the child module, and the 128-bit instruction selecting an engine, shape, mode, and numeric parameters.

Line 60: `.status_input_beats(status_input_beats),` This connects the child instance's named port 'status_input_beats' to parent expression 'status_input_beats'. The connection is a physical net bundle after synthesis; direction is declared in the child module, and the value named 'status input beats' in this block.

Line 61: `.status_output_beats(status_output_beats),` This connects the child instance's named port 'status_output_beats' to parent expression 'status_output_beats'. The connection is a physical net bundle after synthesis; direction is declared in the child module, and the value named 'status output beats' in this block.

Line 62: `.debug_training_tiles(debug_training_tiles),` This connects the child instance's named port 'debug_training_tiles' to parent expression 'debug_training_tiles'. The connection is a physical net bundle after synthesis; direction is declared in the child module, and the value named 'debug training tiles' in this block.

Line 63: `.debug_training_cycles(debug_training_cycles),` This connects the child instance's named port 'debug_training_cycles' to parent expression 'debug_training_cycles'. The connection is a physical net bundle after synthesis; direction is declared in the child module, and the value named 'debug training cycles' in this block.

Line 64: `.s_axis_tvalid(s_axis_tvalid), .s_axis_tready(s_axis_tready),` This connects the child instance's named port ‘s_axis_tvalid‘ to parent expression ‘s_axis_tvalid), .s_axis_tready(s_axis_tready‘. The connection is a physical net bundle after synthesis; direction is declared in the child module, and the producer's statement that its current payload is meaningful.

Line 65: `.s_axis_tdata(s_axis_tdata), .s_axis_tlast(s_axis_tlast),` This connects the child instance's named port ‘s_axis_tdata‘ to parent expression ‘s_axis_tdata), .s_axis_tlast(s_axis_tlast‘. The connection is a physical net bundle after synthesis; direction is declared in the child module, and the AXI-Stream marker for the final beat of a packet or command payload.

Line 66: `.m_axis_tvalid(m_axis_tvalid), .m_axis_tready(m_axis_tready),` This connects the child instance's named port ‘m_axis_tvalid‘ to parent expression ‘m_axis_tvalid), .m_axis_tready(m_axis_tready‘. The connection is a physical net bundle after synthesis; direction is declared in the child module, and the producer's statement that its current payload is meaningful.

Line 67: `.m_axis_tdata(m_axis_tdata), .m_axis_tlast(m_axis_tlast)` This connects the child instance's named port ‘m_axis_tdata‘ to parent expression ‘m_axis_tdata), .m_axis_tlast(m_axis_tlast‘. The connection is a physical net bundle after synthesis; direction is declared in the child module, and the AXI-Stream marker for the final beat of a packet or command payload.

Line 68: `);` Within the module's structural declarations, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge universal core RTL block in simulation. The expression is a literal or structural operator and has no hidden software state.

Line 70: `always #2.5 clk = ~clk;` Within the module's structural declarations, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge universal core RTL block in simulation. The important operands are always: the value named 'always' in this block; clk: the clock that makes all registers advance together.

Line 72: `task automatic submit_command(input logic [127:0] value);` Within the simulation task submit command, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge universal core RTL block in simulation. The important operands are task: the value named 'task' in this block; automatic: the value named 'automatic' in this block; submit_command: the 128-bit instruction selecting an engine, shape, mode, and numeric parameters.

Line 73: `begin` This structural keyword opens or closes the branch/process scope described as the simulation task submit command; it has no arithmetic value of its own.

Line 74: `while (!command_ready) @(negedge clk);` Within the simulation task submit command, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge universal core RTL block in simulation. The important operands are while: the value named 'while' in this block; command_ready: the consumer's statement that it can accept a payload this cycle; negedge: the value named 'negedge' in this block.

Line 75: `@(negedge clk);` Within the simulation task submit command, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge universal core RTL block in simulation. The important operands are negedge: the value named 'negedge' in this block; clk: the clock that makes all registers advance together.

Line 76: `command_data = value;` This makes command_data, the 128-bit instruction selecting an engine, shape, mode, and numeric parameters, equal to ‘value‘. It is driven by combinational or procedural logic in the current evaluation. The important operands are value: the value named 'value' in this block. Context: the simulation task submit command.

Line 77: `command_valid = 1'b1;` This makes command_valid, the producer's statement that its current payload is meaningful, equal to ‘1'b1‘. It is driven by combinational or procedural logic in the current evaluation. The important operands are b1: the value named 'b1' in this block. Context: the simulation task submit command.

Line 78: `@(posedge clk);` Within the simulation task submit command, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge universal core RTL block in simulation. The important operands are posedge: the value named 'posedge' in this block; clk: the clock that makes all registers advance together.

Line 79: `@(negedge clk);` Within the simulation task submit command, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge universal core RTL block in simulation. The important operands are negedge: the value named 'negedge' in this block; clk: the clock that makes all registers advance together.

Line 80: `command_valid = 1'b0;` This makes command_valid, the producer's statement that its current payload is meaningful, equal to '1'b0'. It is driven by combinational or procedural logic in the current evaluation. The important operands are b0: the value named 'b0' in this block. Context: the simulation task submit command.

Line 81: `command_data = 128'd0;` This makes command_data, the 128-bit instruction selecting an engine, shape, mode, and numeric parameters, equal to '128'd0'. It is driven by combinational or procedural logic in the current evaluation. The important operands are d0: the value named 'd0' in this block. Context: the simulation task submit command.

Line 82: `commands_expected++;` Within the simulation task submit command, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge universal core RTL block in simulation. The important operands are commands_expected: the 128-bit instruction selecting an engine, shape, mode, and numeric parameters.

Line 83: `end` This structural keyword opens or closes the branch/process scope described as the simulation task submit command; it has no arithmetic value of its own.

Line 84: `endtask` Within the simulation task submit command, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge universal core RTL block in simulation. The important operands are endtask: the value named 'endtask' in this block.

Line 86: `task automatic send_word(input logic [63:0] value, input logic last_value);` Within the simulation task send word, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge universal core RTL block in simulation. The important operands are task: the value named 'task' in this block; automatic: the value named 'automatic' in this block; send_word: the value named 'send word' in this block.

Line 87: `begin` This structural keyword opens or closes the branch/process scope described as the simulation task send word; it has no arithmetic value of its own.

Line 88: `while (!s_axis_tready) @(negedge clk);` Within the simulation task send word, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge universal core RTL block in simulation. The important operands are while: the value named 'while' in this block; s_axis_tready: the consumer's statement that it can accept a payload this cycle; negedge: the value named 'negedge' in this block.

Line 89: `s_axis_tdata = value;` This makes s_axis_tdata, the value named 's axis tdata' in this block, equal to 'value'. It is driven by combinational or procedural logic in the current evaluation. The important operands are value: the value named 'value' in this block. Context: the simulation task send word.

Line 90: `s_axis_tlast = last_value;` This makes s_axis_tlast, the AXI-Stream marker for the final beat of a packet or command payload, equal to 'last_value'. It is driven by combinational or procedural logic in the current evaluation. The important operands are last_value: the AXI-Stream marker for the final beat of a packet or command payload. Context: the simulation task send word.

Line 91: `s_axis_tvalid = 1'b1;` This makes s_axis_tvalid, the producer's statement that its current payload is meaningful, equal to '1'b1'. It is driven by combinational or procedural logic in the current evaluation. The important operands are b1: the value named 'b1' in this block. Context: the simulation task send word.

Line 92: `@(posedge clk);` Within the simulation task send word, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge universal core RTL block in simulation. The important operands are posedge: the value named 'posedge' in this block; clk: the clock that makes all registers advance together.

Line 93: `@(negedge clk);` Within the simulation task send word, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge universal core RTL block in simulation. The important operands are negedge: the value named 'negedge' in this block; clk: the clock that makes all registers advance together.

Line 94: `s_axis_tvalid = 1'b0;` This makes s_axis_tvalid, the producer's statement that its current payload is meaningful, equal to '1'b0'. It is driven by combinational or procedural logic in the current evaluation. The important operands are b0: the value named 'b0' in this block. Context: the simulation task send word.

Line 95: `s_axis_tlast = 1'b0;` This makes s_axis_tlast, the AXI-Stream marker for the final beat of a packet or command payload, equal to '1'b0'. It is driven by combinational or procedural logic in the current evaluation. The important operands are b0: the value named 'b0' in this block. Context: the simulation task send word.

Line 96: `s_axis_tdata = 64'd0;` This makes s_axis_tdata, the value named 's axis tdata' in this block, equal to '64'd0'. It is driven by combinational or procedural logic in the current evaluation. The important operands are d0: the value named 'd0' in this block. Context: the simulation task send word.

Line 97: `end` This structural keyword opens or closes the branch/process scope described as the simulation task send word; it has no arithmetic value of its own.

Line 98: `endtask` Within the simulation task send word, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge universal core RTL block in simulation. The important operands are endtask: the value named 'endtask' in this block.

Line 100: `task automatic receive_word(` Within the simulation task receive word, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge universal core RTL block in simulation. The important operands are task: the value named 'task' in this block; automatic: the value named 'automatic' in this block; receive_word: the value named 'receive word' in this block.

Line 101: `output logic [63:0] value,` This declares value as a output port with width [63:0]. It carries the value named 'value' in this block across the module boundary; a port is a bundle of physical FPGA nets, not a software argument.

Line 102: `output logic last_value,` This declares last_value as a output port with width one bit. It carries the AXI-Stream marker for the final beat of a packet or command payload across the module boundary; a port is a bundle of physical FPGA nets, not a software argument.

Line 103: `input int stall_cycles` This declares int as a input port with width one bit. It carries the value named 'int' in this block across the module boundary; a port is a bundle of physical FPGA nets, not a software argument.

Line 104: `);` Within the simulation task receive word, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge universal core RTL block in simulation. The expression is a literal or structural operator and has no hidden software state.

Line 105: `begin` This structural keyword opens or closes the branch/process scope described as the simulation task receive word; it has no arithmetic value of its own.

Line 106: `while (!m_axis_tvalid) @(negedge clk);` Within the simulation task receive word, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge universal core RTL block in simulation. The important operands are while: the value named 'while' in this block; m_axis_tvalid: the producer's statement that its current payload is meaningful; negedge: the value named 'negedge' in this block.

Line 107: `repeat (stall_cycles) @(negedge clk);` Within the simulation task receive word, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge universal core RTL block in simulation. The important operands are repeat: the value named 'repeat' in this block; stall_cycles: the value named 'stall cycles' in this block; negedge: the value named 'negedge' in this block.

Line 108: `value = m_axis_tdata;` This makes value, the value named 'value' in this block, equal to 'm_axis_tdata'. It is driven by combinational or procedural logic in the current evaluation. The important operands are m_axis_tdata: the value named 'm axis tdata' in this block. Context: the simulation task receive word.

Line 109: `last_value = m_axis_tlast;` This makes last_value, the AXI-Stream marker for the final beat of a packet or command payload, equal to 'm_axis_tlast'. It is driven by combinational or procedural logic in the current evaluation. The important operands are m_axis_tlast: the AXI-Stream marker for the final beat of a packet or command payload. Context: the simulation task receive word.

Line 110: `m_axis_tready = 1'b1;` This makes m_axis_tready, the consumer's statement that it can accept a payload this cycle, equal to '1'b1'. It is driven by combinational or procedural logic in the current evaluation. The important operands are b1: the value named 'b1' in this block. Context: the simulation task receive word.

Line 111: `@(posedge clk);` Within the simulation task receive word, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge universal core RTL block in simulation. The important operands are posedge: the value named 'posedge' in this block; clk: the clock that makes all registers advance together.

Line 112: `@(negedge clk);` Within the simulation task receive word, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge universal core RTL block in simulation. The important operands are negedge: the value named 'negedge' in this block; clk: the clock that makes all registers advance together.

Line 113: `m_axis_tready = 1'b0;` This makes m_axis_tready, the consumer's statement that it can accept a payload this cycle, equal to '1'b0'. It is driven by combinational or procedural logic in the current evaluation. The important operands are b0: the value named 'b0' in this block. Context: the simulation task receive word.

Line 114: `end` This structural keyword opens or closes the branch/process scope described as the simulation task receive word; it has no arithmetic value of its own.

Line 115: `endtask` Within the simulation task receive word, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge universal core RTL block in simulation. The important operands are endtask: the value named 'endtask' in this block.

Line 117: `task automatic wait_done;` Within the simulation task task, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge universal core RTL block in simulation. The important operands are task: the value named 'task' in this block; automatic: the value named 'automatic' in this block; wait_done: the value named 'wait done' in this block.

Line 118: `int timeout;` Within the simulation task task, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge universal core RTL block in simulation. The important operands are timeout: the value named 'timeout' in this block.

Line 119: `begin` This structural keyword opens or closes the branch/process scope described as the simulation task task; it has no arithmetic value of its own.

Line 120: `timeout = 0;` This makes timeout, the value named 'timeout' in this block, equal to '0'. It is driven by combinational or procedural logic in the current evaluation. The expression is a literal or structural operator and has no hidden software state. Context: the simulation task task.

Line 121: `while (!command_done && timeout < 100000) begin` Within the simulation task task, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge universal core RTL block in simulation. The important operands are while: the value named 'while' in this block; command_done: the 128-bit instruction selecting an engine, shape, mode, and numeric parameters; timeout: the value named 'timeout' in this block.

Line 122: `@(negedge clk);` Within the simulation task task, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge universal core RTL block in simulation. The important operands are negedge: the value named 'negedge' in this block; clk: the clock that makes all registers advance together.

Line 123: `timeout++;` Within the simulation task task, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge universal core RTL block in simulation. The important operands are timeout: the value named 'timeout' in this block.

Line 124: `end` This structural keyword opens or closes the branch/process scope described as the simulation task task; it has no arithmetic value of its own.

Line 125: `if (!command_done) begin` This condition selects the following hardware branch only when '!command_done' is true. Both branches exist as gates; the condition controls a multiplexer rather than making software jump. The important operands are command_done: the 128-bit instruction selecting an engine, shape, mode, and numeric parameters. Context: the simulation task task.

Line 126: `errors++;` Within the simulation task task, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge universal core RTL block in simulation. The important operands are errors: the value named 'errors' in this block.

Line 127: `$display("ERROR universal command timeout opcode=%0d state=%0d",` This is a simulation check or diagnostic. It can stop a failing test and print evidence, but it is not part of the synthesized PYNQ circuit.

Line 128: `status_active_opcode, dut.state);` Within the simulation task task, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge universal core RTL block in simulation. The important operands are status_active_opcode: the value named 'status active opcode' in this block; dut: the value named 'dut' in this block; state: the finite-state-machine phase retained in flip-flops.

Line 129: `end` This structural keyword opens or closes the branch/process scope described as the simulation task task; it has no arithmetic value of its own.

Line 130: `end` This structural keyword opens or closes the branch/process scope described as the simulation task task; it has no arithmetic value of its own.

Line 131: `endtask` Within the simulation task task, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge universal core RTL block in simulation. The important operands are endtask: the value named 'endtask' in this block.

Line 133: `function automatic logic [127:0] tensor_command(` Within the combinational helper tensor command, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge universal core RTL block in simulation. The important operands are function: the value named 'function' in this block; automatic: the value named 'automatic' in this block; tensor_command: the 128-bit instruction selecting an engine, shape, mode, and numeric parameters.

Line 134: `input logic [3:0] opcode,` This declares opcode as a input port with width [3:0]. It carries the value named 'opcode' in this block across the module boundary; a port is a bundle of physical FPGA nets, not a software argument.

Line 135: `input int rows,` This declares int as a input port with width one bit. It carries the value named 'int' in this block across the module boundary; a port is a bundle of physical FPGA nets, not a software argument.

Line 136: `input int columns,` This declares int as a input port with width one bit. It carries the value named 'int' in this block across the module boundary; a port is a bundle of physical FPGA nets, not a software argument.

Line 137: `input int count,` This declares int as a input port with width one bit. It carries the value named 'int' in this block across the module boundary; a port is a bundle of physical FPGA nets, not a software argument.

Line 138: `input int activation_zp,` This declares int as a input port with width one bit. It carries the value named 'int' in this block across the module boundary; a port is a bundle of physical FPGA nets, not a software argument.

Line 139: `input int weight_zp` This declares int as a input port with width one bit. It carries the value named 'int' in this block across the module boundary; a port is a bundle of physical FPGA nets, not a software argument.

Line 140: `);` Within the combinational helper tensor command, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge universal core RTL block in simulation. The expression is a literal or structural operator and has no hidden software state.

Line 141: `logic [127:0] value;` This declares hardware signal storage or wiring in the combinational helper tensor command. Specifically, value is the value named 'value' in this block. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 142: `begin` This structural keyword opens or closes the branch/process scope described as the combinational helper tensor command; it has no arithmetic value of its own.

Line 143: `value = 128'd0;` This makes value, the value named 'value' in this block, equal to '128'd0'. It is driven by combinational or procedural logic in the current evaluation. The important operands are d0: the value named 'd0' in this block. Context: the combinational helper tensor command.

Line 144: `value[3:0] = opcode;` This makes value[3:0], the value named 'value' in this block, equal to 'opcode'. It is driven by combinational or procedural logic in the current evaluation. The important operands are opcode: the value named 'opcode' in this block. Context: the combinational helper tensor command.

Line 145: `value[7:4] = 4'(rows);` This makes value[7:4], the value named 'value' in this block, equal to '4'(rows)'. It is driven by combinational or procedural logic in the current evaluation. The important operands are rows: one output-row position processed by the tensor tile. Context: the combinational helper tensor command.

Line 146: `value[13:8] = 6'(columns);` This makes value[13:8], the value named 'value' in this block, equal to '6'(columns)'. It is driven by combinational or procedural logic in the current evaluation. The important operands are columns: one output-feature position processed in parallel. Context: the combinational helper tensor command.

Line 147: `value[25:14] = 12'(count);` This makes value[25:14], the value named 'value' in this block, equal to '12'(count)'. It is driven by combinational or procedural logic in the current evaluation. The important operands are count: the value named 'count' in this block. Context: the combinational helper tensor command.

Line 148: `value[33:26] = 8'(activation_zp);` This makes value[33:26], the value named 'value' in this block, equal to '8'(activation_zp)'. It is driven by combinational or procedural logic in the current evaluation. The important operands are activation_zp: an input feature value consumed by a neuron or multiply-accumulate operation. Context: the combinational helper tensor command.

Line 149: `value[41:34] = 8'(weight_zp);` This makes value[41:34], the value named 'value' in this block, equal to '8'(weight_zp)'. It is driven by combinational or procedural logic in the current evaluation. The important operands are weight_zp: a learned coefficient multiplied by an activation. Context: the combinational helper tensor command.

Line 150: `tensor_command = value;` This makes tensor_command, the 128-bit instruction selecting an engine, shape, mode, and numeric parameters, equal to 'value'. It is driven by combinational or procedural logic in the current evaluation. The important operands are value: the value named 'value' in this block. Context: the combinational helper tensor command.

Line 151: `end` This structural keyword opens or closes the branch/process scope described as the combinational helper tensor command; it has no arithmetic value of its own.

Line 152: `endfunction` Within the combinational helper tensor command, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge universal core RTL block in simulation. The important operands are endfunction: the value named 'endfunction' in this block.

Line 154: `initial begin` This opens simulation initialization. In a testbench it drives starting values and stimulus; project synthesis does not rely on this block as a replacement for explicit reset behavior.

Line 155: `logic [127:0] command;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, command is the 128-bit instruction selecting an engine, shape, mode, and numeric parameters. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 156: `logic [63:0] received_word;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, received_word is the value named 'received word' in this block. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 157: `logic received_last;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, received_last is the AXI-Stream marker for the final beat of a packet or command payload. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 158: `logic [255:0] received_vector;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, received_vector is the value named 'received vector' in this block. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 159: `logic [127:0] received_weights;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, received_weights is a learned coefficient multiplied by an activation. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 160: `logic [191:0] received_velocities;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, received_velocities is the value named 'received velocities' in this block. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 161: `logic [767:0] received_lif_trace;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, received_lif_trace is the value named 'received lif trace' in this block. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 162: `logic [511:0] received_train_dx;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, received_train_dx is the value named 'received train dx' in this block. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 163: `logic [575:0] received_train_dw;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, received_train_dw is the value named 'received train dw' in this block. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 164: `logic [255:0] alpha_query;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, alpha_query is the programmable weight assigned to matching zero spikes in alpha-XNOR attention. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 165: `logic [255:0] alpha_key;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, alpha_key is the programmable weight assigned to matching zero spikes in alpha-XNOR attention. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 166: `int alpha_spikes;` Within the module's structural declarations, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge universal core RTL block in simulation. The important operands are alpha_spikes: a binary event produced when a neuron crosses its threshold.

Line 167: `int alpha_zeros;` Within the module's structural declarations, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge universal core RTL block in simulation. The important operands are alpha_zeros: the programmable weight assigned to matching zero spikes in alpha-XNOR attention.

Line 168: `int alpha_expected;` Within the module's structural declarations, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge universal core RTL block in simulation. The important operands are alpha_expected: the programmable weight assigned to matching zero spikes in alpha-XNOR attention.

Line 169: `int seed;` Within the module's structural declarations, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge universal core RTL block in simulation. The important operands are seed: the value named 'seed' in this block.

Line 171: `$readmemh("tb/fixtures/vector_commands.mem", vector_command_mem);` Within the module's structural declarations, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge universal core RTL block in simulation. The important operands are readmemh: the value named 'readmemh' in this block; tb: the value named 'tb' in this block; fixtures: the value named 'fixtures' in this block.

Line 172: `$readmemh("tb/fixtures/vector_a.mem", vector_a_mem);` Within the module's structural declarations, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge universal core RTL block in simulation. The important operands are readmemh: the value named 'readmemh' in this block; tb: the value named 'tb' in this block; fixtures: the value named 'fixtures' in this block.

Line 173: `$readmemh("tb/fixtures/vector_b.mem", vector_b_mem);` Within the module's structural declarations, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge universal core RTL block in simulation. The important operands are readmemh: the value named 'readmemh' in this block; tb: the value named 'tb' in this block; fixtures: the value named 'fixtures' in this block.

Line 174: `$readmemh("tb/fixtures/vector_expected.mem", vector_expected_mem);` Within the module's structural declarations, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge universal core RTL block in simulation. The important operands are readmemh: the value named 'readmemh' in this block; tb: the value named 'tb' in this block; fixtures: the value named 'fixtures' in this block.

Line 175: `$readmemh("tb/fixtures/optimizer_parameters.mem", optimizer_parameter_mem);` Within the module's structural declarations, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge universal core RTL block in simulation. The important operands are readmemh: the value named 'readmemh' in this block; tb: the value named 'tb' in this block; fixtures: the value named 'fixtures' in this block.

Line 176: `$readmemh("tb/fixtures/optimizer_weights.mem", optimizer_weight_mem);` Within the module's structural declarations, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge universal core RTL block in simulation. The important operands are readmemh: the value named 'readmemh' in this block; tb: the value named 'tb' in this block; fixtures: the value named 'fixtures' in this block.

Line 177: `$readmemh("tb/fixtures/optimizer_gradients.mem", optimizer_gradient_mem);` Within the module's structural declarations, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge universal core RTL block in simulation. The important operands are readmemh: the value named 'readmemh' in this block; tb: the value named 'tb' in this block; fixtures: the value named 'fixtures' in this block.

Line 178: `$readmemh("tb/fixtures/optimizer_velocities.mem", optimizer_velocity_mem);` Within the module's structural declarations, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge universal core RTL block in simulation. The important operands are readmemh: the value named 'readmemh' in this block; tb: the value named 'tb' in this block; fixtures: the value named 'fixtures' in this block.

Line 179: `$readmemh("tb/fixtures/optimizer_expected_weights.mem", optimizer_expected_weight_mem);` Within the module's structural declarations, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge universal core RTL block in simulation. The important operands are readmemh: the value named 'readmemh' in this block; tb: the value named 'tb' in this block; fixtures: the value named 'fixtures' in this block.

Line 180: `$readmemh("tb/fixtures/optimizer_expected_velocities.mem", optimizer_expected_velocity_mem);` Within the module's structural declarations, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge universal core RTL block in simulation. The important operands are readmemh: the value named 'readmemh' in this block; tb: the value named 'tb' in this block; fixtures: the value named 'fixtures' in this block.

Line 181: `$readmemh("tb/fixtures/layernorm_values.mem", ln_value_mem);` Within the module's structural declarations, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge universal core RTL block in simulation. The important operands are readmemh: the value named 'readmemh' in this block; tb: the value named 'tb' in this block; fixtures: the value named 'fixtures' in this block.

Line 182: `$readmemh("tb/fixtures/layernorm_gammas.mem", ln_gamma_mem);` Within the module's structural declarations, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge universal core RTL block in simulation. The important operands are readmemh: the value named 'readmemh' in this block; tb: the value named 'tb' in this block; fixtures: the value named 'fixtures' in this block.

Line 183: `$readmemh("tb/fixtures/layernorm_betas.mem", ln_beta_mem);` Within the module's structural declarations, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge universal core RTL block in simulation. The important operands are readmemh: the value named 'readmemh' in this block; tb: the value named 'tb' in this block; fixtures: the value named 'fixtures' in this block.

Line 184: `$readmemh("tb/fixtures/layernorm_expected.mem", ln_expected_mem);` Within the module's structural declarations, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge universal core RTL block in simulation. The important operands are readmemh: the value named 'readmemh' in this block; tb: the value named 'tb' in this block; fixtures: the value named 'fixtures' in this block.

Line 185: `$readmemh("tb/fixtures/softmax_scores.mem", sm_score_mem);` Within the module's structural declarations, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge universal core RTL block in simulation. The important operands are readmemh: the value named 'readmemh' in this block; tb: the value named 'tb' in this block; fixtures: the value named 'fixtures' in this block.

Line 186: `$readmemh("tb/fixtures/softmax_expected.mem", sm_expected_mem);` Within the module's structural declarations, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge universal core RTL block in simulation. The important operands are readmemh: the value named 'readmemh' in this block; tb: the value named 'tb' in this block; fixtures: the value named 'fixtures' in this block.

Line 188: `seed = 32'hc01ec7ed;` This makes seed, the value named 'seed' in this block, equal to '32'hc01ec7ed'. It is driven by combinational or procedural logic in the current evaluation. The important operands are hc01ec7ed: the value named 'hc01ec7ed' in this block. Context: the module's structural declarations.

Line 189: `repeat (5) @(negedge clk);` Within the module's structural declarations, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge universal core RTL block in simulation. The important operands are repeat: the value named 'repeat' in this block; negedge: the value named 'negedge' in this block; clk: the clock that makes all registers advance together.

Line 190: `rst_n = 1'b1;` This makes rst_n, the active-low synchronous reset, equal to '1'b1'. It is driven by combinational or procedural logic in the current evaluation. The important operands are b1: the value named 'b1' in this block. Context: the module's structural declarations.

Line 192: `// Clear every sticky status source, including the nested tensor core.` Design intent: Clear every sticky status source, including the nested tensor core. This comment anchors the surrounding logic in the block that drives, backpressures, and checks the neuraedge universal core RTL block in simulation.

Line 193: `submit_command({124'd0, CMD_CLEAR_STATUS});` Within the module's structural declarations, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge universal core RTL block in simulation. The important operands are submit_command: the 128-bit instruction selecting an engine, shape, mode, and numeric parameters; d0: the value named 'd0' in this block; CMD_CLEAR_STATUS: the value named 'cmd clear status' in this block.

Line 194: `wait_done();` Within the module's structural declarations, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge universal core RTL block in simulation. The important operands are wait_done: the value named 'wait done' in this block.

Line 196: `// Empty centered tensor tile: compaction emits one sentinel issue and` Design intent: Empty centered tensor tile: compaction emits one sentinel issue and This comment anchors the surrounding logic in the block that drives, backpressures, and checks the neuraedge universal core RTL block in simulation.

Line 197: `// the exact corrected result remains zero.` Design intent: the exact corrected result remains zero. This comment anchors the surrounding logic in the block that drives, backpressures, and checks the neuraedge universal core RTL block in simulation.

Line 198: `submit_command(tensor_command(CMD_LOAD_ACTIVATIONS, 0, 0, 1, 128, 0));` Within the module's structural declarations, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge universal core RTL block in simulation. The important operands are submit_command: the 128-bit instruction selecting an engine, shape, mode, and numeric parameters; tensor_command: the 128-bit instruction selecting an engine, shape, mode, and numeric parameters; CMD_LOAD_ACTIVATIONS: an input feature value consumed by a neuron or multiply-accumulate operation.

Line 199: `send_word(64'h8080808080808080, 1'b1);` Within the module's structural declarations, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge universal core RTL block in simulation. The important operands are send_word: the value named 'send word' in this block; h8080808080808080: the value named 'h8080808080808080' in this block; b1: the value named 'b1' in this block.

Line 200: `wait_done();` Within the module's structural declarations, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge universal core RTL block in simulation. The important operands are wait_done: the value named 'wait done' in this block.

Line 201: `submit_command(tensor_command(CMD_LOAD_WEIGHTS_OUTER, 0, 0, 1, 0, 0));` Within the module's structural declarations, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge universal core RTL block in simulation. The important operands are submit_command: the 128-bit instruction selecting an engine, shape, mode, and numeric parameters; tensor_command: the 128-bit instruction selecting an engine, shape, mode, and numeric parameters; CMD_LOAD_WEIGHTS_OUTER: a learned coefficient multiplied by an activation.

Line 202: `send_word(64'h0102030405060708, 1'b0);` Within the module's structural declarations, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge universal core RTL block in simulation. The important operands are send_word: the value named 'send word' in this block; h0102030405060708: the value named 'h0102030405060708' in this block; b0: the value named 'b0' in this block.

Line 203: `send_word(64'h1112131415161718, 1'b1);` Within the module's structural declarations, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge universal core RTL block in simulation. The important operands are send_word: the value named 'send word' in this block; h1112131415161718: the value named 'h1112131415161718' in this block; b1: the value named 'b1' in this block.

Line 204: `wait_done();` Within the module's structural declarations, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge universal core RTL block in simulation. The important operands are wait_done: the value named 'wait done' in this block.

Line 205: `submit_command(tensor_command(CMD_COMPUTE_DENSE_OUTER, 1, 1, 1, 128, 0));` Within the module's structural declarations, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge universal core RTL block in simulation. The important operands are submit_command: the 128-bit instruction selecting an engine, shape, mode, and numeric parameters; tensor_command: the 128-bit instruction selecting an engine, shape, mode, and numeric parameters; CMD_COMPUTE_DENSE_OUTER: the value named 'cmd compute dense outer' in this block.

Line 206: `receive_word(received_word, received_last, 2);` Within the module's structural declarations, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge universal core RTL block in simulation. The important operands are receive_word: the value named 'receive word' in this block; received_word: the value named 'received word' in this block; received_last: the AXI-Stream marker for the final beat of a packet or command payload.

Line 207: `if (!received_last || $signed(received_word[47:0]) != 0) begin` This condition selects the following hardware branch only when '!received_last || $signed(received_word[47:0]) != 0' is true. Both branches exist as gates; the condition controls a multiplexer rather than making software jump. The important operands are received_last: the AXI-Stream marker for the final beat of a packet or command payload; received_word: the value named 'received word' in this block. Context: the module's structural declarations.

Line 208: `errors++;` Within the module's structural declarations, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge universal core RTL block in simulation. The important operands are errors: the value named 'errors' in this block.

Line 209: `$display("ERROR universal tensor result=%0d last=%0d", $signed(received_word[47:0]), received_last)` This is a simulation check or diagnostic. It can stop a failing test and print evidence, but it is not part of the synthesized PYNQ circuit.

Line 210: `end` This structural keyword opens or closes the branch/process scope described as the module's structural declarations; it has no arithmetic value of its own.

Line 212: `// Alpha-XNOR command and eight-beat binary vector transfer.` Design intent: Alpha-XNOR command and eight-beat binary vector transfer. This comment anchors the surrounding logic in the block that drives, backpressures, and checks the neuraedge universal core RTL block in simulation.

Line 213: `for (int word_index = 0; word_index < 8; word_index++) begin` This generate/procedural loop repeats the following operation across lanes or entries. In synthesizable RTL, a fixed loop is expanded into parallel or scheduled hardware rather than executed by a CPU. Context: the module's structural declarations.

Line 214: `alpha_query[word_index*32 +: 32] = $urandom(seed);` Within the module's structural declarations, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge universal core RTL block in simulation. The important operands are alpha_query: the programmable weight assigned to matching zero spikes in alpha-XNOR attention; word_index: an integer selecting one tensor element, lane, bank, or state entry; urandom: the value named 'urandom' in this block.

Line 215: `alpha_key[word_index*32 +: 32] = $urandom(seed);` Within the module's structural declarations, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge universal core RTL block in simulation. The important operands are alpha_key: the programmable weight assigned to matching zero spikes in alpha-XNOR attention; word_index: an integer selecting one tensor element, lane, bank, or state entry; urandom: the value named 'urandom' in this block.

Line 216: `end` This structural keyword opens or closes the branch/process scope described as the module's structural declarations; it has no arithmetic value of its own.

Line 217: `alpha_spikes = 0;` This makes alpha_spikes, a binary event produced when a neuron crosses its threshold, equal to '0'. It is driven by combinational or procedural logic in the current evaluation. The expression is a literal or structural operator and has no hidden software state. Context: the module's structural declarations.

Line 218: `alpha_zeros = 0;` This makes alpha_zeros, the programmable weight assigned to matching zero spikes in alpha-XNOR attention, equal to '0'. It is driven by combinational or procedural logic in the current evaluation. The expression is a literal or structural operator and has no hidden software state. Context: the module's structural declarations.

Line 219: `for (int bit_index = 0; bit_index < 256; bit_index++) begin` This generate/procedural loop repeats the following operation across lanes or entries. In synthesizable RTL, a fixed loop is expanded into parallel or scheduled hardware rather than executed by a CPU. Context: the module's structural declarations.

Line 220: `alpha_spikes += alpha_query[bit_index] && alpha_key[bit_index];` Within the module's structural declarations, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge universal core RTL block in simulation. The important operands are alpha_spikes: a binary event produced when a neuron crosses its threshold; alpha_query: the programmable weight assigned to matching zero spikes in alpha-XNOR attention; bit_index: an integer selecting one tensor element, lane, bank, or state entry.

Line 221: `alpha_zeros += !alpha_query[bit_index] && !alpha_key[bit_index];` Within the module's structural declarations, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge universal core RTL block in simulation. The important operands are alpha_zeros: the programmable weight assigned to matching zero spikes in alpha-XNOR attention; alpha_query: the programmable weight assigned to matching zero spikes in alpha-XNOR attention; bit_index: an integer selecting one tensor element, lane, bank, or state entry.

Line 222: `end` This structural keyword opens or closes the branch/process scope described as the module's structural declarations; it has no arithmetic value of its own.

Line 223: `alpha_expected = alpha_spikes * 256 + alpha_zeros * 127;` This makes alpha_expected, the programmable weight assigned to matching zero spikes in alpha-XNOR attention, equal to 'alpha_spikes * 256 + alpha_zeros * 127'. It is driven by combinational or procedural logic in the current evaluation. The important operands are alpha_spikes: a binary event produced when a neuron crosses its threshold; alpha_zeros: the programmable weight assigned to matching zero spikes in alpha-XNOR attention. Context: the module's structural declarations.

Line 224: `command = 128'd0;` This makes command, the 128-bit instruction selecting an engine, shape, mode, and numeric parameters, equal to '128'd0'. It is driven by combinational or procedural logic in the current evaluation. The important operands are d0: the value named 'd0' in this block. Context: the module's structural declarations.

Line 225: `command[3:0] = CMD_ALPHA_XNOR;` This makes command[3:0], the 128-bit instruction selecting an engine, shape, mode, and numeric parameters, equal to ‘CMD_ALPHA_XNOR‘. It is driven by combinational or procedural logic in the current evaluation. The important operands are CMD_ALPHA_XNOR: the programmable weight assigned to matching zero spikes in alpha-XNOR attention. Context: the module’s structural declarations.

Line 226: `command[50:42] = 9'd256;` This makes command[50:42], the 128-bit instruction selecting an engine, shape, mode, and numeric parameters, equal to ‘9’d256‘. It is driven by combinational or procedural logic in the current evaluation. The important operands are d256: the value named ’d256’ in this block. Context: the module’s structural declarations.

Line 227: `command[59:51] = 9'd127;` This makes command[59:51], the 128-bit instruction selecting an engine, shape, mode, and numeric parameters, equal to ‘9’d127‘. It is driven by combinational or procedural logic in the current evaluation. The important operands are d127: the value named ’d127’ in this block. Context: the module’s structural declarations.

Line 228: `submit_command(command);` Within the module’s structural declarations, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge universal core RTL block in simulation. The important operands are submit_command: the 128-bit instruction selecting an engine, shape, mode, and numeric parameters; command: the 128-bit instruction selecting an engine, shape, mode, and numeric parameters.

Line 229: `for (int beat = 0; beat < 4; beat++) send_word(alpha_query[beat*64 +: 64], 1'b0);` This generate/procedural loop repeats the following operation across lanes or entries. In synthesizable RTL, a fixed loop is expanded into parallel or scheduled hardware rather than executed by a CPU. Context: the module’s structural declarations.

Line 230: `for (int beat = 0; beat < 4; beat++) send_word(alpha_key[beat*64 +: 64], beat == 3);` This generate/procedural loop repeats the following operation across lanes or entries. In synthesizable RTL, a fixed loop is expanded into parallel or scheduled hardware rather than executed by a CPU. Context: the module’s structural declarations.

Line 231: `receive_word(received_word, received_last, 3);` Within the module’s structural declarations, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge universal core RTL block in simulation. The important operands are receive_word: the value named ’receive word’ in this block; received_word: the value named ’received word’ in this block; received_last: the AXI-Stream marker for the final beat of a packet or command payload.

Line 232: `if (!received_last || received_word[17:0] != alpha_expected` Within the module’s structural declarations, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge universal core RTL block in simulation. The important operands are received_last: the AXI-Stream marker for the final beat of a packet or command payload; received_word: the value named ’received word’ in this block; alpha_expected: the programmable weight assigned to matching zero spikes in alpha-XNOR attention.

Line 233: `|| received_word[26:18] != alpha_spikes || received_word[35:27] != alpha_zeros) begin` Within the module’s structural declarations, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge universal core RTL block in simulation. The important operands are received_word: the value named ’received word’ in this block; alpha_spikes: a binary event produced when a neuron crosses its threshold; alpha_zeros: the programmable weight assigned to matching zero spikes in alpha-XNOR attention.

Line 234: `errors++;` Within the module’s structural declarations, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge universal core RTL block in simulation. The important operands are errors: the value named ’errors’ in this block.

Line 235: `$display("ERROR universal alpha-XNOR result");` This is a simulation check or diagnostic. It can stop a failing test and print evidence, but it is not part of the synthesized PYNQ circuit.

Line 236: `end` This structural keyword opens or closes the branch/process scope described as the module's structural declarations; it has no arithmetic value of its own.

Line 238: `// Vector command uses fixture case 50 (REQUANTIZE) through the shared stream.` Design intent: Vector command uses fixture case 50 (REQUANTIZE) through the shared stream. This comment anchors the surrounding logic in the block that drives, backpressures, and checks the neuraedge universal core RTL block in simulation.

Line 239: `command = 128'd0;` This makes command, the 128-bit instruction selecting an engine, shape, mode, and numeric parameters, equal to '128'd0'. It is driven by combinational or procedural logic in the current evaluation. The important operands are d0: the value named 'd0' in this block. Context: the module's structural declarations.

Line 240: `command[3:0] = CMD_VECTOR_ALU;` This makes command[3:0], the 128-bit instruction selecting an engine, shape, mode, and numeric parameters, equal to 'CMD_VECTOR_ALU'. It is driven by combinational or procedural logic in the current evaluation. The important operands are CMD_VECTOR_ALU: the value named 'cmd vector alu' in this block. Context: the module's structural declarations.

Line 241: `command[108:4] = vector_command_mem[50][104:0];` This makes command[108:4], the 128-bit instruction selecting an engine, shape, mode, and numeric parameters, equal to 'vector_command_mem[50][104:0]'. It is driven by combinational or procedural logic in the current evaluation. The important operands are vector_command_mem: the 128-bit instruction selecting an engine, shape, mode, and numeric parameters. Context: the module's structural declarations.

Line 242: `submit_command(command);` Within the module's structural declarations, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge universal core RTL block in simulation. The important operands are submit_command: the 128-bit instruction selecting an engine, shape, mode, and numeric parameters; command: the 128-bit instruction selecting an engine, shape, mode, and numeric parameters.

Line 243: `send_word({vector_command_mem[50][168:137], vector_command_mem[50][136:105]}, 1'b0);` Within the module's structural declarations, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge universal core RTL block in simulation. The important operands are send_word: the value named 'send word' in this block; vector_command_mem: the 128-bit instruction selecting an engine, shape, mode, and numeric parameters; b0: the value named 'b0' in this block.

Line 244: `for (int beat = 0; beat < 4; beat++) send_word(vector_a_mem[50][beat*64 +:  64], 1'b0);` This generate/procedural loop repeats the following operation across lanes or entries. In synthesizable RTL, a fixed loop is expanded into parallel or scheduled hardware rather than executed by a CPU. Context: the module's structural declarations.

Line 245: `for (int beat = 0; beat < 4; beat++) send_word(vector_b_mem[50][beat*64 +:  64], beat == 3);` This generate/procedural loop repeats the following operation across lanes or entries. In synthesizable RTL, a fixed loop is expanded into parallel or scheduled hardware rather than executed by a CPU. Context: the module's structural declarations.

Line 246: `for (int beat = 0; beat < 4; beat++) begin` This generate/procedural loop repeats the following operation across lanes or entries. In synthesizable RTL, a fixed loop is expanded into parallel or scheduled hardware rather than executed by a CPU. Context: the module's structural declarations.

Line 247: `receive_word(received_word, received_last, beat % 2);` Within the module's structural declarations, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge universal core RTL block in simulation. The important operands are receive_word: the value named 'receive word' in this block; received_word: the value named 'received word' in this block; received_last: the AXI-Stream marker for the final beat of a packet or command payload.

Line 248: `received_vector[beat*64 +: 64] = received_word;` Within the module's structural declarations, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge universal core RTL block in simulation. The important operands are received_vector: the value named 'received vector' in this block; beat: the value named 'beat' in this block; received_word: the value named 'received word' in this block.

Line 249: `if (received_last != (beat == 3)) errors++;` This condition selects the following hardware branch only when 'received_last != (beat == 3)' is true. Both branches exist as gates; the condition controls a multiplexer rather than making software jump. The important operands are received_last: the AXI-Stream marker for the final beat of a packet or command payload; beat: the value named 'beat' in this block. Context: the module's structural declarations.

Line 250: `end` This structural keyword opens or closes the branch/process scope described as the module's structural declarations; it has no arithmetic value of its own.

Line 251: `if (received_vector !== vector_expected_mem[50]) begin` This condition selects the following hardware branch only when 'received_vector !== vector_expected_mem[50]' is true. Both branches exist as gates; the condition controls a multiplexer rather than making software jump. The important operands are received_vector: the value named 'received vector' in this block; vector_expected_mem: local FPGA storage addressed by surrounding index logic. Context: the module's structural declarations.

Line 252: `errors++;` Within the module's structural declarations, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge universal core RTL block in simulation. The important operands are errors: the value named 'errors' in this block.

Line 253: `$display("ERROR universal vector result");` This is a simulation check or diagnostic. It can stop a failing test and print evidence, but it is not part of the synthesized PYNQ circuit.

Line 254: `end` This structural keyword opens or closes the branch/process scope described as the module's structural declarations; it has no arithmetic value of its own.

Line 256: `// LayerNorm fixture case 2 starts after the first five samples.` Design intent: LayerNorm fixture case 2 starts after the first five samples. This comment anchors the surrounding logic in the block that drives, backpressures, and checks the neuraedge universal core RTL block in simulation.

Line 257: `command = 128'd0;` This makes command, the 128-bit instruction selecting an engine, shape, mode, and numeric parameters, equal to '128'd0'. It is driven by combinational or procedural logic in the current evaluation. The important operands are d0: the value named 'd0' in this block. Context: the module's structural declarations.

Line 258: `command[3:0] = CMD_LAYERNORM;` This makes command[3:0], the 128-bit instruction selecting an engine, shape, mode, and numeric parameters, equal to 'CMD_LAYERNORM'. It is driven by combinational or procedural logic in the current evaluation. The important operands are CMD_LAYERNORM: the value named 'cmd layernorm' in this block. Context: the module's structural declarations.

Line 259: `command[15:4] = 12'd7;` This makes command[15:4], the 128-bit instruction selecting an engine, shape, mode, and numeric parameters, equal to '12'd7'. It is driven by combinational or procedural logic in the current evaluation. The important operands are d7: the value named 'd7' in this block. Context: the module's structural declarations.

Line 260: `command[47:16] = 32'd7;` This makes command[47:16], the 128-bit instruction selecting an engine, shape, mode, and numeric parameters, equal to '32'd7'. It is driven by combinational or procedural logic in the current evaluation. The important operands are d7: the value named 'd7' in this block. Context: the module's structural declarations.

Line 261: `submit_command(command);` Within the module's structural declarations, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge universal core RTL block in simulation. The important operands are submit_command: the 128-bit instruction selecting an engine, shape, mode, and numeric parameters; command: the 128-bit instruction selecting an engine, shape, mode, and numeric parameters.

Line 262: `for (int sample = 0; sample < 7; sample++) begin` This generate/procedural loop repeats the following operation across lanes or entries. In synthesizable RTL, a fixed loop is expanded into parallel or scheduled hardware rather than executed by a CPU. Context: the module's structural declarations.

Line 263: `logic [63:0] first_word;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, first_word is the value named 'first word' in this block. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 264: `first_word = {ln_beta_mem[5+sample][15:0], ln_gamma_mem[5+sample], ln_value_mem[5+sample]};` This makes first_word, the value named 'first word' in this block, equal to '{ln_beta_mem[5+sample][15:0], ln_gamma_mem[5+san ln_value_mem[5+sample]}'. It is driven by combinational or procedural logic in the current evaluation. The important operands are ln_beta_mem: the learned additive LayerNorm parameter; sample: the value named 'sample' in this block; ln_gamma_mem: the learned multiplicative LayerNorm parameter. Context: the module's structural declarations.

Line 265: `send_word(first_word, 1'b0);` Within the module's structural declarations, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge universal core RTL block in simulation. The important operands are send_word: the value named 'send word' in this block; first_word: the value named 'first word' in this block; b0: the value named 'b0' in this block.

Line 266: `send_word({56'd0, ln_beta_mem[5+sample][23:16]}, sample == 6);` Within the module's structural declarations, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge universal core RTL block in simulation. The important operands are send_word: the value named 'send word' in this block; d0: the value named 'd0' in this block; ln_beta_mem: the learned additive LayerNorm parameter.

Line 267: `end` This structural keyword opens or closes the branch/process scope described as the module's structural declarations; it has no arithmetic value of its own.

Line 268: `for (int sample = 0; sample < 7; sample++) begin` This generate/procedural loop repeats the following operation across lanes or entries. In synthesizable RTL, a fixed loop is expanded into parallel or scheduled hardware rather than executed by a CPU. Context: the module's structural declarations.

Line 269: `receive_word(received_word, received_last, sample % 2);` Within the module's structural declarations, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge universal core RTL block in simulation. The important operands are receive_word: the value named 'receive word' in this block; received_word: the value named 'received word' in this block; received_last: the AXI-Stream marker for the final beat of a packet or command payload.

Line 270: `if ($signed(received_word[31:0]) !== ln_expected_mem[5+sample]` This condition selects the following hardware branch only when '$signed(received_word[31:0]' is true. Both branches exist as gates; the condition controls a multiplexer rather than making software jump. The important operands are received_word: the value named 'received word' in this block. Context: the module's structural declarations.

Line 271: `|| received_last != (sample == 6)) begin` Within the module's structural declarations, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge universal core RTL block in simulation. The important operands are received_last: the AXI-Stream marker for the final beat of a packet or command payload; sample: the value named 'sample' in this block.

Line 272: `errors++;` Within the module's structural declarations, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge universal core RTL block in simulation. The important operands are errors: the value named 'errors' in this block.

Line 273: `$display("ERROR universal LayerNorm sample=%0d got=%0d expected=%0d",` This is a simulation check or diagnostic. It can stop a failing test and print evidence, but it is not part of the synthesized PYNQ circuit.

Line 274: `sample, $signed(received_word[31:0]), ln_expected_mem[5+sample]);` Within the module's structural declarations, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge universal core RTL block in simulation. The important operands are sample: the value named 'sample' in this block; received_word: the value named 'received word' in this block; ln_expected_mem: local FPGA storage addressed by surrounding index logic.

Line 275: `end` This structural keyword opens or closes the branch/process scope described as the module's structural declarations; it has no arithmetic value of its own.

Line 276: `end` This structural keyword opens or closes the branch/process scope described as the module's structural declarations; it has no arithmetic value of its own.

Line 278: `// Softmax fixture case 2 also starts after five entries.` Design intent: Softmax fixture case 2 also starts after five entries. This comment anchors the surrounding logic in the block that drives, backpressures, and checks the neuraedge universal core RTL block in simulation.

Line 279: `command = 128'd0;` This makes command, the 128-bit instruction selecting an engine, shape, mode, and numeric parameters, equal to '128'd0'. It is driven by combinational or procedural logic in the current evaluation. The important operands are d0: the value named 'd0' in this block. Context: the module's structural declarations.

Line 280: `command[3:0] = CMD_LOG_SOFTMAX;` This makes command[3:0], the 128-bit instruction selecting an engine, shape, mode, and numeric parameters, equal to 'CMD_LOG_SOFTMAX'. It is driven by combinational or procedural logic in the current evaluation. The important operands are CMD_LOG_SOFTMAX: the value named 'cmd log softmax' in this block. Context: the module's structural declarations.

Line 281: `command[12:4] = 9'd7;` This makes command[12:4], the 128-bit instruction selecting an engine, shape, mode, and numeric parameters, equal to '9'd7'. It is driven by combinational or procedural logic in the current evaluation. The important operands are d7: the value named 'd7' in this block. Context: the module's structural declarations.

Line 282: `command[17:13] = 5'd2;` This makes command[17:13], the 128-bit instruction selecting an engine, shape, mode, and numeric parameters, equal to '5'd2'. It is driven by combinational or procedural logic in the current evaluation. The important operands are d2: the value named 'd2' in this block. Context: the module's structural declarations.

Line 283: `submit_command(command);` Within the module's structural declarations, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge universal core RTL block in simulation. The important operands are submit_command: the 128-bit instruction selecting an engine, shape, mode, and numeric parameters; command: the 128-bit instruction selecting an engine, shape, mode, and numeric parameters.

Line 284: `for (int sample = 0; sample < 7; sample++) begin` This generate/procedural loop repeats the following operation across lanes or entries. In synthesizable RTL, a fixed loop is expanded into parallel or scheduled hardware rather than executed by a CPU. Context: the module's structural declarations.

Line 285: `send_word({40'd0, sm_score_mem[5+sample]}, sample == 6);` Within the module's structural declarations, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge universal core RTL block in simulation. The important operands are send_word: the value named 'send word' in this block; d0: the value named 'd0' in this block; sm_score_mem: local FPGA storage addressed by surrounding index logic.

Line 286: `end` This structural keyword opens or closes the branch/process scope described as the module's structural declarations; it has no arithmetic value of its own.

Line 287: `for (int sample = 0; sample < 7; sample++) begin` This generate/procedural loop repeats the following operation across lanes or entries. In synthesizable RTL, a fixed loop is expanded into parallel or scheduled hardware rather than executed by a CPU. Context: the module's structural declarations.

Line 288: `receive_word(received_word, received_last, 1);` Within the module's structural declarations, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge universal core RTL block in simulation. The important operands are receive_word: the value named 'receive word' in this block; received_word: the value named 'received word' in this block; received_last: the AXI-Stream marker for the final beat of a packet or command payload.

Line 289: `if (received_word[15:0] !== sm_expected_mem[5+sample]` Within the module's structural declarations, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge universal core RTL block in simulation. The important operands are received_word: the value named 'received word' in this block; sm_expected_mem: local FPGA storage addressed by surrounding index logic; sample: the value named 'sample' in this block.

Line 290: `|| received_last != (sample == 6)) begin` Within the module's structural declarations, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge universal core RTL block in simulation. The important operands are received_last: the AXI-Stream marker for the final beat of a packet or command payload; sample: the value named 'sample' in this block.

Line 291: `errors++;` Within the module's structural declarations, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge universal core RTL block in simulation. The important operands are errors: the value named 'errors' in this block.

Line 292: `$display("ERROR universal softmax sample=%0d", sample);` This is a simulation check or diagnostic. It can stop a failing test and print evidence, but it is not part of the synthesized PYNQ circuit.

Line 293: `end` This structural keyword opens or closes the branch/process scope described as the module's structural declarations; it has no arithmetic value of its own.

Line 294: `end` This structural keyword opens or closes the branch/process scope described as the module's structural declarations; it has no arithmetic value of its own.

Line 296: `// One state-clearing LIF timestep with analytically obvious currents.` Design intent: One state-clearing LIF timestep with analytically obvious currents. This comment anchors the surrounding logic in the block that drives, backpressures, and checks the neuraedge universal core RTL block in simulation.

Line 297: `command = 128'd0;` This makes command, the 128-bit instruction selecting an engine, shape, mode, and numeric parameters, equal to '128'd0'. It is driven by combinational or procedural logic in the current evaluation. The important operands are d0: the value named 'd0' in this block. Context: the module's structural declarations.

Line 298: `command[3:0] = CMD_LIF_STEP;` This makes command[3:0], the 128-bit instruction selecting an engine, shape, mode, and numeric parameters, equal to 'CMD_LIF_STEP'. It is driven by combinational or procedural logic in the current evaluation. The important operands are CMD_LIF_STEP: the value named 'cmd lif step' in this block. Context: the module's structural declarations.

Line 299: `command[8:4] = 5'd2;` This makes command[8:4], the 128-bit instruction selecting an engine, shape, mode, and numeric parameters, equal to '5'd2'. It is driven by combinational or procedural logic in the current evaluation. The important operands are d2: the value named 'd2' in this block. Context: the module's structural declarations.

Line 300: `command[32:9] = 24'sd50;` This makes command[32:9], the 128-bit instruction selecting an engine, shape, mode, and numeric parameters, equal to '24'sd50'. It is driven by combinational or procedural logic in the current evaluation. The important operands are sd50: the value named 'sd50' in this block. Context: the module's structural declarations.

Line 301: `command[56:33] = 24'sd0;` This makes command[56:33], the 128-bit instruction selecting an engine, shape, mode, and numeric parameters, equal to '24'sd0'. It is driven by combinational or procedural logic in the current evaluation. The important operands are sd0: the value named 'sd0' in this block. Context: the module's structural declarations.

Line 302: `command[57] = 1'b1;` This makes command[57], the 128-bit instruction selecting an engine, shape, mode, and numeric parameters, equal to '1'b1'. It is driven by combinational or procedural logic in the current evaluation. The important operands are b1: the value named 'b1' in this block. Context: the module's structural declarations.

Line 303: `submit_command(command);` Within the module's structural declarations, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge universal core RTL block in simulation. The important operands are submit_command: the 128-bit instruction selecting an engine, shape, mode, and numeric parameters; command: the 128-bit instruction selecting an engine, shape, mode, and numeric parameters.

Line 304: `for (int beat = 0; beat < 8; beat++) begin` This generate/procedural loop repeats the following operation across lanes or entries. In synthesizable RTL, a fixed loop is expanded into parallel or scheduled hardware rather than executed by a CPU. Context: the module's structural declarations.

Line 305: `logic [63:0] currents;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, currents is the value named 'currents' in this block. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 306: `currents = 64'd0;` This makes currents, the value named 'currents' in this block, equal to '64'd0'. It is driven by combinational or procedural logic in the current evaluation. The important operands are d0: the value named 'd0' in this block. Context: the module's structural declarations.

Line 307: `for (int lane = 0; lane < 4; lane++) begin` This generate/procedural loop repeats the following operation across lanes or entries. In synthesizable RTL, a fixed loop is expanded into parallel or scheduled hardware rather than executed by a CPU. Context: the module's structural declarations.

Line 308: `currents[lane*16 +:  16] = 16'(5 * (beat*4 + lane));` Within the module's structural declarations, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge universal core RTL block in simulation. The important operands are currents: the value named 'currents' in this block; lane: one parallel arithmetic element within a vector or tensor datapath; beat: the value named 'beat' in this block.

Line 309: `end` This structural keyword opens or closes the branch/process scope described as the module's structural declarations; it has no arithmetic value of its own.

Line 310: `send_word(currents, beat == 7);` Within the module's structural declarations, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge universal core RTL block in simulation. The important operands are send_word: the value named 'send word' in this block; currents: the value named 'currents' in this block; beat: the value named 'beat' in this block.

Line 311: `end` This structural keyword opens or closes the branch/process scope described as the module's structural declarations; it has no arithmetic value of its own.

Line 312: `receive_word(received_word, received_last, 2);` Within the module's structural declarations, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge universal core RTL block in simulation. The important operands are receive_word: the value named 'receive word' in this block; received_word: the value named 'received word' in this block; received_last: the AXI-Stream marker for the final beat of a packet or command payload.

Line 313: `if (!received_last || received_word[63:32] != 1` Within the module's structural declarations, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge universal core RTL block in simulation. The important operands are received_last: the AXI-Stream marker for the final beat of a packet or command payload; received_word: the value named 'received word' in this block.

Line 314: `|| received_word[31:0] != 32'hfffffc00) begin` Within the module's structural declarations, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge universal core RTL block in simulation. The important operands are received_word: the value named 'received word' in this block; hfffffc00: the value named 'hfffffc00' in this block.

Line 315: `errors++;` Within the module's structural declarations, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge universal core RTL block in simulation. The important operands are errors: the value named 'errors' in this block.

Line 316: `$display("ERROR universal LIF got=%h", received_word);` This is a simulation check or diagnostic. It can stop a failing test and print evidence, but it is not part of the synthesized PYNQ circuit.

Line 317: `end` This structural keyword opens or closes the branch/process scope described as the module's structural declarations; it has no arithmetic value of its own.

Line 319: `// Trace mode returns the same metadata plus every pre-reset membrane.` Design intent: Trace mode returns the same metadata plus every pre-reset membrane. This comment anchors the surrounding logic in the block that drives, backpressures, and checks the neuraedge universal core RTL block in simulation.

Line 320: `// These are the h[t] values required by surrogate-gradient BPTT.` Design intent: These are the h[t] values required by surrogate-gradient BPTT. This comment anchors the surrounding logic in the block that drives, backpressures, and checks the neuraedge universal core RTL block in simulation.

Line 321: `command[58] = 1'b1;` This makes command[58], the 128-bit instruction selecting an engine, shape, mode, and numeric parameters, equal to '1'b1'. It is driven by combinational or procedural logic in the current evaluation. The important operands are b1: the value named 'b1' in this block. Context: the module's structural declarations.

Line 322: `submit_command(command);` Within the module's structural declarations, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge universal core RTL block in simulation. The important operands are submit_command: the 128-bit instruction selecting an engine, shape, mode, and numeric parameters; command: the 128-bit instruction selecting an engine, shape, mode, and numeric parameters.

Line 323: `for (int beat = 0; beat < 8; beat++) begin` This generate/procedural loop repeats the following operation across lanes or entries. In synthesizable RTL, a fixed loop is expanded into parallel or scheduled hardware rather than executed by a CPU. Context: the module's structural declarations.

Line 324: `logic [63:0] currents;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, currents is the value named 'currents' in this block. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 325: `currents = 64'd0;` This makes currents, the value named 'currents' in this block, equal to '64'd0'. It is driven by combinational or procedural logic in the current evaluation. The important operands are d0: the value named 'd0' in this block. Context: the module's structural declarations.

Line 326: `for (int lane = 0; lane < 4; lane++) begin` This generate/procedural loop repeats the following operation across lanes or entries. In synthesizable RTL, a fixed loop is expanded into parallel or scheduled hardware rather than executed by a CPU. Context: the module's structural declarations.

Line 327: `currents[lane*16 +:  16] = 16'(5 * (beat*4 + lane));` Within the module's structural declarations, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge universal core RTL block in simulation. The important operands are currents: the value named 'currents' in this block; lane: one parallel arithmetic element within a vector or tensor datapath; beat: the value named 'beat' in this block.

Line 328: `end` This structural keyword opens or closes the branch/process scope described as the module's structural declarations; it has no arithmetic value of its own.

Line 329: `send_word(currents, beat == 7);` Within the module's structural declarations, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge universal core RTL block in simulation. The important operands are send_word: the value named 'send word' in this block; currents: the value named 'currents' in this block; beat: the value named 'beat' in this block.

Line 330: `end` This structural keyword opens or closes the branch/process scope described as the module's structural declarations; it has no arithmetic value of its own.

Line 331: `receive_word(received_word, received_last, 1);` Within the module's structural declarations, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge universal core RTL block in simulation. The important operands are receive_word: the value named 'receive word' in this block; received_word: the value named 'received word' in this block; received_last: the AXI-Stream marker for the final beat of a packet or command payload.

Line 332: `if (received_last || received_word[63:32] != 1` Within the module's structural declarations, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge universal core RTL block in simulation. The important operands are received_last: the AXI-Stream marker for the final beat of a packet or command payload; received_word: the value named 'received word' in this block.

Line 333: `|| received_word[31:0] != 32'hfffffc00) begin` Within the module's structural declarations, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge universal core RTL block in simulation. The important operands are received_word: the value named 'received word' in this block; hfffffc00: the value named 'hfffffc00' in this block.

Line 334: `errors++;` Within the module's structural declarations, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge universal core RTL block in simulation. The important operands are errors: the value named 'errors' in this block.

Line 335: `$display("ERROR universal traced LIF metadata got=%h last=%b",` This is a simulation check or diagnostic. It can stop a failing test and print evidence, but it is not part of the synthesized PYNQ circuit.

Line 336: `received_word, received_last);` Within the module's structural declarations, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge universal core RTL block in simulation. The important operands are received_word: the value named 'received word' in this block; received_last: the AXI-Stream marker for the final beat of a packet or command payload.

Line 337: `end` This structural keyword opens or closes the branch/process scope described as the module's structural declarations; it has no arithmetic value of its own.

Line 338: `received_lif_trace = '0;` This makes received_lif_trace, the value named 'received lif trace' in this block, equal to ''0'. It is driven by combinational or procedural logic in the current evaluation. The expression is a literal or structural operator and has no hidden software state. Context: the module's structural declarations.

Line 339: `for (int beat = 0; beat < 12; beat++) begin` This generate/procedural loop repeats the following operation across lanes or entries. In synthesizable RTL, a fixed loop is expanded into parallel or scheduled hardware rather than executed by a CPU. Context: the module's structural declarations.

Line 340: `receive_word(received_word, received_last, beat % 3);` Within the module's structural declarations, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge universal core RTL block in simulation. The important operands are receive_word: the value named 'receive word' in this block; received_word: the value named 'received word' in this block; received_last: the AXI-Stream marker for the final beat of a packet or command payload.

Line 341: `received_lif_trace[beat*64 +: 64] = received_word;` Within the module's structural declarations, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge universal core RTL block in simulation. The important operands are received_lif_trace: the value named 'received lif trace' in this block; beat: the value named 'beat' in this block; received_word: the value named 'received word' in this block.

Line 342: `if (received_last != (beat == 11)) errors++;` This condition selects the following hardware branch only when ‘received_last != (beat == 11)‘ is true. Both branches exist as gates; the condition controls a multiplexer rather than making software jump. The important operands are received_last: the AXI-Stream marker for the final beat of a packet or command payload; beat: the value named 'beat' in this block. Context: the module's structural declarations.

Line 343: `end` This structural keyword opens or closes the branch/process scope described as the module's structural declarations; it has no arithmetic value of its own.

Line 344: `for (int lane = 0; lane < 32; lane++) begin` This generate/procedural loop repeats the following operation across lanes or entries. In synthesizable RTL, a fixed loop is expanded into parallel or scheduled hardware rather than executed by a CPU. Context: the module's structural declarations.

Line 345: `if ($signed(received_lif_trace[lane*24 +: 24]) != 5 * lane) begin` This condition selects the following hardware branch only when ‘$signed(received_lif_trace[lane*24 +: 24]) != 5 * lane‘ is true. Both branches exist as gates; the condition controls a multiplexer rather than making software jump. The important operands are received_lif_trace: the value named 'received lif trace' in this block; lane: one parallel arithmetic element within a vector or tensor datapath. Context: the module's structural declarations.

Line 346: `errors++;` Within the module's structural declarations, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge universal core RTL block in simulation. The important operands are errors: the value named 'errors' in this block.

Line 347: `if (errors <= 20) begin` This statement continues through source line 351; the explanation uses the complete expression rather than only the first visual fragment. This condition selects the following hardware branch only when ‘errors <= 20) begin $display("ERROR universal traced LIF lane=%0d got=%0d expected=%0d", lane, $signed(received_lif_trace[lane*24 +: 24]), 5 * lane‘ is true. Both branches exist as gates; the condition controls a multiplexer rather than making software jump. The important operands are errors: the value named 'errors' in this block; display: the value named 'display' in this block; ERROR: the value named 'error' in this block. Context: the module's structural declarations.

Line 348: `$display("ERROR universal traced LIF lane=%0d got=%0d expected=%0d",` This is continuation line 2 of the 5-line logical statement that begins at source line 347. Its exact fragment is ‘$display("ERROR universal traced LIF lane=%0d got=%0d expected=%0d",‘. The important operands are display: the value named 'display' in this block; ERROR: the value named 'error' in this block; universal: the value named 'universal' in this block. Read together, the complete operation is: This condition selects the following hardware branch only when ‘errors <= 20) begin $display("ERROR universal traced LIF lane=%0d got=%0d expected=%0d", lane, $signed(received_lif_trace[lane*24 +: 24]), 5 * lane‘ is true. Both branches exist as gates; the condition controls a multiplexer rather than making software jump. The important operands are errors: the value named 'errors' in this block; display: the value named 'display' in this block; ERROR: the value named 'error' in this block. Context: the module's structural declarations.

Line 349: `lane,` This is continuation line 3 of the 5-line logical statement that begins at source line 347. Its exact fragment is ‘lane,‘. The important operands are lane: one parallel arithmetic element within a vector or tensor datapath. Read together, the complete operation is: This condition selects the following hardware branch only when ‘errors <= 20) begin $display("ERROR universal traced LIF lane=%0d got=%0d expected=%0d", lane, $signed(received_lif_trace[lane*24 +: 24]), 5 * lane‘ is true. Both branches exist as gates; the condition controls a multiplexer rather than making software jump. The important operands are errors: the value named ’errors’ in this block; display: the value named ’display’ in this block; ERROR: the value named ’error’ in this block. Context: the module’s structural declarations.

Line 350: `$signed(received_lif_trace[lane*24 +: 24]),` This is continuation line 4 of the 5-line logical statement that begins at source line 347. Its exact fragment is ‘$signed(received_lif_trace[lane*24 +: 24]),‘. The important operands are received_lif_trace: the value named ’received lif trace’ in this block; lane: one parallel arithmetic element within a vector or tensor datapath. Read together, the complete operation is: This condition selects the following hardware branch only when ‘errors <= 20) begin $display("ERROR universal traced LIF lane=%0d got=%0d expected=%0d", lane, $signed(received_lif_trace[lane*24 +: 24]), 5 * lane‘ is true. Both branches exist as gates; the condition controls a multiplexer rather than making software jump. The important operands are errors: the value named ’errors’ in this block; display: the value named ’display’ in this block; ERROR: the value named ’error’ in this block. Context: the module’s structural declarations.

Line 351: `5 * lane);` This is continuation line 5 of the 5-line logical statement that begins at source line 347. Its exact fragment is ‘5 * lane);‘. The important operands are lane: one parallel arithmetic element within a vector or tensor datapath. Read together, the complete operation is: This condition selects the following hardware branch only when ‘errors <= 20) begin $display("ERROR universal traced LIF lane=%0d got=%0d expected=%0d", lane, $signed(received_lif_trace[lane*24 +: 24]), 5 * lane‘ is true. Both branches exist as gates; the condition controls a multiplexer rather than making software jump. The important operands are errors: the value named ’errors’ in this block; display: the value named ’display’ in this block; ERROR: the value named ’error’ in this block. Context: the module’s structural declarations.

Line 352: `end` This structural keyword opens or closes the branch/process scope described as the module’s structural declarations; it has no arithmetic value of its own.

Line 353: `end` This structural keyword opens or closes the branch/process scope described as the module’s structural declarations; it has no arithmetic value of its own.

Line 354: `end` This structural keyword opens or closes the branch/process scope described as the module’s structural declarations; it has no arithmetic value of its own.

Line 356: `// Full eight-lane on-chip SGDW update using fixture case zero.` Design intent: Full eight-lane on-chip SGDW update using fixture case zero. This comment anchors the surrounding logic in the block that drives, backpressures, and checks the neuraedge universal core RTL block in simulation.

Line 357: `command = 128’d0;` This makes command, the 128-bit instruction selecting an engine, shape, mode, and numeric parameters, equal to ‘128’d0‘. It is driven by combinational or procedural logic in the current evaluation. The important operands are d0: the value named ’d0’ in this block. Context: the module’s structural declarations.

Line 358: `command[3:0] = CMD_SGD_UPDATE;` This makes command[3:0], the 128-bit instruction selecting an engine, shape, mode, and numeric parameters, equal to ‘CMD_SGD_UPDATE‘. It is driven by combinational or procedural logic in the current evaluation. The important operands are CMD_SGD_UPDATE: the value named ’cmd sgd update’ in this block. Context: the module’s structural declarations.

Line 359: `command[21:4] = optimizer_parameter_mem[0][17:0];` This makes command[21:4], the 128-bit instruction selecting an engine, shape, mode, and numeric parameters, equal to ‘optimizer_parameter_mem[0][17:0]‘. It is driven by combinational or procedural logic in the current evaluation. The important operands are optimizer_parameter_mem: local FPGA storage addressed by surrounding index logic. Context: the module’s structural declarations.

Line 360: `command[38:22] = optimizer_parameter_mem[0][34:18];` This makes command[38:22], the 128-bit instruction selecting an engine, shape, mode, and numeric parameters, equal to 'optimizer_parameter_mem[0][34:18]'. It is driven by combinational or procedural logic in the current evaluation. The important operands are optimizer_parameter_mem: local FPGA storage addressed by surrounding index logic. Context: the module's structural declarations.

Line 361: `command[55:39] = optimizer_parameter_mem[0][51:35];` This makes command[55:39], the 128-bit instruction selecting an engine, shape, mode, and numeric parameters, equal to 'optimizer_parameter_mem[0][51:35]'. It is driven by combinational or procedural logic in the current evaluation. The important operands are optimizer_parameter_mem: local FPGA storage addressed by surrounding index logic. Context: the module's structural declarations.

Line 362: `command[60:56] = optimizer_parameter_mem[0][56:52];` This makes command[60:56], the 128-bit instruction selecting an engine, shape, mode, and numeric parameters, equal to 'optimizer_parameter_mem[0][56:52]'. It is driven by combinational or procedural logic in the current evaluation. The important operands are optimizer_parameter_mem: local FPGA storage addressed by surrounding index logic. Context: the module's structural declarations.

Line 363: `submit_command(command);` Within the module's structural declarations, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge universal core RTL block in simulation. The important operands are submit_command: the 128-bit instruction selecting an engine, shape, mode, and numeric parameters; command: the 128-bit instruction selecting an engine, shape, mode, and numeric parameters.

Line 364: `for (int lane = 0; lane < 8; lane++) begin` This generate/procedural loop repeats the following operation across lanes or entries. In synthesizable RTL, a fixed loop is expanded into parallel or scheduled hardware rather than executed by a CPU. Context: the module's structural declarations.

Line 365: `send_word({optimizer_velocity_mem[0][lane*24 +: 24],` Within the module's structural declarations, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge universal core RTL block in simulation. The important operands are send_word: the value named 'send word' in this block; optimizer_velocity_mem: the momentum history retained by the SGD optimizer; lane: one parallel arithmetic element within a vector or tensor datapath.

Line 366: `optimizer_gradient_mem[0][lane*24 +: 24],` Within the module's structural declarations, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge universal core RTL block in simulation. The important operands are optimizer_gradient_mem: the signed loss derivative used to update a learned parameter; lane: one parallel arithmetic element within a vector or tensor datapath.

Line 367: `optimizer_weight_mem[0][lane*16 +: 16]}, lane == 7);` Within the module's structural declarations, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge universal core RTL block in simulation. The important operands are optimizer_weight_mem: a learned coefficient multiplied by an activation; lane: one parallel arithmetic element within a vector or tensor datapath.

Line 368: `end` This structural keyword opens or closes the branch/process scope described as the module's structural declarations; it has no arithmetic value of its own.

Line 369: `for (int lane = 0; lane < 8; lane++) begin` This generate/procedural loop repeats the following operation across lanes or entries. In synthesizable RTL, a fixed loop is expanded into parallel or scheduled hardware rather than executed by a CPU. Context: the module's structural declarations.

Line 370: `receive_word(received_word, received_last, lane % 3);` Within the module's structural declarations, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge universal core RTL block in simulation. The important operands are receive_word: the value named 'receive word' in this block; received_word: the value named 'received word' in this block; received_last: the AXI-Stream marker for the final beat of a packet or command payload.

Line 371: `received_weights[lane*16 +: 16] = received_word[15:0];` Within the module's structural declarations, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge universal core RTL block in simulation. The important operands are received_weights: a learned coefficient multiplied by an activation; lane: one parallel arithmetic element within a vector or tensor datapath; received_word: the value named 'received word' in this block.

Line 372: `received_velocities[lane*24 +: 24] = received_word[39:16];` Within the module's structural declarations, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge universal core RTL block in simulation. The important operands are received_velocities: the value named 'received velocities' in this block; lane: one parallel arithmetic element within a vector or tensor datapath; received_word: the value named 'received word' in this block.

Line 373: `if (received_last != (lane == 7)) errors++;` This condition selects the following hardware branch only when 'received_last != (lane == 7)' is true. Both branches exist as gates; the condition controls a multiplexer rather than making software jump. The important operands are received_last: the AXI-Stream marker for the final beat of a packet or command payload; lane: one parallel arithmetic element within a vector or tensor datapath. Context: the module's structural declarations.

Line 374: `end` This structural keyword opens or closes the branch/process scope described as the module's structural declarations; it has no arithmetic value of its own.

Line 375: `if (received_weights !== optimizer_expected_weight_mem[0]` Within the module's structural declarations, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge universal core RTL block in simulation. The important operands are received_weights: a learned coefficient multiplied by an activation; optimizer_expected_weight_mem: a learned coefficient multiplied by an activation.

Line 376: `|| received_velocities !== optimizer_expected_velocity_mem[0]) begin` Within the module's structural declarations, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge universal core RTL block in simulation. The important operands are received_velocities: the value named 'received velocities' in this block; optimizer_expected_velocity_mem: the momentum history retained by the SGD optimizer.

Line 377: `errors++;` Within the module's structural declarations, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge universal core RTL block in simulation. The important operands are errors: the value named 'errors' in this block.

Line 378: `$display("ERROR universal optimizer result");` This is a simulation check or diagnostic. It can stop a failing test and print evidence, but it is not part of the synthesized PYNQ circuit.

Line 379: `end` This structural keyword opens or closes the branch/process scope described as the module's structural declarations; it has no arithmetic value of its own.

Line 381: `// Backpropagate one complete Y=XW tile through the universal stream.` Design intent: Backpropagate one complete Y=XW tile through the universal stream. This comment anchors the surrounding logic in the block that drives, backpressures, and checks the neuraedge universal core RTL block in simulation.

Line 382: `// X, W, and dY are s16; dX is shifted once and dW is unshifted.` Design intent: X, W, and dY are s16; dX is shifted once and dW is unshifted. This comment anchors the surrounding logic in the block that drives, backpressures, and checks the neuraedge universal core RTL block in simulation.

Line 383: `command = 128'd0;` This makes command, the 128-bit instruction selecting an engine, shape, mode, and numeric parameters, equal to '128'd0'. It is driven by combinational or procedural logic in the current evaluation. The important operands are d0: the value named 'd0' in this block. Context: the module's structural declarations.

Line 384: `command[3:0] = CMD_TRAIN_LINEAR_BACKWARD;` This makes command[3:0], the 128-bit instruction selecting an engine, shape, mode, and numeric parameters, equal to ‘CMD_TRAIN_LINEAR_BACKWARD‘. It is driven by combinational or procedural logic in the current evaluation. The important operands are CMD_TRAIN_LINEAR_BACKWARD: the value named 'cmd train linear backward' in this block. Context: the module's structural declarations.

Line 385: `command[7:4] = 4'd2;` This makes command[7:4], the 128-bit instruction selecting an engine, shape, mode, and numeric parameters, equal to ‘4'd2‘. It is driven by combinational or procedural logic in the current evaluation. The important operands are d2: the value named 'd2' in this block. Context: the module's structural declarations.

Line 386: `command[11:8] = 4'd3;` This makes command[11:8], the 128-bit instruction selecting an engine, shape, mode, and numeric parameters, equal to ‘4'd3‘. It is driven by combinational or procedural logic in the current evaluation. The important operands are d3: the value named 'd3' in this block. Context: the module's structural declarations.

Line 387: `command[15:12] = 4'd2;` This makes command[15:12], the 128-bit instruction selecting an engine, shape, mode, and numeric parameters, equal to ‘4'd2‘. It is driven by combinational or procedural logic in the current evaluation. The important operands are d2: the value named 'd2' in this block. Context: the module's structural declarations.

Line 388: `command[20:16] = 5'd1;` This makes command[20:16], the 128-bit instruction selecting an engine, shape, mode, and numeric parameters, equal to ‘5'd1‘. It is driven by combinational or procedural logic in the current evaluation. The important operands are d1: the value named 'd1' in this block. Context: the module's structural declarations.

Line 389: `command[25:21] = 5'd0;` This makes command[25:21], the 128-bit instruction selecting an engine, shape, mode, and numeric parameters, equal to ‘5'd0‘. It is driven by combinational or procedural logic in the current evaluation. The important operands are d0: the value named 'd0' in this block. Context: the module's structural declarations.

Line 390: `submit_command(command);` Within the module's structural declarations, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge universal core RTL block in simulation. The important operands are submit_command: the 128-bit instruction selecting an engine, shape, mode, and numeric parameters; command: the 128-bit instruction selecting an engine, shape, mode, and numeric parameters.

Line 391: `send_word(64'h00000003fffe0001, 1'b0);` Within the module's structural declarations, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge universal core RTL block in simulation. The important operands are send_word: the value named 'send word' in this block; h00000003fffe0001: the value named 'h00000003fffe0001' in this block; b0: the value named 'b0' in this block.

Line 392: `send_word(64'h0000000000000000, 1'b0);` Within the module's structural declarations, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge universal core RTL block in simulation. The important operands are send_word: the value named 'send word' in this block; h0000000000000000: the value named 'h0000000000000000' in this block; b0: the value named 'b0' in this block.

Line 393: `send_word(64'h0000fffa0005fffc, 1'b0);` Within the module's structural declarations, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge universal core RTL block in simulation. The important operands are send_word: the value named 'send word' in this block; h0000fffa0005fffc: the value named 'h0000fffa0005fffc' in this block; b0: the value named 'b0' in this block.

Line 394: `send_word(64'h0000000000000000, 1'b0);` Within the module's structural declarations, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge universal core RTL block in simulation. The important operands are send_word: the value named 'send word' in this block; h0000000000000000: the value named 'h0000000000000000' in this block; b0: the value named 'b0' in this block.

Line 395: `send_word(64'h00000000fff80007, 1'b0);` Within the module's structural declarations, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge universal core RTL block in simulation. The important operands are send_word: the value named 'send word' in this block; h00000000fff80007: the value named 'h00000000fff80007' in this block; b0: the value named 'b0' in this block.

Line 396: `send_word(64'h0000000000000000, 1'b0);` Within the module's structural declarations, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge universal core RTL block in simulation. The important operands are send_word: the value named 'send word' in this block; h0000000000000000: the value named 'h0000000000000000' in this block; b0: the value named 'b0' in this block.

Line 397: `send_word(64'h00000000000a0009, 1'b0);` Within the module's structural declarations, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge universal core RTL block in simulation. The important operands are send_word: the value named 'send word' in this block; h00000000000a0009: the value named 'h00000000000a0009' in this block; b0: the value named 'b0' in this block.

Line 398: `send_word(64'h0000000000000000, 1'b0);` Within the module's structural declarations, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge universal core RTL block in simulation. The important operands are send_word: the value named 'send word' in this block; h0000000000000000: the value named 'h0000000000000000' in this block; b0: the value named 'b0' in this block.

Line 399: `send_word(64'h00000000000cfff5, 1'b0);` Within the module's structural declarations, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge universal core RTL block in simulation. The important operands are send_word: the value named 'send word' in this block; h00000000000cfff5: the value named 'h00000000000cfff5' in this block; b0: the value named 'b0' in this block.

Line 400: `send_word(64'h0000000000000000, 1'b0);` Within the module's structural declarations, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge universal core RTL block in simulation. The important operands are send_word: the value named 'send word' in this block; h0000000000000000: the value named 'h0000000000000000' in this block; b0: the value named 'b0' in this block.

Line 401: `send_word(64'h00000000fff2000d, 1'b0);` Within the module's structural declarations, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge universal core RTL block in simulation. The important operands are send_word: the value named 'send word' in this block; h00000000fff2000d: the value named 'h00000000fff2000d' in this block; b0: the value named 'b0' in this block.

Line 402: `send_word(64'h0000000000000000, 1'b0);` Within the module's structural declarations, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge universal core RTL block in simulation. The important operands are send_word: the value named 'send word' in this block; h0000000000000000: the value named 'h0000000000000000' in this block; b0: the value named 'b0' in this block.

Line 403: `send_word(64'h000000000010fff1, 1'b0);` Within the module's structural declarations, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge universal core RTL block in simulation. The important operands are send_word: the value named 'send word' in this block; h000000000010fff1: the value named 'h000000000010fff1' in this block; b0: the value named 'b0' in this block.

Line 404: `send_word(64'h0000000000000000, 1'b1);` Within the module's structural declarations, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge universal core RTL block in simulation. The important operands are send_word: the value named 'send word' in this block; h0000000000000000: the value named 'h0000000000000000' in this block; b1: the value named 'b1' in this block.

Line 405: `received_train_dx = '0;` This makes received_train_dx, the value named 'received train dx' in this block, equal to ''0'. It is driven by combinational or procedural logic in the current evaluation. The expression is a literal or structural operator and has no hidden software state. Context: the module's structural declarations.

Line 406: `for (int beat = 0; beat < 8; beat++) begin` This generate/procedural loop repeats the following operation across lanes or entries. In synthesizable RTL, a fixed loop is expanded into parallel or scheduled hardware rather than executed by a CPU. Context: the module's structural declarations.

Line 407: `receive_word(received_word, received_last, beat % 3);` Within the module's structural declarations, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge universal core RTL block in simulation. The important operands are receive_word: the value named 'receive word' in this block; received_word: the value named 'received word' in this block; received_last: the AXI-Stream marker for the final beat of a packet or command payload.

Line 408: `received_train_dx[beat*64 +: 64] = received_word;` Within the module's structural declarations, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge universal core RTL block in simulation. The important operands are received_train_dx: the value named 'received train dx' in this block; beat: the value named 'beat' in this block; received_word: the value named 'received word' in this block.

Line 409: `if (received_last) errors++;` This condition selects the following hardware branch only when 'received_last' is true. Both branches exist as gates; the condition controls a multiplexer rather than making software jump. The important operands are received_last: the AXI-Stream marker for the final beat of a packet or command payload. Context: the module's structural declarations.

Line 410: `end` This structural keyword opens or closes the branch/process scope described as the module's structural declarations; it has no arithmetic value of its own.

Line 411: `received_train_dw = '0;` This makes received_train_dw, the value named 'received train dw' in this block, equal to ''0'. It is driven by combinational or procedural logic in the current evaluation. The expression is a literal or structural operator and has no hidden software state. Context: the module's structural declarations.

Line 412: `for (int beat = 0; beat < 9; beat++) begin` This generate/procedural loop repeats the following operation across lanes or entries. In synthesizable RTL, a fixed loop is expanded into parallel or scheduled hardware rather than executed by a CPU. Context: the module's structural declarations.

Line 413: `receive_word(received_word, received_last, (beat + 1) % 3);` Within the module's structural declarations, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge universal core RTL block in simulation. The important operands are receive_word: the value named 'receive word' in this block; received_word: the value named 'received word' in this block; received_last: the AXI-Stream marker for the final beat of a packet or command payload.

Line 414: `received_train_dw[beat*64 +: 64] = received_word;` Within the module's structural declarations, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge universal core RTL block in simulation. The important operands are received_train_dw: the value named 'received train dw' in this block; beat: the value named 'beat' in this block; received_word: the value named 'received word' in this block.

Line 415: `if (received_last != (beat == 8)) errors++;` This condition selects the following hardware branch only when 'received_last != (beat == 8)' is true. Both branches exist as gates; the condition controls a multiplexer rather than making software jump. The important operands are received_last: the AXI-Stream marker for the final beat of a packet or command payload; beat: the value named 'beat' in this block. Context: the module's structural declarations.

Line 416: `end` This structural keyword opens or closes the branch/process scope described as the module's structural declarations; it has no arithmetic value of its own.

Line 417: `train_expected_dx[0][0] = 102;` This makes train_expected_dx[0][0], the value named 'train expected dx' in this block, equal to '102'. It is driven by combinational or procedural logic in the current evaluation. The expression is a literal or structural operator and has no hidden software state. Context: the module's structural declarations.

Line 418: `train_expected_dx[0][1] = -12;` This makes train_expected_dx[0][1], the value named 'train expected dx' in this block, equal to '-12'. It is driven by combinational or procedural logic in the current evaluation. The expression is a literal or structural operator and has no hidden software state. Context: the module's structural declarations.

Line 419: `train_expected_dx[0][2] = -156;` This makes train_expected_dx[0][2], the value named 'train expected dx' in this block, equal to '-156'. It is driven by combinational or procedural logic in the current evaluation. The expression is a literal or structural operator and has no hidden software state. Context: the module's structural declarations.

Line 420: `train_expected_dx[1][0] = -117;` This makes train_expected_dx[1][0], the value named 'train expected dx' in this block, equal to '-117'. It is driven by combinational or procedural logic in the current evaluation. The expression is a literal or structural operator and has no hidden software state. Context: the module's structural declarations.

Line 421: `train_expected_dx[1][1] = 13;` This makes train_expected_dx[1][1], the value named 'train expected dx' in this block, equal to '13'. It is driven by combinational or procedural logic in the current evaluation. The expression is a literal or structural operator and has no hidden software state. Context: the module's structural declarations.

Line 422: `train_expected_dx[1][2] = 179;` This makes train_expected_dx[1][2], the value named 'train expected dx' in this block, equal to '179'. It is driven by combinational or procedural logic in the current evaluation. The expression is a literal or structural operator and has no hidden software state. Context: the module's structural declarations.

Line 423: `for (int row = 0; row < 2; row++) begin` This generate/procedural loop repeats the following operation across lanes or entries. In synthesizable RTL, a fixed loop is expanded into parallel or scheduled hardware rather than executed by a CPU. Context: the module's structural declarations.

Line 424: `for (int lane = 3; lane < 8; lane++) train_expected_dx[row][lane] = 0;` This generate/procedural loop repeats the following operation across lanes or entries. In synthesizable RTL, a fixed loop is expanded into parallel or scheduled hardware rather than executed by a CPU. Context: the module's structural declarations.

Line 425: `for (int lane = 0; lane < 8; lane++) begin` This generate/procedural loop repeats the following operation across lanes or entries. In synthesizable RTL, a fixed loop is expanded into parallel or scheduled hardware rather than executed by a CPU. Context: the module's structural declarations.

Line 426: `if ($signed(received_train_dx[(row*8+lane)*32 +: 32])` This condition selects the following hardware branch only when '$signed(received_train_dx[(row*8+lane)*32 +: 32]' is true. Both branches exist as gates; the condition controls a multiplexer rather than making software jump. The important operands are received_train_dx: the value named 'received train dx' in this block; row: one output-row position processed by the tensor tile; lane: one parallel arithmetic element within a vector or tensor datapath. Context: the module's structural declarations.

Line 427: `!= train_expected_dx[row][lane]) begin` Within the module's structural declarations, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge universal core RTL block in simulation. The important operands are train_expected_dx: the value named 'train expected dx' in this block; row: one output-row position processed by the tensor tile; lane: one parallel arithmetic element within a vector or tensor datapath.

Line 428: `errors++;` Within the module's structural declarations, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge universal core RTL block in simulation. The important operands are errors: the value named 'errors' in this block.

Line 429: `$display("ERROR universal backward dX row=%0d lane=%0d got=%0d expected=%0d",` This is a simulation check or diagnostic. It can stop a failing test and print evidence, but it is not part of the synthesized PYNQ circuit.

Line 430: `row, lane,` Within the module's structural declarations, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge universal core RTL block in simulation. The important operands are row: one output-row position processed by the tensor tile; lane: one parallel arithmetic element within a vector or tensor datapath.

Line 431: `$signed(received_train_dx[(row*8+lane)*32 +: 32]),` Within the module's structural declarations, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge universal core RTL block in simulation. The important operands are received_train_dx: the value named 'received train dx' in this block; row: one output-row position processed by the tensor tile; lane: one parallel arithmetic element within a vector or tensor datapath.

Line 432: `train_expected_dx[row][lane]);` Within the module's structural declarations, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge universal core RTL block in simulation. The important operands are train_expected_dx: the value named 'train expected dx' in this block; row: one output-row position processed by the tensor tile; lane: one parallel arithmetic element within a vector or tensor datapath.

Line 433: `end` This structural keyword opens or closes the branch/process scope described as the module's structural declarations; it has no arithmetic value of its own.

Line 434: `end` This structural keyword opens or closes the branch/process scope described as the module's structural declarations; it has no arithmetic value of its own.

Line 435: `end` This structural keyword opens or closes the branch/process scope described as the module's structural declarations; it has no arithmetic value of its own.

Line 436: `train_expected_dw[0][0] = 73;` This makes train_expected_dw[0][0], the value named 'train expected dw' in this block, equal to '73'. It is driven by combinational or procedural logic in the current evaluation. The expression is a literal or structural operator and has no hidden software state. Context: the module's structural declarations.

Line 437: `train_expected_dw[0][1] = -78;` This makes train_expected_dw[0][1], the value named 'train expected dw' in this block, equal to '-78'. It is driven by combinational or procedural logic in the current evaluation. The expression is a literal or structural operator and has no hidden software state. Context: the module's structural declarations.

Line 438: `train_expected_dw[1][0] = -101;` This makes train_expected_dw[1][0], the value named 'train expected dw' in this block, equal to '-101'. It is driven by combinational or procedural logic in the current evaluation. The expression is a literal or structural operator and has no hidden software state. Context: the module's structural declarations.

Line 439: `train_expected_dw[1][1] = 108;` This makes train_expected_dw[1][1], the value named 'train expected dw' in this block, equal to '108'. It is driven by combinational or procedural logic in the current evaluation. The expression is a literal or structural operator and has no hidden software state. Context: the module's structural declarations.

Line 440: `train_expected_dw[2][0] = 129;` This makes train_expected_dw[2][0], the value named 'train expected dw' in this block, equal to '129'. It is driven by combinational or procedural logic in the current evaluation. The expression is a literal or structural operator and has no hidden software state. Context: the module's structural declarations.

Line 441: `train_expected_dw[2][1] = -138;` This makes train_expected_dw[2][1], the value named 'train expected dw' in this block, equal to '-138'. It is driven by combinational or procedural logic in the current evaluation. The expression is a literal or structural operator and has no hidden software state. Context: the module's structural declarations.

Line 442: `for (int row = 0; row < 3; row++) begin` This generate/procedural loop repeats the following operation across lanes or entries. In synthesizable RTL, a fixed loop is expanded into parallel or scheduled hardware rather than executed by a CPU. Context: the module's structural declarations.

Line 443: `for (int lane = 2; lane < 8; lane++) train_expected_dw[row][lane] = 0;` This generate/procedural loop repeats the following operation across lanes or entries. In synthesizable RTL, a fixed loop is expanded into parallel or scheduled hardware rather than executed by a CPU. Context: the module's structural declarations.

Line 444: `for (int lane = 0; lane < 8; lane++) begin` This generate/procedural loop repeats the following operation across lanes or entries. In synthesizable RTL, a fixed loop is expanded into parallel or scheduled hardware rather than executed by a CPU. Context: the module's structural declarations.

Line 445: `if ($signed(received_train_dw[row*192+lane*24 +: 24])` This condition selects the following hardware branch only when '$signed(received_train_dw[row*192+lane*24 +: 24]' is true. Both branches exist as gates; the condition controls a multiplexer rather than making software jump. The important operands are received_train_dw: the value named 'received train dw' in this block; row: one output-row position processed by the tensor tile; lane: one parallel arithmetic element within a vector or tensor datapath. Context: the module's structural declarations.

Line 446: `!= train_expected_dw[row][lane]) begin` Within the module's structural declarations, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge universal core RTL block in simulation. The important operands are train_expected_dw: the value named 'train expected dw' in this block; row: one output-row position processed by the tensor tile; lane: one parallel arithmetic element within a vector or tensor datapath.

Line 447: `errors++;` Within the module's structural declarations, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge universal core RTL block in simulation. The important operands are errors: the value named 'errors' in this block.

Line 448: `$display("ERROR universal backward dW row=%0d lane=%0d got=%0d expected=%0d",` This is a simulation check or diagnostic. It can stop a failing test and print evidence, but it is not part of the synthesized PYNQ circuit.

Line 449: `row, lane,` Within the module's structural declarations, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge universal core RTL block in simulation. The important operands are row: one output-row position processed by the tensor tile; lane: one parallel arithmetic element within a vector or tensor datapath.

Line 450: `$signed(received_train_dw[row*192+lane*24 +: 24]),` Within the module's structural declarations, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge universal core RTL block in simulation. The important operands are received_train_dw: the value named 'received train dw' in this block; row: one output-row position processed by the tensor tile; lane: one parallel arithmetic element within a vector or tensor datapath.

Line 451: `train_expected_dw[row][lane]);` Within the module's structural declarations, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge universal core RTL block in simulation. The important operands are train_expected_dw: the value named 'train expected dw' in this block; row: one output-row position processed by the tensor tile; lane: one parallel arithmetic element within a vector or tensor datapath.

Line 452: `end` This structural keyword opens or closes the branch/process scope described as the module's structural declarations; it has no arithmetic value of its own.

Line 453: `end` This structural keyword opens or closes the branch/process scope described as the module's structural declarations; it has no arithmetic value of its own.

Line 454: `end` This structural keyword opens or closes the branch/process scope described as the module's structural declarations; it has no arithmetic value of its own.

Line 455: `wait_done();` Within the module's structural declarations, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge universal core RTL block in simulation. The important operands are wait_done: the value named 'wait done' in this block.

Line 457: `// Program and evaluate all eight ports of the activation LUT.` Design intent: Program and evaluate all eight ports of the activation LUT. This comment anchors the surrounding logic in the block that drives, backpressures, and checks the neuraedge universal core RTL block in simulation.

Line 458: `command = 128'd0;` This makes command, the 128-bit instruction selecting an engine, shape, mode, and numeric parameters, equal to '128'd0'. It is driven by combinational or procedural logic in the current evaluation. The important operands are d0: the value named 'd0' in this block. Context: the module's structural declarations.

Line 459: `command[3:0] = CMD_ACTIVATION_LUT;` This makes command[3:0], the 128-bit instruction selecting an engine, shape, mode, and numeric parameters, equal to 'CMD_ACTIVATION_LUT'. It is driven by combinational or procedural logic in the current evaluation. The important operands are CMD_ACTIVATION_LUT: an input feature value consumed by a neuron or multiply-accumulate operation. Context: the module's structural declarations.

Line 460: `command[7:4] = 4'd0;` This makes command[7:4], the 128-bit instruction selecting an engine, shape, mode, and numeric parameters, equal to '4'd0'. It is driven by combinational or procedural logic in the current evaluation. The important operands are d0: the value named 'd0' in this block. Context: the module's structural declarations.

Line 461: `submit_command(command);` Within the module's structural declarations, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge universal core RTL block in simulation. The important operands are submit_command: the 128-bit instruction selecting an engine, shape, mode, and numeric parameters; command: the 128-bit instruction selecting an engine, shape, mode, and numeric parameters.

Line 462: `wait_done();` Within the module's structural declarations, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge universal core RTL block in simulation. The important operands are wait_done: the value named 'wait done' in this block.

Line 463: `command[7:4] = 4'd1;` This makes command[7:4], the 128-bit instruction selecting an engine, shape, mode, and numeric parameters, equal to '4'd1'. It is driven by combinational or procedural logic in the current evaluation. The important operands are d1: the value named 'd1' in this block. Context: the module's structural declarations.

Line 464: `command[19:8] = 12'd8;` This makes command[19:8], the 128-bit instruction selecting an engine, shape, mode, and numeric parameters, equal to '12'd8'. It is driven by combinational or procedural logic in the current evaluation. The important operands are d8: the value named 'd8' in this block. Context: the module's structural declarations.

Line 465: `submit_command(command);` Within the module's structural declarations, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge universal core RTL block in simulation. The important operands are submit_command: the 128-bit instruction selecting an engine, shape, mode, and numeric parameters; command: the 128-bit instruction selecting an engine, shape, mode, and numeric parameters.

Line 466: `for (int address = 0; address < 8; address++) begin` This generate/procedural loop repeats the following operation across lanes or entries. In synthesizable RTL, a fixed loop is expanded into parallel or scheduled hardware rather than executed by a CPU. Context: the module's structural declarations.

Line 467: `send_word({40'd0, 16'(address*address-3), 8'(address)}, address == 7);` Within the module's structural declarations, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge universal core RTL block in simulation. The important operands are send_word: the value named 'send word' in this block; d0: the value named 'd0' in this block; address: the value named 'address' in this block.

Line 468: `end` This structural keyword opens or closes the branch/process scope described as the module's structural declarations; it has no arithmetic value of its own.

Line 469: `wait_done();` Within the module's structural declarations, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge universal core RTL block in simulation. The important operands are wait_done: the value named 'wait done' in this block.

Line 470: `command = 128'd0;` This makes command, the 128-bit instruction selecting an engine, shape, mode, and numeric parameters, equal to '128'd0'. It is driven by combinational or procedural logic in the current evaluation. The important operands are d0: the value named 'd0' in this block. Context: the module's structural declarations.

Line 471: `command[3:0] = CMD_ACTIVATION_LUT;` This makes command[3:0], the 128-bit instruction selecting an engine, shape, mode, and numeric parameters, equal to 'CMD_ACTIVATION_LUT'. It is driven by combinational or procedural logic in the current evaluation. The important operands are CMD_ACTIVATION_LUT: an input feature value consumed by a neuron or multiply-accumulate operation. Context: the module's structural declarations.

Line 472: `command[7:4] = 4'd2;` This makes command[7:4], the 128-bit instruction selecting an engine, shape, mode, and numeric parameters, equal to '4'd2'. It is driven by combinational or procedural logic in the current evaluation. The important operands are d2: the value named 'd2' in this block. Context: the module's structural declarations.

Line 473: `submit_command(command);` Within the module's structural declarations, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge universal core RTL block in simulation. The important operands are submit_command: the 128-bit instruction selecting an engine, shape, mode, and numeric parameters; command: the 128-bit instruction selecting an engine, shape, mode, and numeric parameters.

Line 474: `send_word(64'h0706050403020100, 1'b1);` Within the module's structural declarations, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge universal core RTL block in simulation. The important operands are send_word: the value named 'send word' in this block; h0706050403020100: the value named 'h0706050403020100' in this block; b1: the value named 'b1' in this block.

Line 475: `received_vector = '0;` This makes received_vector, the value named 'received vector' in this block, equal to ''0'. It is driven by combinational or procedural logic in the current evaluation. The expression is a literal or structural operator and has no hidden software state. Context: the module's structural declarations.

Line 476: `for (int beat = 0; beat < 2; beat++) begin` This generate/procedural loop repeats the following operation across lanes or entries. In synthesizable RTL, a fixed loop is expanded into parallel or scheduled hardware rather than executed by a CPU. Context: the module's structural declarations.

Line 477: `receive_word(received_word, received_last, beat);` Within the module's structural declarations, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge universal core RTL block in simulation. The important operands are receive_word: the value named 'receive word' in this block; received_word: the value named 'received word' in this block; received_last: the AXI-Stream marker for the final beat of a packet or command payload.

Line 478: `received_vector[beat*64 +: 64] = received_word;` Within the module's structural declarations, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge universal core RTL block in simulation. The important operands are received_vector: the value named 'received vector' in this block; beat: the value named 'beat' in this block; received_word: the value named 'received word' in this block.

Line 479: `end` This structural keyword opens or closes the branch/process scope described as the module's structural declarations; it has no arithmetic value of its own.

Line 480: `for (int lane = 0; lane < 8; lane++) begin` This generate/procedural loop repeats the following operation across lanes or entries. In synthesizable RTL, a fixed loop is expanded into parallel or scheduled hardware rather than executed by a CPU. Context: the module's structural declarations.

Line 481: `if ($signed(received_vector[lane*16 +: 16]) != lane*lane-3) begin` This condition selects the following hardware branch only when '$signed(received_vector[lane*16 +: 16]) != lane*lane-3' is true. Both branches exist as gates; the condition controls a multiplexer rather than making software jump. The important operands are received_vector: the value named 'received vector' in this block; lane: one parallel arithmetic element within a vector or tensor datapath. Context: the module's structural declarations.

Line 482: `errors++;` Within the module's structural declarations, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge universal core RTL block in simulation. The important operands are errors: the value named 'errors' in this block.

Line 483: `$display("ERROR universal LUT lane=%0d", lane);` This is a simulation check or diagnostic. It can stop a failing test and print evidence, but it is not part of the synthesized PYNQ circuit.

Line 484: `end` This structural keyword opens or closes the branch/process scope described as the module's structural declarations; it has no arithmetic value of its own.

Line 485: `end` This structural keyword opens or closes the branch/process scope described as the module's structural declarations; it has no arithmetic value of its own.

Line 486: `wait_done();` Within the module's structural declarations, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge universal core RTL block in simulation. The important operands are wait_done: the value named 'wait done' in this block.

Line 488: `if (status_error || status_busy || status_command_count != commands_expected` Within the module's structural declarations, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge universal core RTL block in simulation. The important operands are status_error: the value named 'status error' in this block; status_busy: the value named 'status busy' in this block; status_command_count: the 128-bit instruction selecting an engine, shape, mode, and numeric parameters.

Line 489: `|| status_input_beats != 88 || status_output_beats != 61` Within the module's structural declarations, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge universal core RTL block in simulation. The important operands are status_input_beats: the value named 'status input beats' in this block; status_output_beats: the value named 'status output beats' in this block.

Line 490: `|| debug_training_tiles != 1 || debug_training_cycles == 0) begin` Within the module's structural declarations, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge universal core RTL block in simulation. The important operands are debug_training_tiles: the value named 'debug training tiles' in this block; debug_training_cycles: the value named 'debug training cycles' in this block.

Line 491: `errors++;` Within the module's structural declarations, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge universal core RTL block in simulation. The important operands are errors: the value named 'errors' in this block.

Line 492: `$display("ERROR universal final status error=%0d busy=%0d commands=%0d/%0d inputs=%0d outputs=%0d training=...` This is a simulation check or diagnostic. It can stop a failing test and print evidence, but it is not part of the synthesized PYNQ circuit.

Line 493: `status_error, status_busy, status_command_count, commands_expected,` Within the module's structural declarations, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge universal core RTL block in simulation. The important operands are status_error: the value named 'status error' in this block; status_busy: the value named 'status busy' in this block; status_command_count: the 128-bit instruction selecting an engine, shape, mode, and numeric parameters.

Line 494: `status_input_beats, status_output_beats,` Within the module's structural declarations, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge universal core RTL block in simulation. The important operands are status_input_beats: the value named 'status input beats' in this block; status_output_beats: the value named 'status output beats' in this block.

Line 495: `debug_training_tiles, debug_training_cycles);` Within the module's structural declarations, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge universal core RTL block in simulation. The important operands are debug_training_tiles: the value named 'debug training tiles' in this block; debug_training_cycles: the value named 'debug training cycles' in this block.

Line 496: `end` This structural keyword opens or closes the branch/process scope described as the module's structural declarations; it has no arithmetic value of its own.

Line 497: `if (errors != 0) begin` This condition selects the following hardware branch only when 'errors != 0' is true. Both branches exist as gates; the condition controls a multiplexer rather than making software jump. The important operands are errors: the value named 'errors' in this block. Context: the module's structural declarations.

Line 498: `$display("tb_neuraedge_universal_core FAILED errors=%0d", errors);` This is a simulation check or diagnostic. It can stop a failing test and print evidence, but it is not part of the synthesized PYNQ circuit.

Line 499: `$finish;` This is a simulation check or diagnostic. It can stop a failing test and print evidence, but it is not part of the synthesized PYNQ circuit.

Line 500: `end else begin` This structural keyword opens or closes the branch/process scope described as the module's structural declarations; it has no arithmetic value of its own.

Line 501: `$display("tb_neuraedge_universal_core PASSED commands=%0d input_beats=%0d output_beats=%0d",` This is a simulation check or diagnostic. It can stop a failing test and print evidence, but it is not part of the synthesized PYNQ circuit.

Line 502: `status_command_count, status_input_beats, status_output_beats);` Within the module's structural declarations, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge universal core RTL block in simulation. The important operands are status_command_count: the 128-bit instruction selecting an engine, shape, mode, and numeric parameters; status_input_beats: the value named 'status input beats' in this block; status_output_beats: the value named 'status output beats' in this block.

Line 503: `$finish;` This is a simulation check or diagnostic. It can stop a failing test and print evidence, but it is not part of the synthesized PYNQ circuit.

Line 504: `end` This structural keyword opens or closes the branch/process scope described as the module's structural declarations; it has no arithmetic value of its own.

Line 505: `end` This structural keyword opens or closes the branch/process scope described as the module's structural declarations; it has no arithmetic value of its own.

Line 507: `initial begin` This opens simulation initialization. In a testbench it drives starting values and stimulus; project synthesis does not rely on this block as a replacement for explicit reset behavior.

Line 508: `#2_000_000;` Within the module's structural declarations, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge universal core RTL block in simulation. The expression is a literal or structural operator and has no hidden software state.

Line 509: `$fatal(1, "tb_neuraedge_universal_core watchdog timeout state=%0d opcode=%0d",` This is a simulation check or diagnostic. It can stop a failing test and print evidence, but it is not part of the synthesized PYNQ circuit.

Line 510: `dut.state, status_active_opcode);` Within the module's structural declarations, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge universal core RTL block in simulation. The important operands are dut: the value named 'dut' in this block; state: the finite-state-machine phase retained in flip-flops; status_active_opcode: the value named 'status active opcode' in this block.

Line 511: `end` This structural keyword opens or closes the branch/process scope described as the module's structural declarations; it has no arithmetic value of its own.

Line 512: `endmodule` This closes the current hardware definition; no circuit behavior is attached to the keyword itself.

Line 514: `` `default_nettype wire `` This SystemVerilog preprocessor line controls compilation of the block that drives, backpressures, and checks the neuraedge universal core RTL block in simulation.

60 tb/tb_neuraedge_vector_alu.sv

Role in the complete system: drives, backpressures, and checks the neuraedge vector alu RTL block in simulation.

60.1 Beginner architecture map

Dataflow responsibility This file's end-to-end responsibility is to drives, backpressures, and checks the neuraedge vector alu RTL block in simulation.

Simulation-only status tb_neuraedge_vector_alu is not synthesized into the FPGA. It generates clocks, reset, commands, stalls, and expected values around the design under test, then terminates with an explicit result marker.

Evidence produced The file contains approximately 3 explicit assertions, failure diagnostics, or pass/fail markers. Its VCD/WDB trace is useful evidence only when the final pass marker is present; a simulator exit code by itself is insufficient.

60.3 Line annotations

Line 1: `` `timescale 1ns / 1ps `` This simulation directive selects nanoseconds as the time unit and picoseconds as the timestamp precision; it does not create FPGA logic.

Line 2: `` `default_nettype none `` This compiler directive forbids accidental implicit one-bit wires, turning misspelled signal names into errors instead of unintended hardware.

Line 3: `` `include "tb/fixtures/operator_fixture_params.svh" `` This SystemVerilog preprocessor line controls compilation of the block that drives, backpressures, and checks the neuraedge vector alu RTL block in simulation.

Line 5: `module tb_neuraedge_vector_alu;` This opens tb_neuraedge_vector_alu;, an independently compiled hardware definition. Its ports and statements collectively describe circuitry that drives, backpressures, and checks the neuraedge vector alu RTL block in simulation.

**Line 6: `localparam int CASES = `NEURAEDGE_VECTOR_CASES;`** This fixes CASES to `NEURAEDGE_VECTOR_CASES during elaboration. Vivado uses that constant to shape or simplify the generated circuit; CASES denotes the value named 'cases' in this block.

Line 8: `logic clk = 1'b0;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, clk is the clock that makes all registers advance together. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 9: `logic rst_n = 1'b0;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, rst_n is the active-low synchronous reset. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 10: `logic input_valid = 1'b0;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, input_valid is the producer's statement that its current payload is meaningful. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 11: `logic input_ready;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, input_ready is the consumer's statement that it can accept a payload this cycle. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 12: `logic [3:0] operation = 4'd0;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, operation is the value named 'operation' in this block. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 13: `logic [255:0] operand_a = '0;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, operand_a is the value named 'operand a' in this block. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 14: `logic [255:0] operand_b = '0;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, operand_b is the value named 'operand b' in this block. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 15: `logic signed [15:0] multiplier_q15 = 16'sd0;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, multiplier_q15 is the value named 'multiplier q15' in this block. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 16: `logic [4:0] right_shift = 5'd0;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, right_shift is the value named 'right shift' in this block. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 17: `logic signed [15:0] output_zero_point = 16'sd0;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, output_zero_point is the integer code representing real numeric zero in affine quantization. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 18: `logic signed [31:0] threshold = 32'sd0;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, threshold is the membrane level at which a neuron emits a spike. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 19: `logic [31:0] surrogate_window = 32'd0;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, surrogate_window is the value named 'surrogate window' in this block. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 20: `logic signed [31:0] clamp_minimum = 32'sh80000000;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, clamp_minimum is the value named 'clamp minimum' in this block. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 21: `logic signed [31:0] clamp_maximum = 32'sh7fffffff;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, clamp_maximum is the value named 'clamp maximum' in this block. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 22: `logic output_valid;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, output_valid is the producer's statement that its current payload is meaningful. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 23: `logic output_ready = 1'b0;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, output_ready is the consumer's statement that it can accept a payload this cycle. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 24: `logic [255:0] result;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, result is the value named 'result' in this block. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 25: `logic config_error;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, config_error is the value named 'config error' in this block. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 27: `logic [191:0] command_mem [0:CASES-1];` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, command_mem is the 128-bit instruction selecting an engine, shape, mode, and numeric parameters. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 28: `logic [255:0] operand_a_mem [0:CASES-1];` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, operand_a_mem is local FPGA storage addressed by surrounding index logic. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 29: `logic [255:0] operand_b_mem [0:CASES-1];` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, operand_b_mem is local FPGA storage addressed by surrounding index logic. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 30: `logic [255:0] expected_mem [0:CASES-1];` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, expected_mem is local FPGA storage addressed by surrounding index logic. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 31: `int errors = 0;` Within the module's structural declarations, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge vector alu RTL block in simulation. The important operands are errors: the value named 'errors' in this block.

Line 32: `int checked = 0;` Within the module's structural declarations, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge vector alu RTL block in simulation. The important operands are checked: the value named 'checked' in this block.

Line 33: `logic held_valid = 1'b0;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, held_valid is the producer's statement that its current payload is meaningful. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 34: `logic [255:0] held_result;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, held_result is the value named 'held result' in this block. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 36: `neuraedge_vector_alu dut (` This instantiates module neuraedge_vector_alu as dut. Synthesis creates that subordinate circuit and connects its ports in the lines that follow.

Line 37: `.clk(clk),` This connects the child instance's named port ‘clk‘ to parent expression ‘clk‘. The connection is a physical net bundle after synthesis; direction is declared in the child module, and the clock that makes all registers advance together.

Line 38: `.rst_n(rst_n),` This connects the child instance's named port ‘rst_n‘ to parent expression ‘rst_n‘. The connection is a physical net bundle after synthesis; direction is declared in the child module, and the active-low synchronous reset.

Line 39: `.input_valid(input_valid),` This connects the child instance's named port ‘input_valid‘ to parent expression ‘input_valid‘. The connection is a physical net bundle after synthesis; direction is declared in the child module, and the producer's statement that its current payload is meaningful.

Line 40: `.input_ready(input_ready),` This connects the child instance's named port ‘input_ready‘ to parent expression ‘input_ready‘. The connection is a physical net bundle after synthesis; direction is declared in the child module, and the consumer's statement that it can accept a payload this cycle.

Line 41: `.operation(operation),` This connects the child instance's named port ‘operation‘ to parent expression ‘operation‘. The connection is a physical net bundle after synthesis; direction is declared in the child module, and the value named 'operation' in this block.

Line 42: `.operand_a(operand_a),` This connects the child instance's named port ‘operand_a‘ to parent expression ‘operand_a‘. The connection is a physical net bundle after synthesis; direction is declared in the child module, and the value named 'operand a' in this block.

Line 43: `.operand_b(operand_b),` This connects the child instance's named port ‘operand_b‘ to parent expression ‘operand_b‘. The connection is a physical net bundle after synthesis; direction is declared in the child module, and the value named 'operand b' in this block.

Line 44: `.multiplier_q15(multiplier_q15),` This connects the child instance's named port 'multiplier_q15' to parent expression 'multiplier_q15'. The connection is a physical net bundle after synthesis; direction is declared in the child module, and the value named 'multiplier q15' in this block.

Line 45: `.right_shift(right_shift),` This connects the child instance's named port 'right_shift' to parent expression 'right_shift'. The connection is a physical net bundle after synthesis; direction is declared in the child module, and the value named 'right shift' in this block.

Line 46: `.output_zero_point(output_zero_point),` This connects the child instance's named port 'output_zero_point' to parent expression 'output_zero_point'. The connection is a physical net bundle after synthesis; direction is declared in the child module, and the integer code representing real numeric zero in affine quantization.

Line 47: `.threshold(threshold),` This connects the child instance's named port 'threshold' to parent expression 'threshold'. The connection is a physical net bundle after synthesis; direction is declared in the child module, and the membrane level at which a neuron emits a spike.

Line 48: `.surrogate_window(surrogate_window),` This connects the child instance's named port 'surrogate_window' to parent expression 'surrogate_window'. The connection is a physical net bundle after synthesis; direction is declared in the child module, and the value named 'surrogate window' in this block.

Line 49: `.clamp_minimum(clamp_minimum),` This connects the child instance's named port 'clamp_minimum' to parent expression 'clamp_minimum'. The connection is a physical net bundle after synthesis; direction is declared in the child module, and the value named 'clamp minimum' in this block.

Line 50: `.clamp_maximum(clamp_maximum),` This connects the child instance's named port 'clamp_maximum' to parent expression 'clamp_maximum'. The connection is a physical net bundle after synthesis; direction is declared in the child module, and the value named 'clamp maximum' in this block.

Line 51: `.output_valid(output_valid),` This connects the child instance's named port 'output_valid' to parent expression 'output_valid'. The connection is a physical net bundle after synthesis; direction is declared in the child module, and the producer's statement that its current payload is meaningful.

Line 52: `.output_ready(output_ready),` This connects the child instance's named port 'output_ready' to parent expression 'output_ready'. The connection is a physical net bundle after synthesis; direction is declared in the child module, and the consumer's statement that it can accept a payload this cycle.

Line 53: `.result(result),` This connects the child instance's named port 'result' to parent expression 'result'. The connection is a physical net bundle after synthesis; direction is declared in the child module, and the value named 'result' in this block.

Line 54: `.config_error(config_error)` This connects the child instance's named port 'config_error' to parent expression 'config_error'. The connection is a physical net bundle after synthesis; direction is declared in the child module, and the value named 'config error' in this block.

Line 55: `);` Within the module's structural declarations, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge vector alu RTL block in simulation. The expression is a literal or structural operator and has no hidden software state.

Line 57: `always #2.5 clk = ~clk;` Within the module's structural declarations, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge vector alu RTL block in simulation. The important operands are always: the value named 'always' in this block; clk: the clock that makes all registers advance together.

Line 59: `always @(posedge clk) begin` Within the module's structural declarations, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge vector alu RTL block in simulation. The important operands are always: the value named 'always' in this block; posedge: the value named 'posedge' in this block; clk: the clock that makes all registers advance together.

Line 60: `if (held_valid && (!output_valid || result !== held_result)) begin` This condition selects the following hardware branch only when 'held_valid && (!output_valid || result !== held_result)' is true. Both branches exist as gates; the condition controls a multiplexer rather than making software jump. The important operands are held_valid: the producer's statement that its current payload is meaningful; output_valid: the producer's statement that its current payload is meaningful; result: the value named 'result' in this block. Context: the module's structural declarations.

Line 61: `errors++;` Within the module's structural declarations, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge vector alu RTL block in simulation. The important operands are errors: the value named 'errors' in this block.

Line 62: `$display("ERROR vector ALU output changed while stalled");` This is a simulation check or diagnostic. It can stop a failing test and print evidence, but it is not part of the synthesized PYNQ circuit.

Line 63: `end` This structural keyword opens or closes the branch/process scope described as the module's structural declarations; it has no arithmetic value of its own.

Line 64: `held_valid <= output_valid && !output_ready;` This makes held_valid, the producer's statement that its current payload is meaningful, equal to 'output_valid && !output_ready'. It updates after the active clock edge together with other nonblocking assignments. The important operands are output_valid: the producer's statement that its current payload is meaningful; output_ready: the consumer's statement that it can accept a payload this cycle. Context: the module's structural declarations.

Line 65: `held_result <= result;` This makes held_result, the value named 'held result' in this block, equal to 'result'. It updates after the active clock edge together with other nonblocking assignments. The important operands are result: the value named 'result' in this block. Context: the module's structural declarations.

Line 66: `end` This structural keyword opens or closes the branch/process scope described as the module's structural declarations; it has no arithmetic value of its own.

Line 68: `initial begin` This opens simulation initialization. In a testbench it drives starting values and stimulus; project synthesis does not rely on this block as a replacement for explicit reset behavior.

Line 69: `$readmemh("tb/fixtures/vector_commands.mem", command_mem);` Within the module's structural declarations, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge vector alu RTL block in simulation. The important operands are readmemh: the value named 'readmemh' in this block; tb: the value named 'tb' in this block; fixtures: the value named 'fixtures' in this block.

Line 70: `$readmemh("tb/fixtures/vector_a.mem", operand_a_mem);` Within the module's structural declarations, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge vector alu RTL block in simulation. The important operands are readmemh: the value named 'readmemh' in this block; tb: the value named 'tb' in this block; fixtures: the value named 'fixtures' in this block.

Line 71: `$readmemh("tb/fixtures/vector_b.mem", operand_b_mem);` Within the module's structural declarations, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge vector alu RTL block in simulation. The important operands are readmemh: the value named 'readmemh' in this block; tb: the value named 'tb' in this block; fixtures: the value named 'fixtures' in this block.

Line 72: `$readmemh("tb/fixtures/vector_expected.mem", expected_mem);` Within the module's structural declarations, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge vector alu RTL block in simulation. The important operands are readmemh: the value named 'readmemh' in this block; tb: the value named 'tb' in this block; fixtures: the value named 'fixtures' in this block.

Line 74: `repeat (5) @(negedge clk);` Within the module's structural declarations, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge vector alu RTL block in simulation. The important operands are repeat: the value named 'repeat' in this block; negedge: the value named 'negedge' in this block; clk: the clock that makes all registers advance together.

Line 75: `rst_n = 1'b1;` This makes rst_n, the active-low synchronous reset, equal to '1'b1'. It is driven by combinational or procedural logic in the current evaluation. The important operands are b1: the value named 'b1' in this block. Context: the module's structural declarations.

Line 77: `for (int case_index = 0; case_index < CASES; case_index++) begin` This generate/procedural loop repeats the following operation across lanes or entries. In synthesizable RTL, a fixed loop is expanded into parallel or scheduled hardware rather than executed by a CPU. Context: the module's structural declarations.

Line 78: `logic [191:0] command;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, command is the 128-bit instruction selecting an engine, shape, mode, and numeric parameters. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 79: `command = command_mem[case_index];` This makes command, the 128-bit instruction selecting an engine, shape, mode, and numeric parameters, equal to 'command_mem[case_index]'. It is driven by combinational or procedural logic in the current evaluation. The important operands are command_mem: the 128-bit instruction selecting an engine, shape, mode, and numeric parameters; case_index: an integer selecting one tensor element, lane, bank, or state entry. Context: the module's structural declarations.

Line 80: `while (!input_ready) @(negedge clk);` Within the module's structural declarations, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge vector alu RTL block in simulation. The important operands are while: the value named 'while' in this block; input_ready: the consumer's statement that it can accept a payload this cycle; negedge: the value named 'negedge' in this block.

Line 81: `@(negedge clk);` Within the module's structural declarations, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge vector alu RTL block in simulation. The important operands are negedge: the value named 'negedge' in this block; clk: the clock that makes all registers advance together.

Line 82: `operation = command[3:0];` This makes operation, the value named 'operation' in this block, equal to 'command[3:0]'. It is driven by combinational or procedural logic in the current evaluation. The important operands are command: the 128-bit instruction selecting an engine, shape, mode, and numeric parameters. Context: the module's structural declarations.

Line 83: `multiplier_q15 = command[19:4];` This makes multiplier_q15, the value named 'multiplier q15' in this block, equal to 'command[19:4]'. It is driven by combinational or procedural logic in the current evaluation. The important operands are command: the 128-bit instruction selecting an engine, shape, mode, and numeric parameters. Context: the module's structural declarations.

Line 84: `right_shift = command[24:20];` This makes right_shift, the value named 'right shift' in this block, equal to 'command[24:20]'. It is driven by combinational or procedural logic in the current evaluation. The important operands are command: the 128-bit instruction selecting an engine, shape, mode, and numeric parameters. Context: the module's structural declarations.

Line 85: `output_zero_point = command[40:25];` This makes output_zero_point, the integer code representing real numeric zero in affine quantization, equal to ‘command[40:25]‘. It is driven by combinational or procedural logic in the current evaluation. The important operands are command: the 128-bit instruction selecting an engine, shape, mode, and numeric parameters. Context: the module’s structural declarations.

Line 86: `threshold = command[72:41];` This makes threshold, the membrane level at which a neuron emits a spike, equal to ‘command[72:41]‘. It is driven by combinational or procedural logic in the current evaluation. The important operands are command: the 128-bit instruction selecting an engine, shape, mode, and numeric parameters. Context: the module’s structural declarations.

Line 87: `surrogate_window = command[104:73];` This makes surrogate_window, the value named ’surrogate window’ in this block, equal to ‘command[104:73]‘. It is driven by combinational or procedural logic in the current evaluation. The important operands are command: the 128-bit instruction selecting an engine, shape, mode, and numeric parameters. Context: the module’s structural declarations.

Line 88: `clamp_minimum = command[136:105];` This makes clamp_minimum, the value named ’clamp minimum’ in this block, equal to ‘command[136:105]‘. It is driven by combinational or procedural logic in the current evaluation. The important operands are command: the 128-bit instruction selecting an engine, shape, mode, and numeric parameters. Context: the module’s structural declarations.

Line 89: `clamp_maximum = command[168:137];` This makes clamp_maximum, the value named ’clamp maximum’ in this block, equal to ‘command[168:137]‘. It is driven by combinational or procedural logic in the current evaluation. The important operands are command: the 128-bit instruction selecting an engine, shape, mode, and numeric parameters. Context: the module’s structural declarations.

Line 90: `operand_a = operand_a_mem[case_index];` This makes operand_a, the value named ’operand a’ in this block, equal to ‘operand_a_mem[case_index]‘. It is driven by combinational or procedural logic in the current evaluation. The important operands are operand_a_mem: local FPGA storage addressed by surrounding index logic; case_index: an integer selecting one tensor element, lane, bank, or state entry. Context: the module’s structural declarations.

Line 91: `operand_b = operand_b_mem[case_index];` This makes operand_b, the value named ’operand b’ in this block, equal to ‘operand_b_mem[case_index]‘. It is driven by combinational or procedural logic in the current evaluation. The important operands are operand_b_mem: local FPGA storage addressed by surrounding index logic; case_index: an integer selecting one tensor element, lane, bank, or state entry. Context: the module’s structural declarations.

Line 92: `input_valid = 1'b1;` This makes input_valid, the producer’s statement that its current payload is meaningful, equal to ‘1’b1‘. It is driven by combinational or procedural logic in the current evaluation. The important operands are b1: the value named ’b1’ in this block. Context: the module’s structural declarations.

Line 93: `@(posedge clk);` Within the module’s structural declarations, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge vector alu RTL block in simulation. The important operands are posedge: the value named ’posedge’ in this block; clk: the clock that makes all registers advance together.

Line 94: `@(negedge clk);` Within the module’s structural declarations, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge vector alu RTL block in simulation. The important operands are negedge: the value named ’negedge’ in this block; clk: the clock that makes all registers advance together.

Line 95: `input_valid = 1'b0;` This makes input_valid, the producer’s statement that its current payload is meaningful, equal to ‘1’b0‘. It is driven by combinational or procedural logic in the current evaluation. The important operands are b0: the value named ’b0’ in this block. Context: the module’s structural declarations.

Line 97: `while (!output_valid) @(negedge clk);` Within the module’s structural declarations, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge vector alu RTL block in simulation. The important operands are while: the value named ’while’ in this block; output_valid: the producer’s statement that its current payload is meaningful; negedge: the value named ’negedge’ in this block.

Line 98: `repeat (case_index % 5) @(negedge clk);` Within the module's structural declarations, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge vector alu RTL block in simulation. The important operands are repeat: the value named 'repeat' in this block; case_index: an integer selecting one tensor element, lane, bank, or state entry; negedge: the value named 'negedge' in this block.

Line 99: `if (!output_valid || config_error || result !== expected_mem[case_index]) begin` This condition selects the following hardware branch only when '!output_valid || config_error || result !== expected_mem[case_index]' is true. Both branches exist as gates; the condition controls a multiplexer rather than making software jump. The important operands are output_valid: the producer's statement that its current payload is meaningful; config_error: the value named 'config error' in this block; result: the value named 'result' in this block. Context: the module's structural declarations.

Line 100: `errors++;` Within the module's structural declarations, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge vector alu RTL block in simulation. The important operands are errors: the value named 'errors' in this block.

Line 101: `if (errors <= 20) begin` This statement continues through source line 102; the explanation uses the complete expression rather than only the first visual fragment. This condition selects the following hardware branch only when 'errors <= 20) begin $display("ERROR vector case=%0d op=%0d config=%0d", case_index, operation, config_error' is true. Both branches exist as gates; the condition controls a multiplexer rather than making software jump. The important operands are errors: the value named 'errors' in this block; display: the value named 'display' in this block; ERROR: the value named 'error' in this block. Context: the module's structural declarations.

Line 102: `$display("ERROR vector case=%0d op=%0d config=%0d", case_index, operation, config_error);` This is continuation line 2 of the 2-line logical statement that begins at source line 101. Its exact fragment is '$display("ERROR vector case=%0d op=%0d config=%0d", case_index, operation, config_error);'. The important operands are display: the value named 'display' in this block; ERROR: the value named 'error' in this block; vector: the value named 'vector' in this block. Read together, the complete operation is: This condition selects the following hardware branch only when 'errors <= 20) begin $display("ERROR vector case=%0d op=%0d config=%0d", case_index, operation, config_error' is true. Both branches exist as gates; the condition controls a multiplexer rather than making software jump. The important operands are errors: the value named 'errors' in this block; display: the value named 'display' in this block; ERROR: the value named 'error' in this block. Context: the module's structural declarations.

Line 103: `for (int lane = 0; lane < 8; lane++) begin` This generate/procedural loop repeats the following operation across lanes or entries. In synthesizable RTL, a fixed loop is expanded into parallel or scheduled hardware rather than executed by a CPU. Context: the module's structural declarations.

Line 104: `if (result[lane*32 +: 32] !== expected_mem[case_index][lane*32 +: 32]) begin` This condition selects the following hardware branch only when 'result[lane*32 +: 32] !== expected_mem[case_index][lane*32 +: 32]' is true. Both branches exist as gates; the condition controls a multiplexer rather than making software jump. The important operands are result: the value named 'result' in this block; lane: one parallel arithmetic element within a vector or tensor datapath; expected_mem: local FPGA storage addressed by surrounding index logic. Context: the module's structural declarations.

Line 105: `$display(" lane=%0d got=%0d expected=%0d", lane,` This is a simulation check or diagnostic. It can stop a failing test and print evidence, but it is not part of the synthesized PYNQ circuit.

Line 106: `$signed(result[lane*32 +: 32]),` Within the module's structural declarations, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge vector alu RTL block in simulation. The important operands are result: the value named 'result' in this block; lane: one parallel arithmetic element within a vector or tensor datapath.

Line 107: `$signed(expected_mem[case_index][lane*32 +: 32]));` Within the module's structural declarations, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge vector alu RTL block in simulation. The important operands are expected_mem: local FPGA storage addressed by surrounding index logic;

case_index: an integer selecting one tensor element, lane, bank, or state entry; lane: one parallel arithmetic element within a vector or tensor datapath.

Line 108: `end` This structural keyword opens or closes the branch/process scope described as the module's structural declarations; it has no arithmetic value of its own.

Line 109: `end` This structural keyword opens or closes the branch/process scope described as the module's structural declarations; it has no arithmetic value of its own.

Line 110: `end` This structural keyword opens or closes the branch/process scope described as the module's structural declarations; it has no arithmetic value of its own.

Line 111: `end` This structural keyword opens or closes the branch/process scope described as the module's structural declarations; it has no arithmetic value of its own.

Line 112: `checked++;` Within the module's structural declarations, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge vector alu RTL block in simulation. The important operands are checked: the value named 'checked' in this block.

Line 113: `output_ready = 1'b1;` This makes output_ready, the consumer's statement that it can accept a payload this cycle, equal to '1'b1'. It is driven by combinational or procedural logic in the current evaluation. The important operands are b1: the value named 'b1' in this block. Context: the module's structural declarations.

Line 114: `@(posedge clk);` Within the module's structural declarations, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge vector alu RTL block in simulation. The important operands are posedge: the value named 'posedge' in this block; clk: the clock that makes all registers advance together.

Line 115: `@(negedge clk);` Within the module's structural declarations, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge vector alu RTL block in simulation. The important operands are negedge: the value named 'negedge' in this block; clk: the clock that makes all registers advance together.

Line 116: `output_ready = 1'b0;` This makes output_ready, the consumer's statement that it can accept a payload this cycle, equal to '1'b0'. It is driven by combinational or procedural logic in the current evaluation. The important operands are b0: the value named 'b0' in this block. Context: the module's structural declarations.

Line 117: `end` This structural keyword opens or closes the branch/process scope described as the module's structural declarations; it has no arithmetic value of its own.

Line 119: `// Unsupported operations are visible as deterministic configuration errors.` Design intent: Unsupported operations are visible as deterministic configuration errors. This comment anchors the surrounding logic in the block that drives, backpressures, and checks the neuraedge vector alu RTL block in simulation.

Line 120: `while (!input_ready) @(negedge clk);` Within the module's structural declarations, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge vector alu RTL block in simulation. The important operands are while: the value named 'while' in this block; input_ready: the consumer's statement that it can accept a payload this cycle; negedge: the value named 'negedge' in this block.

Line 121: `@(negedge clk);` Within the module's structural declarations, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge vector alu RTL block in simulation. The important operands are negedge: the value named 'negedge' in this block; clk: the clock that makes all registers advance together.

Line 122: `operation = 4'hf;` This makes operation, the value named 'operation' in this block, equal to '4'hf'. It is driven by combinational or procedural logic in the current evaluation. The important operands are hf: the value named 'hf' in this block. Context: the module's structural declarations.

Line 123: `input_valid = 1'b1;` This makes input_valid, the producer's statement that its current payload is meaningful, equal to '1'b1'. It is driven by combinational or procedural logic in the current evaluation. The important operands are b1: the value named 'b1' in this block. Context: the module's structural declarations.

Line 124: `@(posedge clk);` Within the module's structural declarations, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge vector alu RTL block in simulation. The important operands are posedge: the value named 'posedge' in this block; clk: the clock that makes all registers advance together.

Line 125: `@(negedge clk);` Within the module's structural declarations, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge vector alu RTL block in simulation. The important operands are negedge: the value named 'negedge' in this block; clk: the clock that makes all registers advance together.

Line 126: `input_valid = 1'b0;` This makes input_valid, the producer's statement that its current payload is meaningful, equal to '1'b0'. It is driven by combinational or procedural logic in the current evaluation. The important operands are b0: the value named 'b0' in this block. Context: the module's structural declarations.

Line 127: `while (!output_valid) @(negedge clk);` Within the module's structural declarations, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge vector alu RTL block in simulation. The important operands are while: the value named 'while' in this block; output_valid: the producer's statement that its current payload is meaningful; negedge: the value named 'negedge' in this block.

Line 128: `if (!output_valid || !config_error || result != 0) begin` This condition selects the following hardware branch only when '!output_valid || !config_error || result != 0' is true. Both branches exist as gates; the condition controls a multiplexer rather than making software jump. The important operands are output_valid: the producer's statement that its current payload is meaningful; config_error: the value named 'config error' in this block; result: the value named 'result' in this block. Context: the module's structural declarations.

Line 129: `errors++;` Within the module's structural declarations, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge vector alu RTL block in simulation. The important operands are errors: the value named 'errors' in this block.

Line 130: `$display("ERROR vector ALU invalid opcode handling");` This is a simulation check or diagnostic. It can stop a failing test and print evidence, but it is not part of the synthesized PYNQ circuit.

Line 131: `end` This structural keyword opens or closes the branch/process scope described as the module's structural declarations; it has no arithmetic value of its own.

Line 132: `output_ready = 1'b1;` This makes output_ready, the consumer's statement that it can accept a payload this cycle, equal to '1'b1'. It is driven by combinational or procedural logic in the current evaluation. The important operands are b1: the value named 'b1' in this block. Context: the module's structural declarations.

Line 133: `@(posedge clk);` Within the module's structural declarations, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge vector alu RTL block in simulation. The important operands are posedge: the value named 'posedge' in this block; clk: the clock that makes all registers advance together.

Line 134: `@(negedge clk);` Within the module's structural declarations, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge vector alu RTL block in simulation. The important operands are negedge: the value named 'negedge' in this block; clk: the clock that makes all registers advance together.

Line 136: `if (errors != 0) begin` This condition selects the following hardware branch only when 'errors != 0' is true. Both branches exist as gates; the condition controls a multiplexer rather than making software jump. The important operands are errors: the value named 'errors' in this block. Context: the module's structural declarations.

Line 137: `$display("tb_neuraedge_vector_alu FAILED errors=%0d checked=%0d", errors, checked);` This is a simulation check or diagnostic. It can stop a failing test and print evidence, but it is not part of the synthesized PYNQ circuit.

Line 138: `$finish;` This is a simulation check or diagnostic. It can stop a failing test and print evidence, but it is not part of the synthesized PYNQ circuit.

Line 139: `end else begin` This structural keyword opens or closes the branch/process scope described as the module's structural declarations; it has no arithmetic value of its own.

Line 140: `$display("tb_neuraedge_vector_alu PASSED checked=%0d", checked);` This is a simulation check or diagnostic. It can stop a failing test and print evidence, but it is not part of the synthesized PYNQ circuit.

Line 141: `$finish;` This is a simulation check or diagnostic. It can stop a failing test and print evidence, but it is not part of the synthesized PYNQ circuit.

Line 142: `end` This structural keyword opens or closes the branch/process scope described as the module's structural declarations; it has no arithmetic value of its own.

Line 143: `end` This structural keyword opens or closes the branch/process scope described as the module's structural declarations; it has no arithmetic value of its own.

Line 145: `initial begin` This opens simulation initialization. In a testbench it drives starting values and stimulus; project synthesis does not rely on this block as a replacement for explicit reset behavior.

Line 146: `#500_000;` Within the module's structural declarations, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge vector alu RTL block in simulation. The expression is a literal or structural operator and has no hidden software state.

Line 147: `$fatal(1, "tb_neuraedge_vector_alu watchdog timeout");` This is a simulation check or diagnostic. It can stop a failing test and print evidence, but it is not part of the synthesized PYNQ circuit.

Line 148: `end` This structural keyword opens or closes the branch/process scope described as the module's structural declarations; it has no arithmetic value of its own.

Line 149: `endmodule` This closes the current hardware definition; no circuit behavior is attached to the keyword itself.

Line 151: `` `default_nettype wire `` This SystemVerilog preprocessor line controls compilation of the block that drives, backpressures, and checks the neuraedge vector alu RTL block in simulation.

61 tests/test_build_contract.py

Role in the complete system: checks build contract behavior independently with Python assertions.

61.1 Beginner architecture map

Dataflow responsibility This file's end-to-end responsibility is to checks build contract behavior independently with Python assertions.

Where it runs This is sequential host software. Python objects live in CPU memory; they become FPGA work only when the compiler packs a command or payload and the PYNQ driver transfers those bytes through AXI DMA or AXI-Lite.

Public structure Classes: PynqBuildContractTests. Functions: setUp, test_dma_accepts_a_complete_spikingformer_layer_pr test_accelerator_and_dma_address_map_is_stable, test_three_clock_domains_are_explicit, test_control_and_stream_ test_descriptor_rtl_is_packaged, test_deployment_artifacts_require_physical_acceptance. Each function annotation below names its enclosing function so an array operation is tied to the model, compiler, driver, test, or report phase that uses it.

Numeric and failure boundary Shapes, signedness, byte order, scaling, and saturation are part of the hardware contract. Validation exceptions are functional safety checks: rejecting malformed input before DMA is different from silently clipping, reshaping, or continuing with an incompatible artifact.

61.2 Complete source

```
"""Static checks for board-build settings that simulations cannot observe."""

from __future__ import annotations

61.3 Line annotations

Line 1: `"""Static checks for board-build settings that simulations cannot observe."""` This is executable documentation attached to the file whose role is to checks build contract behavior independently with Python assertions. It states the intended contract that tests and callers should enforce, but the text itself does not transform data or issue hardware work.

Line 3: `from __future__ import annotations` This imports the named Python API so the file whose role is to checks build contract behavior independently with Python assertions can use it explicitly. Imports execute on the host processor and create no FPGA hardware.

Line 5: `import re` This imports the named Python API so the file whose role is to checks build contract behavior independently with Python assertions can use it explicitly. Imports execute on the host processor and create no FPGA hardware.

Line 6: `import unittest` This imports the named Python API so the file whose role is to checks build contract behavior independently with Python assertions can use it explicitly. Imports execute on the host processor and create no FPGA hardware.

Line 7: `from pathlib import Path` This imports the named Python API so the file whose role is to checks build contract behavior independently with Python assertions can use it explicitly. Imports execute on the host processor and create no FPGA hardware.

Line 10: `ROOT = Path(__file__).resolve().parents[1]` This assigns ‘Path(___file___).resolve().parents[1]‘ to ‘ROOT ‘ in host memory. Here ROOT means the value named ’root’ in this block. The important operands are Path: the value named ’path’ in this block; ___file___: the value named ’file’ in this block; resolve: the value named ’resolve’ in this block. Context: the file whose role is to checks build contract behavior independently with Python assertions.

Line 13: `class PynqBuildContractTests(unittest.TestCase):` This defines class PynqBuildContractTests, which groups data and methods for pynq build contract tests. Instances exist in host memory and organize the flow that checks build contract behavior independently with Python assertions.

Line 14: `def setUp(self) -> None:` This starts function setUp. Its indented body performs set up as part of the file that checks build contract behavior independently with Python assertions; it runs only when called.

Line 15: `self.script = (ROOT / "scripts" / "build_pynq_full.tcl").read_text(` This statement continues through source line 16; the explanation uses the complete expression rather than only the first visual fragment. This assigns ‘(ROOT / "scripts" / "build_pynq_full.tcl").read_text(encoding="ascii")‘ to ‘self.script ‘ in host memory. Here script means the value named ’script’ in this block. The important operands are ROOT: the value named ’root’ in this block; scripts: the value named ’scripts’ in this block; build_pynq_full: the value named ’build pynq full’ in this block. Context: the function setUp, which handles set up.

Line 16: `encoding="ascii")` This is continuation line 2 of the 2-line logical statement that begins at source line 15. Its exact fragment is ‘encoding="ascii")‘. The important operands are encoding: the value named ’encoding’ in this block; ascii: the value named ’ascii’ in this block. Read together, the complete operation is: This assigns ‘(ROOT / "scripts" / "build_pynq_full.tcl").read_text(encoding="ascii")‘ to ‘self.script ‘ in host memory. Here script means the value named ’script’ in this block. The important operands are ROOT: the value named ’root’ in this block; scripts: the value named ’scripts’ in this block; build_pynq_full: the value named ’build pynq full’ in this block. Context: the function setUp, which handles set up.

Line 18: `def test_dma_accepts_a_complete_spikingformer_layer_program(self) -> None:` This starts function test_dma_accepts_a_complete_spikingformer_layer_program. Its indented body performs test dma accepts a complete spikingformer layer program as part of the file that checks build contract behavior independently with Python assertions; it runs only when called.

Line 19: `match = re.search(r"CONFIG\.c_sg_length_width\s+\{(\d+)\}", self.script)` This assigns ‘re.search(r"CONFI self.script)‘ to ‘match ‘ in host memory. Here match means the value named ’match’ in this block. The important operands are re: the value named ’re’ in this block; search: the value named ’search’ in this block; r: the value named ’r’ in this block. Context: the function test_dma_accepts_a_complete_spikingformer_layer_program, which handles test dma accepts a complete spikingformer layer program.

Line 20: `self.assertIsNotNone(match, "AXI DMA length width must be explicit")` This calls ‘self.assertIsNotNone‘ with ‘match, "AXI DMA length width must be explicit"‘ inside the function test_dma_accepts_a_complete_spikingformer_layer_p which handles test dma accepts a complete spikingformer layer program. The call advances the host-side job that checks build contract behavior independently with Python assertions.

Line 21: `self.assertEqual(int(match.group(1)), 26)` This calls ‘self.assertEqual‘ with ‘int(match.group(1)), 26‘ inside the function test_dma_accepts_a_complete_spikingformer_layer_program, which handles test dma accepts a complete spikingformer layer program. The call advances the host-side job that checks build contract behavior independently with Python assertions.

Line 22: `self.assertGreater((1 << int(match.group(1))) - 1, 43_300_000)` This calls ‘self.assertGreater‘ with ‘(1 << int(match.group(1))) - 1, 43_300_000‘ inside the function test_dma_accepts_a_complete_spikingformer_layer_program, which handles test dma accepts a complete spikingformer layer program. The call advances the host-side job that checks build contract behavior independently with Python assertions.

Line 24: `def test_accelerator_and_dma_address_map_is_stable(self) -> None:` This starts function test_accelerator_an Its indented body performs test accelerator and dma address map is stable as part of the file that checks build contract behavior independently with Python assertions; it runs only when called.

Line 25: `self.assertIn("0x43C00000", self.script)` This calls ‘self.assertIn‘ with ‘"0x43C00000", self.script‘ inside the function test_accelerator_and_dma_address_map_is_stable, which handles test accelerator and dma address map is stable. The call advances the host-side job that checks build contract behavior independently with Python assertions.

Line 26: `self.assertIn("0x40400000", self.script)` This calls ‘self.assertIn‘ with ‘"0x40400000", self.script‘ inside the function test_accelerator_and_dma_address_map_is_stable, which handles test accelerator and dma address map is stable. The call advances the host-side job that checks build contract behavior independently with Python assertions.

Line 28: `def test_three_clock_domains_are_explicit(self) -> None:` This starts function test_three_clock_domains_ar Its indented body performs test three clock domains are explicit as part of the file that checks build contract behavior independently with Python assertions; it runs only when called.

Line 29: `expected_frequencies = {` This statement continues through source line 33; the explanation uses the complete expression rather than only the first visual fragment. This assigns ‘{ 0: "100.000000", 1: "125.000000", 2: "200.000000", }‘ to ‘expected_frequencies ‘ in host memory. Here expected_frequencies means the value named ’expected frequencies’ in this block. The expression is a literal or structural operator and has no hidden software state. Context: the function test_three_clock_domains_are_explicit, which handles test three clock domains are explicit.

Line 30: `0: "100.000000",` This is continuation line 2 of the 5-line logical statement that begins at source line 29. Its exact fragment is ‘0: "100.000000",‘. The expression is a literal or structural operator and has no hidden software state. Read together, the complete operation is: This assigns ‘{ 0: "100.000000", 1: "125.000000", 2: "200.000000", }‘ to ‘expected_frequencies ‘ in host memory. Here expected_frequencies means the value named ’expected frequencies’ in this block. The expression is a literal or structural operator and has no hidden software state. Context: the function test_three_clock_domains_are_explicit, which handles test three clock domains are explicit.

Line 31: `1: "125.000000",` This is continuation line 3 of the 5-line logical statement that begins at source line 29. Its exact fragment is ‘1: "125.000000",‘. The expression is a literal or structural operator and has no hidden software state. Read together, the complete operation is: This assigns ‘{ 0: "100.000000", 1: "125.000000", 2: "200.000000", }‘ to ‘expected_frequencies ‘ in host memory. Here expected_frequencies means the value named ’expected frequencies’ in this block. The expression is a literal or structural operator and has no hidden software state. Context: the function test_three_clock_domains_are_explicit, which handles test three clock domains are explicit.

Line 32: `2: "200.000000",` This is continuation line 4 of the 5-line logical statement that begins at source line 29. Its exact fragment is ‘2: "200.000000",‘. The expression is a literal or structural operator and has no hidden software state. Read together, the complete operation is: This assigns ‘{ 0: "100.000000", 1: "125.000000", 2: "200.000000", }‘ to ‘expected_frequencies ‘ in host memory. Here expected_frequencies means the value named ’expected frequencies’ in this block. The expression is a literal or structural operator and has no hidden software state. Context: the function test_three_clock_domains_are_explicit, which handles test three clock domains are explicit.

Line 33: `}` This is continuation line 5 of the 5-line logical statement that begins at source line 29. Its exact fragment is ‘}‘. The expression is a literal or structural operator and has no hidden software state. Read together, the complete operation is: This assigns ‘{ 0: "100.000000", 1: "125.000000", 2: "200.000000", }‘ to ‘expected_frequencies ‘ in host memory. Here expected_frequencies means the value named ’expected frequencies’ in this block. The expression is a literal or structural operator and has no hidden software state. Context: the function test_three_clock_domains_are_explicit, which handles test three clock domains are explicit.

Line 34: `for clock_index, frequency in expected_frequencies.items():` This iterates clock_index, frequency over ‘expected_frequencies.items()‘. Each iteration repeats the indented host operation, commonly once per layer, tile, timestep, or test case in the function test_three_clock_domains_are_explicit, which handles test three clock domains are explicit.

Line 35: `self.assertIn(` This statement continues through source line 39; the explanation uses the complete expression rather than only the first visual fragment. This calls ‘self.assertIn‘ with ‘ f"CONFIG.PCW_FPGA{clock_index}_PERIPHERA " f"{{{frequency}}}", self.script, ‘ inside the function test_three_clock_domains_are_explicit, which handles test three

clock domains are explicit. The call advances the host-side job that checks build contract behavior independently with Python assertions.

Line 36: `f"CONFIG.PCW_FPGA{clock_index}_PERIPHERAL_FREQMHZ "` This is continuation line 2 of the 5-line logical statement that begins at source line 35. Its exact fragment is ‘f"CONFIG.PCW_FPGA{clock_index}_PERIPHERAL_FREQMHZ "‘. The important operands are script: the value named ’script’ in this block; index: an integer selecting one tensor element, lane, bank, or state entry; file: the value named ’file’ in this block. Read together, the complete operation is: This calls ‘self.assertLess‘ with ‘ self.script.index("if {$hold_whs < 0.0}"), self.script.index("file copy -force $generated_bit"), "the accepted bitstream must be published only after timing gates", ‘ inside the function test_deployment_artifacts_require_physical_ac which handles test deployment artifacts require physical acceptance. The call advances the host-side job that checks build contract behavior independently with Python assertions.

Line 84: `"the accepted bitstream must be published only after timing gates",` This is continuation line 4 of the 5-line logical statement that begins at source line 81. Its exact fragment is ‘"the accepted bitstream must be published only after timing gates",‘. The important operands are the: the value named ’the’ in this block; accepted: the value named ’accepted’ in this block; bitstream: the value named ’bitstream’ in this block. Read together, the complete operation is: This calls ‘self.assertLess‘ with ‘ self.script.index("if {$hold_whs < 0.0}"), self.script.index("file copy -force $generated_bit"), "the accepted bitstream must be published only after timing gates", ‘ inside the function test_deployment_artifacts_require_physical_acceptance, which handles test deployment artifacts require physical acceptance. The call advances the host-side job that checks build contract behavior independently with Python assertions.

Line 85: `)` This is continuation line 5 of the 5-line logical statement that begins at source line 81. Its exact fragment is ‘)‘. The expression is a literal or structural operator and has no hidden software state. Read together, the complete operation is: This calls ‘self.assertLess‘ with ‘ self.script.index("if {$hold_whs < 0.0}"), self.script.index("file copy -force $generated_bit"), "the accepted bitstream must be published only after timing gates", ‘ inside the function test_deployment_artifacts_require_physical_acceptance, which handles test deployment artifacts require physical acceptance. The call advances the host-side job that checks build contract behavior independently with Python assertions.

Line 88: `if __name__ == "__main__":` This executes the following indented host-code branch only when ‘___name___ == "___main___"‘ is true. The important operands are ___name___: the value named ’name’ in this block; ___main___: the value named ’main’ in this block. Context: the file whose role is to checks build contract behavior independently with Python assertions.

Line 89: `unittest.main()` This calls ‘unittest.main‘ with “ inside the file whose role is to checks build contract behavior independently with Python assertions. The call advances the host-side job that checks build contract behavior independently with Python assertions.

62 tests/test_debug_report.py

Role in the complete system: checks debug report behavior independently with Python assertions.

62.1 Beginner architecture map

Dataflow responsibility This file's end-to-end responsibility is to checks debug report behavior independently with Python assertions.

Where it runs This is sequential host software. Python objects live in CPU memory; they become FPGA work only when the compiler packs a command or payload and the PYNQ driver transfers those bytes through AXI DMA or AXI-Lite.

Public structure Classes: DebugReportTests. Functions: test_vcd_parser_keeps_exact_fsm_state_ahead_of_clear_state, test_final_vivado_report_parsers_recover_verified_metrics. Each function annotation below names its enclosing function so an array operation is tied to the model, compiler, driver, test, or report phase that uses it.

Numeric and failure boundary Shapes, signedness, byte order, scaling, and saturation are part of the hardware contract. Validation exceptions are functional safety checks: rejecting malformed input before DMA is different from silently clipping, reshaping, or continuing with an incompatible artifact.

62.3 Line annotations

Line 1: `from __future__ import annotations` This imports the named Python API so the file whose role is to checks debug report behavior independently with Python assertions can use it explicitly. Imports execute on the host processor and create no FPGA hardware.

Line 3: `import tempfile` This imports the named Python API so the file whose role is to checks debug report behavior independently with Python assertions can use it explicitly. Imports execute on the host processor and create no FPGA hardware.

Line 4: `import unittest` This imports the named Python API so the file whose role is to checks debug report behavior independently with Python assertions can use it explicitly. Imports execute on the host processor and create no FPGA hardware.

Line 5: `from pathlib import Path` This imports the named Python API so the file whose role is to checks debug report behavior independently with Python assertions can use it explicitly. Imports execute on the host processor and create no FPGA hardware.

Line 7: `from generate_debug_report import (` This statement continues through source line 16; the explanation uses the complete expression rather than only the first visual fragment. This imports the named Python API so the file whose role is to checks debug report behavior independently with Python assertions can use it explicitly. Imports execute on the host processor and create no FPGA hardware.

Line 8: `choose_wave_signals,` This is continuation line 2 of the 10-line logical statement that begins at source line 7. Its exact fragment is ‘choose_wave_signals,‘. The important operands are choose_wave_signals: the value named ’choose wave signals’ in this block. Read together, the complete operation is: This imports the named Python API so the file whose role is to checks debug report behavior independently with Python assertions can use it explicitly. Imports execute on the host processor and create no FPGA hardware.

Line 9: `parse_cdc_summary,` This is continuation line 3 of the 10-line logical statement that begins at source line 7. Its exact fragment is ‘parse_cdc_summary,‘. The important operands are parse_cdc_summary: the value named ’parse

cdc summary' in this block. Read together, the complete operation is: This imports the named Python API so the file whose role is to checks debug report behavior independently with Python assertions can use it explicitly. Imports execute on the host processor and create no FPGA hardware.

Line 10: `parse_clock_timing,` This is continuation line 4 of the 10-line logical statement that begins at source line 7. Its exact fragment is 'parse_clock_timing,'. The important operands are parse_clock_timing: the value named 'parse clock timing' in this block. Read together, the complete operation is: This imports the named Python API so the file whose role is to checks debug report behavior independently with Python assertions can use it explicitly. Imports execute on the host processor and create no FPGA hardware.

Line 11: `parse_drc_summary,` This is continuation line 5 of the 10-line logical statement that begins at source line 7. Its exact fragment is 'parse_drc_summary,'. The important operands are parse_drc_summary: the value named 'parse drc summary' in this block. Read together, the complete operation is: This imports the named Python API so the file whose role is to checks debug report behavior independently with Python assertions can use it explicitly. Imports execute on the host processor and create no FPGA hardware.

Line 12: `parse_implementation_summary,` This is continuation line 6 of the 10-line logical statement that begins at source line 7. Its exact fragment is 'parse_implementation_summary,'. The important operands are parse_implementation_summar the value named 'parse implementation summary' in this block. Read together, the complete operation is: This imports the named Python API so the file whose role is to checks debug report behavior independently with Python assertions can use it explicitly. Imports execute on the host processor and create no FPGA hardware.

Line 13: `parse_power_report,` This is continuation line 7 of the 10-line logical statement that begins at source line 7. Its exact fragment is 'parse_power_report,'. The important operands are parse_power_report: the value named 'parse power report' in this block. Read together, the complete operation is: This imports the named Python API so the file whose role is to checks debug report behavior independently with Python assertions can use it explicitly. Imports execute on the host processor and create no FPGA hardware.

Line 14: `parse_utilization_hierarchy,` This is continuation line 8 of the 10-line logical statement that begins at source line 7. Its exact fragment is 'parse_utilization_hierarchy,'. The important operands are parse_utilization_hierarchy: the value named 'parse utilization hierarchy' in this block. Read together, the complete operation is: This imports the named Python API so the file whose role is to checks debug report behavior independently with Python assertions can use it explicitly. Imports execute on the host processor and create no FPGA hardware.

Line 15: `parse_vcd,` This is continuation line 9 of the 10-line logical statement that begins at source line 7. Its exact fragment is 'parse_vcd,'. The important operands are parse_vcd: the value named 'parse vcd' in this block. Read together, the complete operation is: This imports the named Python API so the file whose role is to checks debug report behavior independently with Python assertions can use it explicitly. Imports execute on the host processor and create no FPGA hardware.

Line 16: `)` This is continuation line 10 of the 10-line logical statement that begins at source line 7. Its exact fragment is ')'. The expression is a literal or structural operator and has no hidden software state. Read together, the complete operation is: This imports the named Python API so the file whose role is to checks debug report behavior independently with Python assertions can use it explicitly. Imports execute on the host processor and create no FPGA hardware.

Line 19: `class DebugReportTests(unittest.TestCase):` This defines class DebugReportTests, which groups data and methods for debug report tests. Instances exist in host memory and organize the flow that checks debug report behavior independently with Python assertions.

Line 20: `def test_vcd_parser_keeps_exact_fsm_state_ahead_of_clear_state(self) -> None:` This starts function test_vcd_parser_keeps_exact_fsm_state_ahead_of_clear_state. Its indented body performs test vcd parser keeps exact fsm state ahead of clear state as part of the file that checks debug report behavior independently with Python assertions; it runs only when called.

Line 21: `fixture = """$timescale 1ps $end` This statement continues through source line 40; the explanation uses the complete expression rather than only the first visual fragment. This assigns ‘"""$timescale 1ps $end $scope module top $end $var reg 1 ! clk $end $var reg 1 \" clear_state $end $scope module dut $end $var reg 3 # state [2:0] $end $var reg 1 $ program_active $end $upscope $end $upscope $end $enddefinitions $end #0 0! 0\" b0 # 0$ #5 1! b1 # 1$ """‘ to ‘fixture ‘ in host memory. Here fixture means the value named ’fixture’ in this block. The important operands are timescale: the real-value spacing represented by one quantized integer step; scope: the value named ’scope’ in this block; module: the value named ’module’ in this block. Context: the function test_vcd_parser_keeps_exact_fsm_state_ahead_of_clear_state, which handles test vcd parser keeps exact fsm state ahead of clear state.

Line 22: `$scope module top $end` This is continuation line 2 of the 20-line logical statement that begins at source line 21. Its exact fragment is ‘$scope module top $end‘. The important operands are scope: the value named ’scope’ in this block; module: the value named ’module’ in this block; top: the value named ’top’ in this block. Read together, the complete operation is: This assigns ‘"""$timescale 1ps $end $scope module top $end $var reg 1 ! clk $end $var reg 1 \" clear_state $end $scope module dut $end $var reg 3 # state [2:0] $end $var reg 1 $ program_active $end $upscope $end $upscope $end $enddefinitions $end #0 0! 0\" b0 # 0$ #5 1! b1 # 1$ """‘ to ‘fixture ‘ in host memory. Here fixture means the value named ’fixture’ in this block. The important operands are timescale: the real-value spacing represented by one quantized integer step; scope: the value named ’scope’ in this block; module: the value named ’module’ in this block. Context: the function test_vcd_parser_keeps_exact_fsm_state_ahead_of_clear_state, which handles test vcd parser keeps exact fsm state ahead of clear state.

Line 23: `$var reg 1 ! clk $end` This is continuation line 3 of the 20-line logical statement that begins at source line 21. Its exact fragment is ‘$var reg 1 ! clk $end‘. The important operands are var: the value named ’var’ in this block; reg: the value named ’reg’ in this block; clk: the clock that makes all registers advance together. Read together, the complete operation is: This assigns ‘"""$timescale 1ps $end $scope module top $end $var reg 1 ! clk $end $var reg 1 \" clear_state $end $scope module dut $end $var reg 3 # state [2:0] $end $var reg 1 $ program_active $end $upscope $end $upscope $end $enddefinitions $end #0 0! 0\" b0 # 0$ #5 1! b1 # 1$ """‘ to ‘fixture ‘ in host memory. Here fixture means the value named ’fixture’ in this block. The important operands are timescale: the real-value spacing represented by one quantized integer step; scope: the value named ’scope’ in this block; module: the value named ’module’ in this block. Context: the function test_vcd_parser_keeps_exact_fsm_state_ahead_of_clear_state, which handles test vcd parser keeps exact fsm state ahead of clear state.

Line 24: `$var reg 1 \" clear_state $end` This is continuation line 4 of the 20-line logical statement that begins at source line 21. Its exact fragment is ‘$var reg 1 \" clear_state $end‘. The important operands are var: the value named ’var’ in this block; reg: the value named ’reg’ in this block; clear_state: the finite-state-machine phase retained in flip-flops. Read together, the complete operation is: This assigns ‘"""$timescale 1ps $end $scope module top $end $var reg 1 ! clk $end $var reg 1 \" clear_state $end $scope module dut $end $var reg 3 # state [2:0] $end $var reg 1 $ program_active $end $upscope $end $upscope $end $enddefinitions $end #0 0! 0\" b0 # 0$ #5 1! b1 # 1$ """‘ to ‘fixture ‘ in host memory. Here fixture means the value named ’fixture’ in this block. The important operands are timescale: the real-value spacing represented by one quantized integer step; scope: the value named ’scope’ in this block; module: the value named ’module’ in this block. Context: the function test_vcd_parser_keeps_exact_fsm_state_ahead_of_clear_state, which handles test vcd parser keeps exact fsm state ahead of clear state.

Line 25: `$scope module dut $end` This is continuation line 5 of the 20-line logical statement that begins at source line 21. Its exact fragment is ‘$scope module dut $end‘. The important operands are scope: the value named ’scope’ in this block; module: the value named ’module’ in this block; dut: the value named ’dut’ in this block. Read together, the complete operation is: This assigns ‘"""$timescale 1ps $end $scope module top $end $var reg 1 ! clk $end $var reg 1 \" clear_state $end $scope module dut $end $var reg 3 # state [2:0] $end $var reg 1 $ program_active $end $upscope $end $upscope $end $enddefinitions $end #0 0! 0\" b0 # 0$ #5 1! b1 # 1$ """‘ to ‘fixture ‘ in host memory. Here fixture means the value named ’fixture’ in this block. Context: the function test_vcd_parser_keeps_exact_fsm_state_ahead_of_clear_state, which handles test vcd parser keeps exact fsm state ahead of clear state.

Line 41: `with tempfile.TemporaryDirectory() as temporary_directory:` This opens a managed resource scope for ‘tempfile.TemporaryDirectory() as temporary_directory‘ so files, tracing, or temporary state are finalized even if the function test_vcd_parser_keeps_exact_fsm_state_ahead_of_clear_state, which handles test vcd parser keeps exact fsm state ahead of clear state raises an error.

Line 42: `path = Path(temporary_directory) / "fixture.vcd"` This assigns ‘Path(temporary_directory) / "fixture.vcd"‘ to ‘path ‘ in host memory. Here path means the value named ’path’ in this block. The important operands are Path: the value named ’path’ in this block; temporary_directory: the value named ’temporary directory’ in this block; fixture: the value named ’fixture’ in this block. Context: the function test_vcd_parser_keeps_exact_fsm_state_ahead_of_clear_sta which handles test vcd parser keeps exact fsm state ahead of clear state.

Line 43: `path.write_text(fixture, encoding="utf-8")` This calls ‘path.write_text‘ with ‘fixture, encoding="utf-8"‘ inside the function test_vcd_parser_keeps_exact_fsm_state_ahead_of_clear_state, which handles test vcd parser keeps exact fsm state ahead of clear state. The call advances the host-side job that checks debug report behavior independently with Python assertions.

Line 44: `timescale, signals = parse_vcd(path)` This assigns ‘parse_vcd(path)‘ to ‘timescale, signals ‘ in host memory. Here timescale means the real-value spacing represented by one quantized integer step. The important operands are parse_vcd: the value named ’parse vcd’ in this block; path: the value named ’path’ in this block. Context: the function test_vcd_parser_keeps_exact_fsm_state_ahead_of_clear_state, which handles test vcd parser keeps exact fsm state ahead of clear state.

Line 46: `selected = choose_wave_signals(signals)` This assigns ‘choose_wave_signals(signals)‘ to ‘selected ‘ in host memory. Here selected means the value named ’selected’ in this block. The important operands are choose_wave_signals: the value named ’choose wave signals’ in this block; signals: the value named ’signals’ in this block. Context: the function test_vcd_parser_keeps_exact_fsm_state_ahead_of_clear_state, which handles test vcd parser keeps exact fsm state ahead of clear state.

Line 47: `leaves = [signal.name.rsplit("/", 1)[-1] for signal in selected]` This assigns ‘[signal.name.rsplit("/", 1)[-1] for signal in selected]‘ to ‘leaves ‘ in host memory. Here leaves means the value named ’leaves’ in this block. The important operands are signal: the value named ’signal’ in this block; name: the value named ’name’ in this block; rsplit: the value named ’rsplit’ in this block. Context: the function test_vcd_parser_keeps_exact_fsm_state_ahead_of_clear_state, which handles test vcd parser keeps exact fsm state ahead of clear state.

Line 48: `self.assertEqual(timescale, "1ps")` This calls ‘self.assertEqual‘ with ‘timescale, "1ps"‘ inside the function test_vcd_parser_keeps_exact_fsm_state_ahead_of_clear_state, which handles test vcd parser keeps exact fsm state ahead of clear state. The call advances the host-side job that checks debug report behavior independently with Python assertions.

Line 49: `self.assertIn("state", leaves)` This calls ‘self.assertIn‘ with ‘"state", leaves‘ inside the function test_vcd_parser_k which handles test vcd parser keeps exact fsm state ahead of clear state. The call advances the host-side job that checks debug report behavior independently with Python assertions.

Line 50: `self.assertIn("program_active", leaves)` This calls ‘self.assertIn‘ with ‘"program_active", leaves‘ inside the function test_vcd_parser_keeps_exact_fsm_state_ahead_of_clear_state, which handles test vcd parser keeps exact fsm state ahead of clear state. The call advances the host-side job that checks debug report behavior independently with Python assertions.

Line 51: `self.assertNotIn("clear_state", leaves)` This calls ‘self.assertNotIn‘ with ‘"clear_state", leaves‘ inside the function test_vcd_parser_keeps_exact_fsm_state_ahead_of_clear_state, which handles test vcd parser keeps exact fsm state ahead of clear state. The call advances the host-side job that checks debug report behavior independently with Python assertions.

Line 52: `self.assertEqual(signals["/top/dut/state"].transitions[-1], (5, 1.0))` This calls ‘self.assertEqual‘ with ‘signals["/top/dut/state"].transitions[-1], (5, 1.0)‘ inside the function test_vcd_parser_keeps_exact_fsm_state_ahead_of_cle which handles test vcd parser keeps exact fsm state ahead of clear state. The call advances the host-side job that checks debug report behavior independently with Python assertions.

Line 54: `def test_final_vivado_report_parsers_recover_verified_metrics(self) -> None:` This starts function test_final_vivado_report_parsers_recover_verified_metrics. Its indented body performs test final vivado report parsers recover verified metrics as part of the file that checks debug report behavior independently with Python assertions; it runs only when called.

Line 55: `root = Path(__file__).resolve().parents[1]` This assigns ‘Path(___file___).resolve().parents[1]‘ to ‘root ‘ in host memory. Here root means the value named ’root’ in this block. The important operands are Path: the value named ’path’ in this block; ___file___: the value named ’file’ in this block; resolve: the value named ’resolve’ in this block. Context: the function test_final_vivado_report_parsers_recover_verified_metrics, which handles test final vivado report parsers recover verified metrics.

Line 56: `reports = root / "outputs" / "pynq_full"` This assigns ‘root / "outputs" / "pynq_full"‘ to ‘reports ‘ in host memory. Here reports means the value named ’reports’ in this block. The important operands are root: the value named ’root’ in this block; outputs: the value named ’outputs’ in this block; pynq_full: the value named ’pynq full’ in this block. Context: the function test_final_vivado_report_parsers_recover_verified_metrics, which handles test final vivado report parsers recover verified metrics.

Line 57: `implementation = parse_implementation_summary(` This statement continues through source line 59; the explanation uses the complete expression rather than only the first visual fragment. This assigns ‘parse_implementation_summary(reports / "full_implementation_summary.txt")‘ to ‘implementation ‘ in host memory. Here implementation means the value named ’implementation’ in this block. The important operands are parse_implementation_summary: the value named ’parse implementation summary’ in this block; reports: the value named ’reports’ in this block; full_implementation_summar the value named ’full implementation summary’ in this block. Context: the function test_final_vivado_report_parsers_recover_ver which handles test final vivado report parsers recover verified metrics.

Line 58: `reports / "full_implementation_summary.txt"` This is continuation line 2 of the 3-line logical statement that begins at source line 57. Its exact fragment is ‘reports / "full_implementation_summary.txt"‘. The important operands are reports: the value named ’reports’ in this block; full_implementation_summary: the value named ’full implementation summary’ in this block; txt: the value named ’txt’ in this block. Read together, the complete operation is: This assigns ‘parse_implementation_summary(reports / "full_implementation_summary.txt")‘ to ‘implementation ‘ in host memory. Here implementation means the value named ’implementation’ in this block. The important operands are parse_implementation_summary: the value named ’parse implementation summary’ in this block; reports: the value named ’reports’ in this block; full_implementation_summary: the value named ’full implementation summary’ in this block. Context: the function test_final_vivado_report_parsers_recover_verified_metrics, which handles test final vivado report parsers recover verified metrics.

Line 59: `)` This is continuation line 3 of the 3-line logical statement that begins at source line 57. Its exact fragment is ‘)‘. The expression is a literal or structural operator and has no hidden software state. Read together, the complete operation is: This assigns ‘parse_implementation_summary(reports / "full_implementation_summary.txt")‘ to ‘implementation ‘ in host memory. Here implementation means the value named ’implementation’ in this block. The important operands are parse_implementation_summary: the value named ’parse implementation summary’ in this block; reports: the value named ’reports’ in this block; full_implementation_summary: the value named ’full implementation summary’ in this block. Context: the function test_final_vivado_report_parsers_recover_verified_metrics, which handles test final vivado report parsers recover verified metrics.

Line 60: `clocks = parse_clock_timing(reports / "full_routed_timing_summary.rpt")` This assigns ‘parse_clock_timing / "full_routed_timing_summary.rpt")‘ to ‘clocks ‘ in host memory. Here clocks means the value named ’clocks’ in this block. The important operands are parse_clock_timing: the value named ’parse clock timing’ in this block; reports: the value named ’reports’ in this block; full_routed_timing_summary: the value named ’full routed timing summary’ in this block. Context: the function test_final_vivado_report_parsers_recover_verified_metrics, which handles test final vivado report parsers recover verified metrics.

Line 61: `utilization = parse_utilization_hierarchy(` This statement continues through source line 63; the explanation uses the complete expression rather than only the first visual fragment. This assigns ‘parse_utilization_hierarchy(reports / "full_routed_utilization_hierarchical.rpt")‘ to ‘utilization ‘ in host memory. Here utilization means the value named ’utilization’ in this block. The important operands are parse_utilization_hierarchy: the value named ’parse utilization hierarchy’ in this block; reports: the value named ’reports’ in this block; full_routed_utilization_hierarchical: the value named ’full routed utilization hierarchical’ in this block. Context: the function test_final_vivado_report_parsers_recover_ver which handles test final vivado report parsers recover verified metrics.

Line 62: `reports / "full_routed_utilization_hierarchical.rpt"` This is continuation line 2 of the 3-line logical statement that begins at source line 61. Its exact fragment is ‘reports / "full_routed_utilization_hierarchical.rpt"‘. The important operands are reports: the value named ’reports’ in this block; full_routed_utilization_hierarchical: the value named ’full routed utilization hierarchical’ in this block; rpt: the value named ’rpt’ in this block. Read together, the complete operation is: This assigns ‘parse_utilization_hierarchy(reports / "full_routed_utilization_hierarchical.rpt")‘ to ‘utilization ‘ in host memory. Here utilization means the value named ’utilization’ in this block. The important operands are parse_utilization_hierarchy: the value named ’parse utilization hierarchy’ in this block; reports: the value named ’reports’ in this block; full_routed_utilization_hierarchical: the value named ’full routed utilization hierarchical’ in this block. Context: the function test_final_vivado_report_parsers_recover_verified_metrics, which handles test final vivado report parsers recover verified metrics.

Line 63: `)` This is continuation line 3 of the 3-line logical statement that begins at source line 61. Its exact fragment is ‘)‘. The expression is a literal or structural operator and has no hidden software state. Read together, the

complete operation is: This assigns ‘parse_utilization_hierarchy(reports / "full_routed_utilization_hierarchical.rpt")‘ to ‘utilization ‘ in host memory. Here utilization means the value named ’utilization’ in this block. The important operands are parse_utilization_hierarchy: the value named ’parse utilization hierarchy’ in this block; reports: the value named ’reports’ in this block; full_routed_utilization_hierarchical: the value named ’full routed utilization hierarchical’ in this block. Context: the function test_final_vivado_report_parsers_recover_verified_metrics, which handles test final vivado report parsers recover verified metrics.

Line 64: `drc = parse_drc_summary(reports / "full_drc.rpt")` This assigns ‘parse_drc_summary(reports / "full_drc.rpt")‘ to ‘drc ‘ in host memory. Here drc means the value named ’drc’ in this block. The important operands are parse_drc_summary: the value named ’parse drc summary’ in this block; reports: the value named ’reports’ in this block; full_drc: the value named ’full drc’ in this block. Context: the function test_final_vivado_report_parsers_recover_verified_metrics, which handles test final vivado report parsers recover verified metrics.

Line 65: `cdc = parse_cdc_summary(reports / "full_cdc.rpt")` This assigns ‘parse_cdc_summary(reports / "full_cdc.rpt")‘ to ‘cdc ‘ in host memory. Here cdc means the value named ’cdc’ in this block. The important operands are parse_cdc_summary: the value named ’parse cdc summary’ in this block; reports: the value named ’reports’ in this block; full_cdc: the value named ’full cdc’ in this block. Context: the function test_final_vivado_report_parsers_recover_verified_metrics, which handles test final vivado report parsers recover verified metrics.

Line 66: `power = parse_power_report(` This statement continues through source line 69; the explanation uses the complete expression rather than only the first visual fragment. This assigns ‘parse_power_report(root / "outputs" / "power_activity_full" / "vivado_reports" / "routed_saif_power.rpt")‘ to ‘power ‘ in host memory. Here power means the value named ’power’ in this block. The important operands are parse_power_report: the value named ’parse power report’ in this block; root: the value named ’root’ in this block; outputs: the value named ’outputs’ in this block. Context: the function test_final_vivado_report_parsers_recover_verified_metrics, which handles test final vivado report parsers recover verified metrics.

Line 67: `root / "outputs" / "power_activity_full" / "vivado_reports"` This is continuation line 2 of the 4-line logical statement that begins at source line 66. Its exact fragment is ‘root / "outputs" / "power_activity_full" / "vivado_reports"‘. The important operands are root: the value named ’root’ in this block; outputs: the value named ’outputs’ in this block; power_activity_full: the value named ’power activity full’ in this block. Read together, the complete operation is: This assigns ‘parse_power_report(root / "outputs" / "power_activity_full" / "vivado_reports" / "routed_saif_power.rpt")‘ to ‘power ‘ in host memory. Here power means the value named ’power’ in this block. The important operands are parse_power_report: the value named ’parse power report’ in this block; root: the value named ’root’ in this block; outputs: the value named ’outputs’ in this block. Context: the function test_final_vivado_report_parsers_recover_verified_metrics, which handles test final vivado report parsers recover verified metrics.

Line 68: `/ "routed_saif_power.rpt"` This is continuation line 3 of the 4-line logical statement that begins at source line 66. Its exact fragment is ‘/ "routed_saif_power.rpt"‘. The important operands are routed_saif_power: the value named ’routed saif power’ in this block; rpt: the value named ’rpt’ in this block. Read together, the complete operation is: This assigns ‘parse_power_report(root / "outputs" / "power_activity_full" / "vivado_reports" / "routed_saif_power.rpt")‘ to ‘power ‘ in host memory. Here power means the value named ’power’ in this block. The important operands are parse_power_report: the value named ’parse power report’ in this block; root: the value named ’root’ in this block; outputs: the value named ’outputs’ in this block. Context: the function test_final_vivado_report_parsers_recov which handles test final vivado report parsers recover verified metrics.

Line 69: `)` This is continuation line 4 of the 4-line logical statement that begins at source line 66. Its exact fragment is ‘)‘. The expression is a literal or structural operator and has no hidden software state. Read together, the complete operation is: This assigns ‘parse_power_report(root / "outputs" / "power_activity_full" / "vivado_reports" / "routed_saif_power.rpt")‘ to ‘power ‘ in host memory. Here power means the value named ’power’ in this block. The important operands are parse_power_report: the value named ’parse power report’ in this block; root: the value named ’root’ in this block; outputs: the value named ’outputs’ in this block. Context: the function test_final_vivado_report_parsers_recov which handles test final vivado report parsers recover verified metrics.

Line 71: `self.assertEqual(` This statement continues through source line 74; the explanation uses the complete expression rather than only the first visual fragment. This calls ‘self.assertEqual‘ with ‘ clocks["clk_fpga_2"], (implementation["setup_wns_ns"], implementation["hold_whs_ns"]), ‘ inside the function test_final_vivado_report_parsers_recover_verified_ which handles test final vivado report parsers recover verified metrics. The call advances the host-side job that checks debug report behavior independently with Python assertions.

Line 72: `clocks["clk_fpga_2"],` This is continuation line 2 of the 4-line logical statement that begins at source line 71. Its exact fragment is ‘clocks["clk_fpga_2"],‘. The important operands are clocks: the value named ’clocks’ in this block; clk_fpga_2: the clock that makes all registers advance together. Read together, the complete operation is: This calls ‘self.assertEqual‘ with ‘ clocks["clk_fpga_2"], (implementation["setup_wns_ns"], implementation["hold_whs_ns"]), ‘ inside the function test_final_vivado_report_parsers_recover_verified_metrics, which handles test final vivado report parsers recover verified metrics. The call advances the host-side job that checks debug report behavior independently with Python assertions.

Line 73: `(implementation["setup_wns_ns"], implementation["hold_whs_ns"]),` This is continuation line 3 of the 4-line logical statement that begins at source line 71. Its exact fragment is ‘(implementation["setup_wns_ns"], implementation["hold_whs_ns"]),‘. The important operands are implementation: the value named ’implementation’ in this block; setup_wns_ns: the value named ’setup wns ns’ in this block; hold_whs_ns: the value named ’hold whs ns’ in this block. Read together, the complete operation is: This calls ‘self.assertEqual‘ with ‘ clocks["clk_fpga_2"], (implementation["setup_wns_ns"], implementation["hold_whs_ns"]), ‘ inside the function test_final_vivado_report_parsers_recover_verified_ which handles test final vivado report parsers recover verified metrics. The call advances the host-side job that checks debug report behavior independently with Python assertions.

Line 74: `)` This is continuation line 4 of the 4-line logical statement that begins at source line 71. Its exact fragment is ‘)‘. The expression is a literal or structural operator and has no hidden software state. Read together, the complete operation is: This calls ‘self.assertEqual‘ with ‘ clocks["clk_fpga_2"], (implementation["setup_wns_ns"], implementation["hold_whs_ns"]), ‘ inside the function test_final_vivado_report_parsers_recover_verified_metrics, which handles test final vivado report parsers recover verified metrics. The call advances the host-side job that checks debug report behavior independently with Python assertions.

Line 75: `self.assertEqual(` This statement continues through source line 78; the explanation uses the complete expression rather than only the first visual fragment. This calls ‘self.assertEqual‘ with ‘ utilization["system_wrapper"]["dsp"], int(implementation["dsp48_count"]), ‘ inside the function test_final_vivado_report_parsers_recover_verified_metrics, which handles test final vivado report parsers recover verified metrics. The call advances the host-side job that checks debug report behavior independently with Python assertions.

Line 76: `utilization["system_wrapper"]["dsp"],` This is continuation line 2 of the 4-line logical statement that begins at source line 75. Its exact fragment is ‘utilization["system_wrapper"]["dsp"],‘. The important operands are utilization: the value named ’utilization’ in this block; system_wrapper: the value named ’system wrapper’ in this block; dsp: the value named ’dsp’ in this block. Read together, the complete operation is: This calls ‘self.assertEqual‘ with ‘ utilization["system_wrapper"]["dsp"], int(implementation["dsp48_count"]), ‘ inside the function test_final_vivado_report_parsers_recove which handles test final vivado report parsers recover verified metrics. The call advances the host-side job that checks debug report behavior independently with Python assertions.

Line 77: `int(implementation["dsp48_count"]),` This is continuation line 3 of the 4-line logical statement that begins at source line 75. Its exact fragment is ‘int(implementation["dsp48_count"]),‘. The important operands are implementation: the value named ’implementation’ in this block; dsp48_count: an integer count retained for control or measurable telemetry. Read together, the complete operation is: This calls ‘self.assertEqual‘ with ‘ utilization["system_wrapper"]["dsp"], int(implementation["dsp48_count"]), ‘ inside the function test_final_vivado_report_parsers_recove which handles test final vivado report parsers recover verified metrics. The call advances the host-side job that checks debug report behavior independently with Python assertions.

Line 78: `)` This is continuation line 4 of the 4-line logical statement that begins at source line 75. Its exact fragment is ‘)‘. The expression is a literal or structural operator and has no hidden software state. Read together, the complete operation is: This calls ‘self.assertEqual‘ with ‘ utilization["system_wrapper"]["dsp"], int(implementation["dsp48_count"]), ‘ inside the function test_final_vivado_report_parsers_recover_verified_metrics, which handles test final vivado report parsers

recover verified metrics. The call advances the host-side job that checks debug report behavior independently with Python assertions.

Line 79: `self.assertFalse(any(row[1] == "Error" for row in drc))` This calls ‘self.assertFalse‘ with ‘any(row[1] == "Error" for row in drc)‘ inside the function test_final_vivado_report_parsers_recover_verified_metrics, which handles test final vivado report parsers recover verified metrics. The call advances the host-side job that checks debug report behavior independently with Python assertions.

Line 80: `self.assertGreater(sum(row[3] for row in drc), 0)` This calls ‘self.assertGreater‘ with ‘sum(row[3] for row in drc), 0‘ inside the function test_final_vivado_report_parsers_recover_verified_metrics, which handles test final vivado report parsers recover verified metrics. The call advances the host-side job that checks debug report behavior independently with Python assertions.

Line 81: `self.assertTrue(any(row[0] == "CDC-15" for row in cdc))` This calls ‘self.assertTrue‘ with ‘any(row[0] == "CDC-15" for row in cdc)‘ inside the function test_final_vivado_report_parsers_recover_verified_metrics, which handles test final vivado report parsers recover verified metrics. The call advances the host-side job that checks debug report behavior independently with Python assertions.

Line 82: `self.assertGreater(power["total"], 0.0)` This calls ‘self.assertGreater‘ with ‘power["total"], 0.0‘ inside the function test_final_vivado_report_parsers_recover_verified_metrics, which handles test final vivado report parsers recover verified metrics. The call advances the host-side job that checks debug report behavior independently with Python assertions.

Line 83: `self.assertRegex(power["matched"], r"\d+%\s+\(\d+/\d+\)")` This calls ‘self.assertRegex‘ with ‘power["matched" r"\d+%\s+\(\d+/\d+\)"‘ inside the function test_final_vivado_report_parsers_recover_verified_metrics, which handles test final vivado report parsers recover verified metrics. The call advances the host-side job that checks debug report behavior independently with Python assertions.

Line 86: `if __name__ == "__main__":` This executes the following indented host-code branch only when ‘___name___ == "___main___"‘ is true. The important operands are ___name___: the value named ’name’ in this block; ___main___: the value named ’main’ in this block. Context: the file whose role is to checks debug report behavior independently with Python assertions.

Line 87: `unittest.main()` This calls ‘unittest.main‘ with “ inside the file whose role is to checks debug report behavior independently with Python assertions. The call advances the host-side job that checks debug report behavior independently with Python assertions.

63 tests/test_documentation_generator.py

Role in the complete system: checks documentation generator behavior independently with Python assertions.

63.1 Beginner architecture map

Dataflow responsibility This file's end-to-end responsibility is to checks documentation generator behavior independently with Python assertions.

Where it runs This is sequential host software. Python objects live in CPU memory; they become FPGA work only when the compiler packs a command or payload and the PYNQ driver transfers those bytes through AXI DMA or AXI-Lite.

Public structure Classes: DocumentationGeneratorTests. Functions: test_every_nonblank_source_line_is_covered_and_hash
test_rtl_context_returns_to_structure_after_clocked_process, test_multiline_statements_are_explained_as_complete_
Each function annotation below names its enclosing function so an array operation is tied to the model, compiler, driver, test, or report phase that uses it.

Numeric and failure boundary Shapes, signedness, byte order, scaling, and saturation are part of the hardware contract. Validation exceptions are functional safety checks: rejecting malformed input before DMA is different from silently clipping, reshaping, or continuing with an incompatible artifact.

```

63.3 Line annotations

Line 1: `from __future__ import annotations` This imports the named Python API so the file whose role is to checks documentation generator behavior independently with Python assertions can use it explicitly. Imports execute on the host processor and create no FPGA hardware.

Line 3: `import json` This imports the named Python API so the file whose role is to checks documentation generator behavior independently with Python assertions can use it explicitly. Imports execute on the host processor and create no FPGA hardware.

Line 4: `import tempfile` This imports the named Python API so the file whose role is to checks documentation generator behavior independently with Python assertions can use it explicitly. Imports execute on the host processor and create no FPGA hardware.

Line 5: `import unittest` This imports the named Python API so the file whose role is to checks documentation generator behavior independently with Python assertions can use it explicitly. Imports execute on the host processor and create no FPGA hardware.

Line 6: `from pathlib import Path` This imports the named Python API so the file whose role is to checks documentation generator behavior independently with Python assertions can use it explicitly. Imports execute on the host processor and create no FPGA hardware.

Line 8: `from generate_source_reference import (` This statement continues through source line 15; the explanation uses the complete expression rather than only the first visual fragment. This imports the named Python API so the file whose role is to checks documentation generator behavior independently with Python assertions can use it explicitly. Imports execute on the host processor and create no FPGA hardware.

Line 9: `generate,` This is continuation line 2 of the 8-line logical statement that begins at source line 8. Its exact fragment is ‘generate,‘. The important operands are generate: the value named ’generate’ in this block. Read together, the complete operation is: This imports the named Python API so the file whose role is to checks documentation generator behavior independently with Python assertions can use it explicitly. Imports execute on the host processor and create no FPGA hardware.

Line 10: `project_root,` This is continuation line 3 of the 8-line logical statement that begins at source line 8. Its exact fragment is 'project_root,'. The important operands are project_root: the value named 'project root' in this block. Read together, the complete operation is: This imports the named Python API so the file whose role is to checks documentation generator behavior independently with Python assertions can use it explicitly. Imports execute on the host processor and create no FPGA hardware.

Line 11: `python_statement_spans,` This is continuation line 4 of the 8-line logical statement that begins at source line 8. Its exact fragment is 'python_statement_spans,'. The important operands are python_statement_spans: the finite-state-machine phase retained in flip-flops. Read together, the complete operation is: This imports the named Python API so the file whose role is to checks documentation generator behavior independently with Python assertions can use it explicitly. Imports execute on the host processor and create no FPGA hardware.

Line 12: `source_entries,` This is continuation line 5 of the 8-line logical statement that begins at source line 8. Its exact fragment is 'source_entries,'. The important operands are source_entries: the value named 'source entries' in this block. Read together, the complete operation is: This imports the named Python API so the file whose role is to checks documentation generator behavior independently with Python assertions can use it explicitly. Imports execute on the host processor and create no FPGA hardware.

Line 13: `sv_contexts,` This is continuation line 6 of the 8-line logical statement that begins at source line 8. Its exact fragment is 'sv_contexts,'. The important operands are sv_contexts: the value named 'sv contexts' in this block. Read together, the complete operation is: This imports the named Python API so the file whose role is to checks documentation generator behavior independently with Python assertions can use it explicitly. Imports execute on the host processor and create no FPGA hardware.

Line 14: `sv_statement_spans,` This is continuation line 7 of the 8-line logical statement that begins at source line 8. Its exact fragment is 'sv_statement_spans,'. The important operands are sv_statement_spans: the finite-state-machine phase retained in flip-flops. Read together, the complete operation is: This imports the named Python API so the file whose role is to checks documentation generator behavior independently with Python assertions can use it explicitly. Imports execute on the host processor and create no FPGA hardware.

Line 15: `)` This is continuation line 8 of the 8-line logical statement that begins at source line 8. Its exact fragment is ')'. The expression is a literal or structural operator and has no hidden software state. Read together, the complete operation is: This imports the named Python API so the file whose role is to checks documentation generator behavior independently with Python assertions can use it explicitly. Imports execute on the host processor and create no FPGA hardware.

Line 18: `class DocumentationGeneratorTests(unittest.TestCase):` This defines class DocumentationGeneratorTests, which groups data and methods for documentation generator tests. Instances exist in host memory and organize the flow that checks documentation generator behavior independently with Python assertions.

Line 19: `def test_every_nonblank_source_line_is_covered_and_hashed(self) -> None:` This starts function test_every_nonblank_source_line_is_covered_and_hashed. Its indented body performs test every nonblank source line is covered and hashed as part of the file that checks documentation generator behavior independently with Python assertions; it runs only when called.

Line 20: `with tempfile.TemporaryDirectory() as temporary_directory:` This opens a managed resource scope for 'tempfile.TemporaryDirectory() as temporary_directory' so files, tracing, or temporary state are finalized even if the function test_every_nonblank_source_line_is_covered_and_hashed, which handles test every nonblank source line is covered and hashed raises an error.

Line 21: `tex_path, manifest_path = generate(Path(temporary_directory))` This assigns 'generate(Path(temporary_direc to 'tex_path, manifest_path ' in host memory. Here tex_path means the value named 'tex path' in this block. The important operands are generate: the value named 'generate' in this block; Path: the value named 'path' in this block; temporary_directory: the value named 'temporary directory' in this block. Context: the function test_every_nonblank_source_line_is_c which handles test every nonblank source line is covered and hashed.

Line 22: `manifest = json.loads(manifest_path.read_text(encoding="utf-8"))` This assigns ‘json.loads(manifest_path.rea 8"))‘ to ‘manifest ‘ in host memory. Here manifest means the value named ’manifest’ in this block. The important operands are json: the value named ’json’ in this block; loads: the value named ’loads’ in this block; manifest_path: the value named ’manifest path’ in this block. Context: the function test_every_nonblank_source_line_is_covered_and_hashed, which handles test every nonblank source line is covered and hashed.

Line 23: `entries = source_entries(project_root())` This assigns ‘source_entries(project_root())‘ to ‘entries ‘ in host memory. Here entries means the value named ’entries’ in this block. The important operands are source_entries: the value named ’source entries’ in this block; project_root: the value named ’project root’ in this block. Context: the function test_every_nonblank_source_line_is_covered_and_hashed, which handles test every nonblank source line is covered and hashed.

Line 25: `self.assertEqual(manifest["summary"]["file_count"], len(entries))` This calls ‘self.assertEqual‘ with ‘manifest["summary"]["file_count"], len(entries)‘ inside the function test_every_nonblank_source_line_is_covered_and_hash which handles test every nonblank source line is covered and hashed. The call advances the host-side job that checks documentation generator behavior independently with Python assertions.

Line 26: `self.assertEqual(` This statement continues through source line 29; the explanation uses the complete expression rather than only the first visual fragment. This calls ‘self.assertEqual‘ with ‘ manifest["summary"]["nonblank_lines"], manifest["summary"]["explained_nonblank_lines"], ‘ inside the function test_every_nonblank_source_line_is_covered_and_hashe which handles test every nonblank source line is covered and hashed. The call advances the host-side job that checks documentation generator behavior independently with Python assertions.

Line 27: `manifest["summary"]["nonblank_lines"],` This is continuation line 2 of the 4-line logical statement that begins at source line 26. Its exact fragment is ‘manifest["summary"]["nonblank_lines"],‘. The important operands are manifest: the value named ’manifest’ in this block; summary: the value named ’summary’ in this block; nonblank_lines: the value named ’nonblank lines’ in this block. Read together, the complete operation is: This calls ‘self.assertEqual‘ with ‘ manifest["summary"]["nonblank_lines"], manifest["summary"]["explained_nonblank_lines"], ‘ inside the function test_every_nonblank_source_line_is_covered_and_hashed, which handles test every nonblank source line is covered and hashed. The call advances the host-side job that checks documentation generator behavior independently with Python assertions.

Line 28: `manifest["summary"]["explained_nonblank_lines"],` This is continuation line 3 of the 4-line logical statement that begins at source line 26. Its exact fragment is ‘manifest["summary"]["explained_nonblank_lines"],‘. The important operands are manifest: the value named ’manifest’ in this block; summary: the value named ’summary’ in this block; explained_nonblank_lines: the value named ’explained nonblank lines’ in this block. Read together, the complete operation is: This calls ‘self.assertEqual‘ with ‘ manifest["summary"]["nonblank_lines"], manifest["summary"]["explained_nonblank_lines"], ‘ inside the function test_every_nonblank_source_line_is_covered_and_hashed, which handles test every nonblank source line is covered and hashed. The call advances the host-side job that checks documentation generator behavior independently with Python assertions.

Line 29: `)` This is continuation line 4 of the 4-line logical statement that begins at source line 26. Its exact fragment is ‘)‘. The expression is a literal or structural operator and has no hidden software state. Read together, the complete operation is: This calls ‘self.assertEqual‘ with ‘ manifest["summary"]["nonblank_lines"], manifest["summary"]["explained_nonblank_lines"], ‘ inside the function test_every_nonblank_source_line_is_covered_and_hashed, which handles test every nonblank source line is covered and hashed. The call advances the host-side job that checks documentation generator behavior independently with Python assertions.

Line 30: `self.assertTrue(tex_path.read_text(encoding="utf-8").endswith("\\end{document}\n"))` This calls ‘self.assertTrue‘ with ‘tex_path.read_text(encoding="utf-8").endswith("\\end{document}\n")‘ inside the function test_every_nonb which handles test every nonblank source line is covered and hashed. The call advances the host-side job that checks documentation generator behavior independently with Python assertions.

Line 31: `generated_tex = tex_path.read_text(encoding="utf-8")` This assigns ‘tex_path.read_text(encoding="utf-8")‘ to ‘generated_tex ‘ in host memory. Here generated_tex means the value named ’generated tex’ in this block. The

important operands are tex_path: the value named 'tex path' in this block; read_text: the value named 'read text' in this block; encoding: the value named 'encoding' in this block. Context: the function test_every_nonblank_source_line_is_covered_an
which handles test every nonblank source line is covered and hashed.

Line 32: `self.assertIn("Beginner architecture map", generated_tex)` This calls ‘self.assertIn‘ with ‘"Beginner architecture map", generated_tex‘ inside the function test_every_nonblank_source_line_is_covered_and_hashed, which handles test every nonblank source line is covered and hashed. The call advances the host-side job that checks documentation generator behavior independently with Python assertions.

Line 33: `self.assertIn("What becomes FPGA hardware", generated_tex)` This calls ‘self.assertIn‘ with ‘"What becomes FPGA hardware", generated_tex‘ inside the function test_every_nonblank_source_line_is_covered_and_hashed, which handles test every nonblank source line is covered and hashed. The call advances the host-side job that checks documentation generator behavior independently with Python assertions.

Line 34: `self.assertIn("Two unsigned byte weights", generated_tex)` This calls ‘self.assertIn‘ with ‘"Two unsigned byte weights", generated_tex‘ inside the function test_every_nonblank_source_line_is_covered_and_hashed, which handles test every nonblank source line is covered and hashed. The call advances the host-side job that checks documentation generator behavior independently with Python assertions.

Line 35: `listing_paths = [` This statement continues through source line 39; the explanation uses the complete expression rather than only the first visual fragment. This assigns ‘[line.removeprefix("\\lstinputlisting{").removesuffix("}") for line in generated_tex.splitlines() if line.startswith("\\lstinputlisting{")]‘ to ‘listing_paths ‘ in host memory. Here listing_paths means the value named 'listing paths' in this block. The important operands are line: the value named 'line' in this block; removeprefix: the value named 'removeprefix' in this block; lstinputlisting: the value named 'lstinputlisting' in this block. Context: the function test_every_nonblank_source_line_is_covered_and_hashed, which handles test every nonblank source line is covered and hashed.

Line 36: `line.removeprefix("\\lstinputlisting{").removesuffix("}")` This is continuation line 2 of the 5-line logical statement that begins at source line 35. Its exact fragment is ‘line.removeprefix("\\lstinputlisting{").removesuffix("}")‘. The important operands are line: the value named 'line' in this block; removeprefix: the value named 'removeprefix' in this block; lstinputlisting: the value named 'lstinputlisting' in this block. Read together, the complete operation is: This assigns ‘[line.removeprefix("\\lstinputlisting{").removesuffix("}") for line in generated_tex.splitlines() if line.startswith("\\lstinputlisting{")]‘ to ‘listing_paths ‘ in host memory. Here listing_paths means the value named 'listing paths' in this block. The important operands are line: the value named 'line' in this block; removeprefix: the value named 'removeprefix' in this block; lstinputlisting: the value named 'lstinputlisting' in this block. Context: the function test_every_nonblank_source_line_is_covered_and_hashed, which handles test every nonblank source line is covered and hashed.

Line 37: `for line in generated_tex.splitlines()` This is continuation line 3 of the 5-line logical statement that begins at source line 35. Its exact fragment is ‘for line in generated_tex.splitlines()‘. The important operands are for: the value named 'for' in this block; line: the value named 'line' in this block; in: the value named 'in' in this block. Read together, the complete operation is: This assigns ‘[line.removeprefix("\\lstinputlisting{").removesuffix("}") for line in generated_tex.splitlines() if line.startswith("\\lstinputlisting{")]‘ to ‘listing_paths ‘ in host memory. Here listing_paths means the value named 'listing paths' in this block. The important operands are line: the value named 'line' in this block; removeprefix: the value named 'removeprefix' in this block; lstinputlisting: the value named 'lstinputlisting' in this block. Context: the function test_every_nonblank_source_line_is_covered_and_hashed, which handles test every nonblank source line is covered and hashed.

Line 38: `if line.startswith("\\lstinputlisting{")` This is continuation line 4 of the 5-line logical statement that begins at source line 35. Its exact fragment is ‘if line.startswith("\\lstinputlisting{")‘. The important operands are line: the value named 'line' in this block; startswith: the value named 'startswith' in this block; lstinputlisting: the value named 'lstinputlisting' in this block. Read together, the complete operation is: This assigns ‘[line.removeprefix("\\lstinputlisting{").removes
for line in generated_tex.splitlines() if line.startswith("\\lstinputlisting{")]‘ to ‘listing_paths ‘ in host memory. Here listing_paths means the value named 'listing paths' in this block. The important operands are line: the value named

'line' in this block; removeprefix: the value named 'removeprefix' in this block; lstinputlisting: the value named 'lstinputlisting' in this block. Context: the function test_every_nonblank_source_line_is_covered_and_hashed, which handles test every nonblank source line is covered and hashed.

Line 39: `]` This is continuation line 5 of the 5-line logical statement that begins at source line 35. Its exact fragment is ']'. The expression is a literal or structural operator and has no hidden software state. Read together, the complete operation is: This assigns '[line.removeprefix("\\lstinputlisting{").removesuffix("}") for line in generated_tex.splitlines() if line.startswith("\\lstinputlisting{")]' to 'listing_paths ' in host memory. Here listing_paths means the value named 'listing paths' in this block. The important operands are line: the value named 'line' in this block; removeprefix: the value named 'removeprefix' in this block; lstinputlisting: the value named 'lstinputlisting' in this block. Context: the function test_every_nonblank_source_line_is_covered_and_hashed, which handles test every nonblank source line is covered and hashed.

Line 40: `self.assertEqual(len(listing_paths), len(entries))` This calls 'self.assertEqual' with 'len(listing_paths), len(entries)' inside the function test_every_nonblank_source_line_is_covered_and_hashed, which handles test every nonblank source line is covered and hashed. The call advances the host-side job that checks documentation generator behavior independently with Python assertions.

Line 41: `for listing_path in listing_paths:` This iterates listing_path over 'listing_paths'. Each iteration repeats the indented host operation, commonly once per layer, tile, timestep, or test case in the function test_every_nonblank_source_ which handles test every nonblank source line is covered and hashed.

Line 42: `self.assertTrue(` This statement continues through source line 45; the explanation uses the complete expression rather than only the first visual fragment. This calls 'self.assertTrue' with ' (tex_path.parent / listing_path).resolve().is_file(), listing_path, ' inside the function test_every_nonblank_source_line_is_covered_and_hashed, which handles test every nonblank source line is covered and hashed. The call advances the host-side job that checks documentation generator behavior independently with Python assertions.

Line 43: `(tex_path.parent / listing_path).resolve().is_file(),` This is continuation line 2 of the 4-line logical statement that begins at source line 42. Its exact fragment is '(tex_path.parent / listing_path).resolve().is_file(),'. The important operands are tex_path: the value named 'tex path' in this block; parent: the value named 'parent' in this block; listing_path: the value named 'listing path' in this block. Read together, the complete operation is: This calls 'self.assertTrue' with ' (tex_path.parent / listing_path).resolve().is_file(), listing_path, ' inside the function test_every_nonblank_source_line_is_covered_and_hashed, which handles test every nonblank source line is covered and hashed. The call advances the host-side job that checks documentation generator behavior independently with Python assertions.

Line 44: `listing_path,` This is continuation line 3 of the 4-line logical statement that begins at source line 42. Its exact fragment is 'listing_path,'. The important operands are listing_path: the value named 'listing path' in this block. Read together, the complete operation is: This calls 'self.assertTrue' with ' (tex_path.parent / listing_path).resolve().is_file(), listing_path, ' inside the function test_every_nonblank_source_line_is_covered_and_hashed, which handles test every nonblank source line is covered and hashed. The call advances the host-side job that checks documentation generator behavior independently with Python assertions.

Line 45: `)` This is continuation line 4 of the 4-line logical statement that begins at source line 42. Its exact fragment is ')'. The expression is a literal or structural operator and has no hidden software state. Read together, the complete operation is: This calls 'self.assertTrue' with ' (tex_path.parent / listing_path).resolve().is_file(), listing_path, ' inside the function test_every_nonblank_source_line_is_covered_and_hashed, which handles test every nonblank source line is covered and hashed. The call advances the host-side job that checks documentation generator behavior independently with Python assertions.

Line 46: `for file_record in manifest["files"]:` This iterates file_record over 'manifest["files"]'. Each iteration repeats the indented host operation, commonly once per layer, tile, timestep, or test case in the function test_every_nonblank_source which handles test every nonblank source line is covered and hashed.

Line 47: `self.assertEqual(` This statement continues through source line 50; the explanation uses the complete expression rather than only the first visual fragment. This calls ‘self.assertEqual‘ with ‘ file_record["nonblank_lines"], file_record["explained_nonblank_lines"], ‘ inside the function test_every_nonblank_source_line_is_covered_and_hashed, which handles test every nonblank source line is covered and hashed. The call advances the host-side job that checks documentation generator behavior independently with Python assertions.

Line 48: `file_record["nonblank_lines"],` This is continuation line 2 of the 4-line logical statement that begins at source line 47. Its exact fragment is ‘file_record["nonblank_lines"],‘. The important operands are file_record: the value named ’file record’ in this block; nonblank_lines: the value named ’nonblank lines’ in this block. Read together, the complete operation is: This calls ‘self.assertEqual‘ with ‘ file_record["nonblank_lines"], file_record["explained_nonblank_lines"], ‘ inside the function test_every_nonblank_source_line_is_covered_and_hashed, which handles test every nonblank source line is covered and hashed. The call advances the host-side job that checks documentation generator behavior independently with Python assertions.

Line 49: `file_record["explained_nonblank_lines"],` This is continuation line 3 of the 4-line logical statement that begins at source line 47. Its exact fragment is ‘file_record["explained_nonblank_lines"],‘. The important operands are file_record: the value named ’file record’ in this block; explained_nonblank_lines: the value named ’explained nonblank lines’ in this block. Read together, the complete operation is: This calls ‘self.assertEqual‘ with ‘ file_record["nonblank_lines"], file_record["explained_nonblank_lines"], ‘ inside the function test_every_nonblank_source_line_is_covered_and_hashed, which handles test every nonblank source line is covered and hashed. The call advances the host-side job that checks documentation generator behavior independently with Python assertions.

Line 50: `)` This is continuation line 4 of the 4-line logical statement that begins at source line 47. Its exact fragment is ‘)‘. The expression is a literal or structural operator and has no hidden software state. Read together, the complete operation is: This calls ‘self.assertEqual‘ with ‘ file_record["nonblank_lines"], file_record["explained_nonblank_lines"], ‘ inside the function test_every_nonblank_source_line_is_covered_and_hashed, which handles test every nonblank source line is covered and hashed. The call advances the host-side job that checks documentation generator behavior independently with Python assertions.

Line 51: `self.assertEqual(len(file_record["sha256"]), 64)` This calls ‘self.assertEqual‘ with ‘len(file_record["sha256"]), 64‘ inside the function test_every_nonblank_source_line_is_covered_and_hashed, which handles test every nonblank source line is covered and hashed. The call advances the host-side job that checks documentation generator behavior independently with Python assertions.

Line 53: `def test_rtl_context_returns_to_structure_after_clocked_process(self) -> None:` This starts function test_rtl_context_returns_to_structure_after_clocked_process. Its indented body performs test rtl context returns to structure after clocked process as part of the file that checks documentation generator behavior independently with Python assertions; it runs only when called.

Line 54: `lines = [` This statement continues through source line 59; the explanation uses the complete expression rather than only the first visual fragment. Inside the function test_rtl_context_returns_to_structure_after_clocked_process, which handles test rtl context returns to structure after clocked process, this statement advances the host implementation that checks documentation generator behavior independently with Python assertions. The important operands are lines: the value named ’lines’ in this block; always_ff: the value named ’always ff’ in this block; posedge: the value named ’posedge’ in this block.

Line 55: `"always_ff @(posedge clk) begin",` This is continuation line 2 of the 6-line logical statement that begins at source line 54. Its exact fragment is ‘"always_ff @(posedge clk) begin",‘. The important operands are always_ff: the value named ’always ff’ in this block; posedge: the value named ’posedge’ in this block; clk: the clock that makes all registers advance together. Read together, the complete operation is: Inside the function test_rtl_context_returns_to_structure_after_ which handles test rtl context returns to structure after clocked process, this statement advances the host implementation that checks documentation generator behavior independently with Python assertions. The important operands are lines: the value named ’lines’ in this block; always_ff: the value named ’always ff’ in this block; posedge: the value named ’posedge’ in this block.

Line 56: `" state <= next_state;",` This is continuation line 3 of the 6-line logical statement that begins at source line 54. Its exact fragment is ‘" state <= next_state;",‘. The important operands are state: the finite-state-machine phase retained in flip-flops; next_state: the finite-state-machine phase retained in flip-flops. Read together, the complete operation is: Inside the function test_rtl_context_returns_to_structure_after_clocked_process, which handles test rtl context returns to structure after clocked process, this statement advances the host implementation that checks documentation generator behavior independently with Python assertions. The important operands are lines: the value named 'lines' in this block; always_ff: the value named 'always ff' in this block; posedge: the value named 'posedge' in this block.

Line 57: `"end",` This is continuation line 4 of the 6-line logical statement that begins at source line 54. Its exact fragment is ‘"end",‘. The expression is a literal or structural operator and has no hidden software state. Read together, the complete operation is: Inside the function test_rtl_context_returns_to_structure_after_clocked_process, which handles test rtl context returns to structure after clocked process, this statement advances the host implementation that checks documentation generator behavior independently with Python assertions. The important operands are lines: the value named 'lines' in this block; always_ff: the value named 'always ff' in this block; posedge: the value named 'posedge' in this block.

Line 58: `"logic later_signal;",` This is continuation line 5 of the 6-line logical statement that begins at source line 54. Its exact fragment is ‘"logic later_signal;",‘. The important operands are later_signal: the value named 'later signal' in this block. Read together, the complete operation is: Inside the function test_rtl_context_returns_to_structure_after_clocked_pr which handles test rtl context returns to structure after clocked process, this statement advances the host implementation that checks documentation generator behavior independently with Python assertions. The important operands are lines: the value named 'lines' in this block; always_ff: the value named 'always ff' in this block; posedge: the value named 'posedge' in this block.

Line 59: `]` This is continuation line 6 of the 6-line logical statement that begins at source line 54. Its exact fragment is ‘]‘. The expression is a literal or structural operator and has no hidden software state. Read together, the complete operation is: Inside the function test_rtl_context_returns_to_structure_after_clocked_process, which handles test rtl context returns to structure after clocked process, this statement advances the host implementation that checks documentation generator behavior independently with Python assertions. The important operands are lines: the value named 'lines' in this block; always_ff: the value named 'always ff' in this block; posedge: the value named 'posedge' in this block.

Line 60: `contexts = sv_contexts(lines)` This assigns ‘sv_contexts(lines)‘ to ‘contexts ‘ in host memory. Here contexts means the value named 'contexts' in this block. The important operands are sv_contexts: the value named 'sv contexts' in this block; lines: the value named 'lines' in this block. Context: the function test_rtl_context_returns_to_structure_after_ which handles test rtl context returns to structure after clocked process.

Line 61: `self.assertIn("clocked process", contexts[2])` This calls ‘self.assertIn‘ with ‘"clocked process", contexts[2]‘ inside the function test_rtl_context_returns_to_structure_after_clocked_process, which handles test rtl context returns to structure after clocked process. The call advances the host-side job that checks documentation generator behavior independently with Python assertions.

Line 62: `self.assertEqual(contexts[4], "the module's structural declarations")` This calls ‘self.assertEqual‘ with ‘contexts[4], "the module's structural declarations"‘ inside the function test_rtl_context_returns_to_structure_after_clocked_ which handles test rtl context returns to structure after clocked process. The call advances the host-side job that checks documentation generator behavior independently with Python assertions.

Line 64: `def test_multiline_statements_are_explained_as_complete_operations(self) -> None:` This starts function test_multiline_statements_are_explained_as_complete_operations. Its indented body performs test multiline statements are explained as complete operations as part of the file that checks documentation generator behavior independently with Python assertions; it runs only when called.

Line 65: `rtl_lines = [` This statement continues through source line 70; the explanation uses the complete expression rather than only the first visual fragment. Inside the function test_multiline_statements_are_explained_as_complete_operations,

which handles test multiline statements are explained as complete operations, this statement advances the host implementation that checks documentation generator behavior independently with Python assertions. The important operands are rtl_lines: the value named 'rtl lines' in this block; always_ff: the value named 'always ff' in this block; posedge: the value named 'posedge' in this block.

Line 66: `"always_ff @(posedge clk) begin",` This is continuation line 2 of the 6-line logical statement that begins at source line 65. Its exact fragment is '"always_ff @(posedge clk) begin",'. The important operands are always_ff: the value named 'always ff' in this block; posedge: the value named 'posedge' in this block; clk: the clock that makes all registers advance together. Read together, the complete operation is: Inside the function test_multiline_statements_are_explained_as_ which handles test multiline statements are explained as complete operations, this statement advances the host implementation that checks documentation generator behavior independently with Python assertions. The important operands are rtl_lines: the value named 'rtl lines' in this block; always_ff: the value named 'always ff' in this block; posedge: the value named 'posedge' in this block.

Line 67: `" result_r <= left_r",` This is continuation line 3 of the 6-line logical statement that begins at source line 65. Its exact fragment is '" result_r <= left_r",'. The important operands are result_r: the value named 'result r' in this block; left_r: the value named 'left r' in this block. Read together, the complete operation is: Inside the function test_multiline_statements_are_explained_as_complete_operations, which handles test multiline statements are explained as complete operations, this statement advances the host implementation that checks documentation generator behavior independently with Python assertions. The important operands are rtl_lines: the value named 'rtl lines' in this block; always_ff: the value named 'always ff' in this block; posedge: the value named 'posedge' in this block.

Line 70: `]` This is continuation line 6 of the 6-line logical statement that begins at source line 65. Its exact fragment is ']'. The expression is a literal or structural operator and has no hidden software state. Read together, the complete operation is: Inside the function test_multiline_statements_are_explained_as_complete_operations, which handles test multiline statements are explained as complete operations, this statement advances the host implementation that checks documentation generator behavior independently with Python assertions. The important operands are rtl_lines: the value named 'rtl lines' in this block; always_ff: the value named 'always ff' in this block; posedge: the value named 'posedge' in this block.

Line 71: `rtl_spans = sv_statement_spans(rtl_lines)` This assigns 'sv_statement_spans(rtl_lines)' to 'rtl_spans ' in host memory. Here rtl_spans means the value named 'rtl spans' in this block. The important operands are sv_statement_spans: the finite-state-machine phase retained in flip-flops; rtl_lines: the value named 'rtl lines' in this block. Context: the function test_multiline_statements_are_explained_as_complete_operations, which handles test multiline statements are explained as complete operations.

Line 72: `self.assertEqual((rtl_spans[2].start, rtl_spans[2].end), (2, 3))` This calls 'self.assertEqual' with '(rtl_spans[2].start, rtl_spans[2].end), (2, 3)' inside the function test_multiline_statements_are_explained_as_complete_operatio which handles test multiline statements are explained as complete operations. The call advances the host-side job that checks documentation generator behavior independently with Python assertions.

Line 73: `self.assertIn("left_r + right_r", rtl_spans[3].text)` This calls ‘self.assertIn‘ with ‘"left_r + right_r", rtl_spans[3].text‘ inside the function test_multiline_statements_are_explained_as_complete_operations, which handles test multiline statements are explained as complete operations. The call advances the host-side job that checks documentation generator behavior independently with Python assertions.

Line 75: `python_text = "value = function(\n operand_a,\n operand_b,\n)\n"` This assigns ‘"value = function(\n operand_a,\n operand_b,\n)\n"‘ to ‘python_text ‘ in host memory. Here python_text means the value named ’python text’ in this block. The important operands are value: the value named ’value’ in this block; function: the value named ’function’ in this block; n: the value named ’n’ in this block. Context: the function test_multiline_statements_are_explained which handles test multiline statements are explained as complete operations.

Line 76: `python_spans = python_statement_spans(python_text)` This assigns ‘python_statement_spans(python_text)‘ to ‘python_spans ‘ in host memory. Here python_spans means the value named ’python spans’ in this block. The important operands are python_statement_spans: the finite-state-machine phase retained in flip-flops; python_text: the value named ’python text’ in this block. Context: the function test_multiline_statements_are_explained_as_complete_operations, which handles test multiline statements are explained as complete operations.

Line 77: `self.assertEqual((python_spans[1].start, python_spans[1].end), (1, 4))` This calls ‘self.assertEqual‘ with ‘(python_spans[1].start, python_spans[1].end), (1, 4)‘ inside the function test_multiline_statements_are_explained_as_comp which handles test multiline statements are explained as complete operations. The call advances the host-side job that checks documentation generator behavior independently with Python assertions.

Line 78: `self.assertIn("operand_a", python_spans[3].text)` This calls ‘self.assertIn‘ with ‘"operand_a", python_spans[3].t inside the function test_multiline_statements_are_explained_as_complete_operations, which handles test multiline statements are explained as complete operations. The call advances the host-side job that checks documentation generator behavior independently with Python assertions.

Line 81: `if __name__ == "__main__":` This executes the following indented host-code branch only when ‘___name___ == "___main___"‘ is true. The important operands are ___name___: the value named ’name’ in this block; ___main___: the value named ’main’ in this block. Context: the file whose role is to checks documentation generator behavior independently with Python assertions.

Line 82: `unittest.main()` This calls ‘unittest.main‘ with “ inside the file whose role is to checks documentation generator behavior independently with Python assertions. The call advances the host-side job that checks documentation generator behavior independently with Python assertions.

64 tests/test_neuraedge_compiler.py

Role in the complete system: checks neuraedge compiler behavior independently with Python assertions.

64.1 Beginner architecture map

Dataflow responsibility This file's end-to-end responsibility is to checks neuraedge compiler behavior independently with Python assertions.

Where it runs This is sequential host software. Python objects live in CPU memory; they become FPGA work only when the compiler packs a command or payload and the PYNQ driver transfers those bytes through AXI DMA or AXI-Lite.

Public structure Classes: TensorTransactionEmulator, CompilerTests. Functions: _decode_bytes, direct_conv2d, ___init___, execute, execute_program, assert_shape, setUp, check_case, test_outer_mode_irregular_tiles_both_dataflows, test_dot8_single_row_with_padding, test_reduction_larger_than_local_memory, test_zero_skipping_and_boundary_va test_binary_and_ternary_sparse_paths, test_grouped_u8_convolution_with_stride_padding_and_dilation, test_depthw test_validation. Each function annotation below names its enclosing function so an array operation is tied to the model, compiler, driver, test, or report phase that uses it.

Numeric and failure boundary Shapes, signedness, byte order, scaling, and saturation are part of the hardware contract. Validation exceptions are functional safety checks: rejecting malformed input before DMA is different from silently clipping, reshaping, or continuing with an incompatible artifact.

Line 1: `from __future__ import annotations` This imports the named Python API so the file whose role is to checks neuraedge compiler behavior independently with Python assertions can use it explicitly. Imports execute on the host processor and create no FPGA hardware.

Line 3: `import unittest` This imports the named Python API so the file whose role is to checks neuraedge compiler behavior independently with Python assertions can use it explicitly. Imports execute on the host processor and create no FPGA hardware.

Line 5: `import numpy as np` This imports the named Python API so the file whose role is to checks neuraedge compiler behavior independently with Python assertions can use it explicitly. Imports execute on the host processor and create no FPGA hardware.

Line 7: `from neuraedge_compiler import (` This statement continues through source line 12; the explanation uses the complete expression rather than only the first visual fragment. This imports the named Python API so the file whose role is to checks neuraedge compiler behavior independently with Python assertions can use it explicitly. Imports execute on the host processor and create no FPGA hardware.

Line 8: `compile_spike_conv2d,` This is continuation line 2 of the 6-line logical statement that begins at source line 7. Its exact fragment is 'compile_spike_conv2d,'. The important operands are compile_spike_conv2d: a binary event produced when a neuron crosses its threshold. Read together, the complete operation is: This imports the named Python API so the file whose role is to checks neuraedge compiler behavior independently with Python assertions can use it explicitly. Imports execute on the host processor and create no FPGA hardware.

Line 9: `compile_spike_gemm,` This is continuation line 3 of the 6-line logical statement that begins at source line 7. Its exact fragment is 'compile_spike_gemm,'. The important operands are compile_spike_gemm: a binary event produced when a neuron crosses its threshold. Read together, the complete operation is: This imports the named Python API so the file whose role is to checks neuraedge compiler behavior independently with Python assertions can use it explicitly. Imports execute on the host processor and create no FPGA hardware.

Line 10: `compile_u8_conv2d,` This is continuation line 4 of the 6-line logical statement that begins at source line 7. Its exact fragment is 'compile_u8_conv2d,'. The important operands are compile_u8_conv2d: the value named 'compile u8 conv2d' in this block. Read together, the complete operation is: This imports the named Python API so the file whose role is to checks neuraedge compiler behavior independently with Python assertions can use it explicitly. Imports execute on the host processor and create no FPGA hardware.

Line 11: `compile_u8_gemm,` This is continuation line 5 of the 6-line logical statement that begins at source line 7. Its exact fragment is 'compile_u8_gemm,'. The important operands are compile_u8_gemm: the value named 'compile u8 gemm' in this block. Read together, the complete operation is: This imports the named Python API so the file whose role is to checks neuraedge compiler behavior independently with Python assertions can use it explicitly. Imports execute on the host processor and create no FPGA hardware.

Line 12: `)` This is continuation line 6 of the 6-line logical statement that begins at source line 7. Its exact fragment is ')'. The expression is a literal or structural operator and has no hidden software state. Read together, the complete operation is: This imports the named Python API so the file whose role is to checks neuraedge compiler behavior independently with Python assertions can use it explicitly. Imports execute on the host processor and create no FPGA hardware.

Line 13: `from neuraedge_golden import Dataflow, direct_centered_gemm` This imports the named Python API so the file whose role is to checks neuraedge compiler behavior independently with Python assertions can use it explicitly. Imports execute on the host processor and create no FPGA hardware.

Line 14: `from neuraedge_protocol import Command128, Opcode, StreamBeat` This imports the named Python API so the file whose role is to checks neuraedge compiler behavior independently with Python assertions can use it explicitly. Imports execute on the host processor and create no FPGA hardware.

Line 17: `def _decode_bytes(word: int) -> list[int]:` This starts function _decode_bytes. Its indented body performs decode bytes as part of the file that checks neuraedge compiler behavior independently with Python assertions; it runs only when called.

Line 18: `return [(word >> (8 * lane)) & 0xFF for lane in range(8)]` This returns '[(word >> (8 * lane)) & 0xFF for lane in range(8)]' to the caller of the function _decode_bytes, which handles decode bytes, ending this invocation. The important operands are word: the value named 'word' in this block; lane: one parallel arithmetic element within a vector or tensor datapath; for: the value named 'for' in this block.

Line 21: `class TensorTransactionEmulator:` This defines class TensorTransactionEmulator, which groups data and methods for tensor transaction emulator. Instances exist in host memory and organize the flow that checks neuraedge compiler behavior independently with Python assertions.

Line 22: `"""Independent stateful interpretation of the public tensor stream ABI."""` This is executable documentation attached to the class TensorTransactionEmulator, which handles tensor transaction emulator. It states the intended contract that tests and callers should enforce, but the text itself does not transform data or issue hardware work.

Line 24: `def __init__(self) -> None:` This starts function ___init___. Its indented body performs init as part of the file that checks neuraedge compiler behavior independently with Python assertions; it runs only when called.

Line 25: `self.activations: np.ndarray | None = None` This assigns 'None' to 'self.activations' in host memory. Here activations means an input feature value consumed by a neuron or multiply-accumulate operation. The important operands are None: the value named 'none' in this block. Context: the function ___init___, which handles init.

Line 26: `self.weights: np.ndarray | None = None` This assigns 'None' to 'self.weights' in host memory. Here weights means a learned coefficient multiplied by an activation. The important operands are None: the value named 'none' in this block. Context: the function ___init___, which handles init.

Line 28: `def execute(` This starts function execute. Its indented body performs execute as part of the file that checks neuraedge compiler behavior independently with Python assertions; it runs only when called.

Line 29: `self,` Inside the function execute, which handles execute, this statement advances the host implementation that checks neuraedge compiler behavior independently with Python assertions. The expression is a literal or structural operator and has no hidden software state.

Line 30: `command: Command128,` Inside the function execute, which handles execute, this statement advances the host implementation that checks neuraedge compiler behavior independently with Python assertions. The important operands are command: the 128-bit instruction selecting an engine, shape, mode, and numeric parameters; Command128: the 128-bit instruction selecting an engine, shape, mode, and numeric parameters.

Line 31: `input_beats: tuple[StreamBeat, ...] = (),` This assigns '(),' to 'input_beats' in host memory. Here input_beats means the value named 'input beats' in this block. The expression is a literal or structural operator and has no hidden software state. Context: the function execute, which handles execute.

Line 32: `*,` Inside the function execute, which handles execute, this statement advances the host implementation that checks neuraedge compiler behavior independently with Python assertions. The expression is a literal or structural operator and has no hidden software state.

Line 33: `output_beats: int = 0,` This assigns '0,' to 'output_beats' in host memory. Here output_beats means the value named 'output beats' in this block. The expression is a literal or structural operator and has no hidden software state. Context: the function execute, which handles execute.

Line 34: `timeout_seconds: float = 5.0,` This assigns '5.0,' to 'timeout_seconds' in host memory. Here timeout_seconds means the value named 'timeout seconds' in this block. The expression is a literal or structural operator and has no hidden software state. Context: the function execute, which handles execute.

Line 35: `) -> tuple[int, ...]:` Inside the function execute, which handles execute, this statement advances the host implementation that checks neuraedge compiler behavior independently with Python assertions. The important operands are tuple: the value named 'tuple' in this block.

Line 36: `del timeout_seconds` Inside the function execute, which handles execute, this statement advances the host implementation that checks neuraedge compiler behavior independently with Python assertions. The important operands are del: the value named 'del' in this block; timeout_seconds: the value named 'timeout seconds' in this block.

Line 37: `value = command.value` This assigns 'command.value' to 'value ' in host memory. Here value means the value named 'value' in this block. The important operands are command: the 128-bit instruction selecting an engine, shape, mode, and numeric parameters; value: the value named 'value' in this block. Context: the function execute, which handles execute.

Line 38: `opcode = command.opcode` This assigns ‘command.opcode‘ to ‘opcode ‘ in host memory. Here opcode means the value named ’opcode’ in this block. The important operands are command: the 128-bit instruction selecting an engine, shape, mode, and numeric parameters; opcode: the value named ’opcode’ in this block. Context: the function execute, which handles execute.

Line 39: `issues = (value >> 14) & 0xFFF` This assigns ‘(value >> 14) & 0xFFF‘ to ‘issues ‘ in host memory. Here issues means the value named ’issues’ in this block. The important operands are value: the value named ’value’ in this block. Context: the function execute, which handles execute.

Line 41: `if opcode == Opcode.LOAD_ACTIVATIONS:` This executes the following indented host-code branch only when ‘opcode == Opcode.LOAD_ACTIVATIONS‘ is true. The important operands are opcode: the value named ’opcode’ in this block; Opcode: the value named ’opcode’ in this block; LOAD_ACTIVATIONS: an input feature value consumed by a neuron or multiply-accumulate operation. Context: the function execute, which handles execute.

Line 42: `self.activations = np.asarray([_decode_bytes(beat.data) for beat in input_beats], dtype=np.int64)` This assigns ‘np.asarray([_decode_bytes(beat.data) for beat in input_beats], dtype=np.int64)‘ to ‘self.activations ‘ in host memory. Here activations means an input feature value consumed by a neuron or multiply-accumulate operation. The important operands are asarray: the value named ’asarray’ in this block; _decode_bytes: the value named ’decode bytes’ in this block; beat: the value named ’beat’ in this block. Context: the function execute, which handles execute.

Line 43: `self.assert_shape(self.activations, (issues, 8))` This calls ‘self.assert_shape‘ with ‘self.activations, (issues, 8)‘ inside the function execute, which handles execute. The call advances the host-side job that checks neuraedge compiler behavior independently with Python assertions.

Line 44: `return ()` This returns ‘()‘ to the caller of the function execute, which handles execute, ending this invocation. The expression is a literal or structural operator and has no hidden software state.

Line 45: `if opcode == Opcode.LOAD_WEIGHTS_OUTER:` This executes the following indented host-code branch only when ‘opcode == Opcode.LOAD_WEIGHTS_OUTER‘ is true. The important operands are opcode: the value named ’opcode’ in this block; Opcode: the value named ’opcode’ in this block; LOAD_WEIGHTS_OUTER: a learned coefficient multiplied by an activation. Context: the function execute, which handles execute.

Line 46: `words = [_decode_bytes(beat.data) for beat in input_beats]` This assigns ‘[_decode_bytes(beat.data) for beat in input_beats]‘ to ‘words ‘ in host memory. Here words means the value named ’words’ in this block. The important operands are _decode_bytes: the value named ’decode bytes’ in this block; beat: the value named ’beat’ in this block; data: the value named ’data’ in this block. Context: the function execute, which handles execute.

Line 47: `self.weights = np.asarray(` This statement continues through source line 50; the explanation uses the complete expression rather than only the first visual fragment. This assigns ‘np.asarray([words[2 * issue] + words[2 * issue + 1] for issue in range(issues)], dtype=np.int64,)‘ to ‘self.weights ‘ in host memory. Here weights means a learned coefficient multiplied by an activation. The important operands are asarray: the value named ’asarray’ in this block; words: the value named ’words’ in this block; issue: the value named ’issue’ in this block. Context: the function execute, which handles execute.

Line 48: `[words[2 * issue] + words[2 * issue + 1] for issue in range(issues)],` This is continuation line 2 of the 4-line logical statement that begins at source line 47. Its exact fragment is ‘[words[2 * issue] + words[2 * issue + 1] for issue in range(issues)],‘. The important operands are words: the value named ’words’ in this block; issue: the value named ’issue’ in this block; for: the value named ’for’ in this block. Read together, the complete operation is: This assigns ‘np.asarray([words[2 * issue] + words[2 * issue + 1] for issue in range(issues)], dtype=np.int64,)‘ to ‘self.weights ‘ in host memory. Here weights means a learned coefficient multiplied by an activation. The important operands are asarray: the value named ’asarray’ in this block; words: the value named ’words’ in this block; issue: the value named ’issue’ in this block. Context: the function execute, which handles execute.

Line 49: `dtype=np.int64,` This is continuation line 3 of the 4-line logical statement that begins at source line 47. Its exact fragment is 'dtype=np.int64,'. The important operands are dtype: the value named 'dtype' in this block; int64: the value named 'int64' in this block. Read together, the complete operation is: This assigns 'np.asarray([words[2 * issue] + words[2 * issue + 1] for issue in range(issues)], dtype=np.int64,)' to 'self.weights ' in host memory. Here weights means a learned coefficient multiplied by an activation. The important operands are asarray: the value named 'asarray' in this block; words: the value named 'words' in this block; issue: the value named 'issue' in this block. Context: the function execute, which handles execute.

Line 50: `)` This is continuation line 4 of the 4-line logical statement that begins at source line 47. Its exact fragment is ')'. The expression is a literal or structural operator and has no hidden software state. Read together, the complete operation is: This assigns 'np.asarray([words[2 * issue] + words[2 * issue + 1] for issue in range(issues)], dtype=np.int64,)' to 'self.weights ' in host memory. Here weights means a learned coefficient multiplied by an activation. The important operands are asarray: the value named 'asarray' in this block; words: the value named 'words' in this block; issue: the value named 'issue' in this block. Context: the function execute, which handles execute.

Line 51: `return ()` This returns '()' to the caller of the function execute, which handles execute, ending this invocation. The expression is a literal or structural operator and has no hidden software state.

Line 52: `if opcode == Opcode.LOAD_WEIGHTS_DOT8:` This executes the following indented host-code branch only when 'opcode == Opcode.LOAD_WEIGHTS_DOT8' is true. The important operands are opcode: the value named 'opcode' in this block; Opcode: the value named 'opcode' in this block; LOAD_WEIGHTS_DOT8: a learned coefficient multiplied by an activation. Context: the function execute, which handles execute.

Line 53: `words = [_decode_bytes(beat.data) for beat in input_beats]` This assigns '[_decode_bytes(beat.data) for beat in input_beats]' to 'words ' in host memory. Here words means the value named 'words' in this block. The important operands are _decode_bytes: the value named 'decode bytes' in this block; beat: the value named 'beat' in this block; data: the value named 'data' in this block. Context: the function execute, which handles execute.

Line 54: `self.weights = np.asarray([` This statement continues through source line 58; the explanation uses the complete expression rather than only the first visual fragment. This assigns 'np.asarray([[words[16 * issue + 2 * lane] + words[16 * issue + 2 * lane + 1] for lane in range(8)] for issue in range(issues)], dtype=np.int64)' to 'self.weights ' in host memory. Here weights means a learned coefficient multiplied by an activation. The important operands are asarray: the value named 'asarray' in this block; words: the value named 'words' in this block; issue: the value named 'issue' in this block. Context: the function execute, which handles execute.

Line 55: `[words[16 * issue + 2 * lane] + words[16 * issue + 2 * lane + 1]` This is continuation line 2 of the 5-line logical statement that begins at source line 54. Its exact fragment is '[words[16 * issue + 2 * lane] + words[16 * issue + 2 * lane + 1]'. The important operands are words: the value named 'words' in this block; issue: the value named 'issue' in this block; lane: one parallel arithmetic element within a vector or tensor datapath. Read together, the complete operation is: This assigns 'np.asarray([[words[16 * issue + 2 * lane] + words[16 * issue + 2 * lane + 1] for lane in range(8)] for issue in range(issues)], dtype=np.int64)' to 'self.weights ' in host memory. Here weights means a learned coefficient multiplied by an activation. The important operands are asarray: the value named 'asarray' in this block; words: the value named 'words' in this block; issue: the value named 'issue' in this block. Context: the function execute, which handles execute.

Line 56: `for lane in range(8)]` This is continuation line 3 of the 5-line logical statement that begins at source line 54. Its exact fragment is 'for lane in range(8)]'. The important operands are for: the value named 'for' in this block; lane: one parallel arithmetic element within a vector or tensor datapath; in: the value named 'in' in this block. Read together, the complete operation is: This assigns 'np.asarray([[words[16 * issue + 2 * lane] + words[16 * issue + 2 * lane + 1] for lane in range(8)] for issue in range(issues)], dtype=np.int64)' to 'self.weights ' in host memory. Here weights means a learned coefficient multiplied by an activation. The important operands are asarray: the value named 'asarray' in this block; words: the value named 'words' in this block; issue: the value named 'issue' in this block. Context: the function execute, which handles execute.

Line 57: `for issue in range(issues)` This is continuation line 4 of the 5-line logical statement that begins at source line 54. Its exact fragment is ‘for issue in range(issues)‘. The important operands are for: the value named ’for’ in this block; issue: the value named ’issue’ in this block; in: the value named ’in’ in this block. Read together, the complete operation is: This assigns ‘np.asarray([[words[16 * issue + 2 * lane] + words[16 * issue + 2 * lane + 1] for lane in range(8)] for issue in range(issues)], dtype=np.int64)‘ to ‘self.weights ‘ in host memory. Here weights means a learned coefficient multiplied by an activation. The important operands are asarray: the value named ’asarray’ in this block; words: the value named ’words’ in this block; issue: the value named ’issue’ in this block. Context: the function execute, which handles execute.

Line 58: `], dtype=np.int64)` This is continuation line 5 of the 5-line logical statement that begins at source line 54. Its exact fragment is ‘], dtype=np.int64)‘. The important operands are dtype: the value named ’dtype’ in this block; int64: the value named ’int64’ in this block. Read together, the complete operation is: This assigns ‘np.asarray([[words[16 * issue + 2 * lane] + words[16 * issue + 2 * lane + 1] for lane in range(8)] for issue in range(issues)], dtype=np.int64)‘ to ‘self.weights ‘ in host memory. Here weights means a learned coefficient multiplied by an activation. The important operands are asarray: the value named ’asarray’ in this block; words: the value named ’words’ in this block; issue: the value named ’issue’ in this block. Context: the function execute, which handles execute.

Line 59: `return ()` This returns ‘()‘ to the caller of the function execute, which handles execute, ending this invocation. The expression is a literal or structural operator and has no hidden software state.

Line 61: `if self.activations is None or self.weights is None:` This executes the following indented host-code branch only when ‘self.activations is None or self.weights is None‘ is true. The important operands are activations: an input feature value consumed by a neuron or multiply-accumulate operation; is: the value named ’is’ in this block; None: the value named ’none’ in this block. Context: the function execute, which handles execute.

Line 62: `raise AssertionError("compute was issued before operand loads")` This rejects an invalid state by raising ‘AssertionError("compute was issued before operand loads")‘. Failing before DMA prevents malformed shapes or artifacts from silently becoming hardware results.

Line 63: `rows = (value >> 4) & 0xF` This assigns ‘(value >> 4) & 0xF‘ to ‘rows ‘ in host memory. Here rows means one output-row position processed by the tensor tile. The important operands are value: the value named ’value’ in this block. Context: the function execute, which handles execute.

Line 64: `columns = (value >> 8) & 0x3F` This assigns ‘(value >> 8) & 0x3F‘ to ‘columns ‘ in host memory. Here columns means one output-feature position processed in parallel. The important operands are value: the value named ’value’ in this block. Context: the function execute, which handles execute.

Line 65: `za = (value >> 26) & 0xFF` This assigns ‘(value >> 26) & 0xFF‘ to ‘za ‘ in host memory. Here za means the value named ’za’ in this block. The important operands are value: the value named ’value’ in this block. Context: the function execute, which handles execute.

Line 66: `zb = (value >> 34) & 0xFF` This assigns ‘(value >> 34) & 0xFF‘ to ‘zb ‘ in host memory. Here zb means the value named ’zb’ in this block. The important operands are value: the value named ’value’ in this block. Context: the function execute, which handles execute.

Line 67: `if opcode == Opcode.COMPUTE_DENSE_OUTER:` This executes the following indented host-code branch only when ‘opcode == Opcode.COMPUTE_DENSE_OUTER‘ is true. The important operands are opcode: the value named ’opcode’ in this block; Opcode: the value named ’opcode’ in this block; COMPUTE_DENSE_OUTER: the value named ’compute dense outer’ in this block. Context: the function execute, which handles execute.

Line 68: `result = (self.activations[:, :rows].T - za) @ (self.weights[:, :columns] - zb)` This assigns ‘(self.activations[:, :rows].T - za) @ (self.weights[:, :columns] - zb)‘ to ‘result ‘ in host memory. Here result means the value named ’result’ in this block. The important operands are activations: an input feature value consumed by a neuron or multiply-accumulate operation; rows: one output-row position processed by the tensor tile; T: the value named ’t’ in this block. Context: the function execute, which handles execute.

Line 69: `elif opcode == Opcode.COMPUTE_DENSE_DOT8:` This executes the following indented host-code branch only when ‘opcode == Opcode.COMPUTE_DENSE_DOT8‘ is true. The important operands are opcode: the value named ’opcode’ in this block; Opcode: the value named ’opcode’ in this block; COMPUTE_DENSE_DOT8: the value named ’compute dense dot8’ in this block. Context: the function execute, which handles execute.

Line 70: `lhs = self.activations.reshape(-1) - za` This assigns ‘self.activations.reshape(-1) - za‘ to ‘lhs ‘ in host memory. Here lhs means the value named ’lhs’ in this block. The important operands are activations: an input feature value consumed by a neuron or multiply-accumulate operation; reshape: the value named ’reshape’ in this block; za: the value named ’za’ in this block. Context: the function execute, which handles execute.

Line 71: `rhs = self.weights.reshape(-1, 16)[:, :columns] - zb` This assigns ‘self.weights.reshape(-1, 16)[:, :columns] - zb‘ to ‘rhs ‘ in host memory. Here rhs means the value named ’rhs’ in this block. The important operands are weights: a learned coefficient multiplied by an activation; reshape: the value named ’reshape’ in this block; columns: one output-feature position processed in parallel. Context: the function execute, which handles execute.

Line 72: `result = (lhs @ rhs).reshape(1, columns)` This assigns ‘(lhs @ rhs).reshape(1, columns)‘ to ‘result ‘ in host memory. Here result means the value named ’result’ in this block. The important operands are lhs: the value named ’lhs’ in this block; rhs: the value named ’rhs’ in this block; reshape: the value named ’reshape’ in this block. Context: the function execute, which handles execute.

Line 73: `elif opcode in {Opcode.COMPUTE_BINARY, Opcode.COMPUTE_TERNARY}:` This executes the following indented host-code branch only when ‘opcode in {Opcode.COMPUTE_BINARY, Opcode.COMPUTE_TERNARY}‘ is true. The important operands are opcode: the value named ’opcode’ in this block; in: the value named ’in’ in this block; Opcode: the value named ’opcode’ in this block. Context: the function execute, which handles execute.

Line 74: `lhs = self.activations[:, :rows].T.copy()` This assigns ‘self.activations[:, :rows].T.copy()‘ to ‘lhs ‘ in host memory. Here lhs means the value named ’lhs’ in this block. The important operands are activations: an input feature value consumed by a neuron or multiply-accumulate operation; rows: one output-row position processed by the tensor tile; T: the value named ’t’ in this block. Context: the function execute, which handles execute.

Line 75: `if opcode == Opcode.COMPUTE_TERNARY:` This executes the following indented host-code branch only when ‘opcode == Opcode.COMPUTE_TERNARY‘ is true. The important operands are opcode: the value named ’opcode’ in this block; Opcode: the value named ’opcode’ in this block; COMPUTE_TERNARY: the value named ’compute ternary’ in this block. Context: the function execute, which handles execute.

Line 76: `lhs[lhs >= 128] -= 256` Inside the function execute, which handles execute, this statement advances the host implementation that checks neuraedge compiler behavior independently with Python assertions. The important operands are lhs: the value named ’lhs’ in this block.

Line 77: `rhs = self.weights[:, :columns].copy()` This assigns ‘self.weights[:, :columns].copy()‘ to ‘rhs ‘ in host memory. Here rhs means the value named ’rhs’ in this block. The important operands are weights: a learned coefficient multiplied by an activation; columns: one output-feature position processed in parallel; copy: the value named ’copy’ in this block. Context: the function execute, which handles execute.

Line 78: `rhs[rhs >= 128] -= 256` Inside the function execute, which handles execute, this statement advances the host implementation that checks neuraedge compiler behavior independently with Python assertions. The important operands are rhs: the value named ’rhs’ in this block.

Line 79: `result = lhs @ rhs` This assigns ‘lhs @ rhs‘ to ‘result ‘ in host memory. Here result means the value named ’result’ in this block. The important operands are lhs: the value named ’lhs’ in this block; rhs: the value named ’rhs’ in this block. Context: the function execute, which handles execute.

Line 80: `else:` This begins the alternative host-code branch when the preceding condition was false, still inside the function execute, which handles execute.

Line 81: `raise AssertionError(f"unexpected opcode {opcode}")` This rejects an invalid state by raising ‘AssertionError(f"unexpected opcode {opcode}")‘. Failing before DMA prevents malformed shapes or artifacts from silently becoming hardware results.

Line 83: `words = []` This assigns ‘[]‘ to ‘words ‘ in host memory. Here words means the value named ’words’ in this block. The expression is a literal or structural operator and has no hidden software state. Context: the function execute, which handles execute.

Line 84: `for row in range(rows):` This iterates row over ‘range(rows)‘. Each iteration repeats the indented host operation, commonly once per layer, tile, timestep, or test case in the function execute, which handles execute.

Line 85: `for column in range(columns):` This iterates column over ‘range(columns)‘. Each iteration repeats the indented host operation, commonly once per layer, tile, timestep, or test case in the function execute, which handles execute.

Line 86: `encoded = int(result[row, column]) & ((1 << 48) - 1)` This assigns ‘int(result[row, column]) & ((1 << 48) - 1)‘ to ‘encoded ‘ in host memory. Here encoded means the value named ’encoded’ in this block. The important operands are result: the value named ’result’ in this block; row: one output-row position processed by the tensor tile; column: one output-feature position processed in parallel. Context: the function execute, which handles execute.

Line 87: `encoded |= row << 48` Inside the function execute, which handles execute, this statement advances the host implementation that checks neuraedge compiler behavior independently with Python assertions. The important operands are encoded: the value named ’encoded’ in this block; row: one output-row position processed by the tensor tile.

Line 88: `encoded |= column << 52` Inside the function execute, which handles execute, this statement advances the host implementation that checks neuraedge compiler behavior independently with Python assertions. The important operands are encoded: the value named ’encoded’ in this block; column: one output-feature position processed in parallel.

Line 89: `encoded |= int(len(words) == output_beats - 1) << 58` Inside the function execute, which handles execute, this statement advances the host implementation that checks neuraedge compiler behavior independently with Python assertions. The important operands are encoded: the value named ’encoded’ in this block; len: the value named ’len’ in this block; words: the value named ’words’ in this block.

Line 90: `words.append(encoded)` This calls ‘words.append‘ with ‘encoded‘ inside the function execute, which handles execute. The call advances the host-side job that checks neuraedge compiler behavior independently with Python assertions.

Line 91: `if len(words) != output_beats:` This executes the following indented host-code branch only when ‘len(words) != output_beats‘ is true. The important operands are len: the value named ’len’ in this block; words: the value named ’words’ in this block; output_beats: the value named ’output beats’ in this block. Context: the function execute, which handles execute.

Line 92: `raise AssertionError("compiler requested the wrong output beat count")` This rejects an invalid state by raising ‘AssertionError("compiler requested the wrong output beat count")‘. Failing before DMA prevents malformed shapes or artifacts from silently becoming hardware results.

Line 93: `return tuple(words)` This returns ‘tuple(words)‘ to the caller of the function execute, which handles execute, ending this invocation. The important operands are tuple: the value named ’tuple’ in this block; words: the value named ’words’ in this block.

Line 95: `def execute_program(` This starts function execute_program. Its indented body performs execute program as part of the file that checks neuraedge compiler behavior independently with Python assertions; it runs only when called.

Line 96: `self,` Inside the function execute_program, which handles execute program, this statement advances the host implementation that checks neuraedge compiler behavior independently with Python assertions. The expression is a literal or structural operator and has no hidden software state.

Line 97: `records,` Inside the function execute_program, which handles execute program, this statement advances the host implementation that checks neuraedge compiler behavior independently with Python assertions. The important operands are records: the number of descriptor records accepted since program start.

Line 98: `*,` Inside the function execute_program, which handles execute program, this statement advances the host implementation that checks neuraedge compiler behavior independently with Python assertions. The expression is a literal or structural operator and has no hidden software state.

Line 99: `timeout_seconds: float = 30.0,` This assigns ‘30.0,‘ to ‘timeout_seconds‘ in host memory. Here timeout_seconds means the value named ’timeout seconds’ in this block. The expression is a literal or structural operator and has no hidden software state. Context: the function execute_program, which handles execute program.

Line 100: `) -> tuple[int, ...]:` Inside the function execute_program, which handles execute program, this statement advances the host implementation that checks neuraedge compiler behavior independently with Python assertions. The important operands are tuple: the value named ’tuple’ in this block.

Line 101: `words: list[int] = []` This assigns ‘[]‘ to ‘words‘ in host memory. Here words means the value named ’words’ in this block. The expression is a literal or structural operator and has no hidden software state. Context: the function execute_program, which handles execute program.

Line 102: `for record in records:` This iterates record over ‘records‘. Each iteration repeats the indented host operation, commonly once per layer, tile, timestep, or test case in the function execute_program, which handles execute program.

Line 103: `words.extend(self.execute(` This statement continues through source line 108; the explanation uses the complete expression rather than only the first visual fragment. This calls ‘words.extend‘ with ‘self.execute(record.command, record.input_beats, output_beats=record.output_beats, timeout_seconds=timeout_seconds,)‘ inside the function execute_program, which handles execute program. The call advances the host-side job that checks neuraedge compiler behavior independently with Python assertions.

Line 104: `record.command,` This is continuation line 2 of the 6-line logical statement that begins at source line 103. Its exact fragment is ‘record.command,‘. The important operands are record: the value named ’record’ in this block; command: the 128-bit instruction selecting an engine, shape, mode, and numeric parameters. Read together, the complete operation is: This calls ‘words.extend‘ with ‘self.execute(record.command, record.input_beats, output_beats=record.output_beats, timeout_seconds=timeout_seconds,)‘ inside the function execute_program, which handles execute program. The call advances the host-side job that checks neuraedge compiler behavior independently with Python assertions.

Line 105: `record.input_beats,` This is continuation line 3 of the 6-line logical statement that begins at source line 103. Its exact fragment is ‘record.input_beats,‘. The important operands are record: the value named ’record’ in this block; input_beats: the value named ’input beats’ in this block. Read together, the complete operation is: This calls ‘words.extend‘ with ‘self.execute(record.command, record.input_beats, output_beats=record.output_beats, timeout_seconds=timeout_seconds,)‘ inside the function execute_program, which handles execute program. The call advances the host-side job that checks neuraedge compiler behavior independently with Python assertions.

Line 106: `output_beats=record.output_beats,` This is continuation line 4 of the 6-line logical statement that begins at source line 103. Its exact fragment is ‘output_beats=record.output_beats,‘. The important operands are output_beats: the value named ’output beats’ in this block; record: the value named ’record’ in this block. Read together, the complete operation is: This calls ‘words.extend‘ with ‘self.execute(record.command, record.input_beats, output_beats=record.output_beats, timeout_seconds=timeout_seconds,)‘ inside the function execute_program, which

handles execute program. The call advances the host-side job that checks neuraedge compiler behavior independently with Python assertions.

Line 107: `timeout_seconds=timeout_seconds,` This is continuation line 5 of the 6-line logical statement that begins at source line 103. Its exact fragment is 'timeout_seconds=timeout_seconds,'. The important operands are timeout_seconds: the value named 'timeout seconds' in this block. Read together, the complete operation is: This calls 'words.extend' with 'self.execute(record.command, record.input_beats, output_beats=record.output_beats, timeout_seconds=timeout_seconds,)' inside the function execute_program, which handles execute program. The call advances the host-side job that checks neuraedge compiler behavior independently with Python assertions.

Line 108: `))` This is continuation line 6 of the 6-line logical statement that begins at source line 103. Its exact fragment is '))'. The expression is a literal or structural operator and has no hidden software state. Read together, the complete operation is: This calls 'words.extend' with 'self.execute(record.command, record.input_beats, output_beats=record.output_beats, timeout_seconds=timeout_seconds,)' inside the function execute_program, which handles execute program. The call advances the host-side job that checks neuraedge compiler behavior independently with Python assertions.

Line 109: `return tuple(words)` This returns 'tuple(words)' to the caller of the function execute_program, which handles execute program, ending this invocation. The important operands are tuple: the value named 'tuple' in this block; words: the value named 'words' in this block.

Line 111: `@staticmethod` This decorator changes how the following class or function is constructed. '@staticmethod' is applied at import time on the host and is part of the class TensorTransactionEmulator, which handles tensor transaction emulator; it creates no FPGA circuit by itself.

Line 112: `def assert_shape(array: np.ndarray, shape: tuple[int, ...]) -> None:` This starts function assert_shape. Its indented body performs assert shape as part of the file that checks neuraedge compiler behavior independently with Python assertions; it runs only when called.

Line 113: `if array.shape != shape:` This executes the following indented host-code branch only when 'array.shape != shape' is true. The important operands are array: the value named 'array' in this block; shape: the value named 'shape' in this block. Context: the function assert_shape, which handles assert shape.

Line 114: `raise AssertionError(f"stream shape {array.shape} != {shape}")` This rejects an invalid state by raising 'AssertionError(f"stream shape {array.shape} != {shape}")'. Failing before DMA prevents malformed shapes or artifacts from silently becoming hardware results.

Line 117: `def direct_conv2d(` This starts function direct_conv2d. Its indented body performs direct conv2d as part of the file that checks neuraedge compiler behavior independently with Python assertions; it runs only when called.

Line 118: `activations: np.ndarray,` Inside the function direct_conv2d, which handles direct conv2d, this statement advances the host implementation that checks neuraedge compiler behavior independently with Python assertions. The important operands are activations: an input feature value consumed by a neuron or multiply-accumulate operation; ndarray: the value named 'ndarray' in this block.

Line 119: `weights: np.ndarray,` Inside the function direct_conv2d, which handles direct conv2d, this statement advances the host implementation that checks neuraedge compiler behavior independently with Python assertions. The important operands are weights: a learned coefficient multiplied by an activation; ndarray: the value named 'ndarray' in this block.

Line 120: `bias: np.ndarray,` Inside the function direct_conv2d, which handles direct conv2d, this statement advances the host implementation that checks neuraedge compiler behavior independently with Python assertions. The important operands are bias: an additive learned offset applied after accumulation; ndarray: the value named 'ndarray' in this block.

Line 121: `*,` Inside the function direct_conv2d, which handles direct conv2d, this statement advances the host implementation that checks neuraedge compiler behavior independently with Python assertions. The expression is a literal or structural operator and has no hidden software state.

Line 122: `activation_zero_point: int = 0,` This assigns ‘0,‘ to ‘activation_zero_point‘ in host memory. Here activation_zero_point means an input feature value consumed by a neuron or multiply-accumulate operation. The expression is a literal or structural operator and has no hidden software state. Context: the function direct_conv2d, which handles direct conv2d.

Line 123: `weight_zero_point: int = 0,` This assigns ‘0,‘ to ‘weight_zero_point‘ in host memory. Here weight_zero_point means a learned coefficient multiplied by an activation. The expression is a literal or structural operator and has no hidden software state. Context: the function direct_conv2d, which handles direct conv2d.

Line 124: `stride: tuple[int, int] = (1, 1),` This assigns ‘(1, 1),‘ to ‘stride‘ in host memory. Here stride means the value named ’stride’ in this block. The expression is a literal or structural operator and has no hidden software state. Context: the function direct_conv2d, which handles direct conv2d.

Line 125: `padding: tuple[int, int] = (0, 0),` This assigns ‘(0, 0),‘ to ‘padding‘ in host memory. Here padding means the value named ’padding’ in this block. The expression is a literal or structural operator and has no hidden software state. Context: the function direct_conv2d, which handles direct conv2d.

Line 126: `dilation: tuple[int, int] = (1, 1),` This assigns ‘(1, 1),‘ to ‘dilation‘ in host memory. Here dilation means the value named ’dilation’ in this block. The expression is a literal or structural operator and has no hidden software state. Context: the function direct_conv2d, which handles direct conv2d.

Line 127: `groups: int = 1,` This assigns ‘1,‘ to ‘groups‘ in host memory. Here groups means the value named ’groups’ in this block. The expression is a literal or structural operator and has no hidden software state. Context: the function direct_conv2d, which handles direct conv2d.

Line 128: `) -> np.ndarray:` Inside the function direct_conv2d, which handles direct conv2d, this statement advances the host implementation that checks neuraedge compiler behavior independently with Python assertions. The important operands are ndarray: the value named ’ndarray’ in this block.

Line 129: `batch, input_channels, height, width = activations.shape` This assigns ‘activations.shape‘ to ‘batch, input_channels, height, width ‘ in host memory. Here batch means the value named ’batch’ in this block. The important operands are activations: an input feature value consumed by a neuron or multiply-accumulate operation; shape: the value named ’shape’ in this block. Context: the function direct_conv2d, which handles direct conv2d.

Line 130: `output_channels, channels_per_group, kernel_height, kernel_width = weights.shape` This assigns ‘weights.shape‘ to ‘output_channels, channels_per_group, kernel_height, kernel_width ‘ in host memory. Here output_channels means the value named ’output channels’ in this block. The important operands are weights: a learned coefficient multiplied by an activation; shape: the value named ’shape’ in this block. Context: the function direct_conv2d, which handles direct conv2d.

Line 131: `outputs_per_group = output_channels // groups` This assigns ‘output_channels // groups‘ to ‘outputs_per_group ‘ in host memory. Here outputs_per_group means the value named ’outputs per group’ in this block. The important operands are output_channels: the value named ’output channels’ in this block; groups: the value named ’groups’ in this block. Context: the function direct_conv2d, which handles direct conv2d.

Line 132: `output_height = (height + 2 * padding[0] - dilation[0] * (kernel_height - 1) - 1) // stride[0] + 1` This assigns ‘(height + 2 * padding[0] - dilation[0] * (kernel_height - 1) - 1) // stride[0] + 1‘ to ‘output_height ‘ in host memory. Here output_height means the value named ’output height’ in this block. The important operands are height: the value named ’height’ in this block; padding: the value named ’padding’ in this block; dilation: the value named ’dilation’ in this block. Context: the function direct_conv2d, which handles direct conv2d.

Line 133: `output_width = (width + 2 * padding[1] - dilation[1] * (kernel_width - 1) - 1) // stride[1] + 1` This assigns '(width + 2 * padding[1] - dilation[1] * (kernel_width - 1) - 1) // stride[1] + 1' to 'output_width ' in host memory. Here output_width means the value named 'output width' in this block. The important operands are width: the value named 'width' in this block; padding: the value named 'padding' in this block; dilation: the value named 'dilation' in this block. Context: the function direct_conv2d, which handles direct conv2d.

Line 134: `output = np.zeros((batch, output_channels, output_height, output_width), dtype=np.int64)` This assigns 'np.zeros((batch, output_channels, output_height, output_width), dtype=np.int64)' to 'output ' in host memory. Here output means the value named 'output' in this block. The important operands are zeros: the value named 'zeros' in this block; batch: the value named 'batch' in this block; output_channels: the value named 'output channels' in this block. Context: the function direct_conv2d, which handles direct conv2d.

Line 135: `for n in range(batch):` This iterates n over 'range(batch)'. Each iteration repeats the indented host operation, commonly once per layer, tile, timestep, or test case in the function direct_conv2d, which handles direct conv2d.

Line 136: `for output_channel in range(output_channels):` This iterates output_channel over 'range(output_channels)'. Each iteration repeats the indented host operation, commonly once per layer, tile, timestep, or test case in the function direct_conv2d, which handles direct conv2d.

Line 137: `group = output_channel // outputs_per_group` This assigns 'output_channel // outputs_per_group' to 'group ' in host memory. Here group means the value named 'group' in this block. The important operands are output_channel: the value named 'output channel' in this block; outputs_per_group: the value named 'outputs per group' in this block. Context: the function direct_conv2d, which handles direct conv2d.

Line 138: `input_start = group * channels_per_group` This assigns 'group * channels_per_group' to 'input_start ' in host memory. Here input_start means the value named 'input start' in this block. The important operands are group: the value named 'group' in this block; channels_per_group: the value named 'channels per group' in this block. Context: the function direct_conv2d, which handles direct conv2d.

Line 139: `for output_y in range(output_height):` This iterates output_y over 'range(output_height)'. Each iteration repeats the indented host operation, commonly once per layer, tile, timestep, or test case in the function direct_conv2d, which handles direct conv2d.

Line 140: `for output_x in range(output_width):` This iterates output_x over 'range(output_width)'. Each iteration repeats the indented host operation, commonly once per layer, tile, timestep, or test case in the function direct_conv2d, which handles direct conv2d.

Line 141: `accumulator = int(bias[output_channel])` This assigns 'int(bias[output_channel])' to 'accumulator ' in host memory. Here accumulator means a widened running sum that prevents intermediate overflow. The important operands are bias: an additive learned offset applied after accumulation; output_channel: the value named 'output channel' in this block. Context: the function direct_conv2d, which handles direct conv2d.

Line 142: `for local_channel in range(channels_per_group):` This iterates local_channel over 'range(channels_per_group)'. Each iteration repeats the indented host operation, commonly once per layer, tile, timestep, or test case in the function direct_conv2d, which handles direct conv2d.

Line 143: `input_channel = input_start + local_channel` This assigns 'input_start + local_channel' to 'input_channel ' in host memory. Here input_channel means the value named 'input channel' in this block. The important operands are input_start: the value named 'input start' in this block; local_channel: the value named 'local channel' in this block. Context: the function direct_conv2d, which handles direct conv2d.

Line 144: `for kernel_y in range(kernel_height):` This iterates kernel_y over 'range(kernel_height)'. Each iteration repeats the indented host operation, commonly once per layer, tile, timestep, or test case in the function direct_conv2d, which handles direct conv2d.

Line 145: `input_y = output_y * stride[0] + kernel_y * dilation[0] - padding[0]` This assigns ‘output_y * stride[0] + kernel_y * dilation[0] - padding[0]‘ to ‘input_y ‘ in host memory. Here input_y means the value named ’input y’ in this block. The important operands are output_y: the value named ’output y’ in this block; stride: the value named ’stride’ in this block; kernel_y: the value named ’kernel y’ in this block. Context: the function direct_conv2d, which handles direct conv2d.

Line 146: `for kernel_x in range(kernel_width):` This iterates kernel_x over ‘range(kernel_width)‘. Each iteration repeats the indented host operation, commonly once per layer, tile, timestep, or test case in the function direct_conv2d, which handles direct conv2d.

Line 147: `input_x = output_x * stride[1] + kernel_x * dilation[1] - padding[1]` This assigns ‘output_x * stride[1] + kernel_x * dilation[1] - padding[1]‘ to ‘input_x ‘ in host memory. Here input_x means the value named ’input x’ in this block. The important operands are output_x: the value named ’output x’ in this block; stride: the value named ’stride’ in this block; kernel_x: the value named ’kernel x’ in this block. Context: the function direct_conv2d, which handles direct conv2d.

Line 148: `activation = activation_zero_point` This assigns ‘activation_zero_point‘ to ‘activation ‘ in host memory. Here activation means an input feature value consumed by a neuron or multiply-accumulate operation. The important operands are activation_zero_point: an input feature value consumed by a neuron or multiply-accumulate operation. Context: the function direct_conv2d, which handles direct conv2d.

Line 149: `if 0 <= input_y < height and 0 <= input_x < width:` This executes the following indented host-code branch only when ‘0 <= input_y < height and 0 <= input_x < width‘ is true. The important operands are input_y: the value named ’input y’ in this block; height: the value named ’height’ in this block; and: the value named ’and’ in this block. Context: the function direct_conv2d, which handles direct conv2d.

Line 150: `activation = int(activations[n, input_channel, input_y, input_x])` This assigns ‘int(activations[n, input_channel, input_y, input_x])‘ to ‘activation ‘ in host memory. Here activation means an input feature value consumed by a neuron or multiply-accumulate operation. The important operands are activations: an input feature value consumed by a neuron or multiply-accumulate operation; n: the value named ’n’ in this block; input_channel: the value named ’input channel’ in this block. Context: the function direct_conv2d, which handles direct conv2d.

Line 151: `weight = int(weights[output_channel, local_channel, kernel_y, kernel_x])` This assigns ‘int(weights[outpu
local_channel, kernel_y, kernel_x])‘ to ‘weight ‘ in host memory. Here weight means a learned coefficient multiplied by an activation. The important operands are weights: a learned coefficient multiplied by an activation; output_channel: the value named ’output channel’ in this block; local_channel: the value named ’local channel’ in this block. Context: the function direct_conv2d, which handles direct conv2d.

Line 152: `accumulator += ((activation - activation_zero_point)` This statement continues through source line 153; the explanation uses the complete expression rather than only the first visual fragment. Inside the function direct_conv2d, which handles direct conv2d, this statement advances the host implementation that checks neuraedge compiler behavior independently with Python assertions. The important operands are accumulator: a widened running sum that prevents intermediate overflow; activation: an input feature value consumed by a neuron or multiply-accumulate operation; activation_zero_point: an input feature value consumed by a neuron or multiply-accumulate operation.

Line 153: `* (weight - weight_zero_point))` This is continuation line 2 of the 2-line logical statement that begins at source line 152. Its exact fragment is ‘* (weight - weight_zero_point))‘. The important operands are weight: a learned coefficient multiplied by an activation; weight_zero_point: a learned coefficient multiplied by an activation. Read together, the complete operation is: Inside the function direct_conv2d, which handles direct conv2d, this statement advances the host implementation that checks neuraedge compiler behavior independently with Python assertions. The important operands are accumulator: a widened running sum that prevents intermediate overflow; activation: an input feature value consumed by a neuron or multiply-accumulate operation; activation_zero_point: an input feature value consumed by a neuron or multiply-accumulate operation.

Line 154: `output[n, output_channel, output_y, output_x] = accumulator` This assigns ‘accumulator‘ to ‘output[n, output_channel, output_y, output_x] ‘ in host memory. Here output means the value named ’output’ in this block. The important operands are accumulator: a widened running sum that prevents intermediate overflow. Context: the function direct_conv2d, which handles direct conv2d.

Line 155: `return output` This returns ‘output‘ to the caller of the function direct_conv2d, which handles direct conv2d, ending this invocation. The important operands are output: the value named ’output’ in this block.

Line 158: `class CompilerTests(unittest.TestCase):` This defines class CompilerTests, which groups data and methods for compiler tests. Instances exist in host memory and organize the flow that checks neuraedge compiler behavior independently with Python assertions.

Line 159: `def setUp(self) -> None:` This starts function setUp. Its indented body performs set up as part of the file that checks neuraedge compiler behavior independently with Python assertions; it runs only when called.

Line 160: `self.rng = np.random.default_rng(20260713)` This assigns ‘np.random.default_rng(20260713)‘ to ‘self.rng ‘ in host memory. Here rng means the value named ’rng’ in this block. The important operands are random: the value named ’random’ in this block; default_rng: the value named ’default rng’ in this block. Context: the function setUp, which handles set up.

Line 162: `def check_case(self, rows: int, reduction: int, columns: int, dataflow: Dataflow | None = None) -> None:` This starts function check_case. Its indented body performs check case as part of the file that checks neuraedge compiler behavior independently with Python assertions; it runs only when called.

Line 163: `a = self.rng.integers(0, 256, size=(rows, reduction), dtype=np.uint8)` This assigns ‘self.rng.integers(0, 256, size=(rows, reduction), dtype=np.uint8)‘ to ‘a ‘ in host memory. Here a means the value named ’a’ in this block. The important operands are rng: the value named ’rng’ in this block; integers: the value named ’integers’ in this block; size: the value named ’size’ in this block. Context: the function check_case, which handles check case.

Line 164: `b = self.rng.integers(0, 256, size=(reduction, columns), dtype=np.uint8)` This assigns ‘self.rng.integers(0 256, size=(reduction, columns), dtype=np.uint8)‘ to ‘b ‘ in host memory. Here b means the value named ’b’ in this block. The important operands are rng: the value named ’rng’ in this block; integers: the value named ’integers’ in this block; size: the value named ’size’ in this block. Context: the function check_case, which handles check case.

Line 165: `bias = self.rng.integers(-100000, 100001, size=columns, dtype=np.int64)` This assigns ‘self.rng.integers(-100000, 100001, size=columns, dtype=np.int64)‘ to ‘bias ‘ in host memory. Here bias means an additive learned offset applied after accumulation. The important operands are rng: the value named ’rng’ in this block; integers: the value named ’integers’ in this block; size: the value named ’size’ in this block. Context: the function check_case, which handles check case.

Line 166: `za = int(self.rng.integers(0, 256))` This assigns ‘int(self.rng.integers(0, 256))‘ to ‘za ‘ in host memory. Here za means the value named ’za’ in this block. The important operands are rng: the value named ’rng’ in this block; integers: the value named ’integers’ in this block. Context: the function check_case, which handles check case.

Line 167: `zb = int(self.rng.integers(0, 256))` This assigns ‘int(self.rng.integers(0, 256))‘ to ‘zb ‘ in host memory. Here zb means the value named ’zb’ in this block. The important operands are rng: the value named ’rng’ in this block; integers: the value named ’integers’ in this block. Context: the function check_case, which handles check case.

Line 168: `program = compile_u8_gemm(` This statement continues through source line 171; the explanation uses the complete expression rather than only the first visual fragment. This assigns ‘compile_u8_gemm(a, b, activation_zero_point=za, weight_zero_point=zb, bias=bias, dataflow=dataflow,)‘ to ‘program ‘ in host memory. Here program means the value named ’program’ in this block. The important operands are compile_u8_gemm: the value named ’compile u8 gemm’ in this block; a: the value named ’a’ in this block; b: the value named ’b’ in this block. Context: the function check_case, which handles check case.

Line 169: `a, b, activation_zero_point=za, weight_zero_point=zb, bias=bias,` This is continuation line 2 of the 4-line logical statement that begins at source line 168. Its exact fragment is 'a, b, activation_zero_point=za, weight_zero_point=zb, bias=bias,'. The important operands are a: the value named 'a' in this block; b: the value named 'b' in this block; activation_zero_point: an input feature value consumed by a neuron or multiply-accumulate operation. Read together, the complete operation is: This assigns 'compile_u8_gemm(a, b, activation_zero_point=za, weight_zero_point=zb, bias=bias, dataflow=dataflow,)' to 'program ' in host memory. Here program means the value named 'program' in this block. The important operands are compile_u8_gemm: the value named 'compile u8 gemm' in this block; a: the value named 'a' in this block; b: the value named 'b' in this block. Context: the function check_case, which handles check case.

Line 170: `dataflow=dataflow,` This is continuation line 3 of the 4-line logical statement that begins at source line 168. Its exact fragment is 'dataflow=dataflow,'. The important operands are dataflow: the value named 'dataflow' in this block. Read together, the complete operation is: This assigns 'compile_u8_gemm(a, b, activation_zero_point=za, weight_zero_point=zb, bias=bias, dataflow=dataflow,)' to 'program ' in host memory. Here program means the value named 'program' in this block. The important operands are compile_u8_gemm: the value named 'compile u8 gemm' in this block; a: the value named 'a' in this block; b: the value named 'b' in this block. Context: the function check_case, which handles check case.

Line 171: `)` This is continuation line 4 of the 4-line logical statement that begins at source line 168. Its exact fragment is ')'. The expression is a literal or structural operator and has no hidden software state. Read together, the complete operation is: This assigns 'compile_u8_gemm(a, b, activation_zero_point=za, weight_zero_point=zb, bias=bias, dataflow=dataflow,)' to 'program ' in host memory. Here program means the value named 'program' in this block. The important operands are compile_u8_gemm: the value named 'compile u8 gemm' in this block; a: the value named 'a' in this block; b: the value named 'b' in this block. Context: the function check_case, which handles check case.

Line 172: `actual = program.execute(TensorTransactionEmulator())` This assigns 'program.execute(TensorTransactionEmu to 'actual ' in host memory. Here actual means the value named 'actual' in this block. The important operands are program: the value named 'program' in this block; execute: the value named 'execute' in this block; TensorTransactionEmulator: the value named 'tensor transaction emulator' in this block. Context: the function check_case, which handles check case.

Line 173: `batched = program.execute_batched(TensorTransactionEmulator())` This assigns 'program.execute_batched(Te to 'batched ' in host memory. Here batched means the value named 'batched' in this block. The important operands are program: the value named 'program' in this block; execute_batched: the value named 'execute batched' in this block; TensorTransactionEmulator: the value named 'tensor transaction emulator' in this block. Context: the function check_case, which handles check case.

Line 174: `expected = direct_centered_gemm(a, b, za, zb, bias)` This assigns 'direct_centered_gemm(a, b, za, zb, bias)' to 'expected ' in host memory. Here expected means the value named 'expected' in this block. The important operands are direct_centered_gemm: the value named 'direct centered gemm' in this block; a: the value named 'a' in this block; b: the value named 'b' in this block. Context: the function check_case, which handles check case.

Line 175: `np.testing.assert_array_equal(actual, expected)` This calls 'np.testing.assert_array_equal' with 'actual, expected' inside the function check_case, which handles check case. The call advances the host-side job that checks neuraedge compiler behavior independently with Python assertions.

Line 176: `np.testing.assert_array_equal(batched, expected)` This calls 'np.testing.assert_array_equal' with 'batched, expected' inside the function check_case, which handles check case. The call advances the host-side job that checks neuraedge compiler behavior independently with Python assertions.

Line 177: `self.assertEqual(program.mathematical_macs, rows * reduction * columns)` This calls 'self.assertEqual' with 'program.mathematical_macs, rows * reduction * columns' inside the function check_case, which handles check case. The call advances the host-side job that checks neuraedge compiler behavior independently with Python assertions.

Line 178: `self.assertGreater(program.estimated_input_bytes, 0)` This calls ‘self.assertGreater‘ with ‘program.estimated_ 0‘ inside the function check_case, which handles check case. The call advances the host-side job that checks neuraedge compiler behavior independently with Python assertions.

Line 180: `def test_outer_mode_irregular_tiles_both_dataflows(self) -> None:` This starts function test_outer_mode_ Its indented body performs test outer mode irregular tiles both dataflows as part of the file that checks neuraedge compiler behavior independently with Python assertions; it runs only when called.

Line 181: `self.check_case(13, 37, 29, Dataflow.INPUT_BROADCAST)` This calls ‘self.check_case‘ with ‘13, 37, 29, Dataflow.INPUT_BROADCAST‘ inside the function test_outer_mode_irregular_tiles_both_dataflows, which handles test outer mode irregular tiles both dataflows. The call advances the host-side job that checks neuraedge compiler behavior independently with Python assertions.

Line 182: `self.check_case(17, 33, 19, Dataflow.WEIGHT_BROADCAST)` This calls ‘self.check_case‘ with ‘17, 33, 19, Dataflow.WEIGHT_BROADCAST‘ inside the function test_outer_mode_irregular_tiles_both_dataflows, which handles test outer mode irregular tiles both dataflows. The call advances the host-side job that checks neuraedge compiler behavior independently with Python assertions.

Line 184: `def test_dot8_single_row_with_padding(self) -> None:` This starts function test_dot8_single_row_with_pad Its indented body performs test dot8 single row with padding as part of the file that checks neuraedge compiler behavior independently with Python assertions; it runs only when called.

Line 185: `self.check_case(1, 19, 35)` This calls ‘self.check_case‘ with ‘1, 19, 35‘ inside the function test_dot8_single_row_w which handles test dot8 single row with padding. The call advances the host-side job that checks neuraedge compiler behavior independently with Python assertions.

Line 187: `def test_reduction_larger_than_local_memory(self) -> None:` This starts function test_reduction_larger_tha Its indented body performs test reduction larger than local memory as part of the file that checks neuraedge compiler behavior independently with Python assertions; it runs only when called.

Line 188: `self.check_case(9, 2053, 17)` This calls ‘self.check_case‘ with ‘9, 2053, 17‘ inside the function test_reduction_large which handles test reduction larger than local memory. The call advances the host-side job that checks neuraedge compiler behavior independently with Python assertions.

Line 190: `def test_zero_skipping_and_boundary_values(self) -> None:` This starts function test_zero_skipping_and_bo Its indented body performs test zero skipping and boundary values as part of the file that checks neuraedge compiler behavior independently with Python assertions; it runs only when called.

Line 191: `a = np.full((8, 9), 128, dtype=np.uint8)` This assigns ‘np.full((8, 9), 128, dtype=np.uint8)‘ to ‘a ‘ in host memory. Here a means the value named ’a’ in this block. The important operands are full: the value named ’full’ in this block; dtype: the value named ’dtype’ in this block; uint8: the value named ’uint8’ in this block. Context: the function test_zero_skipping_and_boundary_values, which handles test zero skipping and boundary values.

Line 192: `b = np.full((9, 16), 129, dtype=np.uint8)` This assigns ‘np.full((9, 16), 129, dtype=np.uint8)‘ to ‘b ‘ in host memory. Here b means the value named ’b’ in this block. The important operands are full: the value named ’full’ in this block; dtype: the value named ’dtype’ in this block; uint8: the value named ’uint8’ in this block. Context: the function test_zero_skipping_and_boundary_values, which handles test zero skipping and boundary values.

Line 193: `a[3, 4] = 255` This assigns ‘255‘ to ‘a[3, 4] ‘ in host memory. Here a means the value named ’a’ in this block. The expression is a literal or structural operator and has no hidden software state. Context: the function test_zero_skipping_and_boundary_values, which handles test zero skipping and boundary values.

Line 194: `b[4, 7] = 0` This assigns ‘0‘ to ‘b[4, 7] ‘ in host memory. Here b means the value named ’b’ in this block. The expression is a literal or structural operator and has no hidden software state. Context: the function test_zero_skipping_and_boundary_values, which handles test zero skipping and boundary values.

Line 195: `program = compile_u8_gemm(a, b, activation_zero_point=128, weight_zero_point=129)` This assigns ‘compile_u8_gemm(a, b, activation_zero_point=128, weight_zero_point=129)‘ to ‘program ‘ in host memory. Here program means the value named ’program’ in this block. The important operands are compile_u8_gemm: the value named ’compile u8 gemm’ in this block; a: the value named ’a’ in this block; b: the value named ’b’ in this block. Context: the function test_zero_skipping_and_boundary_values, which handles test zero skipping and boundary values.

Line 196: `np.testing.assert_array_equal(` This statement continues through source line 199; the explanation uses the complete expression rather than only the first visual fragment. This calls ‘np.testing.assert_array_equal‘ with ‘ program.execute(TensorTransactionEmulator()), direct_centered_gemm(a, b, 128, 129), ‘ inside the function test_zero_skipping_and_boundary_values, which handles test zero skipping and boundary values. The call advances the host-side job that checks neuraedge compiler behavior independently with Python assertions.

Line 197: `program.execute(TensorTransactionEmulator()),` This is continuation line 2 of the 4-line logical statement that begins at source line 196. Its exact fragment is ‘program.execute(TensorTransactionEmulator()),‘. The important operands are program: the value named ’program’ in this block; execute: the value named ’execute’ in this block; TensorTransactionEmulator: the value named ’tensor transaction emulator’ in this block. Read together, the complete operation is: This calls ‘np.testing.assert_array_equal‘ with ‘ program.execute(TensorTransactionEmulator()), direct_centered_gemm(a, b, 128, 129), ‘ inside the function test_zero_skipping_and_boundary_values, which handles test zero skipping and boundary values. The call advances the host-side job that checks neuraedge compiler behavior independently with Python assertions.

Line 198: `direct_centered_gemm(a, b, 128, 129),` This is continuation line 3 of the 4-line logical statement that begins at source line 196. Its exact fragment is ‘direct_centered_gemm(a, b, 128, 129),‘. The important operands are direct_centered_gemm: the value named ’direct centered gemm’ in this block; a: the value named ’a’ in this block; b: the value named ’b’ in this block. Read together, the complete operation is: This calls ‘np.testing.assert_array_equal‘ with ‘ program.execute(TensorTransactionEmulator()), direct_centered_gemm(a, b, 128, 129), ‘ inside the function test_zero_skipping_and_boundary_values, which handles test zero skipping and boundary values. The call advances the host-side job that checks neuraedge compiler behavior independently with Python assertions.

Line 199: `)` This is continuation line 4 of the 4-line logical statement that begins at source line 196. Its exact fragment is ‘)‘. The expression is a literal or structural operator and has no hidden software state. Read together, the complete operation is: This calls ‘np.testing.assert_array_equal‘ with ‘ program.execute(TensorTransactionEmulator()), direct_centered_gemm(a, b, 128, 129), ‘ inside the function test_zero_skipping_and_boundary_values, which handles test zero skipping and boundary values. The call advances the host-side job that checks neuraedge compiler behavior independently with Python assertions.

Line 201: `def test_binary_and_ternary_sparse_paths(self) -> None:` This starts function test_binary_and_ternary_spa
Its indented body performs test binary and ternary sparse paths as part of the file that checks neuraedge compiler behavior independently with Python assertions; it runs only when called.

Line 202: `weights = self.rng.integers(-128, 128, size=(41, 23), dtype=np.int16)` This assigns ‘self.rng.integers(-128, 128, size=(41, 23), dtype=np.int16)‘ to ‘weights ‘ in host memory. Here weights means a learned coefficient multiplied by an activation. The important operands are rng: the value named ’rng’ in this block; integers: the value named ’integers’ in this block; size: the value named ’size’ in this block. Context: the function test_binary_and_ternary_sparse_paths, which handles test binary and ternary sparse paths.

Line 203: `binary = self.rng.integers(0, 2, size=(11, 41), dtype=np.int8)` This assigns ‘self.rng.integers(0, 2, size=(11, 41), dtype=np.int8)‘ to ‘binary ‘ in host memory. Here binary means the value named ’binary’ in this block. The important operands are rng: the value named ’rng’ in this block; integers: the value named ’integers’ in this block; size: the value named ’size’ in this block. Context: the function test_binary_and_ternary_sparse_paths, which handles test binary and ternary sparse paths.

Line 204: `ternary = self.rng.integers(-1, 2, size=(9, 41), dtype=np.int8)` This assigns ‘self.rng.integers(-1, 2, size=(9, 41), dtype=np.int8)‘ to ‘ternary ‘ in host memory. Here ternary means the value named ’ternary’ in this block. The important operands are rng: the value named ’rng’ in this block; integers: the value named ’integers’ in this block; size: the value named ’size’ in this block. Context: the function test_binary_and_ternary_sparse_paths, which handles test binary and ternary sparse paths.

Line 205: `binary_program = compile_spike_gemm(binary, weights)` This assigns ‘compile_spike_gemm(binary, weights)‘ to ‘binary_program ‘ in host memory. Here binary_program means the value named ’binary program’ in this block. The important operands are compile_spike_gemm: a binary event produced when a neuron crosses its threshold; binary: the value named ’binary’ in this block; weights: a learned coefficient multiplied by an activation. Context: the function test_binary_and_ternary_sparse_paths, which handles test binary and ternary sparse paths.

Line 206: `ternary_program = compile_spike_gemm(` This statement continues through source line 208; the explanation uses the complete expression rather than only the first visual fragment. This assigns ‘compile_spike_gemm(ternary, weights, ternary=True, dataflow=Dataflow.WEIGHT_BROADCAST,)‘ to ‘ternary_program ‘ in host memory. Here ternary_program means the value named ’ternary program’ in this block. The important operands are compile_spike_gemm: a binary event produced when a neuron crosses its threshold; ternary: the value named ’ternary’ in this block; weights: a learned coefficient multiplied by an activation. Context: the function test_binary_and_ternary_sparse_paths, which handles test binary and ternary sparse paths.

Line 207: `ternary, weights, ternary=True, dataflow=Dataflow.WEIGHT_BROADCAST,` This is continuation line 2 of the 3-line logical statement that begins at source line 206. Its exact fragment is ‘ternary, weights, ternary=True, dataflow=Dataflow.WEIGHT_BROADCAST,‘. The important operands are ternary: the value named ’ternary’ in this block; weights: a learned coefficient multiplied by an activation; dataflow: the value named ’dataflow’ in this block. Read together, the complete operation is: This assigns ‘compile_spike_gemm(ternary, weights, ternary=True, dataflow=Dataflow.WEIGHT_BROADCAST,)‘ to ‘ternary_program ‘ in host memory. Here ternary_program means the value named ’ternary program’ in this block. The important operands are compile_spike_gemm: a binary event produced when a neuron crosses its threshold; ternary: the value named ’ternary’ in this block; weights: a learned coefficient multiplied by an activation. Context: the function test_binary_and_ternary_sparse_paths, which handles test binary and ternary sparse paths.

Line 208: `)` This is continuation line 3 of the 3-line logical statement that begins at source line 206. Its exact fragment is ‘)‘. The expression is a literal or structural operator and has no hidden software state. Read together, the complete operation is: This assigns ‘compile_spike_gemm(ternary, weights, ternary=True, dataflow=Dataflow.WEIGHT_BROADCAST,)‘ to ‘ternary_program ‘ in host memory. Here ternary_program means the value named ’ternary program’ in this block. The important operands are compile_spike_gemm: a binary event produced when a neuron crosses its threshold; ternary: the value named ’ternary’ in this block; weights: a learned coefficient multiplied by an activation. Context: the function test_binary_and_ternary_sparse_paths, which handles test binary and ternary sparse paths.

Line 209: `np.testing.assert_array_equal(` This statement continues through source line 212; the explanation uses the complete expression rather than only the first visual fragment. This calls ‘np.testing.assert_array_equal‘ with ‘ binary_program.execute(TensorTransactionEmulator()), binary.astype(np.int64) @ weights.astype(np.int64), ‘ inside the function test_binary_and_ternary_sparse_paths, which handles test binary and ternary sparse paths. The call advances the host-side job that checks neuraedge compiler behavior independently with Python assertions.

Line 210: `binary_program.execute(TensorTransactionEmulator()),` This is continuation line 2 of the 4-line logical statement that begins at source line 209. Its exact fragment is ‘binary_program.execute(TensorTransactionEmulator()),‘. The important operands are binary_program: the value named ’binary program’ in this block; execute: the value named ’execute’ in this block; TensorTransactionEmulator: the value named ’tensor transaction emulator’ in this block. Read together, the complete operation is: This calls ‘np.testing.assert_array_equal‘ with ‘ binary_program.execute(TensorTransactionEmul binary.astype(np.int64) @ weights.astype(np.int64), ‘ inside the function test_binary_and_ternary_sparse_paths, which handles test binary and ternary sparse paths. The call advances the host-side job that checks neuraedge compiler behavior independently with Python assertions.

Line 211: `binary.astype(np.int64) @ weights.astype(np.int64),` This is continuation line 3 of the 4-line logical statement that begins at source line 209. Its exact fragment is ‘binary.astype(np.int64) @ weights.astype(np.int64),‘.

The important operands are binary: the value named 'binary' in this block; astype: the value named 'astype' in this block; int64: the value named 'int64' in this block. Read together, the complete operation is: This calls ‘np.testing.assert_array_equal‘ with ‘ binary_program.execute(TensorTransactionEmulator()), binary.astype(np.int64) @ weights.astype(np.int64), ‘ inside the function test_binary_and_ternary_sparse_paths, which handles test binary and ternary sparse paths. The call advances the host-side job that checks neuraedge compiler behavior independently with Python assertions.

Line 212: `)` This is continuation line 4 of the 4-line logical statement that begins at source line 209. Its exact fragment is ‘)‘. The expression is a literal or structural operator and has no hidden software state. Read together, the complete operation is: This calls ‘np.testing.assert_array_equal‘ with ‘ binary_program.execute(TensorTransactionEmulator()), binary.astype(np.int64) @ weights.astype(np.int64), ‘ inside the function test_binary_and_ternary_sparse_paths, which handles test binary and ternary sparse paths. The call advances the host-side job that checks neuraedge compiler behavior independently with Python assertions.

Line 213: `np.testing.assert_array_equal(` This statement continues through source line 216; the explanation uses the complete expression rather than only the first visual fragment. This calls ‘np.testing.assert_array_equal‘ with ‘ ternary_program.execute(TensorTransactionEmulator()), ternary.astype(np.int64) @ weights.astype(np.int64), ‘ inside the function test_binary_and_ternary_sparse_paths, which handles test binary and ternary sparse paths. The call advances the host-side job that checks neuraedge compiler behavior independently with Python assertions.

Line 214: `ternary_program.execute(TensorTransactionEmulator()),` This is continuation line 2 of the 4-line logical statement that begins at source line 213. Its exact fragment is ‘ternary_program.execute(TensorTransactionEmulator()),‘. The important operands are ternary_program: the value named 'ternary program' in this block; execute: the value named 'execute' in this block; TensorTransactionEmulator: the value named 'tensor transaction emulator' in this block. Read together, the complete operation is: This calls ‘np.testing.assert_array_equal‘ with ‘ ternary_program.execute(TensorTransactionEmu ternary.astype(np.int64) @ weights.astype(np.int64), ‘ inside the function test_binary_and_ternary_sparse_paths, which handles test binary and ternary sparse paths. The call advances the host-side job that checks neuraedge compiler behavior independently with Python assertions.

Line 215: `ternary.astype(np.int64) @ weights.astype(np.int64),` This is continuation line 3 of the 4-line logical statement that begins at source line 213. Its exact fragment is ‘ternary.astype(np.int64) @ weights.astype(np.int64),‘. The important operands are ternary: the value named 'ternary' in this block; astype: the value named 'astype' in this block; int64: the value named 'int64' in this block. Read together, the complete operation is: This calls ‘np.testing.assert_array_equal‘ with ‘ ternary_program.execute(TensorTransactionEmulator()), ternary.astype(np.int64) @ weights.astype(np.int64), ‘ inside the function test_binary_and_ternary_sparse_paths, which handles test binary and ternary sparse paths. The call advances the host-side job that checks neuraedge compiler behavior independently with Python assertions.

Line 216: `)` This is continuation line 4 of the 4-line logical statement that begins at source line 213. Its exact fragment is ‘)‘. The expression is a literal or structural operator and has no hidden software state. Read together, the complete operation is: This calls ‘np.testing.assert_array_equal‘ with ‘ ternary_program.execute(TensorTransactionEmulator()), ternary.astype(np.int64) @ weights.astype(np.int64), ‘ inside the function test_binary_and_ternary_sparse_paths, which handles test binary and ternary sparse paths. The call advances the host-side job that checks neuraedge compiler behavior independently with Python assertions.

Line 217: `self.assertEqual(binary_program.estimated_spike_adds, int(np.count_nonzero(binary)) * 23)` This calls ‘self.assertEqual‘ with ‘binary_program.estimated_spike_adds, int(np.count_nonzero(binary)) * 23‘ inside the function test_binary_and_ternary_sparse_paths, which handles test binary and ternary sparse paths. The call advances the host-side job that checks neuraedge compiler behavior independently with Python assertions.

Line 218: `self.assertEqual(ternary_program.estimated_spike_adds, int(np.count_nonzero(ternary)) * 23)` This calls ‘self.assertEqual‘ with ‘ternary_program.estimated_spike_adds, int(np.count_nonzero(ternary)) * 23‘ inside the function test_binary_and_ternary_sparse_paths, which handles test binary and ternary sparse paths. The call advances the host-side job that checks neuraedge compiler behavior independently with Python assertions.

Line 220: `def test_grouped_u8_convolution_with_stride_padding_and_dilation(self) -> None:` This starts function test_grouped_u8_convolution_with_stride_padding_and_dilation. Its indented body performs test grouped u8 convolution with stride padding and dilation as part of the file that checks neuraedge compiler behavior independently with Python assertions; it runs only when called.

Line 221: `activations = self.rng.integers(0, 256, size=(1, 4, 5, 6), dtype=np.uint8)` This assigns 'self.rng.integers 256, size=(1, 4, 5, 6), dtype=np.uint8)' to 'activations ' in host memory. Here activations means an input feature value consumed by a neuron or multiply-accumulate operation. The important operands are rng: the value named 'rng' in this block; integers: the value named 'integers' in this block; size: the value named 'size' in this block. Context: the function test_grouped_u8_convolution_with_stride_padding_and_dilation, which handles test grouped u8 convolution with stride padding and dilation.

Line 222: `weights = self.rng.integers(0, 256, size=(6, 2, 2, 3), dtype=np.uint8)` This assigns 'self.rng.integers(0, 256, size=(6, 2, 2, 3), dtype=np.uint8)' to 'weights ' in host memory. Here weights means a learned coefficient multiplied by an activation. The important operands are rng: the value named 'rng' in this block; integers: the value named 'integers' in this block; size: the value named 'size' in this block. Context: the function test_grouped_u8_convolution_with_stride_padding_ which handles test grouped u8 convolution with stride padding and dilation.

Line 223: `bias = self.rng.integers(-5000, 5001, size=6, dtype=np.int64)` This assigns 'self.rng.integers(-5000, 5001, size=6, dtype=np.int64)' to 'bias ' in host memory. Here bias means an additive learned offset applied after accumulation. The important operands are rng: the value named 'rng' in this block; integers: the value named 'integers' in this block; size: the value named 'size' in this block. Context: the function test_grouped_u8_convolution_with_stride_padding_a which handles test grouped u8 convolution with stride padding and dilation.

Line 224: `program = compile_u8_conv2d(` This statement continues through source line 234; the explanation uses the complete expression rather than only the first visual fragment. This assigns 'compile_u8_conv2d(activations, weights, activation_zero_point=117, weight_zero_point=133, bias=bias, stride=(2, 1), padding=(1, 2), dilation=(2, 1), groups=2,)' to 'program ' in host memory. Here program means the value named 'program' in this block. The important operands are compile_u8_conv2d: the value named 'compile u8 conv2d' in this block; activations: an input feature value consumed by a neuron or multiply-accumulate operation; weights: a learned coefficient multiplied by an activation. Context: the function test_grouped_u8_convolution_with_stride_padding_and_dilation, which handles test grouped u8 convolution with stride padding and dilation.

Line 225: `activations,` This is continuation line 2 of the 11-line logical statement that begins at source line 224. Its exact fragment is 'activations,'. The important operands are activations: an input feature value consumed by a neuron or multiply-accumulate operation. Read together, the complete operation is: This assigns 'compile_u8_conv2d(activations, weights, activation_zero_point=117, weight_zero_point=133, bias=bias, stride=(2, 1), padding=(1, 2), dilation=(2, 1), groups=2,)' to 'program ' in host memory. Here program means the value named 'program' in this block. The important operands are compile_u8_conv2d: the value named 'compile u8 conv2d' in this block; activations: an input feature value consumed by a neuron or multiply-accumulate operation; weights: a learned coefficient multiplied by an activation. Context: the function test_grouped_u8_convolution_with_stride_padding_and_dilation, which handles test grouped u8 convolution with stride padding and dilation.

Line 226: `weights,` This is continuation line 3 of the 11-line logical statement that begins at source line 224. Its exact fragment is 'weights,'. The important operands are weights: a learned coefficient multiplied by an activation. Read together, the complete operation is: This assigns 'compile_u8_conv2d(activations, weights, activation_zero_point=117, weight_zero_point=133, bias=bias, stride=(2, 1), padding=(1, 2), dilation=(2, 1), groups=2,)' to 'program ' in host memory. Here program means the value named 'program' in this block. The important operands are compile_u8_conv2d: the value named 'compile u8 conv2d' in this block; activations: an input feature value consumed by a neuron or multiply-accumulate operation; weights: a learned coefficient multiplied by an activation. Context: the function test_grouped_u8_convolution_with_stride_padding_and_dilation, which handles test grouped u8 convolution with stride padding and dilation.

Line 227: `activation_zero_point=117,` This is continuation line 4 of the 11-line logical statement that begins at source line 224. Its exact fragment is 'activation_zero_point=117,'. The important operands are activation_zero_point:

an input feature value consumed by a neuron or multiply-accumulate operation. Read together, the complete operation is: This assigns ‘compile_u8_conv2d(activations, weights, activation_zero_point=117, weight_zero_point=133, bias=bias, stride=(2, 1), padding=(1, 2), dilation=(2, 1), groups=2,)‘ to ‘program ‘ in host memory. Here program means the value named ’program’ in this block. The important operands are compile_u8_conv2d: the value named ’compile u8 conv2d’ in this block; activations: an input feature value consumed by a neuron or multiply-accumulate operation; weights: a learned coefficient multiplied by an activation. Context: the function test_grouped_u8_convolution_with_stride_padding_and_ which handles test grouped u8 convolution with stride padding and dilation.

Line 228: `weight_zero_point=133,` This is continuation line 5 of the 11-line logical statement that begins at source line 224. Its exact fragment is ‘weight_zero_point=133,‘. The important operands are weight_zero_point: a learned coefficient multiplied by an activation. Read together, the complete operation is: This assigns ‘compile_u8_conv2d(activations, weights, activation_zero_point=117, weight_zero_point=133, bias=bias, stride=(2, 1), padding=(1, 2), dilation=(2, 1), groups=2,)‘ to ‘program ‘ in host memory. Here program means the value named ’program’ in this block. The important operands are compile_u8_conv2d: the value named ’compile u8 conv2d’ in this block; activations: an input feature value consumed by a neuron or multiply-accumulate operation; weights: a learned coefficient multiplied by an activation. Context: the function test_grouped_u8_convolution_with_stride_padding_and_dilation, which handles test grouped u8 convolution with stride padding and dilation.

Line 229: `bias=bias,` This is continuation line 6 of the 11-line logical statement that begins at source line 224. Its exact fragment is ‘bias=bias,‘. The important operands are bias: an additive learned offset applied after accumulation. Read together, the complete operation is: This assigns ‘compile_u8_conv2d(activations, weights, activation_zero_point=117, weight_zero_point=133, bias=bias, stride=(2, 1), padding=(1, 2), dilation=(2, 1), groups=2,)‘ to ‘program ‘ in host memory. Here program means the value named ’program’ in this block. The important operands are compile_u8_conv2d: the value named ’compile u8 conv2d’ in this block; activations: an input feature value consumed by a neuron or multiply-accumulate operation; weights: a learned coefficient multiplied by an activation. Context: the function test_grouped_u8_convolution_with_stride_padding_and_dilation, which handles test grouped u8 convolution with stride padding and dilation.

Line 230: `stride=(2, 1),` This is continuation line 7 of the 11-line logical statement that begins at source line 224. Its exact fragment is ‘stride=(2, 1),‘. The important operands are stride: the value named ’stride’ in this block. Read together, the complete operation is: This assigns ‘compile_u8_conv2d(activations, weights, activation_zero_point=117, weight_zero_point=133, bias=bias, stride=(2, 1), padding=(1, 2), dilation=(2, 1), groups=2,)‘ to ‘program ‘ in host memory. Here program means the value named ’program’ in this block. The important operands are compile_u8_conv2d: the value named ’compile u8 conv2d’ in this block; activations: an input feature value consumed by a neuron or multiply-accumulate operation; weights: a learned coefficient multiplied by an activation. Context: the function test_grouped_u8_convolution_with_stride_padding_and_dilation, which handles test grouped u8 convolution with stride padding and dilation.

Line 231: `padding=(1, 2),` This is continuation line 8 of the 11-line logical statement that begins at source line 224. Its exact fragment is ‘padding=(1, 2),‘. The important operands are padding: the value named ’padding’ in this block. Read together, the complete operation is: This assigns ‘compile_u8_conv2d(activations, weights, activation_zero_point=117, weight_zero_point=133, bias=bias, stride=(2, 1), padding=(1, 2), dilation=(2, 1), groups=2,)‘ to ‘program ‘ in host memory. Here program means the value named ’program’ in this block. The important operands are compile_u8_conv2d: the value named ’compile u8 conv2d’ in this block; activations: an input feature value consumed by a neuron or multiply-accumulate operation; weights: a learned coefficient multiplied by an activation. Context: the function test_grouped_u8_convolution_with_stride_padding_and_dilation, which handles test grouped u8 convolution with stride padding and dilation.

Line 232: `dilation=(2, 1),` This is continuation line 9 of the 11-line logical statement that begins at source line 224. Its exact fragment is ‘dilation=(2, 1),‘. The important operands are dilation: the value named ’dilation’ in this block. Read together, the complete operation is: This assigns ‘compile_u8_conv2d(activations, weights, activation_zero_point=117, weight_zero_point=133, bias=bias, stride=(2, 1), padding=(1, 2), dilation=(2, 1), groups=2,)‘ to ‘program ‘ in host memory. Here program means the value named ’program’ in this block. The important operands are compile_u8_conv2d: the value named ’compile u8 conv2d’ in this block; activations: an input feature value consumed by a neuron or multiply-accumulate operation; weights: a learned coefficient multiplied by an activation. Context: the function test_grouped_u8_convolution_with_stride_padding_and_dilation, which handles test grouped u8 convolution with stride padding and dilation.

Line 233: `groups=2,` This is continuation line 10 of the 11-line logical statement that begins at source line 224. Its exact fragment is 'groups=2,'. The important operands are groups: the value named 'groups' in this block. Read together, the complete operation is: This assigns 'compile_u8_conv2d(activations, weights, activation_zero_point=117, weight_zero_point=133, bias=bias, stride=(2, 1), padding=(1, 2), dilation=(2, 1), groups=2,)' to 'program ' in host memory. Here program means the value named 'program' in this block. The important operands are compile_u8_conv2d: the value named 'compile u8 conv2d' in this block; activations: an input feature value consumed by a neuron or multiply-accumulate operation; weights: a learned coefficient multiplied by an activation. Context: the function test_grouped_u8_convolution_with_stride_padding_and_dilation, which handles test grouped u8 convolution with stride padding and dilation.

Line 234: `)` This is continuation line 11 of the 11-line logical statement that begins at source line 224. Its exact fragment is ')'. The expression is a literal or structural operator and has no hidden software state. Read together, the complete operation is: This assigns 'compile_u8_conv2d(activations, weights, activation_zero_point=117, weight_zero_point=133, bias=bias, stride=(2, 1), padding=(1, 2), dilation=(2, 1), groups=2,)' to 'program ' in host memory. Here program means the value named 'program' in this block. The important operands are compile_u8_conv2d: the value named 'compile u8 conv2d' in this block; activations: an input feature value consumed by a neuron or multiply-accumulate operation; weights: a learned coefficient multiplied by an activation. Context: the function test_grouped_u8_convolution_with_stride_padding_and_dilation, which handles test grouped u8 convolution with stride padding and dilation.

Line 235: `actual = program.execute(TensorTransactionEmulator())` This assigns 'program.execute(TensorTransactionEmu to 'actual ' in host memory. Here actual means the value named 'actual' in this block. The important operands are program: the value named 'program' in this block; execute: the value named 'execute' in this block; TensorTransactionEmulator: the value named 'tensor transaction emulator' in this block. Context: the function test_grouped_u8_convolution_with_stride_ which handles test grouped u8 convolution with stride padding and dilation.

Line 236: `expected = direct_conv2d(` This statement continues through source line 240; the explanation uses the complete expression rather than only the first visual fragment. This assigns 'direct_conv2d(activations, weights, bias, activation_zero_point=117, weight_zero_point=133, stride=(2, 1), padding=(1, 2), dilation=(2, 1), groups=2,)' to 'expected ' in host memory. Here expected means the value named 'expected' in this block. The important operands are direct_conv2d: the value named 'direct conv2d' in this block; activations: an input feature value consumed by a neuron or multiply-accumulate operation; weights: a learned coefficient multiplied by an activation. Context: the function test_grouped_u8_convolution_with_stride_padding_and_dilation, which handles test grouped u8 convolution with stride padding and dilation.

Line 237: `activations, weights, bias,` This is continuation line 2 of the 5-line logical statement that begins at source line 236. Its exact fragment is 'activations, weights, bias,'. The important operands are activations: an input feature value consumed by a neuron or multiply-accumulate operation; weights: a learned coefficient multiplied by an activation; bias: an additive learned offset applied after accumulation. Read together, the complete operation is: This assigns 'direct_conv2d(activations, weights, bias, activation_zero_point=117, weight_zero_point=133, stride=(2, 1), padding=(1, 2), dilation=(2, 1), groups=2,)' to 'expected ' in host memory. Here expected means the value named 'expected' in this block. The important operands are direct_conv2d: the value named 'direct conv2d' in this block; activations: an input feature value consumed by a neuron or multiply-accumulate operation; weights: a learned coefficient multiplied by an activation. Context: the function test_grouped_u8_convolution_with_stride_padding_and_dilation, which handles test grouped u8 convolution with stride padding and dilation.

Line 238: `activation_zero_point=117, weight_zero_point=133,` This is continuation line 3 of the 5-line logical statement that begins at source line 236. Its exact fragment is 'activation_zero_point=117, weight_zero_point=133,'. The important operands are activation_zero_point: an input feature value consumed by a neuron or multiply-accumulate operation; weight_zero_point: a learned coefficient multiplied by an activation. Read together, the complete operation is: This assigns 'direct_conv2d(activations, weights, bias, activation_zero_point=117, weight_zero_point=133, stride=(2, 1), padding=(1, 2), dilation=(2, 1), groups=2,)' to 'expected ' in host memory. Here expected means the value named 'expected' in this block. The important operands are direct_conv2d: the value named 'direct conv2d' in this block; activations: an input feature value consumed by a neuron or multiply-accumulate operation; weights: a learned coefficient multiplied by an activation. Context: the function test_grouped_u8_convolution_with_stride_padding_and_dilation, which handles test grouped u8 convolution with stride padding and dilation.

Line 239: `stride=(2, 1), padding=(1, 2), dilation=(2, 1), groups=2,` This is continuation line 4 of the 5-line logical statement that begins at source line 236. Its exact fragment is 'stride=(2, 1), padding=(1, 2), dilation=(2, 1), groups=2,'. The important operands are stride: the value named 'stride' in this block; padding: the value named 'padding' in this block; dilation: the value named 'dilation' in this block. Read together, the complete operation is: This assigns 'direct_conv2d(activations, weights, bias, activation_zero_point=117, weight_zero_point=133, stride=(2, 1), padding=(1, 2), dilation=(2, 1), groups=2,)' to 'expected ' in host memory. Here expected means the value named 'expected' in this block. The important operands are direct_conv2d: the value named 'direct conv2d' in this block; activations: an input feature value consumed by a neuron or multiply-accumulate operation; weights: a learned coefficient multiplied by an activation. Context: the function test_grouped_u8_convolution_with_stride_padding_and_dilation, which handles test grouped u8 convolution with stride padding and dilation.

Line 240: `)` This is continuation line 5 of the 5-line logical statement that begins at source line 236. Its exact fragment is ')'. The expression is a literal or structural operator and has no hidden software state. Read together, the complete operation is: This assigns 'direct_conv2d(activations, weights, bias, activation_zero_point=117, weight_zero_point=133, stride=(2, 1), padding=(1, 2), dilation=(2, 1), groups=2,)' to 'expected ' in host memory. Here expected means the value named 'expected' in this block. The important operands are direct_conv2d: the value named 'direct conv2d' in this block; activations: an input feature value consumed by a neuron or multiply-accumulate operation; weights: a learned coefficient multiplied by an activation. Context: the function test_grouped_u8_convolution_with_stride_padding_and_dilation, which handles test grouped u8 convolution with stride padding and dilation.

Line 241: `np.testing.assert_array_equal(actual, expected)` This calls 'np.testing.assert_array_equal' with 'actual, expected' inside the function test_grouped_u8_convolution_with_stride_padding_and_dilation, which handles test grouped u8 convolution with stride padding and dilation. The call advances the host-side job that checks neuraedge compiler behavior independently with Python assertions.

Line 242: `self.assertEqual(actual.shape, (1, 6, 3, 8))` This calls 'self.assertEqual' with 'actual.shape, (1, 6, 3, 8)' inside the function test_grouped_u8_convolution_with_stride_padding_and_dilation, which handles test grouped u8 convolution with stride padding and dilation. The call advances the host-side job that checks neuraedge compiler behavior independently with Python assertions.

Line 244: `def test_depthwise_binary_and_ternary_spike_convolution(self) -> None:` This starts function test_depthwise_binary_and_ternary_spike_convolution. Its indented body performs test depthwise binary and ternary spike convolution as part of the file that checks neuraedge compiler behavior independently with Python assertions; it runs only when called.

Line 245: `binary = self.rng.integers(0, 2, size=(1, 3, 4, 4), dtype=np.int8)` This assigns 'self.rng.integers(0, 2, size=(1, 3, 4, 4), dtype=np.int8)' to 'binary ' in host memory. Here binary means the value named 'binary' in this block. The important operands are rng: the value named 'rng' in this block; integers: the value named 'integers' in this block; size: the value named 'size' in this block. Context: the function test_depthwise_binary_and_ternary_spike_convolution, which handles test depthwise binary and ternary spike convolution.

Line 246: `ternary = self.rng.integers(-1, 2, size=(1, 3, 4, 4), dtype=np.int8)` This assigns 'self.rng.integers(-1, 2, size=(1, 3, 4, 4), dtype=np.int8)' to 'ternary ' in host memory. Here ternary means the value named 'ternary' in this block. The important operands are rng: the value named 'rng' in this block; integers: the value named 'integers' in this block; size: the value named 'size' in this block. Context: the function test_depthwise_binary_and_ternary_spike_convolution, which handles test depthwise binary and ternary spike convolution.

Line 247: `weights = self.rng.integers(-128, 128, size=(3, 1, 3, 3), dtype=np.int16)` This assigns 'self.rng.integers(128, 128, size=(3, 1, 3, 3), dtype=np.int16)' to 'weights ' in host memory. Here weights means a learned coefficient multiplied by an activation. The important operands are rng: the value named 'rng' in this block; integers: the value named 'integers' in this block; size: the value named 'size' in this block. Context: the function test_depthwise_binary_and_ternary_spike_convolution, which handles test depthwise binary and ternary spike convolution.

Line 248: `bias = self.rng.integers(-50, 51, size=3, dtype=np.int64)` This assigns ‘self.rng.integers(-50, 51, size=3, dtype=np.int64)‘ to ‘bias ‘ in host memory. Here bias means an additive learned offset applied after accumulation. The important operands are rng: the value named ’rng’ in this block; integers: the value named ’integers’ in this block; size: the value named ’size’ in this block. Context: the function test_depthwise_binary_and_ternary_spike_convolution, which handles test depthwise binary and ternary spike convolution.

Line 249: `for spikes, is_ternary in ((binary, False), (ternary, True)):` This iterates spikes, is_ternary over ‘((binary, False), (ternary, True))‘. Each iteration repeats the indented host operation, commonly once per layer, tile, timestep, or test case in the function test_depthwise_binary_and_ternary_spike_convolution, which handles test depthwise binary and ternary spike convolution.

Line 250: `program = compile_spike_conv2d(` This statement continues through source line 253; the explanation uses the complete expression rather than only the first visual fragment. This assigns ‘compile_spike_conv2d(spikes, weights, ternary=is_ternary, bias=bias, padding=1, groups=3,)‘ to ‘program ‘ in host memory. Here program means the value named ’program’ in this block. The important operands are compile_spike_conv2d: a binary event produced when a neuron crosses its threshold; spikes: a binary event produced when a neuron crosses its threshold; weights: a learned coefficient multiplied by an activation. Context: the function test_depthwise_binary_and_ternary_spike_convolution, which handles test depthwise binary and ternary spike convolution.

Line 251: `spikes, weights, ternary=is_ternary, bias=bias,` This is continuation line 2 of the 4-line logical statement that begins at source line 250. Its exact fragment is ‘spikes, weights, ternary=is_ternary, bias=bias,‘. The important operands are spikes: a binary event produced when a neuron crosses its threshold; weights: a learned coefficient multiplied by an activation; ternary: the value named ’ternary’ in this block. Read together, the complete operation is: This assigns ‘compile_spike_conv2d(spikes, weights, ternary=is_ternary, bias=bias, padding=1, groups=3,)‘ to ‘program ‘ in host memory. Here program means the value named ’program’ in this block. The important operands are compile_spike_conv2d: a binary event produced when a neuron crosses its threshold; spikes: a binary event produced when a neuron crosses its threshold; weights: a learned coefficient multiplied by an activation. Context: the function test_depthwise_binary_and_ternary_spike_convolution, which handles test depthwise binary and ternary spike convolution.

Line 252: `padding=1, groups=3,` This is continuation line 3 of the 4-line logical statement that begins at source line 250. Its exact fragment is ‘padding=1, groups=3,‘. The important operands are padding: the value named ’padding’ in this block; groups: the value named ’groups’ in this block. Read together, the complete operation is: This assigns ‘compile_spike_conv2d(spikes, weights, ternary=is_ternary, bias=bias, padding=1, groups=3,)‘ to ‘program ‘ in host memory. Here program means the value named ’program’ in this block. The important operands are compile_spike_conv2d: a binary event produced when a neuron crosses its threshold; spikes: a binary event produced when a neuron crosses its threshold; weights: a learned coefficient multiplied by an activation. Context: the function test_depthwise_binary_and_ternary_spike_convolution, which handles test depthwise binary and ternary spike convolution.

Line 253: `)` This is continuation line 4 of the 4-line logical statement that begins at source line 250. Its exact fragment is ‘)‘. The expression is a literal or structural operator and has no hidden software state. Read together, the complete operation is: This assigns ‘compile_spike_conv2d(spikes, weights, ternary=is_ternary, bias=bias, padding=1, groups=3,)‘ to ‘program ‘ in host memory. Here program means the value named ’program’ in this block. The important operands are compile_spike_conv2d: a binary event produced when a neuron crosses its threshold; spikes: a binary event produced when a neuron crosses its threshold; weights: a learned coefficient multiplied by an activation. Context: the function test_depthwise_binary_and_ternary_spike_convolution, which handles test depthwise binary and ternary spike convolution.

Line 254: `actual = program.execute(TensorTransactionEmulator())` This assigns ‘program.execute(TensorTransactionEmu
to ‘actual ‘ in host memory. Here actual means the value named ’actual’ in this block. The important operands are program: the value named ’program’ in this block; execute: the value named ’execute’ in this block; TensorTransactionEmulator: the value named ’tensor transaction emulator’ in this block. Context: the function test_depthwise_binary_and_ternary_spike_
which handles test depthwise binary and ternary spike convolution.

Line 255: `expected = direct_conv2d(` This statement continues through source line 257; the explanation uses the complete expression rather than only the first visual fragment. This assigns ‘direct_conv2d(spikes, weights, bias, padding=(1, 1), groups=3,)‘ to ‘expected ‘ in host memory. Here expected means the value named ’expected’ in this block. The important operands are direct_conv2d: the value named ’direct conv2d’ in this block; spikes: a binary event produced when a neuron crosses its threshold; weights: a learned coefficient multiplied by an activation. Context: the function test_depthwise_binary_and_ternary_spike_convolution, which handles test depthwise binary and ternary spike convolution.

Line 256: `spikes, weights, bias, padding=(1, 1), groups=3,` This is continuation line 2 of the 3-line logical statement that begins at source line 255. Its exact fragment is ‘spikes, weights, bias, padding=(1, 1), groups=3,‘. The important operands are spikes: a binary event produced when a neuron crosses its threshold; weights: a learned coefficient multiplied by an activation; bias: an additive learned offset applied after accumulation. Read together, the complete operation is: This assigns ‘direct_conv2d(spikes, weights, bias, padding=(1, 1), groups=3,)‘ to ‘expected ‘ in host memory. Here expected means the value named ’expected’ in this block. The important operands are direct_conv2d: the value named ’direct conv2d’ in this block; spikes: a binary event produced when a neuron crosses its threshold; weights: a learned coefficient multiplied by an activation. Context: the function test_depthwise_binary_and_ternary_spike_convolution, which handles test depthwise binary and ternary spike convolution.

Line 257: `)` This is continuation line 3 of the 3-line logical statement that begins at source line 255. Its exact fragment is ‘)‘. The expression is a literal or structural operator and has no hidden software state. Read together, the complete operation is: This assigns ‘direct_conv2d(spikes, weights, bias, padding=(1, 1), groups=3,)‘ to ‘expected ‘ in host memory. Here expected means the value named ’expected’ in this block. The important operands are direct_conv2d: the value named ’direct conv2d’ in this block; spikes: a binary event produced when a neuron crosses its threshold; weights: a learned coefficient multiplied by an activation. Context: the function test_depthwise_binary_and_ternary_spike_convolution, which handles test depthwise binary and ternary spike convolution.

Line 258: `np.testing.assert_array_equal(actual, expected)` This calls ‘np.testing.assert_array_equal‘ with ‘actual, expected‘ inside the function test_depthwise_binary_and_ternary_spike_convolution, which handles test depthwise binary and ternary spike convolution. The call advances the host-side job that checks neuraedge compiler behavior independently with Python assertions.

Line 259: `self.assertEqual(program.estimated_spike_adds,` This statement continues through source line 260; the explanation uses the complete expression rather than only the first visual fragment. This calls ‘self.assertEqual‘ with ‘program.estimated_spike_adds, sum(group.gemm.estimated_spike_adds for group in program.group_programs)‘ inside the function test_depthwise_binary_and_ternary_spike_convolution, which handles test depthwise binary and ternary spike convolution. The call advances the host-side job that checks neuraedge compiler behavior independently with Python assertions.

Line 260: `sum(group.gemm.estimated_spike_adds for group in program.group_programs))` This is continuation line 2 of the 2-line logical statement that begins at source line 259. Its exact fragment is ‘sum(group.gemm.estimated_spike_adds for group in program.group_programs))‘. The important operands are sum: the value named ’sum’ in this block; group: the value named ’group’ in this block; gemm: the value named ’gemm’ in this block. Read together, the complete operation is: This calls ‘self.assertEqual‘ with ‘program.estimated_spike_adds, sum(group.gemm.estimated_spike_adds for group in program.group_programs)‘ inside the function test_depthwise_binary_and_ternary_spike_convolution, which handles test depthwise binary and ternary spike convolution. The call advances the host-side job that checks neuraedge compiler behavior independently with Python assertions.

Line 262: `def test_validation(self) -> None:` This starts function test_validation. Its indented body performs test validation as part of the file that checks neuraedge compiler behavior independently with Python assertions; it runs only when called.

Line 263: `with self.assertRaises(ValueError):` This opens a managed resource scope for ‘self.assertRaises(ValueError)‘ so files, tracing, or temporary state are finalized even if the function test_validation, which handles test validation raises an error.

Line 264: `compile_u8_gemm([[1, 2]], [[1, 2]])` This calls ‘compile_u8_gemm‘ with ‘[[1, 2]], [[1, 2]]‘ inside the function test_validation, which handles test validation. The call advances the host-side job that checks neuraedge compiler behavior independently with Python assertions.

Line 265: `with self.assertRaises(ValueError):` This opens a managed resource scope for ‘self.assertRaises(ValueError)‘ so files, tracing, or temporary state are finalized even if the function test_validation, which handles test validation raises an error.

Line 266: `compile_u8_gemm([[256]], [[1]])` This calls ‘compile_u8_gemm‘ with ‘[[256]], [[1]]‘ inside the function test_validation, which handles test validation. The call advances the host-side job that checks neuraedge compiler behavior independently with Python assertions.

Line 267: `with self.assertRaises(ValueError):` This opens a managed resource scope for ‘self.assertRaises(ValueError)‘ so files, tracing, or temporary state are finalized even if the function test_validation, which handles test validation raises an error.

Line 268: `compile_u8_gemm([[1]], [[1]], bias=[1, 2])` This calls ‘compile_u8_gemm‘ with ‘[[1]], [[1]], bias=[1, 2]‘ inside the function test_validation, which handles test validation. The call advances the host-side job that checks neuraedge compiler behavior independently with Python assertions.

Line 269: `with self.assertRaises(ValueError):` This opens a managed resource scope for ‘self.assertRaises(ValueError)‘ so files, tracing, or temporary state are finalized even if the function test_validation, which handles test validation raises an error.

Line 270: `compile_spike_gemm([[0, 2]], [[1], [2]])` This calls ‘compile_spike_gemm‘ with ‘[[0, 2]], [[1], [2]]‘ inside the function test_validation, which handles test validation. The call advances the host-side job that checks neuraedge compiler behavior independently with Python assertions.

Line 271: `with self.assertRaises(ValueError):` This opens a managed resource scope for ‘self.assertRaises(ValueError)‘ so files, tracing, or temporary state are finalized even if the function test_validation, which handles test validation raises an error.

Line 272: `compile_spike_gemm([[0, -1]], [[1], [2]], ternary=False)` This calls ‘compile_spike_gemm‘ with ‘[[0, -1]], [[1], [2]], ternary=False‘ inside the function test_validation, which handles test validation. The call advances the host-side job that checks neuraedge compiler behavior independently with Python assertions.

Line 273: `with self.assertRaises(ValueError):` This opens a managed resource scope for ‘self.assertRaises(ValueError)‘ so files, tracing, or temporary state are finalized even if the function test_validation, which handles test validation raises an error.

Line 274: `compile_u8_conv2d(np.zeros((1, 3, 4, 4), dtype=np.uint8),` This statement continues through source line 275; the explanation uses the complete expression rather than only the first visual fragment. This calls ‘compile_u8_conv2d‘ with ‘np.zeros((1, 3, 4, 4), dtype=np.uint8), np.zeros((4, 2, 3, 3), dtype=np.uint8), groups=2‘ inside the function test_validation, which handles test validation. The call advances the host-side job that checks neuraedge compiler behavior independently with Python assertions.

Line 275: `np.zeros((4, 2, 3, 3), dtype=np.uint8), groups=2)` This is continuation line 2 of the 2-line logical statement that begins at source line 274. Its exact fragment is ‘np.zeros((4, 2, 3, 3), dtype=np.uint8), groups=2)‘. The important operands are zeros: the value named ’zeros’ in this block; dtype: the value named ’dtype’ in this block; uint8: the value named ’uint8’ in this block. Read together, the complete operation is: This calls ‘compile_u8_conv2d‘ with ‘np.zeros((1, 3, 4, 4), dtype=np.uint8), np.zeros((4, 2, 3, 3), dtype=np.uint8), groups=2‘ inside the function test_validation, which handles test validation. The call advances the host-side job that checks neuraedge compiler behavior independently with Python assertions.

Line 278: `if __name__ == "__main__":` This executes the following indented host-code branch only when ‘___name___ == "___main___"‘ is true. The important operands are ___name___: the value named ’name’ in this block; ___main___: the value named ’main’ in this block. Context: the file whose role is to checks neuraedge compiler behavior independently with Python assertions.

Line 279: `unittest.main()` This calls ‘unittest.main‘ with “ inside the file whose role is to checks neuraedge compiler behavior independently with Python assertions. The call advances the host-side job that checks neuraedge compiler behavior independently with Python assertions.

65 tests/test_neuraedge_golden.py

Role in the complete system: checks neuraedge golden behavior independently with Python assertions.

65.1 Beginner architecture map

Dataflow responsibility This file's end-to-end responsibility is to checks neuraedge golden behavior independently with Python assertions.

Where it runs This is sequential host software. Python objects live in CPU memory; they become FPGA work only when the compiler packs a command or payload and the PYNQ driver transfers those bytes through AXI DMA or AXI-Lite.

Public structure Classes: GoldenModelTests. Functions: setUp, test_signed_encoding_round_trip, test_packed_mac_bounda test_zero_point_correction_matches_direct_expression, test_sparse_index_compaction, test_binary_and_ternary_produ test_alpha_xnor_special_cases, test_log_integer_softmax_properties, test_integer_layer_norm_constant_and_nonconst test_lif_and_ternary_firing, test_dataflow_selection_and_peak_rate, test_signed_rounding_and_saturation, test_linear_backward_matches_independent_scalar_reference, test_sgd_momentum_update, test_sgd_weight_decay_is_ test_vector_alu_operations, rounded, clipped. Each function annotation below names its enclosing function so an array operation is tied to the model, compiler, driver, test, or report phase that uses it.

Numeric and failure boundary Shapes, signedness, byte order, scaling, and saturation are part of the hardware contract. Validation exceptions are functional safety checks: rejecting malformed input before DMA is different from silently clipping, reshaping, or continuing with an incompatible artifact.

65.3 Line annotations

Line 1: `from __future__ import annotations` This imports the named Python API so the file whose role is to checks neuraedge golden behavior independently with Python assertions can use it explicitly. Imports execute on the host processor and create no FPGA hardware.

Line 3: `import unittest` This imports the named Python API so the file whose role is to checks neuraedge golden behavior independently with Python assertions can use it explicitly. Imports execute on the host processor and create no FPGA hardware.

Line 5: `import numpy as np` This imports the named Python API so the file whose role is to checks neuraedge golden behavior independently with Python assertions can use it explicitly. Imports execute on the host processor and create no FPGA hardware.

Line 7: `from neuraedge_golden import (` This statement continues through source line 32; the explanation uses the complete expression rather than only the first visual fragment. This imports the named Python API so the file whose role is to checks neuraedge golden behavior independently with Python assertions can use it explicitly. Imports execute on the host processor and create no FPGA hardware.

Line 8: `Dataflow,` This is continuation line 2 of the 26-line logical statement that begins at source line 7. Its exact fragment is 'Dataflow,'. The important operands are Dataflow: the value named 'dataflow' in this block. Read together, the complete operation is: This imports the named Python API so the file whose role is to checks neuraedge golden behavior independently with Python assertions can use it explicitly. Imports execute on the host processor and create no FPGA hardware.

Line 9: `VectorOperation,` This is continuation line 3 of the 26-line logical statement that begins at source line 7. Its exact fragment is 'VectorOperation,'. The important operands are VectorOperation: the value named 'vector operation' in this block. Read together, the complete operation is: This imports the named Python API so the file whose role is to checks neuraedge golden behavior independently with Python assertions can use it explicitly. Imports execute on the host processor and create no FPGA hardware.

Line 10: `active_dot8_indices,` This is continuation line 4 of the 26-line logical statement that begins at source line 7. Its exact fragment is 'active_dot8_indices,'. The important operands are active_dot8_indices: the value named 'active dot8 indices' in this block. Read together, the complete operation is: This imports the named Python API so the file whose role is to checks neuraedge golden behavior independently with Python assertions can use it explicitly. Imports execute on the host processor and create no FPGA hardware.

Line 11: `active_outer_indices,` This is continuation line 5 of the 26-line logical statement that begins at source line 7. Its exact fragment is 'active_outer_indices,'. The important operands are active_outer_indices: the value named 'active outer indices' in this block. Read together, the complete operation is: This imports the named Python API so the file whose role is to checks neuraedge golden behavior independently with Python assertions can use it explicitly. Imports execute on the host processor and create no FPGA hardware.

Line 12: `alpha_xnor_similarity,` This is continuation line 6 of the 26-line logical statement that begins at source line 7. Its exact fragment is 'alpha_xnor_similarity,'. The important operands are alpha_xnor_similarity: the programmable weight assigned to matching zero spikes in alpha-XNOR attention. Read together, the complete operation is: This imports the named Python API so the file whose role is to checks neuraedge golden behavior independently with Python assertions can use it explicitly. Imports execute on the host processor and create no FPGA hardware.

Line 13: `binary_weighted_gemm,` This is continuation line 7 of the 26-line logical statement that begins at source line 7. Its exact fragment is 'binary_weighted_gemm,'. The important operands are binary_weighted_gemm: a learned coefficient multiplied by an activation. Read together, the complete operation is: This imports the named Python API so the file whose role is to checks neuraedge golden behavior independently with Python assertions can use it explicitly. Imports execute on the host processor and create no FPGA hardware.

Line 14: `choose_dataflow,` This is continuation line 8 of the 26-line logical statement that begins at source line 7. Its exact fragment is 'choose_dataflow,'. The important operands are choose_dataflow: the value named 'choose dataflow' in this block. Read together, the complete operation is: This imports the named Python API so the file whose role is to checks neuraedge golden behavior independently with Python assertions can use it explicitly. Imports execute on the host processor and create no FPGA hardware.

Line 15: `decode_uint8_as_int8,` This is continuation line 9 of the 26-line logical statement that begins at source line 7. Its exact fragment is 'decode_uint8_as_int8,'. The important operands are decode_uint8_as_int8: the value named 'decode uint8 as int8' in this block. Read together, the complete operation is: This imports the named Python API so the file whose role is to checks neuraedge golden behavior independently with Python assertions can use it explicitly. Imports execute on the host processor and create no FPGA hardware.

Line 16: `direct_centered_gemm,` This is continuation line 10 of the 26-line logical statement that begins at source line 7. Its exact fragment is 'direct_centered_gemm,'. The important operands are direct_centered_gemm: the value named 'direct centered gemm' in this block. Read together, the complete operation is: This imports the named Python API so the file whose role is to checks neuraedge golden behavior independently with Python assertions can use it explicitly. Imports execute on the host processor and create no FPGA hardware.

Line 17: `encode_int8_as_uint8,` This is continuation line 11 of the 26-line logical statement that begins at source line 7. Its exact fragment is 'encode_int8_as_uint8,'. The important operands are encode_int8_as_uint8: the value named 'encode int8 as uint8' in this block. Read together, the complete operation is: This imports the named Python API so the file whose role is to checks neuraedge golden behavior independently with Python assertions can use it explicitly. Imports execute on the host processor and create no FPGA hardware.

Line 18: `gemm_u8_zero_point,` This is continuation line 12 of the 26-line logical statement that begins at source line 7. Its exact fragment is 'gemm_u8_zero_point,'. The important operands are gemm_u8_zero_point: the integer code representing real numeric zero in affine quantization. Read together, the complete operation is: This imports the named Python API so the file whose role is to checks neuraedge golden behavior independently with Python assertions can use it explicitly. Imports execute on the host processor and create no FPGA hardware.

Line 19: `integer_layer_norm,` This is continuation line 13 of the 26-line logical statement that begins at source line 7. Its exact fragment is 'integer_layer_norm,'. The important operands are integer_layer_norm: the value named 'integer layer norm' in this block. Read together, the complete operation is: This imports the named Python API so the file whose role is to checks neuraedge golden behavior independently with Python assertions can use it explicitly. Imports execute on the host processor and create no FPGA hardware.

Line 20: `linear_backward_tile,` This is continuation line 14 of the 26-line logical statement that begins at source line 7. Its exact fragment is 'linear_backward_tile,'. The important operands are linear_backward_tile: the value named 'linear backward tile' in this block. Read together, the complete operation is: This imports the named Python API so the file whose role is to checks neuraedge golden behavior independently with Python assertions can use it explicitly. Imports execute on the host processor and create no FPGA hardware.

Line 21: `lif_step,` This is continuation line 15 of the 26-line logical statement that begins at source line 7. Its exact fragment is 'lif_step,'. The important operands are lif_step: the value named 'lif step' in this block. Read together, the complete operation is: This imports the named Python API so the file whose role is to checks neuraedge golden behavior independently with Python assertions can use it explicitly. Imports execute on the host processor and create no FPGA hardware.

Line 22: `log_int_softmax_q15,` This is continuation line 16 of the 26-line logical statement that begins at source line 7. Its exact fragment is 'log_int_softmax_q15,'. The important operands are log_int_softmax_q15: the value named 'log int softmax q15' in this block. Read together, the complete operation is: This imports the named Python API so the file whose role is to checks neuraedge golden behavior independently with Python assertions can use it explicitly. Imports execute on the host processor and create no FPGA hardware.

Line 23: `packed_mac2_u8,` This is continuation line 17 of the 26-line logical statement that begins at source line 7. Its exact fragment is 'packed_mac2_u8,'. The important operands are packed_mac2_u8: the value named 'packed mac2 u8' in this block. Read together, the complete operation is: This imports the named Python API so the file whose role is to checks neuraedge golden behavior independently with Python assertions can use it explicitly. Imports execute on the host processor and create no FPGA hardware.

Line 24: `peak_dense_gops,` This is continuation line 18 of the 26-line logical statement that begins at source line 7. Its exact fragment is 'peak_dense_gops,'. The important operands are peak_dense_gops: the value named 'peak dense gops' in this block. Read together, the complete operation is: This imports the named Python API so the file whose role is to checks neuraedge golden behavior independently with Python assertions can use it explicitly. Imports execute on the host processor and create no FPGA hardware.

Line 25: `quantize_flexible_scale,` This is continuation line 19 of the 26-line logical statement that begins at source line 7. Its exact fragment is 'quantize_flexible_scale,'. The important operands are quantize_flexible_scale: the real-value spacing represented by one quantized integer step. Read together, the complete operation is: This imports the named Python API so the file whose role is to checks neuraedge golden behavior independently with Python assertions can use it explicitly. Imports execute on the host processor and create no FPGA hardware.

Line 26: `round_shift_signed,` This is continuation line 20 of the 26-line logical statement that begins at source line 7. Its exact fragment is 'round_shift_signed,'. The important operands are round_shift_signed: the value named 'round shift signed' in this block. Read together, the complete operation is: This imports the named Python API so the file whose role is to checks neuraedge golden behavior independently with Python assertions can use it explicitly. Imports execute on the host processor and create no FPGA hardware.

Line 27: `saturate_signed,` This is continuation line 21 of the 26-line logical statement that begins at source line 7. Its exact fragment is 'saturate_signed,'. The important operands are saturate_signed: the value named 'saturate signed' in this block. Read together, the complete operation is: This imports the named Python API so the file whose role is to checks neuraedge golden behavior independently with Python assertions can use it explicitly. Imports execute on the host processor and create no FPGA hardware.

Line 28: `sgd_momentum_step,` This is continuation line 22 of the 26-line logical statement that begins at source line 7. Its exact fragment is 'sgd_momentum_step,'. The important operands are sgd_momentum_step: the value named 'sgd momentum step' in this block. Read together, the complete operation is: This imports the named Python API so the file whose role is to checks neuraedge golden behavior independently with Python assertions can use it explicitly. Imports execute on the host processor and create no FPGA hardware.

Line 29: `ternary_spike,` This is continuation line 23 of the 26-line logical statement that begins at source line 7. Its exact fragment is 'ternary_spike,'. The important operands are ternary_spike: a binary event produced when a neuron crosses its threshold. Read together, the complete operation is: This imports the named Python API so the file whose role is to checks neuraedge golden behavior independently with Python assertions can use it explicitly. Imports execute on the host processor and create no FPGA hardware.

Line 30: `ternary_weighted_gemm,` This is continuation line 24 of the 26-line logical statement that begins at source line 7. Its exact fragment is 'ternary_weighted_gemm,'. The important operands are ternary_weighted_gemm: a learned coefficient multiplied by an activation. Read together, the complete operation is: This imports the named Python API so the file whose role is to checks neuraedge golden behavior independently with Python assertions can use it explicitly. Imports execute on the host processor and create no FPGA hardware.

Line 31: `vector_alu,` This is continuation line 25 of the 26-line logical statement that begins at source line 7. Its exact fragment is 'vector_alu,'. The important operands are vector_alu: the value named 'vector alu' in this block. Read together, the complete operation is: This imports the named Python API so the file whose role is to checks neuraedge golden behavior independently with Python assertions can use it explicitly. Imports execute on the host processor and create no FPGA hardware.

Line 32: `)` This is continuation line 26 of the 26-line logical statement that begins at source line 7. Its exact fragment is ')'. The expression is a literal or structural operator and has no hidden software state. Read together, the complete operation is: This imports the named Python API so the file whose role is to checks neuraedge golden behavior independently with Python assertions can use it explicitly. Imports execute on the host processor and create no FPGA hardware.

Line 35: `class GoldenModelTests(unittest.TestCase):` This defines class GoldenModelTests, which groups data and methods for golden model tests. Instances exist in host memory and organize the flow that checks neuraedge golden behavior independently with Python assertions.

Line 36: `def setUp(self) -> None:` This starts function setUp. Its indented body performs set up as part of the file that checks neuraedge golden behavior independently with Python assertions; it runs only when called.

Line 37: `self.rng = np.random.default_rng(20260711)` This assigns 'np.random.default_rng(20260711)' to 'self.rng ' in host memory. Here rng means the value named 'rng' in this block. The important operands are random: the value named 'random' in this block; default_rng: the value named 'default rng' in this block. Context: the function setUp, which handles set up.

Line 39: `def test_signed_encoding_round_trip(self) -> None:` This starts function test_signed_encoding_round_trip. Its indented body performs test signed encoding round trip as part of the file that checks neuraedge golden behavior independently with Python assertions; it runs only when called.

Line 40: `values = np.arange(-128, 128, dtype=np.int16)` This assigns ‘np.arange(-128, 128, dtype=np.int16)‘ to ‘values ‘ in host memory. Here values means the value named ’values’ in this block. The important operands are arange: the value named ’arange’ in this block; dtype: the value named ’dtype’ in this block; int16: the value named ’int16’ in this block. Context: the function test_signed_encoding_round_trip, which handles test signed encoding round trip.

Line 41: `np.testing.assert_array_equal(decode_uint8_as_int8(encode_int8_as_uint8(values)), values)` This calls ‘np.testing.assert_array_equal‘ with ‘decode_uint8_as_int8(encode_int8_as_uint8(values)), values‘ inside the function test_signed_encoding_round_trip, which handles test signed encoding round trip. The call advances the host-side job that checks neuraedge golden behavior independently with Python assertions.

Line 43: `def test_packed_mac_boundaries(self) -> None:` This starts function test_packed_mac_boundaries. Its indented body performs test packed mac boundaries as part of the file that checks neuraedge golden behavior independently with Python assertions; it runs only when called.

Line 44: `for activation in (0, 1, 127, 128, 254, 255):` This iterates activation over ‘(0, 1, 127, 128, 254, 255)‘. Each iteration repeats the indented host operation, commonly once per layer, tile, timestep, or test case in the function test_packed_mac_boundaries, which handles test packed mac boundaries.

Line 45: `for low in (0, 1, 127, 128, 254, 255):` This iterates low over ‘(0, 1, 127, 128, 254, 255)‘. Each iteration repeats the indented host operation, commonly once per layer, tile, timestep, or test case in the function test_packed_mac_boundaries, which handles test packed mac boundaries.

Line 46: `for high in (0, 1, 127, 128, 254, 255):` This iterates high over ‘(0, 1, 127, 128, 254, 255)‘. Each iteration repeats the indented host operation, commonly once per layer, tile, timestep, or test case in the function test_packed_mac_boundaries, which handles test packed mac boundaries.

Line 47: `got_low, got_high = packed_mac2_u8(activation, low, high)` This assigns ‘packed_mac2_u8(activation, low, high)‘ to ‘got_low, got_high ‘ in host memory. Here got_low means the value named ’got low’ in this block. The important operands are packed_mac2_u8: the value named ’packed mac2 u8’ in this block; activation: an input feature value consumed by a neuron or multiply-accumulate operation; low: the value named ’low’ in this block. Context: the function test_packed_mac_boundaries, which handles test packed mac boundaries.

Line 48: `self.assertEqual(got_low, activation * low)` This calls ‘self.assertEqual‘ with ‘got_low, activation * low‘ inside the function test_packed_mac_boundaries, which handles test packed mac boundaries. The call advances the host-side job that checks neuraedge golden behavior independently with Python assertions.

Line 49: `self.assertEqual(got_high, activation * high)` This calls ‘self.assertEqual‘ with ‘got_high, activation * high‘ inside the function test_packed_mac_boundaries, which handles test packed mac boundaries. The call advances the host-side job that checks neuraedge golden behavior independently with Python assertions.

Line 51: `def test_zero_point_correction_matches_direct_expression(self) -> None:` This starts function test_zero_point_correction_matches_direct_expression. Its indented body performs test zero point correction matches direct expression as part of the file that checks neuraedge golden behavior independently with Python assertions; it runs only when called.

Line 52: `for _ in range(100):` This iterates _ over ‘range(100)‘. Each iteration repeats the indented host operation, commonly once per layer, tile, timestep, or test case in the function test_zero_point_correction_matches_direct_expression, which handles test zero point correction matches direct expression.

Line 53: `rows = int(self.rng.integers(1, 9))` This assigns ‘int(self.rng.integers(1, 9))‘ to ‘rows ‘ in host memory. Here rows means one output-row position processed by the tensor tile. The important operands are rng: the value named ’rng’ in this block; integers: the value named ’integers’ in this block. Context: the function test_zero_point_correction_matches_di which handles test zero point correction matches direct expression.

Line 54: `columns = int(self.rng.integers(1, 33))` This assigns ‘int(self.rng.integers(1, 33))‘ to ‘columns ‘ in host memory. Here columns means one output-feature position processed in parallel. The important operands are rng: the value named ’rng’ in this block; integers: the value named ’integers’ in this block. Context: the function test_zero_point_correction_matches_direct_expression, which handles test zero point correction matches direct expression.

Line 55: `reduction = int(self.rng.integers(1, 129))` This assigns ‘int(self.rng.integers(1, 129))‘ to ‘reduction ‘ in host memory. Here reduction means the value named ’reduction’ in this block. The important operands are rng: the value named ’rng’ in this block; integers: the value named ’integers’ in this block. Context: the function test_zero_point_correction_matches_direct_expression, which handles test zero point correction matches direct expression.

Line 56: `a = self.rng.integers(0, 256, size=(rows, reduction), dtype=np.uint8)` This assigns ‘self.rng.integers(0, 256, size=(rows, reduction), dtype=np.uint8)‘ to ‘a ‘ in host memory. Here a means the value named ’a’ in this block. The important operands are rng: the value named ’rng’ in this block; integers: the value named ’integers’ in this block; size: the value named ’size’ in this block. Context: the function test_zero_point_correction_matches_direct_expression, which handles test zero point correction matches direct expression.

Line 57: `b = self.rng.integers(0, 256, size=(reduction, columns), dtype=np.uint8)` This assigns ‘self.rng.integers(0, 256, size=(reduction, columns), dtype=np.uint8)‘ to ‘b ‘ in host memory. Here b means the value named ’b’ in this block. The important operands are rng: the value named ’rng’ in this block; integers: the value named ’integers’ in this block; size: the value named ’size’ in this block. Context: the function test_zero_point_correction_matches_direct_expression, which handles test zero point correction matches direct expression.

Line 58: `za = int(self.rng.integers(0, 256))` This assigns ‘int(self.rng.integers(0, 256))‘ to ‘za ‘ in host memory. Here za means the value named ’za’ in this block. The important operands are rng: the value named ’rng’ in this block; integers: the value named ’integers’ in this block. Context: the function test_zero_point_correction_matches_direct_expression, which handles test zero point correction matches direct expression.

Line 59: `zb = int(self.rng.integers(0, 256))` This assigns ‘int(self.rng.integers(0, 256))‘ to ‘zb ‘ in host memory. Here zb means the value named ’zb’ in this block. The important operands are rng: the value named ’rng’ in this block; integers: the value named ’integers’ in this block. Context: the function test_zero_point_correction_matches_direct_expression, which handles test zero point correction matches direct expression.

Line 60: `bias = self.rng.integers(-(1 << 20), 1 << 20, size=columns, dtype=np.int64)` This assigns ‘self.rng.integers (1 << 20), 1 << 20, size=columns, dtype=np.int64)‘ to ‘bias ‘ in host memory. Here bias means an additive learned offset applied after accumulation. The important operands are rng: the value named ’rng’ in this block; integers: the value named ’integers’ in this block; size: the value named ’size’ in this block. Context: the function test_zero_point_correction_matches which handles test zero point correction matches direct expression.

Line 61: `corrected = gemm_u8_zero_point(a, b, za, zb, bias)` This assigns ‘gemm_u8_zero_point(a, b, za, zb, bias)‘ to ‘corrected ‘ in host memory. Here corrected means the value named ’corrected’ in this block. The important operands are gemm_u8_zero_point: the integer code representing real numeric zero in affine quantization; a: the value named ’a’ in this block; b: the value named ’b’ in this block. Context: the function test_zero_point_correction_matches_direct_ex which handles test zero point correction matches direct expression.

Line 62: `direct = direct_centered_gemm(a, b, za, zb, bias)` This assigns ‘direct_centered_gemm(a, b, za, zb, bias)‘ to ‘direct ‘ in host memory. Here direct means the value named ’direct’ in this block. The important operands are direct_centered_gemm: the value named ’direct centered gemm’ in this block; a: the value named ’a’ in this block;

b: the value named 'b' in this block. Context: the function test_zero_point_correction_matches_direct_expression, which handles test zero point correction matches direct expression.

Line 63: `np.testing.assert_array_equal(corrected, direct)` This calls 'np.testing.assert_array_equal' with 'corrected, direct' inside the function test_zero_point_correction_matches_direct_expression, which handles test zero point correction matches direct expression. The call advances the host-side job that checks neuraedge golden behavior independently with Python assertions.

Line 65: `def test_sparse_index_compaction(self) -> None:` This starts function test_sparse_index_compaction. Its indented body performs test sparse index compaction as part of the file that checks neuraedge golden behavior independently with Python assertions; it runs only when called.

Line 66: `zero = 128` This assigns '128' to 'zero ' in host memory. Here zero means the value named 'zero' in this block. The expression is a literal or structural operator and has no hidden software state. Context: the function test_sparse_index_compaction, which handles test sparse index compaction.

Line 67: `a = np.full((3, 19), zero, dtype=np.uint8)` This assigns 'np.full((3, 19), zero, dtype=np.uint8)' to 'a ' in host memory. Here a means the value named 'a' in this block. The important operands are full: the value named 'full' in this block; zero: the value named 'zero' in this block; dtype: the value named 'dtype' in this block. Context: the function test_sparse_index_compaction, which handles test sparse index compaction.

Line 68: `a[0, 1] = 129` This assigns '129' to 'a[0, 1] ' in host memory. Here a means the value named 'a' in this block. The expression is a literal or structural operator and has no hidden software state. Context: the function test_sparse_index_compaction, which handles test sparse index compaction.

Line 69: `a[2, 9] = 127` This assigns '127' to 'a[2, 9] ' in host memory. Here a means the value named 'a' in this block. The expression is a literal or structural operator and has no hidden software state. Context: the function test_sparse_index_compaction, which handles test sparse index compaction.

Line 70: `a[1, 18] = 0` This assigns '0' to 'a[1, 18] ' in host memory. Here a means the value named 'a' in this block. The expression is a literal or structural operator and has no hidden software state. Context: the function test_sparse_index_compaction, which handles test sparse index compaction.

Line 71: `np.testing.assert_array_equal(active_outer_indices(a, zero), np.array([1, 9, 18]))` This calls 'np.testing.assert_array_equal' with 'active_outer_indices(a, zero), np.array([1, 9, 18])' inside the function test_sparse_index_com which handles test sparse index compaction. The call advances the host-side job that checks neuraedge golden behavior independently with Python assertions.

Line 72: `np.testing.assert_array_equal(active_dot8_indices(a[0], zero), np.array([0]))` This calls 'np.testing.asser with 'active_dot8_indices(a[0], zero), np.array([0])' inside the function test_sparse_index_compaction, which handles test sparse index compaction. The call advances the host-side job that checks neuraedge golden behavior independently with Python assertions.

Line 73: `np.testing.assert_array_equal(active_dot8_indices(a[2], zero), np.array([1]))` This calls 'np.testing.asser with 'active_dot8_indices(a[2], zero), np.array([1])' inside the function test_sparse_index_compaction, which handles test sparse index compaction. The call advances the host-side job that checks neuraedge golden behavior independently with Python assertions.

Line 75: `def test_binary_and_ternary_products(self) -> None:` This starts function test_binary_and_ternary_products. Its indented body performs test binary and ternary products as part of the file that checks neuraedge golden behavior independently with Python assertions; it runs only when called.

Line 76: `weights = self.rng.integers(-127, 128, size=(17, 11), dtype=np.int16)` This assigns ‘self.rng.integers(-127, 128, size=(17, 11), dtype=np.int16)‘ to ‘weights ‘ in host memory. Here weights means a learned coefficient multiplied by an activation. The important operands are rng: the value named ’rng’ in this block; integers: the value named ’integers’ in this block; size: the value named ’size’ in this block. Context: the function test_binary_and_ternary_products, which handles test binary and ternary products.

Line 77: `binary = self.rng.integers(0, 2, size=(5, 17), dtype=np.int8)` This assigns ‘self.rng.integers(0, 2, size=(5, 17), dtype=np.int8)‘ to ‘binary ‘ in host memory. Here binary means the value named ’binary’ in this block. The important operands are rng: the value named ’rng’ in this block; integers: the value named ’integers’ in this block; size: the value named ’size’ in this block. Context: the function test_binary_and_ternary_products, which handles test binary and ternary products.

Line 78: `ternary = self.rng.integers(-1, 2, size=(5, 17), dtype=np.int8)` This assigns ‘self.rng.integers(-1, 2, size=(5, 17), dtype=np.int8)‘ to ‘ternary ‘ in host memory. Here ternary means the value named ’ternary’ in this block. The important operands are rng: the value named ’rng’ in this block; integers: the value named ’integers’ in this block; size: the value named ’size’ in this block. Context: the function test_binary_and_ternary_products, which handles test binary and ternary products.

Line 79: `np.testing.assert_array_equal(binary_weighted_gemm(binary, weights), binary.astype(np.int64) @ weights)` This calls ‘np.testing.assert_array_equal‘ with ‘binary_weighted_gemm(binary, weights), binary.astype(np.int64) @ weights‘ inside the function test_binary_and_ternary_products, which handles test binary and ternary products. The call advances the host-side job that checks neuraedge golden behavior independently with Python assertions.

Line 80: `np.testing.assert_array_equal(ternary_weighted_gemm(ternary, weights), ternary.astype(np.int64) @ weights)` This calls ‘np.testing.assert_array_equal‘ with ‘ternary_weighted_gemm(ternary, weights), ternary.astype(np.int64) @ weights‘ inside the function test_binary_and_ternary_products, which handles test binary and ternary products. The call advances the host-side job that checks neuraedge golden behavior independently with Python assertions.

Line 82: `def test_alpha_xnor_special_cases(self) -> None:` This starts function test_alpha_xnor_special_cases. Its indented body performs test alpha xnor special cases as part of the file that checks neuraedge golden behavior independently with Python assertions; it runs only when called.

Line 83: `q = np.array([[1, 0, 1, 0], [0, 0, 0, 0]], dtype=np.uint8)` This assigns ‘np.array([[1, 0, 1, 0], [0, 0, 0, 0]], dtype=np.uint8)‘ to ‘q ‘ in host memory. Here q means the value named ’q’ in this block. The important operands are array: the value named ’array’ in this block; dtype: the value named ’dtype’ in this block; uint8: the value named ’uint8’ in this block. Context: the function test_alpha_xnor_special_cases, which handles test alpha xnor special cases.

Line 84: `k = np.array([[1, 0, 0, 0], [0, 0, 0, 0]], dtype=np.uint8)` This assigns ‘np.array([[1, 0, 0, 0], [0, 0, 0, 0]], dtype=np.uint8)‘ to ‘k ‘ in host memory. Here k means the value named ’k’ in this block. The important operands are array: the value named ’array’ in this block; dtype: the value named ’dtype’ in this block; uint8: the value named ’uint8’ in this block. Context: the function test_alpha_xnor_special_cases, which handles test alpha xnor special cases.

Line 85: `dot_q8 = alpha_xnor_similarity(q, k, 0)` This assigns ‘alpha_xnor_similarity(q, k, 0)‘ to ‘dot_q8 ‘ in host memory. Here dot_q8 means the value named ’dot q8’ in this block. The important operands are alpha_xnor_similarity: the programmable weight assigned to matching zero spikes in alpha-XNOR attention; q: the value named ’q’ in this block; k: the value named ’k’ in this block. Context: the function test_alpha_xnor_special_cases, which handles test alpha xnor special cases.

Line 86: `xnor_q8 = alpha_xnor_similarity(q, k, 256)` This assigns ‘alpha_xnor_similarity(q, k, 256)‘ to ‘xnor_q8 ‘ in host memory. Here xnor_q8 means the value named ’xnor q8’ in this block. The important operands are alpha_xnor_similarity: the programmable weight assigned to matching zero spikes in alpha-XNOR attention; q: the value named ’q’ in this block; k: the value named ’k’ in this block. Context: the function test_alpha_xnor_special_cases, which handles test alpha xnor special cases.

Line 87: `np.testing.assert_array_equal(dot_q8 // 256, q.astype(np.int64) @ k.astype(np.int64).T)` This calls ‘np.testing.assert_array_equal‘ with ‘dot_q8 // 256, q.astype(np.int64) @ k.astype(np.int64).T‘ inside the function test_alpha_xnor_special_cases, which handles test alpha xnor special cases. The call advances the host-side job that checks neuraedge golden behavior independently with Python assertions.

Line 88: `expected_xnor = np.array([[3, 2], [3, 4]], dtype=np.int64)` This assigns ‘np.array([[3, 2], [3, 4]], dtype=np.int64)‘ to ‘expected_xnor ‘ in host memory. Here expected_xnor means the value named ’expected xnor’ in this block. The important operands are array: the value named ’array’ in this block; dtype: the value named ’dtype’ in this block; int64: the value named ’int64’ in this block. Context: the function test_alpha_xnor_special_cases, which handles test alpha xnor special cases.

Line 89: `np.testing.assert_array_equal(xnor_q8 // 256, expected_xnor)` This calls ‘np.testing.assert_array_equal‘ with ‘xnor_q8 // 256, expected_xnor‘ inside the function test_alpha_xnor_special_cases, which handles test alpha xnor special cases. The call advances the host-side job that checks neuraedge golden behavior independently with Python assertions.

Line 91: `def test_log_integer_softmax_properties(self) -> None:` This starts function test_log_integer_softmax_prope Its indented body performs test log integer softmax properties as part of the file that checks neuraedge golden behavior independently with Python assertions; it runs only when called.

Line 92: `scores = np.array([91, 83, 50, -30], dtype=np.int64)` This assigns ‘np.array([91, 83, 50, -30], dtype=np.int64)‘ to ‘scores ‘ in host memory. Here scores means the value named ’scores’ in this block. The important operands are array: the value named ’array’ in this block; dtype: the value named ’dtype’ in this block; int64: the value named ’int64’ in this block. Context: the function test_log_integer_softmax_properties, which handles test log integer softmax properties.

Line 93: `probabilities = log_int_softmax_q15(scores, difference_shift=3)` This assigns ‘log_int_softmax_q15(scores, difference_shift=3)‘ to ‘probabilities ‘ in host memory. Here probabilities means the value named ’probabilities’ in this block. The important operands are log_int_softmax_q15: the value named ’log int softmax q15’ in this block; scores: the value named ’scores’ in this block; difference_shift: the value named ’difference shift’ in this block. Context: the function test_log_integer_softmax_properties, which handles test log integer softmax properties.

Line 94: `translated = log_int_softmax_q15(scores + 123456, difference_shift=3)` This assigns ‘log_int_softmax_q15 + 123456, difference_shift=3)‘ to ‘translated ‘ in host memory. Here translated means the value named ’translated’ in this block. The important operands are log_int_softmax_q15: the value named ’log int softmax q15’ in this block; scores: the value named ’scores’ in this block; difference_shift: the value named ’difference shift’ in this block. Context: the function test_log_integer_softmax_properties, which handles test log integer softmax properties.

Line 95: `np.testing.assert_array_equal(probabilities, translated)` This calls ‘np.testing.assert_array_equal‘ with ‘probabilities, translated‘ inside the function test_log_integer_softmax_properties, which handles test log integer softmax properties. The call advances the host-side job that checks neuraedge golden behavior independently with Python assertions.

Line 96: `self.assertGreaterEqual(int(probabilities[0]), int(probabilities[1]))` This calls ‘self.assertGreaterEqual‘ with ‘int(probabilities[0]), int(probabilities[1])‘ inside the function test_log_integer_softmax_properties, which handles test log integer softmax properties. The call advances the host-side job that checks neuraedge golden behavior independently with Python assertions.

Line 97: `self.assertGreaterEqual(int(probabilities[1]), int(probabilities[2]))` This calls ‘self.assertGreaterEqual‘ with ‘int(probabilities[1]), int(probabilities[2])‘ inside the function test_log_integer_softmax_properties, which handles test log integer softmax properties. The call advances the host-side job that checks neuraedge golden behavior independently with Python assertions.

Line 98: `self.assertLessEqual(abs(int(probabilities.sum()) - (1 << 15)), 2)` This calls ‘self.assertLessEqual‘ with ‘abs(int(probabilities.sum()) - (1 << 15)), 2‘ inside the function test_log_integer_softmax_properties, which handles test log integer softmax properties. The call advances the host-side job that checks neuraedge golden behavior independently with Python assertions.

Line 100: `def test_integer_layer_norm_constant_and_nonconstant(self) -> None:` This starts function test_integer_lay Its indented body performs test integer layer norm constant and nonconstant as part of the file that checks neuraedge golden behavior independently with Python assertions; it runs only when called.

Line 101: `gamma = np.full(4, 1 << 15, dtype=np.int64)` This assigns ‘np.full(4, 1 << 15, dtype=np.int64)‘ to ‘gamma ‘ in host memory. Here gamma means the learned multiplicative LayerNorm parameter. The important operands are full: the value named ’full’ in this block; dtype: the value named ’dtype’ in this block; int64: the value named ’int64’ in this block. Context: the function test_integer_layer_norm_constant_and_nonconstant, which handles test integer layer norm constant and nonconstant.

Line 102: `beta = np.array([1, 2, 3, 4], dtype=np.int64)` This assigns ‘np.array([1, 2, 3, 4], dtype=np.int64)‘ to ‘beta ‘ in host memory. Here beta means the learned additive LayerNorm parameter. The important operands are array: the value named ’array’ in this block; dtype: the value named ’dtype’ in this block; int64: the value named ’int64’ in this block. Context: the function test_integer_layer_norm_constant_and_nonconstant, which handles test integer layer norm constant and nonconstant.

Line 103: `np.testing.assert_array_equal(integer_layer_norm(np.full(4, 12), gamma, beta), beta)` This calls ‘np.testing.assert_array_equal‘ with ‘integer_layer_norm(np.full(4, 12), gamma, beta), beta‘ inside the function test_integer_layer_norm_constant_and_nonconstant, which handles test integer layer norm constant and nonconstant. The call advances the host-side job that checks neuraedge golden behavior independently with Python assertions.

Line 104: `output = integer_layer_norm(np.array([-9, -3, 3, 9]), gamma, np.zeros(4, dtype=np.int64))` This assigns ‘integer_layer_norm(np.array([-9, -3, 3, 9]), gamma, np.zeros(4, dtype=np.int64))‘ to ‘output ‘ in host memory. Here output means the value named ’output’ in this block. The important operands are integer_layer_norm: the value named ’integer layer norm’ in this block; array: the value named ’array’ in this block; gamma: the learned multiplicative LayerNorm parameter. Context: the function test_integer_layer_norm_constant_and_nonconstant, which handles test integer layer norm constant and nonconstant.

Line 105: `self.assertEqual(int(output.sum()), 0)` This calls ‘self.assertEqual‘ with ‘int(output.sum()), 0‘ inside the function test_integer_layer_norm_constant_and_nonconstant, which handles test integer layer norm constant and nonconstant. The call advances the host-side job that checks neuraedge golden behavior independently with Python assertions.

Line 106: `self.assertTrue(np.all(np.diff(output) >= 0))` This calls ‘self.assertTrue‘ with ‘np.all(np.diff(output) >= 0)‘ inside the function test_integer_layer_norm_constant_and_nonconstant, which handles test integer layer norm constant and nonconstant. The call advances the host-side job that checks neuraedge golden behavior independently with Python assertions.

Line 108: `def test_lif_and_ternary_firing(self) -> None:` This starts function test_lif_and_ternary_firing. Its indented body performs test lif and ternary firing as part of the file that checks neuraedge golden behavior independently with Python assertions; it runs only when called.

Line 109: `next_membrane, spikes = lif_step(np.array([0, 8, 20]), np.array([4, 8, 1]), 2, 12)` This assigns ‘lif_step(np.array([0, 8, 20]), np.array([4, 8, 1]), 2, 12)‘ to ‘next_membrane, spikes ‘ in host memory. Here next_membrane means the persistent LIF neuron state carrying charge between timesteps. The important operands are lif_step: the value named ’lif step’ in this block; array: the value named ’array’ in this block. Context: the function test_lif_and_ternary_firing, which handles test lif and ternary firing.

Line 110: `np.testing.assert_array_equal(spikes, np.array([0, 1, 1], dtype=np.uint8))` This calls ‘np.testing.assert_ with ‘spikes, np.array([0, 1, 1], dtype=np.uint8)‘ inside the function test_lif_and_ternary_firing, which handles test lif and ternary firing. The call advances the host-side job that checks neuraedge golden behavior independently with Python assertions.

Line 111: `np.testing.assert_array_equal(next_membrane, np.array([4, 0, 0]))` This calls ‘np.testing.assert_array_equ with ‘next_membrane, np.array([4, 0, 0])‘ inside the function test_lif_and_ternary_firing, which handles test lif and ternary firing. The call advances the host-side job that checks neuraedge golden behavior independently with Python assertions.

Line 112: `np.testing.assert_array_equal(` This statement continues through source line 115; the explanation uses the complete expression rather than only the first visual fragment. This calls ‘np.testing.assert_array_equal‘ with ‘ ternary_spike(np.array([-8, -7, 0, 7, 8]), 8), np.array([-1, 0, 0, 0, 1], dtype=np.int8), ‘ inside the function test_lif_and_ternary_firing, which handles test lif and ternary firing. The call advances the host-side job that checks neuraedge golden behavior independently with Python assertions.

Line 113: `ternary_spike(np.array([-8, -7, 0, 7, 8]), 8),` This is continuation line 2 of the 4-line logical statement that begins at source line 112. Its exact fragment is ‘ternary_spike(np.array([-8, -7, 0, 7, 8]), 8),‘. The important operands are ternary_spike: a binary event produced when a neuron crosses its threshold; array: the value named ’array’ in this block. Read together, the complete operation is: This calls ‘np.testing.assert_array_equal‘ with ‘ ternary_spike(np.array([-8, -7, 0, 7, 8]), 8), np.array([-1, 0, 0, 0, 1], dtype=np.int8), ‘ inside the function test_lif_and_ternary_firing, which handles test lif and ternary firing. The call advances the host-side job that checks neuraedge golden behavior independently with Python assertions.

Line 114: `np.array([-1, 0, 0, 0, 1], dtype=np.int8),` This is continuation line 3 of the 4-line logical statement that begins at source line 112. Its exact fragment is ‘np.array([-1, 0, 0, 0, 1], dtype=np.int8),‘. The important operands are array: the value named ’array’ in this block; dtype: the value named ’dtype’ in this block; int8: the value named ’int8’ in this block. Read together, the complete operation is: This calls ‘np.testing.assert_array_equal‘ with ‘ ternary_spike(np.array([-8, -7, 0, 7, 8]), 8), np.array([-1, 0, 0, 0, 1], dtype=np.int8), ‘ inside the function test_lif_and_ternary_firing, which handles test lif and ternary firing. The call advances the host-side job that checks neuraedge golden behavior independently with Python assertions.

Line 115: `)` This is continuation line 4 of the 4-line logical statement that begins at source line 112. Its exact fragment is ‘)‘. The expression is a literal or structural operator and has no hidden software state. Read together, the complete operation is: This calls ‘np.testing.assert_array_equal‘ with ‘ ternary_spike(np.array([-8, -7, 0, 7, 8]), 8), np.array([-1, 0, 0, 0, 1], dtype=np.int8), ‘ inside the function test_lif_and_ternary_firing, which handles test lif and ternary firing. The call advances the host-side job that checks neuraedge golden behavior independently with Python assertions.

Line 117: `def test_dataflow_selection_and_peak_rate(self) -> None:` This starts function test_dataflow_selection_and_ Its indented body performs test dataflow selection and peak rate as part of the file that checks neuraedge golden behavior independently with Python assertions; it runs only when called.

Line 118: `wide = choose_dataflow(rows=8, columns=768, reduction=384)` This assigns ‘choose_dataflow(rows=8, columns=768, reduction=384)‘ to ‘wide ‘ in host memory. Here wide means the value named ’wide’ in this block. The important operands are choose_dataflow: the value named ’choose dataflow’ in this block; rows: one output-row position processed by the tensor tile; columns: one output-feature position processed in parallel. Context: the function test_dataflow_selection_and_peak_rate, which handles test dataflow selection and peak rate.

Line 119: `tall = choose_dataflow(rows=4096, columns=16, reduction=144)` This assigns ‘choose_dataflow(rows=4096, columns=16, reduction=144)‘ to ‘tall ‘ in host memory. Here tall means the value named ’tall’ in this block. The important operands are choose_dataflow: the value named ’choose dataflow’ in this block; rows: one output-row position processed by the tensor tile; columns: one output-feature position processed in parallel. Context: the function test_dataflow_selection_and_peak_rate, which handles test dataflow selection and peak rate.

Line 120: `self.assertEqual(wide.mode, Dataflow.INPUT_BROADCAST)` This calls ‘self.assertEqual‘ with ‘wide.mode, Dataflow.INPUT_BROADCAST‘ inside the function test_dataflow_selection_and_peak_rate, which handles test dataflow selection and peak rate. The call advances the host-side job that checks neuraedge golden behavior independently with Python assertions.

Line 121: `self.assertEqual(wide.input_broadcast_bytes, 297984)` This calls ‘self.assertEqual‘ with ‘wide.input_broadcast 297984‘ inside the function test_dataflow_selection_and_peak_rate, which handles test dataflow selection and peak rate. The call advances the host-side job that checks neuraedge golden behavior independently with Python assertions.

Line 122: `self.assertEqual(wide.weight_broadcast_bytes, 442368)` This calls ‘self.assertEqual‘ with ‘wide.weight_broadca 442368‘ inside the function test_dataflow_selection_and_peak_rate, which handles test dataflow selection and peak rate. The call advances the host-side job that checks neuraedge golden behavior independently with Python assertions.

Line 123: `self.assertEqual(tall.mode, Dataflow.WEIGHT_BROADCAST)` This calls ‘self.assertEqual‘ with ‘tall.mode, Dataflow.WEIGHT_BROADCAST‘ inside the function test_dataflow_selection_and_peak_rate, which handles test dataflow selection and peak rate. The call advances the host-side job that checks neuraedge golden behavior independently with Python assertions.

Line 124: `self.assertEqual(tall.input_broadcast_bytes, 1769472)` This calls ‘self.assertEqual‘ with ‘tall.input_broadcast 1769472‘ inside the function test_dataflow_selection_and_peak_rate, which handles test dataflow selection and peak rate. The call advances the host-side job that checks neuraedge golden behavior independently with Python assertions.

Line 125: `self.assertEqual(tall.weight_broadcast_bytes, 592128)` This calls ‘self.assertEqual‘ with ‘tall.weight_broadcas 592128‘ inside the function test_dataflow_selection_and_peak_rate, which handles test dataflow selection and peak rate. The call advances the host-side job that checks neuraedge golden behavior independently with Python assertions.

Line 126: `self.assertAlmostEqual(peak_dense_gops(200e6, 64), 51.2)` This calls ‘self.assertAlmostEqual‘ with ‘peak_dense_gops(200e6, 64), 51.2‘ inside the function test_dataflow_selection_and_peak_rate, which handles test dataflow selection and peak rate. The call advances the host-side job that checks neuraedge golden behavior independently with Python assertions.

Line 128: `def test_signed_rounding_and_saturation(self) -> None:` This starts function test_signed_rounding_and_sat Its indented body performs test signed rounding and saturation as part of the file that checks neuraedge golden behavior independently with Python assertions; it runs only when called.

Line 129: `values = np.array([-9, -8, -7, -1, 0, 1, 7, 8, 9], dtype=np.int64)` This assigns ‘np.array([-9, -8, -7, -1, 0, 1, 7, 8, 9], dtype=np.int64)‘ to ‘values ‘ in host memory. Here values means the value named ’values’ in this block. The important operands are array: the value named ’array’ in this block; dtype: the value named ’dtype’ in this block; int64: the value named ’int64’ in this block. Context: the function test_signed_rounding_and_saturation, which handles test signed rounding and saturation.

Line 130: `np.testing.assert_array_equal(` This statement continues through source line 133; the explanation uses the complete expression rather than only the first visual fragment. This calls ‘np.testing.assert_array_equal‘ with ‘ round_shift_signed(values, 3), np.array([-1, -1, -1, 0, 0, 0, 1, 1, 1], dtype=np.int64), ‘ inside the function test_signed_rounding_and_saturation, which handles test signed rounding and saturation. The call advances the host-side job that checks neuraedge golden behavior independently with Python assertions.

Line 131: `round_shift_signed(values, 3),` This is continuation line 2 of the 4-line logical statement that begins at source line 130. Its exact fragment is ‘round_shift_signed(values, 3),‘. The important operands are round_shift_signed: the value named ’round shift signed’ in this block; values: the value named ’values’ in this block. Read together, the complete operation is: This calls ‘np.testing.assert_array_equal‘ with ‘ round_shift_signed(values, 3), np.array([-1, -1, -1, 0, 0, 0, 1, 1, 1], dtype=np.int64), ‘ inside the function test_signed_rounding_and_saturation, which handles test signed rounding and saturation. The call advances the host-side job that checks neuraedge golden behavior independently with Python assertions.

Line 132: `np.array([-1, -1, -1, 0, 0, 0, 1, 1, 1], dtype=np.int64),` This is continuation line 3 of the 4-line logical statement that begins at source line 130. Its exact fragment is 'np.array([-1, -1, -1, 0, 0, 0, 1, 1, 1], dtype=np.int64),'. The important operands are array: the value named 'array' in this block; dtype: the value named 'dtype' in this block; int64: the value named 'int64' in this block. Read together, the complete operation is: This calls 'np.testing.assert_array_equal' with ' round_shift_signed(values, 3), np.array([-1, -1, -1, 0, 0, 0, 1, 1, 1], dtype=np.int64), ' inside the function test_signed_rounding_and_saturation, which handles test signed rounding and saturation. The call advances the host-side job that checks neuraedge golden behavior independently with Python assertions.

Line 133: `)` This is continuation line 4 of the 4-line logical statement that begins at source line 130. Its exact fragment is ')'. The expression is a literal or structural operator and has no hidden software state. Read together, the complete operation is: This calls 'np.testing.assert_array_equal' with ' round_shift_signed(values, 3), np.array([-1, -1, -1, 0, 0, 0, 1, 1, 1], dtype=np.int64), ' inside the function test_signed_rounding_and_saturation, which handles test signed rounding and saturation. The call advances the host-side job that checks neuraedge golden behavior independently with Python assertions.

Line 134: `np.testing.assert_array_equal(` This statement continues through source line 137; the explanation uses the complete expression rather than only the first visual fragment. This calls 'np.testing.assert_array_equal' with ' saturate_signed(np.array([-40000, -32768, 32767, 40000]), 16), np.array([-32768, -32768, 32767, 32767]), ' inside the function test_signed_rounding_and_saturation, which handles test signed rounding and saturation. The call advances the host-side job that checks neuraedge golden behavior independently with Python assertions.

Line 135: `saturate_signed(np.array([-40000, -32768, 32767, 40000]), 16),` This is continuation line 2 of the 4-line logical statement that begins at source line 134. Its exact fragment is 'saturate_signed(np.array([-40000, -32768, 32767, 40000]), 16),'. The important operands are saturate_signed: the value named 'saturate signed' in this block; array: the value named 'array' in this block. Read together, the complete operation is: This calls 'np.testing.assert_array_equal' with ' saturate_signed(np.array([-40000, -32768, 32767, 40000]), 16), np.array([-32768, -32768, 32767, 32767]), ' inside the function test_signed_rounding_and_saturation, which handles test signed rounding and saturation. The call advances the host-side job that checks neuraedge golden behavior independently with Python assertions.

Line 136: `np.array([-32768, -32768, 32767, 32767]),` This is continuation line 3 of the 4-line logical statement that begins at source line 134. Its exact fragment is 'np.array([-32768, -32768, 32767, 32767]),'. The important operands are array: the value named 'array' in this block. Read together, the complete operation is: This calls 'np.testing.assert_array_equal' with ' saturate_signed(np.array([-40000, -32768, 32767, 40000]), 16), np.array([-32768, -32768, 32767, 32767]), ' inside the function test_signed_rounding_and_saturation, which handles test signed rounding and saturation. The call advances the host-side job that checks neuraedge golden behavior independently with Python assertions.

Line 137: `)` This is continuation line 4 of the 4-line logical statement that begins at source line 134. Its exact fragment is ')'. The expression is a literal or structural operator and has no hidden software state. Read together, the complete operation is: This calls 'np.testing.assert_array_equal' with ' saturate_signed(np.array([-40000, -32768, 32767, 40000]), 16), np.array([-32768, -32768, 32767, 32767]), ' inside the function test_signed_rounding_and_saturation, which handles test signed rounding and saturation. The call advances the host-side job that checks neuraedge golden behavior independently with Python assertions.

Line 139: `def test_linear_backward_matches_independent_scalar_reference(self) -> None:` This starts function test_linear_backward_matches_independent_scalar_reference. Its indented body performs test linear backward matches independent scalar reference as part of the file that checks neuraedge golden behavior independently with Python assertions; it runs only when called.

Line 140: `def rounded(value: int, shift: int) -> int:` This starts function rounded. Its indented body performs rounded as part of the file that checks neuraedge golden behavior independently with Python assertions; it runs only when called.

Line 141: `if shift == 0:` This executes the following indented host-code branch only when 'shift == 0' is true. The important operands are shift: the value named 'shift' in this block. Context: the function rounded, which handles rounded.

Line 142: `return value` This returns ‘value‘ to the caller of the function rounded, which handles rounded, ending this invocation. The important operands are value: the value named ’value’ in this block.

Line 143: `magnitude = abs(value)` This assigns ‘abs(value)‘ to ‘magnitude ‘ in host memory. Here magnitude means the value named ’magnitude’ in this block. The important operands are abs: the value named ’abs’ in this block; value: the value named ’value’ in this block. Context: the function rounded, which handles rounded.

Line 144: `result = (magnitude + (1 << (shift - 1))) >> shift` This assigns ‘(magnitude + (1 << (shift - 1))) >> shift‘ to ‘result ‘ in host memory. Here result means the value named ’result’ in this block. The important operands are magnitude: the value named ’magnitude’ in this block; shift: the value named ’shift’ in this block. Context: the function rounded, which handles rounded.

Line 145: `return -result if value < 0 else result` This returns ‘-result if value < 0 else result‘ to the caller of the function rounded, which handles rounded, ending this invocation. The important operands are result: the value named ’result’ in this block; value: the value named ’value’ in this block.

Line 147: `def clipped(value: int, bits: int) -> int:` This starts function clipped. Its indented body performs clipped as part of the file that checks neuraedge golden behavior independently with Python assertions; it runs only when called.

Line 148: `return max(-(1 << (bits - 1)), min((1 << (bits - 1)) - 1, value))` This returns ‘max(-(1 << (bits - 1)), min((1 << (bits - 1)) - 1, value))‘ to the caller of the function clipped, which handles clipped, ending this invocation. The important operands are max: the value named ’max’ in this block; bits: the value named ’bits’ in this block; min: the value named ’min’ in this block.

Line 150: `for _ in range(100):` This iterates _ over ‘range(100)‘. Each iteration repeats the indented host operation, commonly once per layer, tile, timestep, or test case in the function test_linear_backward_matches_independent_scalar_refer which handles test linear backward matches independent scalar reference.

Line 151: `rows = int(self.rng.integers(1, 9))` This assigns ‘int(self.rng.integers(1, 9))‘ to ‘rows ‘ in host memory. Here rows means one output-row position processed by the tensor tile. The important operands are rng: the value named ’rng’ in this block; integers: the value named ’integers’ in this block. Context: the function test_linear_backward_matches_i which handles test linear backward matches independent scalar reference.

Line 152: `inputs = int(self.rng.integers(1, 9))` This assigns ‘int(self.rng.integers(1, 9))‘ to ‘inputs ‘ in host memory. Here inputs means the value named ’inputs’ in this block. The important operands are rng: the value named ’rng’ in this block; integers: the value named ’integers’ in this block. Context: the function test_linear_backward_matches_independent_ which handles test linear backward matches independent scalar reference.

Line 153: `outputs = int(self.rng.integers(1, 9))` This assigns ‘int(self.rng.integers(1, 9))‘ to ‘outputs ‘ in host memory. Here outputs means the value named ’outputs’ in this block. The important operands are rng: the value named ’rng’ in this block; integers: the value named ’integers’ in this block. Context: the function test_linear_backward_matches_indepen which handles test linear backward matches independent scalar reference.

Line 154: `dx_shift = int(self.rng.integers(0, 13))` This assigns ‘int(self.rng.integers(0, 13))‘ to ‘dx_shift ‘ in host memory. Here dx_shift means the value named ’dx shift’ in this block. The important operands are rng: the value named ’rng’ in this block; integers: the value named ’integers’ in this block. Context: the function test_linear_backward_matches_i which handles test linear backward matches independent scalar reference.

Line 155: `dw_shift = int(self.rng.integers(0, 13))` This assigns ‘int(self.rng.integers(0, 13))‘ to ‘dw_shift ‘ in host memory. Here dw_shift means the value named ’dw shift’ in this block. The important operands are rng: the value named ’rng’ in this block; integers: the value named ’integers’ in this block. Context: the function test_linear_backward_matches_independent_scalar_reference, which handles test linear backward matches independent scalar reference.

Line 156: `x = self.rng.integers(-128, 128, size=(rows, inputs), dtype=np.int64)` This assigns ‘self.rng.integers(-128, 128, size=(rows, inputs), dtype=np.int64)‘ to ‘x ‘ in host memory. Here x means the value named ’x’ in this block. The important operands are rng: the value named ’rng’ in this block; integers: the value named ’integers’ in this block; size: the value named ’size’ in this block. Context: the function test_linear_backward_matches_independent_scalar_reference, which handles test linear backward matches independent scalar reference.

Line 157: `w = self.rng.integers(-32768, 32768, size=(inputs, outputs), dtype=np.int64)` This assigns ‘self.rng.integ 32768, 32768, size=(inputs, outputs), dtype=np.int64)‘ to ‘w ‘ in host memory. Here w means the value named ’w’ in this block. The important operands are rng: the value named ’rng’ in this block; integers: the value named ’integers’ in this block; size: the value named ’size’ in this block. Context: the function test_linear_backward_matches_independent_scalar_referen which handles test linear backward matches independent scalar reference.

Line 158: `dy = self.rng.integers(-32768, 32768, size=(rows, outputs), dtype=np.int64)` This assigns ‘self.rng.intege 32768, 32768, size=(rows, outputs), dtype=np.int64)‘ to ‘dy ‘ in host memory. Here dy means the value named ’dy’ in this block. The important operands are rng: the value named ’rng’ in this block; integers: the value named ’integers’ in this block; size: the value named ’size’ in this block. Context: the function test_linear_backward_matches_independent_scalar_referen which handles test linear backward matches independent scalar reference.

Line 159: `expected_dx = np.zeros((rows, inputs), dtype=np.int64)` This assigns ‘np.zeros((rows, inputs), dtype=np.int6 to ‘expected_dx ‘ in host memory. Here expected_dx means the value named ’expected dx’ in this block. The important operands are zeros: the value named ’zeros’ in this block; rows: one output-row position processed by the tensor tile; inputs: the value named ’inputs’ in this block. Context: the function test_linear_backward_matches_independent_scalar_reference, which handles test linear backward matches independent scalar reference.

Line 160: `expected_dw = np.zeros((inputs, outputs), dtype=np.int64)` This assigns ‘np.zeros((inputs, outputs), dtype=np.int64)‘ to ‘expected_dw ‘ in host memory. Here expected_dw means the value named ’expected dw’ in this block. The important operands are zeros: the value named ’zeros’ in this block; inputs: the value named ’inputs’ in this block; outputs: the value named ’outputs’ in this block. Context: the function test_linear_backward_matches_independent_sc which handles test linear backward matches independent scalar reference.

Line 161: `for row in range(rows):` This iterates row over ‘range(rows)‘. Each iteration repeats the indented host operation, commonly once per layer, tile, timestep, or test case in the function test_linear_backward_matches_independent_scalar_re which handles test linear backward matches independent scalar reference.

Line 162: `for input_index in range(inputs):` This iterates input_index over ‘range(inputs)‘. Each iteration repeats the indented host operation, commonly once per layer, tile, timestep, or test case in the function test_linear_backward_matche which handles test linear backward matches independent scalar reference.

Line 163: `total = sum(` This statement continues through source line 166; the explanation uses the complete expression rather than only the first visual fragment. This assigns ‘sum(int(dy[row, output_index]) * int(w[input_index, output_index]) for output_index in range(outputs))‘ to ‘total ‘ in host memory. Here total means the value named ’total’ in this block. The important operands are sum: the value named ’sum’ in this block; dy: the value named ’dy’ in this block; row: one output-row position processed by the tensor tile. Context: the function test_linear_backward_matches_independent_scal which handles test linear backward matches independent scalar reference.

Line 164: `int(dy[row, output_index]) * int(w[input_index, output_index])` This is continuation line 2 of the 4-line logical statement that begins at source line 163. Its exact fragment is ‘int(dy[row, output_index]) * int(w[input_index, output_index])‘. The important operands are dy: the value named ’dy’ in this block; row: one output-row position processed by the tensor tile; output_index: an integer selecting one tensor element, lane, bank, or state entry. Read together, the complete operation is: This assigns ‘sum(int(dy[row, output_index]) * int(w[input_index, output_index]) for output_index in range(outputs))‘ to ‘total ‘ in host memory. Here total means the value named ’total’ in this block. The important operands are sum: the value named ’sum’ in this block; dy: the value named ’dy’ in this block; row: one output-row position processed by the tensor tile. Context: the function test_linear_backward_matches_independent_scalar_reference, which handles test linear backward matches independent scalar reference.

Line 165: `for output_index in range(outputs)` This is continuation line 3 of the 4-line logical statement that begins at source line 163. Its exact fragment is 'for output_index in range(outputs)'. The important operands are for: the value named 'for' in this block; output_index: an integer selecting one tensor element, lane, bank, or state entry; in: the value named 'in' in this block. Read together, the complete operation is: This assigns 'sum(int(dy[row, output_index]) * int(w[input_index, output_index]) for output_index in range(outputs))' to 'total ' in host memory. Here total means the value named 'total' in this block. The important operands are sum: the value named 'sum' in this block; dy: the value named 'dy' in this block; row: one output-row position processed by the tensor tile. Context: the function test_linear_backward_matches_independent_scalar_reference, which handles test linear backward matches independent scalar reference.

Line 166: `)` This is continuation line 4 of the 4-line logical statement that begins at source line 163. Its exact fragment is ')'. The expression is a literal or structural operator and has no hidden software state. Read together, the complete operation is: This assigns 'sum(int(dy[row, output_index]) * int(w[input_index, output_index]) for output_index in range(outputs))' to 'total ' in host memory. Here total means the value named 'total' in this block. The important operands are sum: the value named 'sum' in this block; dy: the value named 'dy' in this block; row: one output-row position processed by the tensor tile. Context: the function test_linear_backward_matches_independent_scalar_reference, which handles test linear backward matches independent scalar reference.

Line 167: `expected_dx[row, input_index] = clipped(rounded(total, dx_shift), 32)` This assigns 'clipped(rounded(tota dx_shift), 32)' to 'expected_dx[row, input_index] ' in host memory. Here expected_dx means the value named 'expected dx' in this block. The important operands are clipped: the value named 'clipped' in this block; rounded: the value named 'rounded' in this block; total: the value named 'total' in this block. Context: the function test_linear_backward_matches_independ which handles test linear backward matches independent scalar reference.

Line 168: `for input_index in range(inputs):` This iterates input_index over 'range(inputs)'. Each iteration repeats the indented host operation, commonly once per layer, tile, timestep, or test case in the function test_linear_backward_matche which handles test linear backward matches independent scalar reference.

Line 169: `for output_index in range(outputs):` This iterates output_index over 'range(outputs)'. Each iteration repeats the indented host operation, commonly once per layer, tile, timestep, or test case in the function test_linear_backward_matc which handles test linear backward matches independent scalar reference.

Line 170: `total = sum(` This statement continues through source line 173; the explanation uses the complete expression rather than only the first visual fragment. This assigns 'sum(int(x[row, input_index]) * int(dy[row, output_index]) for row in range(rows))' to 'total ' in host memory. Here total means the value named 'total' in this block. The important operands are sum: the value named 'sum' in this block; x: the value named 'x' in this block; row: one output-row position processed by the tensor tile. Context: the function test_linear_backward_matches_independent_scalar_reference, which handles test linear backward matches independent scalar reference.

Line 171: `int(x[row, input_index]) * int(dy[row, output_index])` This is continuation line 2 of the 4-line logical statement that begins at source line 170. Its exact fragment is 'int(x[row, input_index]) * int(dy[row, output_index])'. The important operands are x: the value named 'x' in this block; row: one output-row position processed by the tensor tile; input_index: an integer selecting one tensor element, lane, bank, or state entry. Read together, the complete operation is: This assigns 'sum(int(x[row, input_index]) * int(dy[row, output_index]) for row in range(rows))' to 'total ' in host memory. Here total means the value named 'total' in this block. The important operands are sum: the value named 'sum' in this block; x: the value named 'x' in this block; row: one output-row position processed by the tensor tile. Context: the function test_linear_backward_matches_independent_scalar_reference, which handles test linear backward matches independent scalar reference.

Line 172: `for row in range(rows)` This is continuation line 3 of the 4-line logical statement that begins at source line 170. Its exact fragment is 'for row in range(rows)'. The important operands are for: the value named 'for' in this block; row: one output-row position processed by the tensor tile; in: the value named 'in' in this block. Read together, the complete operation is: This assigns 'sum(int(x[row, input_index]) * int(dy[row, output_index]) for row in range(rows))' to 'total ' in host memory. Here total means the value named 'total' in this block. The important operands are sum: the value named 'sum' in this block; x: the value named 'x' in this block; row: one output-row position processed by the

tensor tile. Context: the function test_linear_backward_matches_independent_scalar_reference, which handles test linear backward matches independent scalar reference.

Line 173: `)` This is continuation line 4 of the 4-line logical statement that begins at source line 170. Its exact fragment is ')'. The expression is a literal or structural operator and has no hidden software state. Read together, the complete operation is: This assigns 'sum(int(x[row, input_index]) * int(dy[row, output_index]) for row in range(rows))' to 'total ' in host memory. Here total means the value named 'total' in this block. The important operands are sum: the value named 'sum' in this block; x: the value named 'x' in this block; row: one output-row position processed by the tensor tile. Context: the function test_linear_backward_matches_independent_scalar_reference, which handles test linear backward matches independent scalar reference.

Line 174: `expected_dw[input_index, output_index] = clipped(rounded(total, dw_shift), 24)` This assigns 'clipped(rounded(total, dw_shift), 24)' to 'expected_dw[input_index, output_index] ' in host memory. Here expected_dw means the value named 'expected dw' in this block. The important operands are clipped: the value named 'clipped' in this block; rounded: the value named 'rounded' in this block; total: the value named 'total' in this block. Context: the function test_linear_backward_matches_independent_scalar_reference, which handles test linear backward matches independent scalar reference.

Line 175: `got_dx, got_dw = linear_backward_tile(` This statement continues through source line 181; the explanation uses the complete expression rather than only the first visual fragment. This assigns 'linear_backward_tile(x, w, dy, input_gradient_shift=dx_shift, weight_gradient_shift=dw_shift,)' to 'got_dx, got_dw ' in host memory. Here got_dx means the value named 'got dx' in this block. The important operands are linear_backward_tile: the value named 'linear backward tile' in this block; x: the value named 'x' in this block; w: the value named 'w' in this block. Context: the function test_linear_backward_matches_independent_scalar_reference, which handles test linear backward matches independent scalar reference.

Line 176: `x,` This is continuation line 2 of the 7-line logical statement that begins at source line 175. Its exact fragment is 'x,'. The important operands are x: the value named 'x' in this block. Read together, the complete operation is: This assigns 'linear_backward_tile(x, w, dy, input_gradient_shift=dx_shift, weight_gradient_shift=dw_shift,)' to 'got_dx, got_dw ' in host memory. Here got_dx means the value named 'got dx' in this block. The important operands are linear_backward_tile: the value named 'linear backward tile' in this block; x: the value named 'x' in this block; w: the value named 'w' in this block. Context: the function test_linear_backward_matches_independent_scalar_reference, which handles test linear backward matches independent scalar reference.

Line 177: `w,` This is continuation line 3 of the 7-line logical statement that begins at source line 175. Its exact fragment is 'w,'. The important operands are w: the value named 'w' in this block. Read together, the complete operation is: This assigns 'linear_backward_tile(x, w, dy, input_gradient_shift=dx_shift, weight_gradient_shift=dw_shift,)' to 'got_dx, got_dw ' in host memory. Here got_dx means the value named 'got dx' in this block. The important operands are linear_backward_tile: the value named 'linear backward tile' in this block; x: the value named 'x' in this block; w: the value named 'w' in this block. Context: the function test_linear_backward_matches_independent_scalar_reference, which handles test linear backward matches independent scalar reference.

Line 178: `dy,` This is continuation line 4 of the 7-line logical statement that begins at source line 175. Its exact fragment is 'dy,'. The important operands are dy: the value named 'dy' in this block. Read together, the complete operation is: This assigns 'linear_backward_tile(x, w, dy, input_gradient_shift=dx_shift, weight_gradient_shift=dw_shift,)' to 'got_dx, got_dw ' in host memory. Here got_dx means the value named 'got dx' in this block. The important operands are linear_backward_tile: the value named 'linear backward tile' in this block; x: the value named 'x' in this block; w: the value named 'w' in this block. Context: the function test_linear_backward_matches_independent_scalar_reference, which handles test linear backward matches independent scalar reference.

Line 179: `input_gradient_shift=dx_shift,` This is continuation line 5 of the 7-line logical statement that begins at source line 175. Its exact fragment is 'input_gradient_shift=dx_shift,'. The important operands are input_gradient_shift: the signed loss derivative used to update a learned parameter; dx_shift: the value named 'dx shift' in this block. Read together, the complete operation is: This assigns 'linear_backward_tile(x, w, dy, input_gradient_shift=dx_shift, weight_gradient_shift=dw_shift,)' to 'got_dx, got_dw ' in host memory. Here got_dx means the value named 'got dx' in this block. The important operands are linear_backward_tile: the value named 'linear

backward tile' in this block; x: the value named 'x' in this block; w: the value named 'w' in this block. Context: the function test_linear_backward_matches_independent_scalar_reference, which handles test linear backward matches independent scalar reference.

Line 180: `weight_gradient_shift=dw_shift,` This is continuation line 6 of the 7-line logical statement that begins at source line 175. Its exact fragment is 'weight_gradient_shift=dw_shift,'. The important operands are weight_gradient_shift: a learned coefficient multiplied by an activation; dw_shift: the value named 'dw shift' in this block. Read together, the complete operation is: This assigns 'linear_backward_tile(x, w, dy, input_gradient_shift=dx_shift, weight_gradient_shift=dw_sh)' to 'got_dx, got_dw ' in host memory. Here got_dx means the value named 'got dx' in this block. The important operands are linear_backward_tile: the value named 'linear backward tile' in this block; x: the value named 'x' in this block; w: the value named 'w' in this block. Context: the function test_linear_backward_matches_independent_scalar_reference, which handles test linear backward matches independent scalar reference.

Line 181: `)` This is continuation line 7 of the 7-line logical statement that begins at source line 175. Its exact fragment is ')'. The expression is a literal or structural operator and has no hidden software state. Read together, the complete operation is: This assigns 'linear_backward_tile(x, w, dy, input_gradient_shift=dx_shift, weight_gradient_shift=dw_shift,)' to 'got_dx, got_dw ' in host memory. Here got_dx means the value named 'got dx' in this block. The important operands are linear_backward_tile: the value named 'linear backward tile' in this block; x: the value named 'x' in this block; w: the value named 'w' in this block. Context: the function test_linear_backward_matches_independent_scalar_reference, which handles test linear backward matches independent scalar reference.

Line 182: `np.testing.assert_array_equal(got_dx, expected_dx)` This calls 'np.testing.assert_array_equal' with 'got_dx, expected_dx' inside the function test_linear_backward_matches_independent_scalar_reference, which handles test linear backward matches independent scalar reference. The call advances the host-side job that checks neuraedge golden behavior independently with Python assertions.

Line 183: `np.testing.assert_array_equal(got_dw, expected_dw)` This calls 'np.testing.assert_array_equal' with 'got_dw, expected_dw' inside the function test_linear_backward_matches_independent_scalar_reference, which handles test linear backward matches independent scalar reference. The call advances the host-side job that checks neuraedge golden behavior independently with Python assertions.

Line 185: `x = np.full((8, 8), 127, dtype=np.int64)` This assigns 'np.full((8, 8), 127, dtype=np.int64)' to 'x ' in host memory. Here x means the value named 'x' in this block. The important operands are full: the value named 'full' in this block; dtype: the value named 'dtype' in this block; int64: the value named 'int64' in this block. Context: the function test_linear_backward_matches_independent_scalar_reference, which handles test linear backward matches independent scalar reference.

Line 186: `w = np.full((8, 8), -32768, dtype=np.int64)` This assigns 'np.full((8, 8), -32768, dtype=np.int64)' to 'w ' in host memory. Here w means the value named 'w' in this block. The important operands are full: the value named 'full' in this block; dtype: the value named 'dtype' in this block; int64: the value named 'int64' in this block. Context: the function test_linear_backward_matches_independent_scalar_reference, which handles test linear backward matches independent scalar reference.

Line 187: `dy = np.full((8, 8), -32768, dtype=np.int64)` This assigns 'np.full((8, 8), -32768, dtype=np.int64)' to 'dy ' in host memory. Here dy means the value named 'dy' in this block. The important operands are full: the value named 'full' in this block; dtype: the value named 'dtype' in this block; int64: the value named 'int64' in this block. Context: the function test_linear_backward_matches_independent_scalar_reference, which handles test linear backward matches independent scalar reference.

Line 188: `got_dx, got_dw = linear_backward_tile(x, w, dy)` This assigns 'linear_backward_tile(x, w, dy)' to 'got_dx, got_dw ' in host memory. Here got_dx means the value named 'got dx' in this block. The important operands are linear_backward_tile: the value named 'linear backward tile' in this block; x: the value named 'x' in this block; w: the value named 'w' in this block. Context: the function test_linear_backward_matches_independent_scalar_reference, which handles test linear backward matches independent scalar reference.

Line 189: `np.testing.assert_array_equal(got_dx, np.full((8, 8), (1 << 31) - 1))` This calls ‘np.testing.assert_array
with ‘got_dx, np.full((8, 8), (1 << 31) - 1)‘ inside the function test_linear_backward_matches_independent_scalar_reference, which handles test linear backward matches independent scalar reference. The call advances the host-side job that checks neuraedge golden behavior independently with Python assertions.

Line 190: `np.testing.assert_array_equal(got_dw, np.full((8, 8), -(1 << 23)))` This calls ‘np.testing.assert_array_eq
with ‘got_dw, np.full((8, 8), -(1 << 23))‘ inside the function test_linear_backward_matches_independent_scalar_reference, which handles test linear backward matches independent scalar reference. The call advances the host-side job that checks neuraedge golden behavior independently with Python assertions.

Line 192: `def test_sgd_momentum_update(self) -> None:` This starts function test_sgd_momentum_update. Its indented body performs test sgd momentum update as part of the file that checks neuraedge golden behavior independently with Python assertions; it runs only when called.

Line 193: `for _ in range(100):` This iterates _ over ‘range(100)‘. Each iteration repeats the indented host operation, commonly once per layer, tile, timestep, or test case in the function test_sgd_momentum_update, which handles test sgd momentum update.

Line 194: `weights = self.rng.integers(-32768, 32768, size=8, dtype=np.int64)` This assigns ‘self.rng.integers(-32768, 32768, size=8, dtype=np.int64)‘ to ‘weights ‘ in host memory. Here weights means a learned coefficient multiplied by an activation. The important operands are rng: the value named ’rng’ in this block; integers: the value named ’integers’ in this block; size: the value named ’size’ in this block. Context: the function test_sgd_momentum_update, which handles test sgd momentum update.

Line 195: `gradients = self.rng.integers(-(1 << 20), 1 << 20, size=8, dtype=np.int64)` This assigns ‘self.rng.integers
(1 << 20), 1 << 20, size=8, dtype=np.int64)‘ to ‘gradients ‘ in host memory. Here gradients means the signed loss derivative used to update a learned parameter. The important operands are rng: the value named ’rng’ in this block; integers: the value named ’integers’ in this block; size: the value named ’size’ in this block. Context: the function test_sgd_momentum_update, which handles test sgd momentum update.

Line 196: `velocities = self.rng.integers(-(1 << 20), 1 << 20, size=8, dtype=np.int64)` This assigns ‘self.rng.intege
(1 << 20), 1 << 20, size=8, dtype=np.int64)‘ to ‘velocities ‘ in host memory. Here velocities means the value named ’velocities’ in this block. The important operands are rng: the value named ’rng’ in this block; integers: the value named ’integers’ in this block; size: the value named ’size’ in this block. Context: the function test_sgd_momentum_update, which handles test sgd momentum update.

Line 197: `next_weight, next_velocity = sgd_momentum_step(` This statement continues through source line 199; the explanation uses the complete expression rather than only the first visual fragment. This assigns ‘sgd_momentum_step(weights, gradients, velocities, 655, 58982, 66)‘ to ‘next_weight, next_velocity ‘ in host memory. Here next_weight means a learned coefficient multiplied by an activation. The important operands are sgd_momentum_step: the value named ’sgd momentum step’ in this block; weights: a learned coefficient multiplied by an activation; gradients: the signed loss derivative used to update a learned parameter. Context: the function test_sgd_momentum_update, which handles test sgd momentum update.

Line 198: `weights, gradients, velocities, 655, 58982, 66` This is continuation line 2 of the 3-line logical statement that begins at source line 197. Its exact fragment is ‘weights, gradients, velocities, 655, 58982, 66‘. The important operands are weights: a learned coefficient multiplied by an activation; gradients: the signed loss derivative used to update a learned parameter; velocities: the value named ’velocities’ in this block. Read together, the complete operation is: This assigns ‘sgd_momentum_step(weights, gradients, velocities, 655, 58982, 66)‘ to ‘next_weight, next_velocity ‘ in host memory. Here next_weight means a learned coefficient multiplied by an activation. The important operands are sgd_momentum_step: the value named ’sgd momentum step’ in this block; weights: a learned coefficient multiplied by an activation; gradients: the signed loss derivative used to update a learned parameter. Context: the function test_sgd_momentum_update, which handles test sgd momentum update.

Line 199: `)` This is continuation line 3 of the 3-line logical statement that begins at source line 197. Its exact fragment is ')'. The expression is a literal or structural operator and has no hidden software state. Read together, the complete operation is: This assigns 'sgd_momentum_step(weights, gradients, velocities, 655, 58982, 66)' to 'next_weight, next_velocity ' in host memory. Here next_weight means a learned coefficient multiplied by an activation. The important operands are sgd_momentum_step: the value named 'sgd momentum step' in this block; weights: a learned coefficient multiplied by an activation; gradients: the signed loss derivative used to update a learned parameter. Context: the function test_sgd_momentum_update, which handles test sgd momentum update.

Line 200: `self.assertTrue(np.all(next_weight >= -32768))` This calls 'self.assertTrue' with 'np.all(next_weight >= -32768)' inside the function test_sgd_momentum_update, which handles test sgd momentum update. The call advances the host-side job that checks neuraedge golden behavior independently with Python assertions.

Line 201: `self.assertTrue(np.all(next_weight <= 32767))` This calls 'self.assertTrue' with 'np.all(next_weight <= 32767)' inside the function test_sgd_momentum_update, which handles test sgd momentum update. The call advances the host-side job that checks neuraedge golden behavior independently with Python assertions.

Line 202: `self.assertTrue(np.all(next_velocity >= -(1 << 23)))` This calls 'self.assertTrue' with 'np.all(next_velocity >= -(1 << 23))' inside the function test_sgd_momentum_update, which handles test sgd momentum update. The call advances the host-side job that checks neuraedge golden behavior independently with Python assertions.

Line 203: `self.assertTrue(np.all(next_velocity <= (1 << 23) - 1))` This calls 'self.assertTrue' with 'np.all(next_velocit <= (1 << 23) - 1)' inside the function test_sgd_momentum_update, which handles test sgd momentum update. The call advances the host-side job that checks neuraedge golden behavior independently with Python assertions.

Line 205: `def test_sgd_weight_decay_is_decoupled_from_velocity(self) -> None:` This starts function test_sgd_weight Its indented body performs test sgd weight decay is decoupled from velocity as part of the file that checks neuraedge golden behavior independently with Python assertions; it runs only when called.

Line 206: `next_weight, next_velocity = sgd_momentum_step(` This statement continues through source line 213; the explanation uses the complete expression rather than only the first visual fragment. This assigns 'sgd_momentum_step(np.full(8, 1000, dtype=np.int64), np.zeros(8, dtype=np.int64), np.full(8, 1000, dtype=np.int64), 65536, 65536, 65536,)' to 'next_weight, next_velocity ' in host memory. Here next_weight means a learned coefficient multiplied by an activation. The important operands are sgd_momentum_step: the value named 'sgd momentum step' in this block; full: the value named 'full' in this block; dtype: the value named 'dtype' in this block. Context: the function test_sgd_weight_decay_is_decoupled_from_velocity, which handles test sgd weight decay is decoupled from velocity.

Line 207: `np.full(8, 1000, dtype=np.int64),` This is continuation line 2 of the 8-line logical statement that begins at source line 206. Its exact fragment is 'np.full(8, 1000, dtype=np.int64),'. The important operands are full: the value named 'full' in this block; dtype: the value named 'dtype' in this block; int64: the value named 'int64' in this block. Read together, the complete operation is: This assigns 'sgd_momentum_step(np.full(8, 1000, dtype=np.int64), np.zeros(8, dtype=np.int64), np.full(8, 1000, dtype=np.int64), 65536, 65536, 65536,)' to 'next_weight, next_velocity ' in host memory. Here next_weight means a learned coefficient multiplied by an activation. The important operands are sgd_momentum_step: the value named 'sgd momentum step' in this block; full: the value named 'full' in this block; dtype: the value named 'dtype' in this block. Context: the function test_sgd_weight_decay_is_decoupled_from_velocity, which handles test sgd weight decay is decoupled from velocity.

Line 208: `np.zeros(8, dtype=np.int64),` This is continuation line 3 of the 8-line logical statement that begins at source line 206. Its exact fragment is 'np.zeros(8, dtype=np.int64),'. The important operands are zeros: the value named 'zeros' in this block; dtype: the value named 'dtype' in this block; int64: the value named 'int64' in this block. Read together, the complete operation is: This assigns 'sgd_momentum_step(np.full(8, 1000, dtype=np.int64), np.zeros(8, dtype=np.int64), np.full(8, 1000, dtype=np.int64), 65536, 65536, 65536,)' to 'next_weight, next_velocity ' in host memory. Here next_weight means a learned coefficient multiplied by an activation. The important operands are sgd_momentum_step: the value named 'sgd momentum step' in this block; full: the value named 'full' in this block; dtype: the value named 'dtype' in this block. Context: the function test_sgd_weight_decay_is_decoupled_from_velocity, which handles test sgd weight decay is decoupled from velocity.

Line 209: `np.full(8, 1000, dtype=np.int64),` This is continuation line 4 of the 8-line logical statement that begins at source line 206. Its exact fragment is 'np.full(8, 1000, dtype=np.int64),'. The important operands are full: the value named 'full' in this block; dtype: the value named 'dtype' in this block; int64: the value named 'int64' in this block. Read together, the complete operation is: This assigns 'sgd_momentum_step(np.full(8, 1000, dtype=np.int64), np.zeros(8, dtype=np.int64), np.full(8, 1000, dtype=np.int64), 65536, 65536, 65536,)' to 'next_weight, next_velocity ' in host memory. Here next_weight means a learned coefficient multiplied by an activation. The important operands are sgd_momentum_step: the value named 'sgd momentum step' in this block; full: the value named 'full' in this block; dtype: the value named 'dtype' in this block. Context: the function test_sgd_weight_decay_is_decoupled_from_velocity, which handles test sgd weight decay is decoupled from velocity.

Line 210: `65536,` This is continuation line 5 of the 8-line logical statement that begins at source line 206. Its exact fragment is '65536,'. The expression is a literal or structural operator and has no hidden software state. Read together, the complete operation is: This assigns 'sgd_momentum_step(np.full(8, 1000, dtype=np.int64), np.zeros(8, dtype=np.int64), np.full(8, 1000, dtype=np.int64), 65536, 65536, 65536,)' to 'next_weight, next_velocity ' in host memory. Here next_weight means a learned coefficient multiplied by an activation. The important operands are sgd_momentum_step: the value named 'sgd momentum step' in this block; full: the value named 'full' in this block; dtype: the value named 'dtype' in this block. Context: the function test_sgd_weight_decay_is_decoupled_from_velocity, which handles test sgd weight decay is decoupled from velocity.

Line 211: `65536,` This is continuation line 6 of the 8-line logical statement that begins at source line 206. Its exact fragment is '65536,'. The expression is a literal or structural operator and has no hidden software state. Read together, the complete operation is: This assigns 'sgd_momentum_step(np.full(8, 1000, dtype=np.int64), np.zeros(8, dtype=np.int64), np.full(8, 1000, dtype=np.int64), 65536, 65536, 65536,)' to 'next_weight, next_velocity ' in host memory. Here next_weight means a learned coefficient multiplied by an activation. The important operands are sgd_momentum_step: the value named 'sgd momentum step' in this block; full: the value named 'full' in this block; dtype: the value named 'dtype' in this block. Context: the function test_sgd_weight_decay_is_decoupled_from_velocity, which handles test sgd weight decay is decoupled from velocity.

Line 212: `65536,` This is continuation line 7 of the 8-line logical statement that begins at source line 206. Its exact fragment is '65536,'. The expression is a literal or structural operator and has no hidden software state. Read together, the complete operation is: This assigns 'sgd_momentum_step(np.full(8, 1000, dtype=np.int64), np.zeros(8, dtype=np.int64), np.full(8, 1000, dtype=np.int64), 65536, 65536, 65536,)' to 'next_weight, next_velocity ' in host memory. Here next_weight means a learned coefficient multiplied by an activation. The important operands are sgd_momentum_step: the value named 'sgd momentum step' in this block; full: the value named 'full' in this block; dtype: the value named 'dtype' in this block. Context: the function test_sgd_weight_decay_is_decoupled_from_velocity, which handles test sgd weight decay is decoupled from velocity.

Line 213: `)` This is continuation line 8 of the 8-line logical statement that begins at source line 206. Its exact fragment is ')'. The expression is a literal or structural operator and has no hidden software state. Read together, the complete operation is: This assigns 'sgd_momentum_step(np.full(8, 1000, dtype=np.int64), np.zeros(8, dtype=np.int64), np.full(8, 1000, dtype=np.int64), 65536, 65536, 65536,)' to 'next_weight, next_velocity ' in host memory. Here next_weight means a learned coefficient multiplied by an activation. The important operands are sgd_momentum_step: the value named 'sgd momentum step' in this block; full: the value named 'full' in this block; dtype: the value named 'dtype' in this block. Context: the function test_sgd_weight_decay_is_decoupled_from_velocity, which handles test sgd weight decay is decoupled from velocity.

Line 214: `np.testing.assert_array_equal(next_velocity, np.full(8, 1000))` This calls 'np.testing.assert_array_equal' with 'next_velocity, np.full(8, 1000)' inside the function test_sgd_weight_decay_is_decoupled_from_velocity, which handles test sgd weight decay is decoupled from velocity. The call advances the host-side job that checks neuraedge golden behavior independently with Python assertions.

Line 215: `np.testing.assert_array_equal(next_weight, np.full(8, -1000))` This calls 'np.testing.assert_array_equal' with 'next_weight, np.full(8, -1000)' inside the function test_sgd_weight_decay_is_decoupled_from_velocity, which handles test sgd weight decay is decoupled from velocity. The call advances the host-side job that checks neuraedge golden behavior independently with Python assertions.

Line 217: `def test_vector_alu_operations(self) -> None:` This starts function test_vector_alu_operations. Its indented body performs test vector alu operations as part of the file that checks neuraedge golden behavior independently with Python assertions; it runs only when called.

Line 218: `a = np.array([-(1 << 31), -100, -8, -1, 0, 7, 100, (1 << 31) - 1])` This assigns 'np.array([-(1 << 31), -100, -8, -1, 0, 7, 100, (1 << 31) - 1])' to 'a ' in host memory. Here a means the value named 'a' in this block. The important operands are array: the value named 'array' in this block. Context: the function test_vector_alu_operations, which handles test vector alu operations.

Line 219: `b = np.array([-1, 300, 8, -2, 1, 9, -300, 1])` This assigns 'np.array([-1, 300, 8, -2, 1, 9, -300, 1])' to 'b ' in host memory. Here b means the value named 'b' in this block. The important operands are array: the value named 'array' in this block. Context: the function test_vector_alu_operations, which handles test vector alu operations.

Line 220: `added = vector_alu(VectorOperation.ADD_SAT, a, b)` This assigns 'vector_alu(VectorOperation.ADD_SAT, a, b)' to 'added ' in host memory. Here added means the value named 'added' in this block. The important operands are vector_alu: the value named 'vector alu' in this block; VectorOperation: the value named 'vector operation' in this block; ADD_SAT: the value named 'add sat' in this block. Context: the function test_vector_alu_operations, which handles test vector alu operations.

Line 221: `self.assertEqual(int(added[0]), -(1 << 31))` This calls 'self.assertEqual' with 'int(added[0]), -(1 << 31)' inside the function test_vector_alu_operations, which handles test vector alu operations. The call advances the host-side job that checks neuraedge golden behavior independently with Python assertions.

Line 222: `self.assertEqual(int(added[-1]), (1 << 31) - 1)` This calls 'self.assertEqual' with 'int(added[-1]), (1 << 31) - 1' inside the function test_vector_alu_operations, which handles test vector alu operations. The call advances the host-side job that checks neuraedge golden behavior independently with Python assertions.

Line 223: `np.testing.assert_array_equal(` This statement continues through source line 226; the explanation uses the complete expression rather than only the first visual fragment. This calls 'np.testing.assert_array_equal' with ' vector_alu(VectorOperation.TERNARY_SPIKE, a, b, threshold=8), np.array([-1, -1, -1, 0, 0, 0, 1, 1]), ' inside the function test_vector_alu_operations, which handles test vector alu operations. The call advances the host-side job that checks neuraedge golden behavior independently with Python assertions.

Line 224: `vector_alu(VectorOperation.TERNARY_SPIKE, a, b, threshold=8),` This is continuation line 2 of the 4-line logical statement that begins at source line 223. Its exact fragment is 'vector_alu(VectorOperation.TERNARY_SPIKE, a, b, threshold=8),'. The important operands are vector_alu: the value named 'vector alu' in this block; VectorOperation: the value named 'vector operation' in this block; TERNARY_SPIKE: a binary event produced when a neuron crosses its threshold. Read together, the complete operation is: This calls 'np.testing.assert_array_equal' with ' vector_alu(VectorOperation.TERNARY_SPIKE, a, b, threshold=8), np.array([-1, -1, -1, 0, 0, 0, 1, 1]), ' inside the function test_vector_alu_operations, which handles test vector alu operations. The call advances the host-side job that checks neuraedge golden behavior independently with Python assertions.

Line 225: `np.array([-1, -1, -1, 0, 0, 0, 1, 1]),` This is continuation line 3 of the 4-line logical statement that begins at source line 223. Its exact fragment is 'np.array([-1, -1, -1, 0, 0, 0, 1, 1]),'. The important operands are array: the value named 'array' in this block. Read together, the complete operation is: This calls 'np.testing.assert_array_equal' with ' vector_alu(VectorOperation.TERNARY_SPIKE, a, b, threshold=8), np.array([-1, -1, -1, 0, 0, 0, 1, 1]), ' inside the function test_vector_alu_operations, which handles test vector alu operations. The call advances the host-side job that checks neuraedge golden behavior independently with Python assertions.

Line 226: `)` This is continuation line 4 of the 4-line logical statement that begins at source line 223. Its exact fragment is ')'. The expression is a literal or structural operator and has no hidden software state. Read together, the complete operation is: This calls 'np.testing.assert_array_equal' with ' vector_alu(VectorOperation.TERNARY_SPIKE, a, b, threshold=8), np.array([-1, -1, -1, 0, 0, 0, 1, 1]), ' inside the function test_vector_alu_operations, which handles test vector alu operations. The call advances the host-side job that checks neuraedge golden behavior independently with Python assertions.

Line 227: `requantized = vector_alu(` This statement continues through source line 236; the explanation uses the complete expression rather than only the first visual fragment. This assigns ‘vector_alu(VectorOperation.REQUANTIZE, a, b, multiplier_q15=16384, right_shift=1, output_zero_point=3, clamp_minimum=-128, clamp_maximum=127,)‘ to ‘requantized ‘ in host memory. Here requantized means the conversion of a wide accumulated result back into a bounded activation code. The important operands are vector_alu: the value named ’vector alu’ in this block; VectorOperation: the value named ’vector operation’ in this block; REQUANTIZE: the conversion of a wide accumulated result back into a bounded activation code. Context: the function test_vector_alu_operations, which handles test vector alu operations.

Line 228: `VectorOperation.REQUANTIZE,` This is continuation line 2 of the 10-line logical statement that begins at source line 227. Its exact fragment is ‘VectorOperation.REQUANTIZE,‘. The important operands are VectorOperation: the value named ’vector operation’ in this block; REQUANTIZE: the conversion of a wide accumulated result back into a bounded activation code. Read together, the complete operation is: This assigns ‘vector_alu(VectorOperation.REQUANTIZE, a, b, multiplier_q15=16384, right_shift=1, output_zero_point=3, clamp_minimum=-128, clamp_maximum=127,)‘ to ‘requantized ‘ in host memory. Here requantized means the conversion of a wide accumulated result back into a bounded activation code. The important operands are vector_alu: the value named ’vector alu’ in this block; VectorOperation: the value named ’vector operation’ in this block; REQUANTIZE: the conversion of a wide accumulated result back into a bounded activation code. Context: the function test_vector_alu_operations, which handles test vector alu operations.

Line 229: `a,` This is continuation line 3 of the 10-line logical statement that begins at source line 227. Its exact fragment is ‘a,‘. The important operands are a: the value named ’a’ in this block. Read together, the complete operation is: This assigns ‘vector_alu(VectorOperation.REQUANTIZE, a, b, multiplier_q15=16384, right_shift=1, output_zero_point=3, clamp_minimum=-128, clamp_maximum=127,)‘ to ‘requantized ‘ in host memory. Here requantized means the conversion of a wide accumulated result back into a bounded activation code. The important operands are vector_alu: the value named ’vector alu’ in this block; VectorOperation: the value named ’vector operation’ in this block; REQUANTIZE: the conversion of a wide accumulated result back into a bounded activation code. Context: the function test_vector_alu_operations, which handles test vector alu operations.

Line 230: `b,` This is continuation line 4 of the 10-line logical statement that begins at source line 227. Its exact fragment is ‘b,‘. The important operands are b: the value named ’b’ in this block. Read together, the complete operation is: This assigns ‘vector_alu(VectorOperation.REQUANTIZE, a, b, multiplier_q15=16384, right_shift=1, output_zero_point=3, clamp_minimum=-128, clamp_maximum=127,)‘ to ‘requantized ‘ in host memory. Here requantized means the conversion of a wide accumulated result back into a bounded activation code. The important operands are vector_alu: the value named ’vector alu’ in this block; VectorOperation: the value named ’vector operation’ in this block; REQUANTIZE: the conversion of a wide accumulated result back into a bounded activation code. Context: the function test_vector_alu_operations, which handles test vector alu operations.

Line 231: `multiplier_q15=16384,` This is continuation line 5 of the 10-line logical statement that begins at source line 227. Its exact fragment is ‘multiplier_q15=16384,‘. The important operands are multiplier_q15: the value named ’multiplier q15’ in this block. Read together, the complete operation is: This assigns ‘vector_alu(VectorOperation.REQUANTIZE, a, b, multiplier_q15=16384, right_shift=1, output_zero_point=3, clamp_minimum=-128, clamp_maximum)‘ to ‘requantized ‘ in host memory. Here requantized means the conversion of a wide accumulated result back into a bounded activation code. The important operands are vector_alu: the value named ’vector alu’ in this block; VectorOperation: the value named ’vector operation’ in this block; REQUANTIZE: the conversion of a wide accumulated result back into a bounded activation code. Context: the function test_vector_alu_operations, which handles test vector alu operations.

Line 232: `right_shift=1,` This is continuation line 6 of the 10-line logical statement that begins at source line 227. Its exact fragment is ‘right_shift=1,‘. The important operands are right_shift: the value named ’right shift’ in this block. Read together, the complete operation is: This assigns ‘vector_alu(VectorOperation.REQUANTIZE, a, b, multiplier_q15=16384, right_shift=1, output_zero_point=3, clamp_minimum=-128, clamp_maximum=127,)‘ to ‘requantized ‘ in host memory. Here requantized means the conversion of a wide accumulated result back into a bounded activation code. The important operands are vector_alu: the value named ’vector alu’ in this block; VectorOperation: the value named ’vector operation’ in this block; REQUANTIZE: the conversion of a wide accumulated result back into a bounded activation code. Context: the function test_vector_alu_operations, which handles test vector alu operations.

Line 233: `output_zero_point=3,` This is continuation line 7 of the 10-line logical statement that begins at source line 227. Its exact fragment is 'output_zero_point=3,'. The important operands are output_zero_point: the integer code representing real numeric zero in affine quantization. Read together, the complete operation is: This assigns 'vector_alu(VectorOperation.REQUANTIZE, a, b, multiplier_q15=16384, right_shift=1, output_zero_point=3, clamp_minimum=-128, clamp_maximum=127,)' to 'requantized ' in host memory. Here requantized means the conversion of a wide accumulated result back into a bounded activation code. The important operands are vector_alu: the value named 'vector alu' in this block; VectorOperation: the value named 'vector operation' in this block; REQUANTIZE: the conversion of a wide accumulated result back into a bounded activation code. Context: the function test_vector_alu_operations, which handles test vector alu operations.

Line 234: `clamp_minimum=-128,` This is continuation line 8 of the 10-line logical statement that begins at source line 227. Its exact fragment is 'clamp_minimum=-128,'. The important operands are clamp_minimum: the value named 'clamp minimum' in this block. Read together, the complete operation is: This assigns 'vector_alu(VectorOperation.REQUANTIZE, a, b, multiplier_q15=16384, right_shift=1, output_zero_point=3, clamp_minimum=-128, clamp_maximum=127,)' to 'requantized ' in host memory. Here requantized means the conversion of a wide accumulated result back into a bounded activation code. The important operands are vector_alu: the value named 'vector alu' in this block; VectorOperation: the value named 'vector operation' in this block; REQUANTIZE: the conversion of a wide accumulated result back into a bounded activation code. Context: the function test_vector_alu_operations, which handles test vector alu operations.

Line 235: `clamp_maximum=127,` This is continuation line 9 of the 10-line logical statement that begins at source line 227. Its exact fragment is 'clamp_maximum=127,'. The important operands are clamp_maximum: the value named 'clamp maximum' in this block. Read together, the complete operation is: This assigns 'vector_alu(VectorOperation.REQUANTIZE, a, b, multiplier_q15=16384, right_shift=1, output_zero_point=3, clamp_minimum=-128, clamp_maximum=127,)' to 'requantized ' in host memory. Here requantized means the conversion of a wide accumulated result back into a bounded activation code. The important operands are vector_alu: the value named 'vector alu' in this block; VectorOperation: the value named 'vector operation' in this block; REQUANTIZE: the conversion of a wide accumulated result back into a bounded activation code. Context: the function test_vector_alu_operations, which handles test vector alu operations.

Line 236: `)` This is continuation line 10 of the 10-line logical statement that begins at source line 227. Its exact fragment is ')'. The expression is a literal or structural operator and has no hidden software state. Read together, the complete operation is: This assigns 'vector_alu(VectorOperation.REQUANTIZE, a, b, multiplier_q15=16384, right_shift=1, output_zero_point=3, clamp_minimum=-128, clamp_maximum=127,)' to 'requantized ' in host memory. Here requantized means the conversion of a wide accumulated result back into a bounded activation code. The important operands are vector_alu: the value named 'vector alu' in this block; VectorOperation: the value named 'vector operation' in this block; REQUANTIZE: the conversion of a wide accumulated result back into a bounded activation code. Context: the function test_vector_alu_operations, which handles test vector alu operations.

Line 237: `self.assertTrue(np.all(requantized >= -128))` This calls 'self.assertTrue' with 'np.all(requantized >= -128)' inside the function test_vector_alu_operations, which handles test vector alu operations. The call advances the host-side job that checks neuraedge golden behavior independently with Python assertions.

Line 238: `self.assertTrue(np.all(requantized <= 127))` This calls 'self.assertTrue' with 'np.all(requantized <= 127)' inside the function test_vector_alu_operations, which handles test vector alu operations. The call advances the host-side job that checks neuraedge golden behavior independently with Python assertions.

Line 240: `multiplier, shift, represented = quantize_flexible_scale(51.03228)` This assigns 'quantize_flexible_scale(to 'multiplier, shift, represented ' in host memory. Here multiplier means the value named 'multiplier' in this block. The important operands are quantize_flexible_scale: the real-value spacing represented by one quantized integer step. Context: the function test_vector_alu_operations, which handles test vector alu operations.

Line 241: `self.assertGreater(multiplier, 0)` This calls 'self.assertGreater' with 'multiplier, 0' inside the function test_vector_alu_operations, which handles test vector alu operations. The call advances the host-side job that checks neuraedge golden behavior independently with Python assertions.

Line 242: `self.assertLess(shift, 0)` This calls ‘self.assertLess‘ with ‘shift, 0‘ inside the function test_vector_alu_operations, which handles test vector alu operations. The call advances the host-side job that checks neuraedge golden behavior independently with Python assertions.

Line 243: `self.assertAlmostEqual(represented, 51.03228, delta=0.002)` This calls ‘self.assertAlmostEqual‘ with ‘represented, 51.03228, delta=0.002‘ inside the function test_vector_alu_operations, which handles test vector alu operations. The call advances the host-side job that checks neuraedge golden behavior independently with Python assertions.

Line 244: `flexible = vector_alu(` This statement continues through source line 250; the explanation uses the complete expression rather than only the first visual fragment. This assigns ‘vector_alu(VectorOperation.FLEX_REQUANTIZE, np.array([1, -1, 100, -100], dtype=np.int64), np.zeros(4, dtype=np.int64), multiplier_q15=multiplier, right_shift=shift,)‘ to ‘flexible ‘ in host memory. Here flexible means the value named ’flexible’ in this block. The important operands are vector_alu: the value named ’vector alu’ in this block; VectorOperation: the value named ’vector operation’ in this block; FLEX_REQUANTIZE: the conversion of a wide accumulated result back into a bounded activation code. Context: the function test_vector_alu_operations, which handles test vector alu operations.

Line 245: `VectorOperation.FLEX_REQUANTIZE,` This is continuation line 2 of the 7-line logical statement that begins at source line 244. Its exact fragment is ‘VectorOperation.FLEX_REQUANTIZE,‘. The important operands are VectorOperation: the value named ’vector operation’ in this block; FLEX_REQUANTIZE: the conversion of a wide accumulated result back into a bounded activation code. Read together, the complete operation is: This assigns ‘vector_alu(VectorOperation.FLEX_REQUANTIZE, np.array([1, -1, 100, -100], dtype=np.int64), np.zeros(4, dtype=np.int64), multiplier_q15=multiplier, right_shift=shift,)‘ to ‘flexible ‘ in host memory. Here flexible means the value named ’flexible’ in this block. The important operands are vector_alu: the value named ’vector alu’ in this block; VectorOperation: the value named ’vector operation’ in this block; FLEX_REQUANTIZE: the conversion of a wide accumulated result back into a bounded activation code. Context: the function test_vector_alu_operations, which handles test vector alu operations.

Line 246: `np.array([1, -1, 100, -100], dtype=np.int64),` This is continuation line 3 of the 7-line logical statement that begins at source line 244. Its exact fragment is ‘np.array([1, -1, 100, -100], dtype=np.int64),‘. The important operands are array: the value named ’array’ in this block; dtype: the value named ’dtype’ in this block; int64: the value named ’int64’ in this block. Read together, the complete operation is: This assigns ‘vector_alu(VectorOperation.FLEX_REQUANTIZE, np.array([1, -1, 100, -100], dtype=np.int64), np.zeros(4, dtype=np.int64), multiplier_q15=multiplier, right_shift=shift,)‘ to ‘flexible ‘ in host memory. Here flexible means the value named ’flexible’ in this block. The important operands are vector_alu: the value named ’vector alu’ in this block; VectorOperation: the value named ’vector operation’ in this block; FLEX_REQUANTIZE: the conversion of a wide accumulated result back into a bounded activation code. Context: the function test_vector_alu_operations, which handles test vector alu operations.

Line 247: `np.zeros(4, dtype=np.int64),` This is continuation line 4 of the 7-line logical statement that begins at source line 244. Its exact fragment is ‘np.zeros(4, dtype=np.int64),‘. The important operands are zeros: the value named ’zeros’ in this block; dtype: the value named ’dtype’ in this block; int64: the value named ’int64’ in this block. Read together, the complete operation is: This assigns ‘vector_alu(VectorOperation.FLEX_REQUANTIZE, np.array([1, -1, 100, -100], dtype=np.int64), np.zeros(4, dtype=np.int64), multiplier_q15=multiplier, right_shift=shift,)‘ to ‘flexible ‘ in host memory. Here flexible means the value named ’flexible’ in this block. The important operands are vector_alu: the value named ’vector alu’ in this block; VectorOperation: the value named ’vector operation’ in this block; FLEX_REQUANTIZE: the conversion of a wide accumulated result back into a bounded activation code. Context: the function test_vector_alu_operations, which handles test vector alu operations.

Line 248: `multiplier_q15=multiplier,` This is continuation line 5 of the 7-line logical statement that begins at source line 244. Its exact fragment is ‘multiplier_q15=multiplier,‘. The important operands are multiplier_q15: the value named ’multiplier q15’ in this block; multiplier: the value named ’multiplier’ in this block. Read together, the complete operation is: This assigns ‘vector_alu(VectorOperation.FLEX_REQUANTIZE, np.array([1, -1, 100, -100], dtype=np.int64), np.zeros(4, dtype=np.int64), multiplier_q15=multiplier, right_shift=shift,)‘ to ‘flexible ‘ in host memory. Here flexible means the value named ’flexible’ in this block. The important operands are vector_alu: the value named ’vector alu’ in this block; VectorOperation: the value named ’vector operation’ in this block; FLEX_REQUANTIZE: the conversion

of a wide accumulated result back into a bounded activation code. Context: the function test_vector_alu_operations, which handles test vector alu operations.

Line 249: `right_shift=shift,` This is continuation line 6 of the 7-line logical statement that begins at source line 244. Its exact fragment is 'right_shift=shift,'. The important operands are right_shift: the value named 'right shift' in this block; shift: the value named 'shift' in this block. Read together, the complete operation is: This assigns 'vector_alu(VectorOperation.FLEX_REQUANTIZE, np.array([1, -1, 100, -100], dtype=np.int64), np.zeros(4, dtype=np.int64), multiplier_q15=multiplier, right_shift=shift,)' to 'flexible ' in host memory. Here flexible means the value named 'flexible' in this block. The important operands are vector_alu: the value named 'vector alu' in this block; VectorOperation: the value named 'vector operation' in this block; FLEX_REQUANTIZE: the conversion of a wide accumulated result back into a bounded activation code. Context: the function test_vector_alu_operations, which handles test vector alu operations.

Line 250: `)` This is continuation line 7 of the 7-line logical statement that begins at source line 244. Its exact fragment is ')'. The expression is a literal or structural operator and has no hidden software state. Read together, the complete operation is: This assigns 'vector_alu(VectorOperation.FLEX_REQUANTIZE, np.array([1, -1, 100, -100], dtype=np.int64), np.zeros(4, dtype=np.int64), multiplier_q15=multiplier, right_shift=shift,)' to 'flexible ' in host memory. Here flexible means the value named 'flexible' in this block. The important operands are vector_alu: the value named 'vector alu' in this block; VectorOperation: the value named 'vector operation' in this block; FLEX_REQUANTIZE: the conversion of a wide accumulated result back into a bounded activation code. Context: the function test_vector_alu_operations, which handles test vector alu operations.

Line 251: `np.testing.assert_allclose(` This statement continues through source line 255; the explanation uses the complete expression rather than only the first visual fragment. This calls 'np.testing.assert_allclose' with ' flexible, np.array([51, -51, 5103, -5103], dtype=np.int64), atol=1, ' inside the function test_vector_alu_operations, which handles test vector alu operations. The call advances the host-side job that checks neuraedge golden behavior independently with Python assertions.

Line 252: `flexible,` This is continuation line 2 of the 5-line logical statement that begins at source line 251. Its exact fragment is 'flexible,'. The important operands are flexible: the value named 'flexible' in this block. Read together, the complete operation is: This calls 'np.testing.assert_allclose' with ' flexible, np.array([51, -51, 5103, -5103], dtype=np.int64), atol=1, ' inside the function test_vector_alu_operations, which handles test vector alu operations. The call advances the host-side job that checks neuraedge golden behavior independently with Python assertions.

Line 253: `np.array([51, -51, 5103, -5103], dtype=np.int64),` This is continuation line 3 of the 5-line logical statement that begins at source line 251. Its exact fragment is 'np.array([51, -51, 5103, -5103], dtype=np.int64),'. The important operands are array: the value named 'array' in this block; dtype: the value named 'dtype' in this block; int64: the value named 'int64' in this block. Read together, the complete operation is: This calls 'np.testing.assert_allclose' with ' flexible, np.array([51, -51, 5103, -5103], dtype=np.int64), atol=1, ' inside the function test_vector_alu_operations, which handles test vector alu operations. The call advances the host-side job that checks neuraedge golden behavior independently with Python assertions.

Line 254: `atol=1,` This is continuation line 4 of the 5-line logical statement that begins at source line 251. Its exact fragment is 'atol=1,'. The important operands are atol: the value named 'atol' in this block. Read together, the complete operation is: This calls 'np.testing.assert_allclose' with ' flexible, np.array([51, -51, 5103, -5103], dtype=np.int64), atol=1, ' inside the function test_vector_alu_operations, which handles test vector alu operations. The call advances the host-side job that checks neuraedge golden behavior independently with Python assertions.

Line 255: `)` This is continuation line 5 of the 5-line logical statement that begins at source line 251. Its exact fragment is ')'. The expression is a literal or structural operator and has no hidden software state. Read together, the complete operation is: This calls 'np.testing.assert_allclose' with ' flexible, np.array([51, -51, 5103, -5103], dtype=np.int64), atol=1, ' inside the function test_vector_alu_operations, which handles test vector alu operations. The call advances the host-side job that checks neuraedge golden behavior independently with Python assertions.

Line 256: `selector = np.array([0, 1, -1, 0], dtype=np.int64)` This assigns ‘np.array([0, 1, -1, 0], dtype=np.int64)‘ to ‘selector ‘ in host memory. Here selector means the value named ’selector’ in this block. The important operands are array: the value named ’array’ in this block; dtype: the value named ’dtype’ in this block; int64: the value named ’int64’ in this block. Context: the function test_vector_alu_operations, which handles test vector alu operations.

Line 257: `payload = np.array([10, 20, 30, 40], dtype=np.int64)` This assigns ‘np.array([10, 20, 30, 40], dtype=np.int64)‘ to ‘payload ‘ in host memory. Here payload means stream data belonging to the current command. The important operands are array: the value named ’array’ in this block; dtype: the value named ’dtype’ in this block; int64: the value named ’int64’ in this block. Context: the function test_vector_alu_operations, which handles test vector alu operations.

Line 258: `np.testing.assert_array_equal(` This statement continues through source line 261; the explanation uses the complete expression rather than only the first visual fragment. This calls ‘np.testing.assert_array_equal‘ with ‘ vector_alu(VectorOperation.SELECT_ZERO, selector, payload), np.array([10, 0, 0, 40]), ‘ inside the function test_vector_alu_operations, which handles test vector alu operations. The call advances the host-side job that checks neuraedge golden behavior independently with Python assertions.

Line 259: `vector_alu(VectorOperation.SELECT_ZERO, selector, payload),` This is continuation line 2 of the 4-line logical statement that begins at source line 258. Its exact fragment is ‘vector_alu(VectorOperation.SELECT_ZERO, selector, payload),‘. The important operands are vector_alu: the value named ’vector alu’ in this block; VectorOperation: the value named ’vector operation’ in this block; SELECT_ZERO: the value named ’select zero’ in this block. Read together, the complete operation is: This calls ‘np.testing.assert_array_equal‘ with ‘ vector_alu(VectorOperation.SELECT_ZERO, selector, payload), np.array([10, 0, 0, 40]), ‘ inside the function test_vector_alu_operations, which handles test vector alu operations. The call advances the host-side job that checks neuraedge golden behavior independently with Python assertions.

Line 260: `np.array([10, 0, 0, 40]),` This is continuation line 3 of the 4-line logical statement that begins at source line 258. Its exact fragment is ‘np.array([10, 0, 0, 40]),‘. The important operands are array: the value named ’array’ in this block. Read together, the complete operation is: This calls ‘np.testing.assert_array_equal‘ with ‘ vector_alu(VectorOperation.SELECT_ZERO, selector, payload), np.array([10, 0, 0, 40]), ‘ inside the function test_vector_alu_operati which handles test vector alu operations. The call advances the host-side job that checks neuraedge golden behavior independently with Python assertions.

Line 261: `)` This is continuation line 4 of the 4-line logical statement that begins at source line 258. Its exact fragment is ‘)‘. The expression is a literal or structural operator and has no hidden software state. Read together, the complete operation is: This calls ‘np.testing.assert_array_equal‘ with ‘ vector_alu(VectorOperation.SELECT_ZERO, selector, payload), np.array([10, 0, 0, 40]), ‘ inside the function test_vector_alu_operations, which handles test vector alu operations. The call advances the host-side job that checks neuraedge golden behavior independently with Python assertions.

Line 262: `np.testing.assert_array_equal(` This statement continues through source line 265; the explanation uses the complete expression rather than only the first visual fragment. This calls ‘np.testing.assert_array_equal‘ with ‘ vector_alu(VectorOperation.SELECT_NONZERO, selector, payload), np.array([0, 20, 30, 0]), ‘ inside the function test_vector_alu_operations, which handles test vector alu operations. The call advances the host-side job that checks neuraedge golden behavior independently with Python assertions.

Line 263: `vector_alu(VectorOperation.SELECT_NONZERO, selector, payload),` This is continuation line 2 of the 4-line logical statement that begins at source line 262. Its exact fragment is ‘vector_alu(VectorOperation.SELECT_NONZERO, selector, payload),‘. The important operands are vector_alu: the value named ’vector alu’ in this block; VectorOperation: the value named ’vector operation’ in this block; SELECT_NONZERO: the value named ’select nonzero’ in this block. Read together, the complete operation is: This calls ‘np.testing.assert_array_equal‘ with ‘ vector_alu(VectorOperation.SELECT_N selector, payload), np.array([0, 20, 30, 0]), ‘ inside the function test_vector_alu_operations, which handles test vector alu operations. The call advances the host-side job that checks neuraedge golden behavior independently with Python assertions.

Line 264: `np.array([0, 20, 30, 0]),` This is continuation line 3 of the 4-line logical statement that begins at source line 262. Its exact fragment is 'np.array([0, 20, 30, 0]),'. The important operands are array: the value named 'array' in this block. Read together, the complete operation is: This calls 'np.testing.assert_array_equal' with ' vector_alu(VectorOperation.SELECT_NONZERO, selector, payload), np.array([0, 20, 30, 0]), ' inside the function test_vector_alu_operations, which handles test vector alu operations. The call advances the host-side job that checks neuraedge golden behavior independently with Python assertions.

Line 265: `)` This is continuation line 4 of the 4-line logical statement that begins at source line 262. Its exact fragment is ')'. The expression is a literal or structural operator and has no hidden software state. The call advances the host-side job that checks neuraedge golden behavior independently with Python assertions.

Line 272: `np.array([0, 1, 1, 1]),` This is continuation line 7 of the 8-line logical statement that begins at source line 266. Its exact fragment is ‘np.array([0, 1, 1, 1]),‘. The important operands are array: the value named ’array’ in this block. Read together, the complete operation is: This calls ‘np.testing.assert_array_equal‘ with ‘ vector_alu(VectorOperation.COMPARE_GE, np.array([1, 2, 2, -1]), np.array([2, 2, 1, -1]),), np.array([0, 1, 1, 1]), ‘ inside the function test_vector_alu_operations, which handles test vector alu operations. The call advances the host-side job that checks neuraedge golden behavior independently with Python assertions.

Line 273: `)` This is continuation line 8 of the 8-line logical statement that begins at source line 266. Its exact fragment is ‘)‘. The expression is a literal or structural operator and has no hidden software state. Read together, the complete operation is: This calls ‘np.testing.assert_array_equal‘ with ‘ vector_alu(VectorOperation.COMPARE_GE, np.array([1, 2, 2, -1]), np.array([2, 2, 1, -1]),), np.array([0, 1, 1, 1]), ‘ inside the function test_vector_alu_operations, which handles test vector alu operations. The call advances the host-side job that checks neuraedge golden behavior independently with Python assertions.

Line 276: `if __name__ == "__main__":` This executes the following indented host-code branch only when ‘___name___ == "___main___"‘ is true. The important operands are ___name___: the value named ’name’ in this block; ___main___: the value named ’main’ in this block. Context: the file whose role is to checks neuraedge golden behavior independently with Python assertions.

Line 277: `unittest.main()` This calls ‘unittest.main‘ with “ inside the file whose role is to checks neuraedge golden behavior independently with Python assertions. The call advances the host-side job that checks neuraedge golden behavior independently with Python assertions.

66 tests/test_neuraedge_protocol.py

Role in the complete system: checks neuraedge protocol behavior independently with Python assertions.

66.1 Beginner architecture map

Dataflow responsibility This file's end-to-end responsibility is to checks neuraedge protocol behavior independently with Python assertions.

Where it runs This is sequential host software. Python objects live in CPU memory; they become FPGA work only when the compiler packs a command or payload and the PYNQ driver transfers those bytes through AXI DMA or AXI-Lite.

Public structure Classes: ProtocolTests. Functions: test_command_words_round_trip, test_tensor_command_fields_and_li test_non_tensor_command_fields, test_tensor_stream_layouts, test_descriptor_program_layout, test_operator_stream_ test_result_decoders. Each function annotation below names its enclosing function so an array operation is tied to the model, compiler, driver, test, or report phase that uses it.

Numeric and failure boundary Shapes, signedness, byte order, scaling, and saturation are part of the hardware contract. Validation exceptions are functional safety checks: rejecting malformed input before DMA is different from silently clipping, reshaping, or continuing with an incompatible artifact.

66.3 Line annotations

Line 1: `import unittest` This imports the named Python API so the file whose role is to checks neuraedge protocol behavior independently with Python assertions can use it explicitly. Imports execute on the host processor and create no FPGA hardware.

Line 3: `from neuraedge_protocol import (` This statement continues through source line 43; the explanation uses the complete expression rather than only the first visual fragment. This imports the named Python API so the file whose role is to checks neuraedge protocol behavior independently with Python assertions can use it explicitly. Imports execute on the host processor and create no FPGA hardware.

Line 4: `Command128,` This is continuation line 2 of the 41-line logical statement that begins at source line 3. Its exact fragment is 'Command128,'. The important operands are Command128: the 128-bit instruction selecting an engine, shape, mode, and numeric parameters. Read together, the complete operation is: This imports the named Python API so the file whose role is to checks neuraedge protocol behavior independently with Python assertions can use it explicitly. Imports execute on the host processor and create no FPGA hardware.

Line 5: `ProgramRecord,` This is continuation line 3 of the 41-line logical statement that begins at source line 3. Its exact fragment is 'ProgramRecord,'. The important operands are ProgramRecord: the value named 'program record' in this block. Read together, the complete operation is: This imports the named Python API so the file whose role is to checks neuraedge protocol behavior independently with Python assertions can use it explicitly. Imports execute on the host processor and create no FPGA hardware.

Line 6: `StreamBeat,` This is continuation line 4 of the 41-line logical statement that begins at source line 3. Its exact fragment is 'StreamBeat,'. The important operands are StreamBeat: the value named 'stream beat' in this block. Read together, the complete operation is: This imports the named Python API so the file whose role is to checks neuraedge protocol behavior independently with Python assertions can use it explicitly. Imports execute on the host processor and create no FPGA hardware.

Line 7: `LinearGradientMode,` This is continuation line 5 of the 41-line logical statement that begins at source line 3. Its exact fragment is 'LinearGradientMode,'. The important operands are LinearGradientMode: the signed loss derivative used to update a learned parameter. Read together, the complete operation is: This imports the named Python API so the file whose role is to checks neuraedge protocol behavior independently with Python assertions can use it explicitly. Imports execute on the host processor and create no FPGA hardware.

Line 8: `LutSuboperation,` This is continuation line 6 of the 41-line logical statement that begins at source line 3. Its exact fragment is 'LutSuboperation,'. The important operands are LutSuboperation: the value named 'lut suboperation' in this block. Read together, the complete operation is: This imports the named Python API so the file whose role is to checks neuraedge protocol behavior independently with Python assertions can use it explicitly. Imports execute on the host processor and create no FPGA hardware.

Line 9: `Opcode,` This is continuation line 7 of the 41-line logical statement that begins at source line 3. Its exact fragment is 'Opcode,'. The important operands are Opcode: the value named 'opcode' in this block. Read together, the complete operation is: This imports the named Python API so the file whose role is to checks neuraedge protocol behavior independently with Python assertions can use it explicitly. Imports execute on the host processor and create no FPGA hardware.

Line 10: `alpha_xnor_command,` This is continuation line 8 of the 41-line logical statement that begins at source line 3. Its exact fragment is 'alpha_xnor_command,'. The important operands are alpha_xnor_command: the 128-bit instruction selecting an engine, shape, mode, and numeric parameters. Read together, the complete operation is: This imports the named Python API so the file whose role is to checks neuraedge protocol behavior independently with Python assertions can use it explicitly. Imports execute on the host processor and create no FPGA hardware.

Line 11: `clear_status_command,` This is continuation line 9 of the 41-line logical statement that begins at source line 3. Its exact fragment is 'clear_status_command,'. The important operands are clear_status_command: the 128-bit instruction selecting an engine, shape, mode, and numeric parameters. Read together, the complete operation is: This imports the named Python API so the file whose role is to checks neuraedge protocol behavior independently with Python assertions can use it explicitly. Imports execute on the host processor and create no FPGA hardware.

Line 12: `layernorm_command,` This is continuation line 10 of the 41-line logical statement that begins at source line 3. Its exact fragment is 'layernorm_command,'. The important operands are layernorm_command: the 128-bit instruction selecting an engine, shape, mode, and numeric parameters. Read together, the complete operation is: This imports the named Python API so the file whose role is to checks neuraedge protocol behavior independently with Python assertions can use it explicitly. Imports execute on the host processor and create no FPGA hardware.

Line 13: `linear_backward_command,` This is continuation line 11 of the 41-line logical statement that begins at source line 3. Its exact fragment is 'linear_backward_command,'. The important operands are linear_backward_command: the 128-bit instruction selecting an engine, shape, mode, and numeric parameters. Read together, the complete operation is: This imports the named Python API so the file whose role is to checks neuraedge protocol behavior independently with Python assertions can use it explicitly. Imports execute on the host processor and create no FPGA hardware.

Line 14: `lif_command,` This is continuation line 12 of the 41-line logical statement that begins at source line 3. Its exact fragment is 'lif_command,'. The important operands are lif_command: the 128-bit instruction selecting an engine, shape, mode, and numeric parameters. Read together, the complete operation is: This imports the named Python API so the file whose role is to checks neuraedge protocol behavior independently with Python assertions can use it explicitly. Imports execute on the host processor and create no FPGA hardware.

Line 15: `log_softmax_command,` This is continuation line 13 of the 41-line logical statement that begins at source line 3. Its exact fragment is 'log_softmax_command,'. The important operands are log_softmax_command: the 128-bit instruction selecting an engine, shape, mode, and numeric parameters. Read together, the complete operation is: This imports the named Python API so the file whose role is to checks neuraedge protocol behavior independently with Python assertions can use it explicitly. Imports execute on the host processor and create no FPGA hardware.

Line 16: `lut_command,` This is continuation line 14 of the 41-line logical statement that begins at source line 3. Its exact fragment is 'lut_command,'. The important operands are lut_command: the 128-bit instruction selecting an engine, shape, mode, and numeric parameters. Read together, the complete operation is: This imports the named Python API so the file whose role is to checks neuraedge protocol behavior independently with Python assertions can use it explicitly. Imports execute on the host processor and create no FPGA hardware.

Line 17: `pack_activation_beats,` This is continuation line 15 of the 41-line logical statement that begins at source line 3. Its exact fragment is 'pack_activation_beats,'. The important operands are pack_activation_beats: an input feature value consumed by a neuron or multiply-accumulate operation. Read together, the complete operation is: This imports the named Python API so the file whose role is to checks neuraedge protocol behavior independently with Python assertions can use it explicitly. Imports execute on the host processor and create no FPGA hardware.

Line 18: `pack_alpha_beats,` This is continuation line 16 of the 41-line logical statement that begins at source line 3. Its exact fragment is 'pack_alpha_beats,'. The important operands are pack_alpha_beats: the programmable weight assigned to matching zero spikes in alpha-XNOR attention. Read together, the complete operation is: This imports the named Python API so the file whose role is to checks neuraedge protocol behavior independently with Python assertions can use it explicitly. Imports execute on the host processor and create no FPGA hardware.

Line 19: `pack_dot8_weight_beats,` This is continuation line 17 of the 41-line logical statement that begins at source line 3. Its exact fragment is 'pack_dot8_weight_beats,'. The important operands are pack_dot8_weight_beats: a learned coefficient multiplied by an activation. Read together, the complete operation is: This imports the named Python API so the file whose role is to checks neuraedge protocol behavior independently with Python assertions can use it explicitly. Imports execute on the host processor and create no FPGA hardware.

Line 20: `pack_layernorm_beats,` This is continuation line 18 of the 41-line logical statement that begins at source line 3. Its exact fragment is 'pack_layernorm_beats,'. The important operands are pack_layernorm_beats: the value named 'pack layernorm beats' in this block. Read together, the complete operation is: This imports the named Python API so the file whose role is to checks neuraedge protocol behavior independently with Python assertions can use it explicitly. Imports execute on the host processor and create no FPGA hardware.

Line 21: `pack_linear_backward_beats,` This is continuation line 19 of the 41-line logical statement that begins at source line 3. Its exact fragment is 'pack_linear_backward_beats,'. The important operands are pack_linear_backward_beats: the value named 'pack linear backward beats' in this block. Read together, the complete operation is: This imports the named Python API so the file whose role is to checks neuraedge protocol behavior independently with Python assertions can use it explicitly. Imports execute on the host processor and create no FPGA hardware.

Line 22: `pack_lif_beats,` This is continuation line 20 of the 41-line logical statement that begins at source line 3. Its exact fragment is 'pack_lif_beats,'. The important operands are pack_lif_beats: the value named 'pack lif beats' in this block. Read together, the complete operation is: This imports the named Python API so the file whose role is to checks neuraedge protocol behavior independently with Python assertions can use it explicitly. Imports execute on the host processor and create no FPGA hardware.

Line 23: `pack_lut_eval_beat,` This is continuation line 21 of the 41-line logical statement that begins at source line 3. Its exact fragment is 'pack_lut_eval_beat,'. The important operands are pack_lut_eval_beat: the value named 'pack lut eval beat' in this block. Read together, the complete operation is: This imports the named Python API so the file whose role is to checks neuraedge protocol behavior independently with Python assertions can use it explicitly. Imports execute on the host processor and create no FPGA hardware.

Line 24: `pack_lut_load_beats,` This is continuation line 22 of the 41-line logical statement that begins at source line 3. Its exact fragment is 'pack_lut_load_beats,'. The important operands are pack_lut_load_beats: the value named 'pack lut load beats' in this block. Read together, the complete operation is: This imports the named Python API so the file whose role is to checks neuraedge protocol behavior independently with Python assertions can use it explicitly. Imports execute on the host processor and create no FPGA hardware.

Line 25: `pack_optimizer_beats,` This is continuation line 23 of the 41-line logical statement that begins at source line 3. Its exact fragment is 'pack_optimizer_beats,'. The important operands are pack_optimizer_beats: the value named 'pack optimizer beats' in this block. Read together, the complete operation is: This imports the named Python API so the file whose role is to checks neuraedge protocol behavior independently with Python assertions can use it explicitly. Imports execute on the host processor and create no FPGA hardware.

Line 26: `pack_outer_weight_beats,` This is continuation line 24 of the 41-line logical statement that begins at source line 3. Its exact fragment is 'pack_outer_weight_beats,'. The important operands are pack_outer_weight_beats: a learned coefficient multiplied by an activation. Read together, the complete operation is: This imports the named Python API so the file whose role is to checks neuraedge protocol behavior independently with Python assertions can use it explicitly. Imports execute on the host processor and create no FPGA hardware.

Line 27: `pack_softmax_beats,` This is continuation line 25 of the 41-line logical statement that begins at source line 3. Its exact fragment is 'pack_softmax_beats,'. The important operands are pack_softmax_beats: the value named 'pack softmax beats' in this block. Read together, the complete operation is: This imports the named Python API so the file whose role is to checks neuraedge protocol behavior independently with Python assertions can use it explicitly. Imports execute on the host processor and create no FPGA hardware.

Line 28: `pack_vector_beats,` This is continuation line 26 of the 41-line logical statement that begins at source line 3. Its exact fragment is 'pack_vector_beats,'. The important operands are pack_vector_beats: the value named 'pack vector beats' in this block. Read together, the complete operation is: This imports the named Python API so the file whose role is to checks neuraedge protocol behavior independently with Python assertions can use it explicitly. Imports execute on the host processor and create no FPGA hardware.

Line 29: `pack_descriptor_program,` This is continuation line 27 of the 41-line logical statement that begins at source line 3. Its exact fragment is 'pack_descriptor_program,'. The important operands are pack_descriptor_program: a DMA record header plus one command and its declared payload. Read together, the complete operation is: This imports the named Python API so the file whose role is to checks neuraedge protocol behavior independently with Python assertions can use it explicitly. Imports execute on the host processor and create no FPGA hardware.

Line 30: `sgd_command,` This is continuation line 28 of the 41-line logical statement that begins at source line 3. Its exact fragment is 'sgd_command,'. The important operands are sgd_command: the 128-bit instruction selecting an engine, shape, mode, and numeric parameters. Read together, the complete operation is: This imports the named Python API so the file whose role is to checks neuraedge protocol behavior independently with Python assertions can use it explicitly. Imports execute on the host processor and create no FPGA hardware.

Line 31: `tensor_command,` This is continuation line 29 of the 41-line logical statement that begins at source line 3. Its exact fragment is 'tensor_command,'. The important operands are tensor_command: the 128-bit instruction selecting an engine, shape, mode, and numeric parameters. Read together, the complete operation is: This imports the named Python API so the file whose role is to checks neuraedge protocol behavior independently with Python assertions can use it explicitly. Imports execute on the host processor and create no FPGA hardware.

Line 32: `unpack_alpha_result,` This is continuation line 30 of the 41-line logical statement that begins at source line 3. Its exact fragment is 'unpack_alpha_result,'. The important operands are unpack_alpha_result: the programmable weight assigned to matching zero spikes in alpha-XNOR attention. Read together, the complete operation is: This imports the named Python API so the file whose role is to checks neuraedge protocol behavior independently with Python assertions can use it explicitly. Imports execute on the host processor and create no FPGA hardware.

Line 33: `unpack_layernorm_result,` This is continuation line 31 of the 41-line logical statement that begins at source line 3. Its exact fragment is 'unpack_layernorm_result,'. The important operands are unpack_layernorm_result: the value named 'unpack layernorm result' in this block. Read together, the complete operation is: This imports the named Python API so the file whose role is to checks neuraedge protocol behavior independently with Python assertions can use it explicitly. Imports execute on the host processor and create no FPGA hardware.

Line 34: `unpack_linear_backward_result,` This is continuation line 32 of the 41-line logical statement that begins at source line 3. Its exact fragment is 'unpack_linear_backward_result,'. The important operands are unpack_linear_backward_result: the value named 'unpack linear backward result' in this block. Read together, the complete operation is: This imports the named Python API so the file whose role is to checks neuraedge protocol behavior independently with Python assertions can use it explicitly. Imports execute on the host processor and create no FPGA hardware.

Line 35: `unpack_lif_result,` This is continuation line 33 of the 41-line logical statement that begins at source line 3. Its exact fragment is 'unpack_lif_result,'. The important operands are unpack_lif_result: the value named 'unpack lif result' in this block. Read together, the complete operation is: This imports the named Python API so the file whose role is to checks neuraedge protocol behavior independently with Python assertions can use it explicitly. Imports execute on the host processor and create no FPGA hardware.

Line 36: `unpack_lif_trace,` This is continuation line 34 of the 41-line logical statement that begins at source line 3. Its exact fragment is 'unpack_lif_trace,'. The important operands are unpack_lif_trace: the value named 'unpack lif trace' in this block. Read together, the complete operation is: This imports the named Python API so the file whose role is to checks neuraedge protocol behavior independently with Python assertions can use it explicitly. Imports execute on the host processor and create no FPGA hardware.

Line 37: `unpack_lut_result,` This is continuation line 35 of the 41-line logical statement that begins at source line 3. Its exact fragment is 'unpack_lut_result,'. The important operands are unpack_lut_result: the value named 'unpack lut result' in this block. Read together, the complete operation is: This imports the named Python API so the file whose role is to checks neuraedge protocol behavior independently with Python assertions can use it explicitly. Imports execute on the host processor and create no FPGA hardware.

Line 38: `unpack_optimizer_result,` This is continuation line 36 of the 41-line logical statement that begins at source line 3. Its exact fragment is 'unpack_optimizer_result,'. The important operands are unpack_optimizer_result: the value named 'unpack optimizer result' in this block. Read together, the complete operation is: This imports the named Python API so the file whose role is to checks neuraedge protocol behavior independently with Python assertions can use it explicitly. Imports execute on the host processor and create no FPGA hardware.

Line 39: `unpack_softmax_result,` This is continuation line 37 of the 41-line logical statement that begins at source line 3. Its exact fragment is 'unpack_softmax_result,'. The important operands are unpack_softmax_result: the value named 'unpack softmax result' in this block. Read together, the complete operation is: This imports the named Python API so the file whose role is to checks neuraedge protocol behavior independently with Python assertions can use it explicitly. Imports execute on the host processor and create no FPGA hardware.

Line 40: `unpack_tensor_result,` This is continuation line 38 of the 41-line logical statement that begins at source line 3. Its exact fragment is 'unpack_tensor_result,'. The important operands are unpack_tensor_result: the value named 'unpack tensor result' in this block. Read together, the complete operation is: This imports the named Python API so the file whose role is to checks neuraedge protocol behavior independently with Python assertions can use it explicitly. Imports execute on the host processor and create no FPGA hardware.

Line 41: `unpack_vector_result,` This is continuation line 39 of the 41-line logical statement that begins at source line 3. Its exact fragment is 'unpack_vector_result,'. The important operands are unpack_vector_result: the value named 'unpack vector result' in this block. Read together, the complete operation is: This imports the named Python API so the file whose role is to checks neuraedge protocol behavior independently with Python assertions can use it explicitly. Imports execute on the host processor and create no FPGA hardware.

Line 42: `vector_command,` This is continuation line 40 of the 41-line logical statement that begins at source line 3. Its exact fragment is 'vector_command,'. The important operands are vector_command: the 128-bit instruction selecting an engine, shape, mode, and numeric parameters. Read together, the complete operation is: This imports the named Python API so the file whose role is to checks neuraedge protocol behavior independently with Python assertions can use it explicitly. Imports execute on the host processor and create no FPGA hardware.

Line 43: `)` This is continuation line 41 of the 41-line logical statement that begins at source line 3. Its exact fragment is ')'. The expression is a literal or structural operator and has no hidden software state. Read together, the complete operation is: This imports the named Python API so the file whose role is to checks neuraedge protocol behavior independently with Python assertions can use it explicitly. Imports execute on the host processor and create no FPGA hardware.

Line 46: `class ProtocolTests(unittest.TestCase):` This defines class ProtocolTests, which groups data and methods for protocol tests. Instances exist in host memory and organize the flow that checks neuraedge protocol behavior independently with Python assertions.

Line 47: `def test_command_words_round_trip(self):` This starts function test_command_words_round_trip. Its indented body performs test command words round trip as part of the file that checks neuraedge protocol behavior independently with Python assertions; it runs only when called.

Line 48: `command = Command128(0xFEDCBA98765432100123456789ABCDEF)` This assigns 'Command128(0xFEDCBA9876543210 to 'command ' in host memory. Here command means the 128-bit instruction selecting an engine, shape, mode, and numeric parameters. The important operands are Command128: the 128-bit instruction selecting an engine, shape, mode, and numeric parameters. Context: the function test_command_words_round_trip, which handles test command words round trip.

Line 49: `self.assertEqual(command.words_le, (0x89ABCDEF, 0x01234567, 0x76543210, 0xFEDCBA98))` This calls 'self.assertEqual' with 'command.words_le, (0x89ABCDEF, 0x01234567, 0x76543210, 0xFEDCBA98)' inside the function test_command_words_round_trip, which handles test command words round trip. The call advances the host-side job that checks neuraedge protocol behavior independently with Python assertions.

Line 50: `self.assertEqual(Command128.from_words_le(command.words_le), command)` This calls 'self.assertEqual' with 'Command128.from_words_le(command.words_le), command' inside the function test_command_words_round_trip, which handles test command words round trip. The call advances the host-side job that checks neuraedge protocol behavior independently with Python assertions.

Line 51: `self.assertEqual(clear_status_command().opcode, Opcode.CLEAR_STATUS)` This calls 'self.assertEqual' with 'clear_status_command().opcode, Opcode.CLEAR_STATUS' inside the function test_command_words_round_trip, which handles test command words round trip. The call advances the host-side job that checks neuraedge protocol behavior independently with Python assertions.

Line 53: `def test_tensor_command_fields_and_limits(self):` This starts function test_tensor_command_fields_and_limi Its indented body performs test tensor command fields and limits as part of the file that checks neuraedge protocol behavior independently with Python assertions; it runs only when called.

Line 54: `command = tensor_command(` This statement continues through source line 61; the explanation uses the complete expression rather than only the first visual fragment. This assigns 'tensor_command(Opcode.COMPUTE_DENSE_OUTER, rows=8, columns=16, issue_count=2048, activation_zero_point=128, weight_zero_point=129,).value' to 'command ' in host memory. Here command means the 128-bit instruction selecting an engine, shape, mode, and numeric parameters. The important operands are tensor_command: the 128-bit instruction selecting an engine, shape, mode, and numeric parameters; Opcode: the value named 'opcode' in this block; COMPUTE_DENSE_OUTER: the value named 'compute dense outer' in this block. Context: the function test_tensor_command_fields_and_limits, which handles test tensor command fields and limits.

Line 55: `Opcode.COMPUTE_DENSE_OUTER,` This is continuation line 2 of the 8-line logical statement that begins at source line 54. Its exact fragment is 'Opcode.COMPUTE_DENSE_OUTER,'. The important operands are Opcode: the value named 'opcode' in this block; COMPUTE_DENSE_OUTER: the value named 'compute dense outer' in this block. Read together, the complete operation is: This assigns 'tensor_command(Opcode.COMPUTE_DENSE_OUTER, rows=8, columns=16, issue_count=2048, activation_zero_point=128, weight_zero_point=129,).value' to 'command ' in host memory. Here command means the 128-bit instruction selecting an engine, shape, mode, and numeric parameters. The important operands are tensor_command: the 128-bit instruction selecting an engine, shape, mode, and numeric parameters; Opcode: the value named 'opcode' in this block; COMPUTE_DENSE_OUTER: the value named 'compute dense outer' in this block. Context: the function test_tensor_command_fields_and_limits, which handles test tensor command fields and limits.

Line 56: `rows=8,` This is continuation line 3 of the 8-line logical statement that begins at source line 54. Its exact fragment is 'rows=8,'. The important operands are rows: one output-row position processed by the tensor tile. Read together, the complete operation is: This assigns 'tensor_command(Opcode.COMPUTE_DENSE_OUTER, rows=8, columns=16, issue_count=2048, activation_zero_point=128, weight_zero_point=129,).value' to 'command ' in host memory. Here command means the 128-bit instruction selecting an engine, shape, mode, and numeric parameters. The important operands are tensor_command: the 128-bit instruction selecting an engine, shape, mode, and numeric parameters; Opcode: the value named 'opcode' in this block; COMPUTE_DENSE_OUTER: the value named 'compute dense outer' in this block. Context: the function test_tensor_command_fields_and_limits, which handles test tensor command fields and limits.

Line 57: `columns=16,` This is continuation line 4 of the 8-line logical statement that begins at source line 54. Its exact fragment is 'columns=16,'. The important operands are columns: one output-feature position processed in parallel. Read together, the complete operation is: This assigns 'tensor_command(Opcode.COMPUTE_DENSE_OUTER, rows=8, columns=16, issue_count=2048, activation_zero_point=128, weight_zero_point=129,).value' to 'command ' in host memory. Here command means the 128-bit instruction selecting an engine, shape, mode, and numeric parameters. The important operands are tensor_command: the 128-bit instruction selecting an engine, shape, mode, and numeric parameters; Opcode: the value named 'opcode' in this block; COMPUTE_DENSE_OUTER: the value named 'compute dense outer' in this block. Context: the function test_tensor_command_fields_and_limits, which handles test tensor command fields and limits.

Line 58: `issue_count=2048,` This is continuation line 5 of the 8-line logical statement that begins at source line 54. Its exact fragment is 'issue_count=2048,'. The important operands are issue_count: an integer count retained for control or measurable telemetry. Read together, the complete operation is: This assigns 'tensor_command(Opcode.COMPUTE_DENSE_OUTER, rows=8, columns=16, issue_count=2048, activation_zero_point=128, weight_zero_point=1).value' to 'command ' in host memory. Here command means the 128-bit instruction selecting an engine, shape, mode, and numeric parameters. The important operands are tensor_command: the 128-bit instruction selecting an engine, shape, mode, and numeric parameters; Opcode: the value named 'opcode' in this block; COMPUTE_DENSE_OUTER: the value named 'compute dense outer' in this block. Context: the function test_tensor_command_fields_and_limits, which handles test tensor command fields and limits.

Line 59: `activation_zero_point=128,` This is continuation line 6 of the 8-line logical statement that begins at source line 54. Its exact fragment is 'activation_zero_point=128,'. The important operands are activation_zero_point:

an input feature value consumed by a neuron or multiply-accumulate operation. Read together, the complete operation is: This assigns ‘tensor_command(Opcode.COMPUTE_DENSE_OUTER, rows=8, columns=16, issue_count=2048, activation_zero_point=128, weight_zero_point=129,).value‘ to ‘command ‘ in host memory. Here command means the 128-bit instruction selecting an engine, shape, mode, and numeric parameters. The important operands are tensor_command: the 128-bit instruction selecting an engine, shape, mode, and numeric parameters; Opcode: the value named ’opcode’ in this block; COMPUTE_DENSE_OUTER: the value named ’compute dense outer’ in this block. Context: the function test_tensor_command_fields_and_limits, which handles test tensor command fields and limits.

Line 60: `weight_zero_point=129,` This is continuation line 7 of the 8-line logical statement that begins at source line 54. Its exact fragment is ‘weight_zero_point=129,‘. The important operands are weight_zero_point: a learned coefficient multiplied by an activation. Read together, the complete operation is: This assigns ‘tensor_command(Opcode.COMPUTE_DENSE_OUTER, rows=8, columns=16, issue_count=2048, activation_zero_point=128, weight_zero_point=1).value‘ to ‘command ‘ in host memory. Here command means the 128-bit instruction selecting an engine, shape, mode, and numeric parameters. The important operands are tensor_command: the 128-bit instruction selecting an engine, shape, mode, and numeric parameters; Opcode: the value named ’opcode’ in this block; COMPUTE_DENSE_OUTER: the value named ’compute dense outer’ in this block. Context: the function test_tensor_command_fields_and_limits, which handles test tensor command fields and limits.

Line 61: `).value` This is continuation line 8 of the 8-line logical statement that begins at source line 54. Its exact fragment is ‘).value‘. The important operands are value: the value named ’value’ in this block. Read together, the complete operation is: This assigns ‘tensor_command(Opcode.COMPUTE_DENSE_OUTER, rows=8, columns=16, issue_count=2048, activation_zero_point=128, weight_zero_point=129,).value‘ to ‘command ‘ in host memory. Here command means the 128-bit instruction selecting an engine, shape, mode, and numeric parameters. The important operands are tensor_command: the 128-bit instruction selecting an engine, shape, mode, and numeric parameters; Opcode: the value named ’opcode’ in this block; COMPUTE_DENSE_OUTER: the value named ’compute dense outer’ in this block. Context: the function test_tensor_command_fields_and_limits, which handles test tensor command fields and limits.

Line 62: `self.assertEqual(command & 0xF, Opcode.COMPUTE_DENSE_OUTER)` This calls ‘self.assertEqual‘ with ‘command & 0xF, Opcode.COMPUTE_DENSE_OUTER‘ inside the function test_tensor_command_fields_and_limits, which handles test tensor command fields and limits. The call advances the host-side job that checks neuraedge protocol behavior independently with Python assertions.

Line 63: `self.assertEqual((command >> 4) & 0xF, 8)` This calls ‘self.assertEqual‘ with ‘(command >> 4) & 0xF, 8‘ inside the function test_tensor_command_fields_and_limits, which handles test tensor command fields and limits. The call advances the host-side job that checks neuraedge protocol behavior independently with Python assertions.

Line 64: `self.assertEqual((command >> 8) & 0x3F, 16)` This calls ‘self.assertEqual‘ with ‘(command >> 8) & 0x3F, 16‘ inside the function test_tensor_command_fields_and_limits, which handles test tensor command fields and limits. The call advances the host-side job that checks neuraedge protocol behavior independently with Python assertions.

Line 65: `self.assertEqual((command >> 14) & 0xFFF, 2048)` This calls ‘self.assertEqual‘ with ‘(command >> 14) & 0xFFF, 2048‘ inside the function test_tensor_command_fields_and_limits, which handles test tensor command fields and limits. The call advances the host-side job that checks neuraedge protocol behavior independently with Python assertions.

Line 66: `self.assertEqual((command >> 26) & 0xFF, 128)` This calls ‘self.assertEqual‘ with ‘(command >> 26) & 0xFF, 128‘ inside the function test_tensor_command_fields_and_limits, which handles test tensor command fields and limits. The call advances the host-side job that checks neuraedge protocol behavior independently with Python assertions.

Line 67: `self.assertEqual((command >> 34) & 0xFF, 129)` This calls ‘self.assertEqual‘ with ‘(command >> 34) & 0xFF, 129‘ inside the function test_tensor_command_fields_and_limits, which handles test tensor command fields and limits. The call advances the host-side job that checks neuraedge protocol behavior independently with Python assertions.

Line 68: `with self.assertRaises(ValueError):` This opens a managed resource scope for ‘self.assertRaises(ValueError)‘ so files, tracing, or temporary state are finalized even if the function test_tensor_command_fields_and_limits, which handles test tensor command fields and limits raises an error.

Line 69: `tensor_command(Opcode.COMPUTE_DENSE_DOT8, rows=2, columns=16, issue_count=1)` This calls ‘tensor_command‘ with ‘Opcode.COMPUTE_DENSE_DOT8, rows=2, columns=16, issue_count=1‘ inside the function test_tensor_command_fields_and_limits, which handles test tensor command fields and limits. The call advances the host-side job that checks neuraedge protocol behavior independently with Python assertions.

Line 70: `with self.assertRaises(ValueError):` This opens a managed resource scope for ‘self.assertRaises(ValueError)‘ so files, tracing, or temporary state are finalized even if the function test_tensor_command_fields_and_limits, which handles test tensor command fields and limits raises an error.

Line 71: `tensor_command(Opcode.LOAD_WEIGHTS_DOT8, issue_count=257)` This calls ‘tensor_command‘ with ‘Opcode.LOAD_WEIGHTS_DOT8, issue_count=257‘ inside the function test_tensor_command_fields_and_limits, which handles test tensor command fields and limits. The call advances the host-side job that checks neuraedge protocol behavior independently with Python assertions.

Line 73: `def test_non_tensor_command_fields(self):` This starts function test_non_tensor_command_fields. Its indented body performs test non tensor command fields as part of the file that checks neuraedge protocol behavior independently with Python assertions; it runs only when called.

Line 74: `alpha = alpha_xnor_command(256, 127).value` This assigns ‘alpha_xnor_command(256, 127).value‘ to ‘alpha ‘ in host memory. Here alpha means the programmable weight assigned to matching zero spikes in alpha-XNOR attention. The important operands are alpha_xnor_command: the 128-bit instruction selecting an engine, shape, mode, and numeric parameters; value: the value named ’value’ in this block. Context: the function test_non_tensor_command_fields, which handles test non tensor command fields.

Line 75: `self.assertEqual((alpha >> 42) & 0x1FF, 256)` This calls ‘self.assertEqual‘ with ‘(alpha >> 42) & 0x1FF, 256‘ inside the function test_non_tensor_command_fields, which handles test non tensor command fields. The call advances the host-side job that checks neuraedge protocol behavior independently with Python assertions.

Line 76: `self.assertEqual((alpha >> 51) & 0x1FF, 127)` This calls ‘self.assertEqual‘ with ‘(alpha >> 51) & 0x1FF, 127‘ inside the function test_non_tensor_command_fields, which handles test non tensor command fields. The call advances the host-side job that checks neuraedge protocol behavior independently with Python assertions.

Line 77: `vector = vector_command(8, multiplier_q15=-3, right_shift=31,` This statement continues through source line 79; the explanation uses the complete expression rather than only the first visual fragment. This assigns ‘vector_command(8, multiplier_q15=-3, right_shift=31, output_zero_point=-8, threshold=-123, surrogate_window=456).value‘ to ‘vector ‘ in host memory. Here vector means the value named ’vector’ in this block. The important operands are vector_command: the 128-bit instruction selecting an engine, shape, mode, and numeric parameters; multiplier_q15: the value named ’multiplier q15’ in this block; right_shift: the value named ’right shift’ in this block. Context: the function test_non_tensor_command_fields, which handles test non tensor command fields.

Line 78: `output_zero_point=-8, threshold=-123,` This is continuation line 2 of the 3-line logical statement that begins at source line 77. Its exact fragment is ‘output_zero_point=-8, threshold=-123,‘. The important operands are output_zero_point: the integer code representing real numeric zero in affine quantization; threshold: the membrane level at which a neuron emits a spike. Read together, the complete operation is: This assigns ‘vector_command(8, multiplier_q15=-3, right_shift=31, output_zero_point=-8, threshold=-123, surrogate_window=456).value‘ to ‘vector ‘ in host memory. Here vector means the value named ’vector’ in this block. The important operands are vector_command: the 128-bit instruction selecting an engine, shape, mode, and numeric parameters; multiplier_q15: the value named ’multiplier q15’ in this block; right_shift: the value named ’right shift’ in this block. Context: the function test_non_tensor_command_fields, which handles test non tensor command fields.

Line 79: `surrogate_window=456).value` This is continuation line 3 of the 3-line logical statement that begins at source line 77. Its exact fragment is 'surrogate_window=456).value'. The important operands are surrogate_window: the value named 'surrogate window' in this block; value: the value named 'value' in this block. Read together, the complete operation is: This assigns 'vector_command(8, multiplier_q15=-3, right_shift=31, output_zero_point=-8, threshold=-123, surrogate_window=456).value' to 'vector ' in host memory. Here vector means the value named 'vector' in this block. The important operands are vector_command: the 128-bit instruction selecting an engine, shape, mode, and numeric parameters; multiplier_q15: the value named 'multiplier q15' in this block; right_shift: the value named 'right shift' in this block. Context: the function test_non_tensor_command_fields, which handles test non tensor command fields.

Line 80: `self.assertEqual((vector >> 4) & 0xF, 8)` This calls 'self.assertEqual' with '(vector >> 4) & 0xF, 8' inside the function test_non_tensor_command_fields, which handles test non tensor command fields. The call advances the host-side job that checks neuraedge protocol behavior independently with Python assertions.

Line 81: `self.assertEqual((vector >> 8) & 0xFFFF, 0xFFFD)` This calls 'self.assertEqual' with '(vector >> 8) & 0xFFFF, 0xFFFD' inside the function test_non_tensor_command_fields, which handles test non tensor command fields. The call advances the host-side job that checks neuraedge protocol behavior independently with Python assertions.

Line 82: `self.assertEqual((vector >> 24) & 0x1F, 31)` This calls 'self.assertEqual' with '(vector >> 24) & 0x1F, 31' inside the function test_non_tensor_command_fields, which handles test non tensor command fields. The call advances the host-side job that checks neuraedge protocol behavior independently with Python assertions.

Line 83: `self.assertEqual((vector >> 29) & 0xFFFF, 0xFFF8)` This calls 'self.assertEqual' with '(vector >> 29) & 0xFFFF, 0xFFF8' inside the function test_non_tensor_command_fields, which handles test non tensor command fields. The call advances the host-side job that checks neuraedge protocol behavior independently with Python assertions.

Line 84: `self.assertEqual((vector >> 45) & 0xFFFFFFFF, (-123) & 0xFFFFFFFF)` This calls 'self.assertEqual' with '(vector >> 45) & 0xFFFFFFFF, (-123) & 0xFFFFFFFF' inside the function test_non_tensor_command_fields, which handles test non tensor command fields. The call advances the host-side job that checks neuraedge protocol behavior independently with Python assertions.

Line 85: `self.assertEqual((vector >> 77) & 0xFFFFFFFF, 456)` This calls 'self.assertEqual' with '(vector >> 77) & 0xFFFFFFFF, 456' inside the function test_non_tensor_command_fields, which handles test non tensor command fields. The call advances the host-side job that checks neuraedge protocol behavior independently with Python assertions.

Line 86: `flexible = vector_command(9, multiplier_q15=24576, right_shift=-6).value` This assigns 'vector_command(9 multiplier_q15=24576, right_shift=-6).value' to 'flexible ' in host memory. Here flexible means the value named 'flexible' in this block. The important operands are vector_command: the 128-bit instruction selecting an engine, shape, mode, and numeric parameters; multiplier_q15: the value named 'multiplier q15' in this block; right_shift: the value named 'right shift' in this block. Context: the function test_non_tensor_command_fields, which handles test non tensor command fields.

Line 87: `self.assertEqual((flexible >> 4) & 0xF, 9)` This calls 'self.assertEqual' with '(flexible >> 4) & 0xF, 9' inside the function test_non_tensor_command_fields, which handles test non tensor command fields. The call advances the host-side job that checks neuraedge protocol behavior independently with Python assertions.

Line 88: `self.assertEqual((flexible >> 24) & 0x1F, (-6) & 0x1F)` This calls 'self.assertEqual' with '(flexible >> 24) & 0x1F, (-6) & 0x1F' inside the function test_non_tensor_command_fields, which handles test non tensor command fields. The call advances the host-side job that checks neuraedge protocol behavior independently with Python assertions.

Line 89: `self.assertEqual((layernorm_command(2048, 17).value >> 4) & 0xFFF, 2048)` This calls 'self.assertEqual' with '(layernorm_command(2048, 17).value >> 4) & 0xFFF, 2048' inside the function test_non_tensor_command_fields, which handles test non tensor command fields. The call advances the host-side job that checks neuraedge protocol behavior independently with Python assertions.

Line 90: `self.assertEqual((log_softmax_command(256, 15).value >> 4) & 0x1FF, 256)` This calls ‘self.assertEqual‘ with ‘(log_softmax_command(256, 15).value >> 4) & 0x1FF, 256‘ inside the function test_non_tensor_command_fields, which handles test non tensor command fields. The call advances the host-side job that checks neuraedge protocol behavior independently with Python assertions.

Line 91: `lif = lif_command(4, -2, -3, clear_state=True, trace_state=True).value` This assigns ‘lif_command(4, -2, -3, clear_state=True, trace_state=True).value‘ to ‘lif ‘ in host memory. Here lif means the value named ’lif’ in this block. The important operands are lif_command: the 128-bit instruction selecting an engine, shape, mode, and numeric parameters; clear_state: the finite-state-machine phase retained in flip-flops; trace_state: the finite-state-machine phase retained in flip-flops. Context: the function test_non_tensor_command_fields, which handles test non tensor command fields.

Line 92: `self.assertEqual((lif >> 57) & 1, 1)` This calls ‘self.assertEqual‘ with ‘(lif >> 57) & 1, 1‘ inside the function test_non_tensor_command_fields, which handles test non tensor command fields. The call advances the host-side job that checks neuraedge protocol behavior independently with Python assertions.

Line 93: `self.assertEqual((lif >> 58) & 1, 1)` This calls ‘self.assertEqual‘ with ‘(lif >> 58) & 1, 1‘ inside the function test_non_tensor_command_fields, which handles test non tensor command fields. The call advances the host-side job that checks neuraedge protocol behavior independently with Python assertions.

Line 94: `optimizer = sgd_command(` This statement continues through source line 95; the explanation uses the complete expression rather than only the first visual fragment. This assigns ‘sgd_command(131071, 65536, 32768, update_right_shift=29).value‘ to ‘optimizer ‘ in host memory. Here optimizer means the value named ’optimizer’ in this block. The important operands are sgd_command: the 128-bit instruction selecting an engine, shape, mode, and numeric parameters; update_right_shift: the value named ’update right shift’ in this block; value: the value named ’value’ in this block. Context: the function test_non_tensor_command_fields, which handles test non tensor command fields.

Line 95: `131071, 65536, 32768, update_right_shift=29).value` This is continuation line 2 of the 2-line logical statement that begins at source line 94. Its exact fragment is ‘131071, 65536, 32768, update_right_shift=29).value‘. The important operands are update_right_shift: the value named ’update right shift’ in this block; value: the value named ’value’ in this block. Read together, the complete operation is: This assigns ‘sgd_command(131071, 65536, 32768, update_right_shift=29).value‘ to ‘optimizer ‘ in host memory. Here optimizer means the value named ’optimizer’ in this block. The important operands are sgd_command: the 128-bit instruction selecting an engine, shape, mode, and numeric parameters; update_right_shift: the value named ’update right shift’ in this block; value: the value named ’value’ in this block. Context: the function test_non_tensor_command_fields, which handles test non tensor command fields.

Line 96: `self.assertEqual((optimizer >> 4) & 0x3FFFF, 131071)` This calls ‘self.assertEqual‘ with ‘(optimizer >> 4) & 0x3FFFF, 131071‘ inside the function test_non_tensor_command_fields, which handles test non tensor command fields. The call advances the host-side job that checks neuraedge protocol behavior independently with Python assertions.

Line 97: `self.assertEqual((optimizer >> 22) & 0x1FFFF, 65536)` This calls ‘self.assertEqual‘ with ‘(optimizer >> 22) & 0x1FFFF, 65536‘ inside the function test_non_tensor_command_fields, which handles test non tensor command fields. The call advances the host-side job that checks neuraedge protocol behavior independently with Python assertions.

Line 98: `self.assertEqual((optimizer >> 39) & 0x1FFFF, 32768)` This calls ‘self.assertEqual‘ with ‘(optimizer >> 39) & 0x1FFFF, 32768‘ inside the function test_non_tensor_command_fields, which handles test non tensor command fields. The call advances the host-side job that checks neuraedge protocol behavior independently with Python assertions.

Line 99: `self.assertEqual((optimizer >> 56) & 0x1F, 29)` This calls ‘self.assertEqual‘ with ‘(optimizer >> 56) & 0x1F, 29‘ inside the function test_non_tensor_command_fields, which handles test non tensor command fields. The call advances the host-side job that checks neuraedge protocol behavior independently with Python assertions.

Line 100: `self.assertEqual(lut_command(LutSuboperation.EVALUATE, 8).opcode, Opcode.ACTIVATION_LUT)` This calls ‘self.assertEqual‘ with ‘lut_command(LutSuboperation.EVALUATE, 8).opcode, Opcode.ACTIVATION_LUT‘ inside the function test_non_tensor_command_fields, which handles test non tensor command fields. The call advances the host-side job that checks neuraedge protocol behavior independently with Python assertions.

Line 102: `backward = linear_backward_command(` This statement continues through source line 111; the explanation uses the complete expression rather than only the first visual fragment. This assigns ‘linear_backward_command(8, 7, 6, input_gradient_shift=31, weight_gradient_shift=17, mode=LinearGradientMode.WEIGHT, accumulate=True, suppress_output=True,).value‘ to ‘backward ‘ in host memory. Here backward means the value named ’backward’ in this block. The important operands are linear_backward_command: the 128-bit instruction selecting an engine, shape, mode, and numeric parameters; input_gradient_shift: the signed loss derivative used to update a learned parameter; weight_gradient_shift: a learned coefficient multiplied by an activation. Context: the function test_non_tensor_command_fields, which handles test non tensor command fields.

Line 103: `8,` This is continuation line 2 of the 10-line logical statement that begins at source line 102. Its exact fragment is ‘8,‘. The expression is a literal or structural operator and has no hidden software state. Read together, the complete operation is: This assigns ‘linear_backward_command(8, 7, 6, input_gradient_shift=31, weight_gradient_shift=17, mode=LinearGradientMode.WEIGHT, accumulate=True, suppress_output=True,).value‘ to ‘backward ‘ in host memory. Here backward means the value named ’backward’ in this block. The important operands are linear_backward_command: the 128-bit instruction selecting an engine, shape, mode, and numeric parameters; input_gradient_shift: the signed loss derivative used to update a learned parameter; weight_gradient_shift: a learned coefficient multiplied by an activation. Context: the function test_non_tensor_command_fields, which handles test non tensor command fields.

Line 104: `7,` This is continuation line 3 of the 10-line logical statement that begins at source line 102. Its exact fragment is ‘7,‘. The expression is a literal or structural operator and has no hidden software state. Read together, the complete operation is: This assigns ‘linear_backward_command(8, 7, 6, input_gradient_shift=31, weight_gradient_shift=17, mode=LinearGradientMode.WEIGHT, accumulate=True, suppress_output=True,).value‘ to ‘backward ‘ in host memory. Here backward means the value named ’backward’ in this block. The important operands are linear_backward_command: the 128-bit instruction selecting an engine, shape, mode, and numeric parameters; input_gradient_shift: the signed loss derivative used to update a learned parameter; weight_gradient_shift: a learned coefficient multiplied by an activation. Context: the function test_non_tensor_command_fields, which handles test non tensor command fields.

Line 105: `6,` This is continuation line 4 of the 10-line logical statement that begins at source line 102. Its exact fragment is ‘6,‘. The expression is a literal or structural operator and has no hidden software state. Read together, the complete operation is: This assigns ‘linear_backward_command(8, 7, 6, input_gradient_shift=31, weight_gradient_shift=17, mode=LinearGradientMode.WEIGHT, accumulate=True, suppress_output=True,).value‘ to ‘backward ‘ in host memory. Here backward means the value named ’backward’ in this block. The important operands are linear_backward_command: the 128-bit instruction selecting an engine, shape, mode, and numeric parameters; input_gradient_shift: the signed loss derivative used to update a learned parameter; weight_gradient_shift: a learned coefficient multiplied by an activation. Context: the function test_non_tensor_command_fields, which handles test non tensor command fields.

Line 106: `input_gradient_shift=31,` This is continuation line 5 of the 10-line logical statement that begins at source line 102. Its exact fragment is ‘input_gradient_shift=31,‘. The important operands are input_gradient_shift: the signed loss derivative used to update a learned parameter. Read together, the complete operation is: This assigns ‘linear_backward_command(8, 7, 6, input_gradient_shift=31, weight_gradient_shift=17, mode=LinearGradientMode.WEIGHT, accumulate=True, suppress_output=True,).value‘ to ‘backward ‘ in host memory. Here backward means the value named ’backward’ in this block. The important operands are linear_backward_command: the 128-bit instruction selecting an engine, shape, mode, and numeric parameters; input_gradient_shift: the signed loss derivative used to update a learned parameter; weight_gradient_shift: a learned coefficient multiplied by an activation. Context: the function test_non_tensor_command_fields, which handles test non tensor command fields.

Line 107: `weight_gradient_shift=17,` This is continuation line 6 of the 10-line logical statement that begins at source line 102. Its exact fragment is 'weight_gradient_shift=17,'. The important operands are weight_gradient_shift: a learned coefficient multiplied by an activation. Read together, the complete operation is: This assigns 'linear_backward_command(8, 7, 6, input_gradient_shift=31, weight_gradient_shift=17, mode=LinearGradientMode.WEIGHT, accumulate=True, suppress_output=True,).value' to 'backward ' in host memory. Here backward means the value named 'backward' in this block. The important operands are linear_backward_command: the 128-bit instruction selecting an engine, shape, mode, and numeric parameters; input_gradient_shift: the signed loss derivative used to update a learned parameter; weight_gradient_shift: a learned coefficient multiplied by an activation. Context: the function test_non_tensor_command_fields, which handles test non tensor command fields.

Line 108: `mode=LinearGradientMode.WEIGHT,` This is continuation line 7 of the 10-line logical statement that begins at source line 102. Its exact fragment is 'mode=LinearGradientMode.WEIGHT,'. The important operands are mode: the value named 'mode' in this block; LinearGradientMode: the signed loss derivative used to update a learned parameter; WEIGHT: a learned coefficient multiplied by an activation. Read together, the complete operation is: This assigns 'linear_backward_command(8, 7, 6, input_gradient_shift=31, weight_gradient_shift=17, mode=LinearGradientMode.WEIGHT, accumulate=True, suppress_output=True,).value' to 'backward ' in host memory. Here backward means the value named 'backward' in this block. The important operands are linear_backward_command: the 128-bit instruction selecting an engine, shape, mode, and numeric parameters; input_gradient_shift: the signed loss derivative used to update a learned parameter; weight_gradient_shift: a learned coefficient multiplied by an activation. Context: the function test_non_tensor_command_fields, which handles test non tensor command fields.

Line 109: `accumulate=True,` This is continuation line 8 of the 10-line logical statement that begins at source line 102. Its exact fragment is 'accumulate=True,'. The important operands are accumulate: the value named 'accumulate' in this block. Read together, the complete operation is: This assigns 'linear_backward_command(8, 7, 6, input_gradient_shift=31, weight_gradient_shift=17, mode=LinearGradientMode.WEIGHT, accumulate=True, suppress_output=True,).value' to 'backward ' in host memory. Here backward means the value named 'backward' in this block. The important operands are linear_backward_command: the 128-bit instruction selecting an engine, shape, mode, and numeric parameters; input_gradient_shift: the signed loss derivative used to update a learned parameter; weight_gradient_shift: a learned coefficient multiplied by an activation. Context: the function test_non_tensor_command_fields, which handles test non tensor command fields.

Line 110: `suppress_output=True,` This is continuation line 9 of the 10-line logical statement that begins at source line 102. Its exact fragment is 'suppress_output=True,'. The important operands are suppress_output: the value named 'suppress output' in this block. Read together, the complete operation is: This assigns 'linear_backward_command(8, 7, 6, input_gradient_shift=31, weight_gradient_shift=17, mode=LinearGradientMode.WEIGHT, accumulate=True, suppress_output=True,).value' to 'backward ' in host memory. Here backward means the value named 'backward' in this block. The important operands are linear_backward_command: the 128-bit instruction selecting an engine, shape, mode, and numeric parameters; input_gradient_shift: the signed loss derivative used to update a learned parameter; weight_gradient_shift: a learned coefficient multiplied by an activation. Context: the function test_non_tensor_command_fields, which handles test non tensor command fields.

Line 111: `).value` This is continuation line 10 of the 10-line logical statement that begins at source line 102. Its exact fragment is ').value'. The important operands are value: the value named 'value' in this block. Read together, the complete operation is: This assigns 'linear_backward_command(8, 7, 6, input_gradient_shift=31, weight_gradient_shift=17, mode=LinearGradientMode.WEIGHT, accumulate=True, suppress_output=True,).value' to 'backward ' in host memory. Here backward means the value named 'backward' in this block. The important operands are linear_backward_command: the 128-bit instruction selecting an engine, shape, mode, and numeric parameters; input_gradient_shift: the signed loss derivative used to update a learned parameter; weight_gradient_shift: a learned coefficient multiplied by an activation. Context: the function test_non_tensor_command_fields, which handles test non tensor command fields.

Line 112: `self.assertEqual(backward & 0xF, Opcode.TRAIN_LINEAR_BACKWARD)` This calls 'self.assertEqual' with 'backward & 0xF, Opcode.TRAIN_LINEAR_BACKWARD' inside the function test_non_tensor_command_fields, which handles test non tensor command fields. The call advances the host-side job that checks neuraedge protocol behavior independently with Python assertions.

Line 113: `self.assertEqual((backward >> 4) & 0xF, 8)` This calls ‘self.assertEqual‘ with ‘(backward >> 4) & 0xF, 8‘ inside the function test_non_tensor_command_fields, which handles test non tensor command fields. The call advances the host-side job that checks neuraedge protocol behavior independently with Python assertions.

Line 114: `self.assertEqual((backward >> 8) & 0xF, 7)` This calls ‘self.assertEqual‘ with ‘(backward >> 8) & 0xF, 7‘ inside the function test_non_tensor_command_fields, which handles test non tensor command fields. The call advances the host-side job that checks neuraedge protocol behavior independently with Python assertions.

Line 115: `self.assertEqual((backward >> 12) & 0xF, 6)` This calls ‘self.assertEqual‘ with ‘(backward >> 12) & 0xF, 6‘ inside the function test_non_tensor_command_fields, which handles test non tensor command fields. The call advances the host-side job that checks neuraedge protocol behavior independently with Python assertions.

Line 116: `self.assertEqual((backward >> 16) & 0x1F, 31)` This calls ‘self.assertEqual‘ with ‘(backward >> 16) & 0x1F, 31‘ inside the function test_non_tensor_command_fields, which handles test non tensor command fields. The call advances the host-side job that checks neuraedge protocol behavior independently with Python assertions.

Line 117: `self.assertEqual((backward >> 21) & 0x1F, 17)` This calls ‘self.assertEqual‘ with ‘(backward >> 21) & 0x1F, 17‘ inside the function test_non_tensor_command_fields, which handles test non tensor command fields. The call advances the host-side job that checks neuraedge protocol behavior independently with Python assertions.

Line 118: `self.assertEqual((backward >> 26) & 0x3, LinearGradientMode.WEIGHT)` This calls ‘self.assertEqual‘ with ‘(backward >> 26) & 0x3, LinearGradientMode.WEIGHT‘ inside the function test_non_tensor_command_fields, which handles test non tensor command fields. The call advances the host-side job that checks neuraedge protocol behavior independently with Python assertions.

Line 119: `self.assertEqual((backward >> 28) & 1, 1)` This calls ‘self.assertEqual‘ with ‘(backward >> 28) & 1, 1‘ inside the function test_non_tensor_command_fields, which handles test non tensor command fields. The call advances the host-side job that checks neuraedge protocol behavior independently with Python assertions.

Line 120: `self.assertEqual((backward >> 29) & 1, 1)` This calls ‘self.assertEqual‘ with ‘(backward >> 29) & 1, 1‘ inside the function test_non_tensor_command_fields, which handles test non tensor command fields. The call advances the host-side job that checks neuraedge protocol behavior independently with Python assertions.

Line 121: `with self.assertRaises(ValueError):` This opens a managed resource scope for ‘self.assertRaises(ValueError)‘ so files, tracing, or temporary state are finalized even if the function test_non_tensor_command_fields, which handles test non tensor command fields raises an error.

Line 122: `linear_backward_command(0, 1, 1)` This calls ‘linear_backward_command‘ with ‘0, 1, 1‘ inside the function test_non_tensor_command_fields, which handles test non tensor command fields. The call advances the host-side job that checks neuraedge protocol behavior independently with Python assertions.

Line 123: `with self.assertRaises(ValueError):` This opens a managed resource scope for ‘self.assertRaises(ValueError)‘ so files, tracing, or temporary state are finalized even if the function test_non_tensor_command_fields, which handles test non tensor command fields raises an error.

Line 124: `linear_backward_command(1, 9, 1)` This calls ‘linear_backward_command‘ with ‘1, 9, 1‘ inside the function test_non_tensor_command_fields, which handles test non tensor command fields. The call advances the host-side job that checks neuraedge protocol behavior independently with Python assertions.

Line 126: `def test_tensor_stream_layouts(self):` This starts function test_tensor_stream_layouts. Its indented body performs test tensor stream layouts as part of the file that checks neuraedge protocol behavior independently with Python assertions; it runs only when called.

Line 127: `activations = pack_activation_beats([[0, 1, 2, 3, 4, 5, 6, 255]])` This assigns 'pack_activation_beats([[0, 1, 2, 3, 4, 5, 6, 255]])' to 'activations ' in host memory. Here activations means an input feature value consumed by a neuron or multiply-accumulate operation. The important operands are pack_activation_beats: an input feature value consumed by a neuron or multiply-accumulate operation. Context: the function test_tensor_stream_layouts, which handles test tensor stream layouts.

Line 128: `self.assertEqual(activations[0].data, 0xFF06050403020100)` This calls 'self.assertEqual' with 'activations[0].data, 0xFF06050403020100' inside the function test_tensor_stream_layouts, which handles test tensor stream layouts. The call advances the host-side job that checks neuraedge protocol behavior independently with Python assertions.

Line 129: `self.assertTrue(activations[0].last)` This calls 'self.assertTrue' with 'activations[0].last' inside the function test_tensor_stream_layouts, which handles test tensor stream layouts. The call advances the host-side job that checks neuraedge protocol behavior independently with Python assertions.

Line 130: `outer = pack_outer_weight_beats([list(range(16))])` This assigns 'pack_outer_weight_beats([list(range(16))])' to 'outer ' in host memory. Here outer means the value named 'outer' in this block. The important operands are pack_outer_weight_beats: a learned coefficient multiplied by an activation; list: the value named 'list' in this block; range: the value named 'range' in this block. Context: the function test_tensor_stream_layouts, which handles test tensor stream layouts.

Line 131: `self.assertEqual([beat.data for beat in outer], [0x0706050403020100, 0x0F0E0D0C0B0A0908])` This calls 'self.assertEqual' with '[beat.data for beat in outer], [0x0706050403020100, 0x0F0E0D0C0B0A0908]' inside the function test_tensor_stream_layouts, which handles test tensor stream layouts. The call advances the host-side job that checks neuraedge protocol behavior independently with Python assertions.

Line 132: `self.assertEqual([beat.last for beat in outer], [False, True])` This calls 'self.assertEqual' with '[beat.last for beat in outer], [False, True]' inside the function test_tensor_stream_layouts, which handles test tensor stream layouts. The call advances the host-side job that checks neuraedge protocol behavior independently with Python assertions.

Line 133: `matrix = [[16 * row + column for column in range(16)] for row in range(8)]` This assigns '[[16 * row + column for column in range(16)] for row in range(8)]' to 'matrix ' in host memory. Here matrix means the value named 'matrix' in this block. The important operands are row: one output-row position processed by the tensor tile; column: one output-feature position processed in parallel; for: the value named 'for' in this block. Context: the function test_tensor_stream_layouts, which handles test tensor stream layouts.

Line 134: `dot8 = pack_dot8_weight_beats([matrix])` This assigns 'pack_dot8_weight_beats([matrix])' to 'dot8 ' in host memory. Here dot8 means the value named 'dot8' in this block. The important operands are pack_dot8_weight_beats: a learned coefficient multiplied by an activation; matrix: the value named 'matrix' in this block. Context: the function test_tensor_stream_layouts, which handles test tensor stream layouts.

Line 135: `self.assertEqual(len(dot8), 16)` This calls 'self.assertEqual' with 'len(dot8), 16' inside the function test_tensor_stream_layouts, which handles test tensor stream layouts. The call advances the host-side job that checks neuraedge protocol behavior independently with Python assertions.

Line 136: `self.assertEqual(dot8[0].data, 0x0706050403020100)` This calls 'self.assertEqual' with 'dot8[0].data, 0x0706050403020100' inside the function test_tensor_stream_layouts, which handles test tensor stream layouts. The call advances the host-side job that checks neuraedge protocol behavior independently with Python assertions.

Line 137: `self.assertEqual(dot8[1].data, 0x0F0E0D0C0B0A0908)` This calls 'self.assertEqual' with 'dot8[1].data, 0x0F0E0D0C0B0A0908' inside the function test_tensor_stream_layouts, which handles test tensor stream layouts. The call advances the host-side job that checks neuraedge protocol behavior independently with Python assertions.

Line 138: `self.assertEqual(dot8[2].data, 0x1716151413121110)` This calls ‘self.assertEqual‘ with ‘dot8[2].data, 0x1716151413121110‘ inside the function test_tensor_stream_layouts, which handles test tensor stream layouts. The call advances the host-side job that checks neuraedge protocol behavior independently with Python assertions.

Line 139: `self.assertTrue(dot8[-1].last)` This calls ‘self.assertTrue‘ with ‘dot8[-1].last‘ inside the function test_tensor_strea which handles test tensor stream layouts. The call advances the host-side job that checks neuraedge protocol behavior independently with Python assertions.

Line 141: `def test_descriptor_program_layout(self):` This starts function test_descriptor_program_layout. Its indented body performs test descriptor program layout as part of the file that checks neuraedge protocol behavior independently with Python assertions; it runs only when called.

Line 142: `records = (` This statement continues through source line 149; the explanation uses the complete expression rather than only the first visual fragment. This assigns ‘(ProgramRecord(clear_status_command(), (StreamBeat(0xAA, False), StreamBeat(0xBB, True)), 0,), ProgramRecord(clear_status_command(), (), 3),)‘ to ‘records ‘ in host memory. Here records means the number of descriptor records accepted since program start. The important operands are ProgramRecord: the value named ’program record’ in this block; clear_status_command: the 128-bit instruction selecting an engine, shape, mode, and numeric parameters; StreamBeat: the value named ’stream beat’ in this block. Context: the function test_descriptor_program_layout, which handles test descriptor program layout.

Line 143: `ProgramRecord(` This is continuation line 2 of the 8-line logical statement that begins at source line 142. Its exact fragment is ‘ProgramRecord(‘. The important operands are ProgramRecord: the value named ’program record’ in this block. Read together, the complete operation is: This assigns ‘(ProgramRecord(clear_status_command(), (StreamBeat(0xAA, False), StreamBeat(0xBB, True)), 0,), ProgramRecord(clear_status_command(), (), 3),)‘ to ‘records ‘ in host memory. Here records means the number of descriptor records accepted since program start. The important operands are ProgramRecord: the value named ’program record’ in this block; clear_status_command: the 128-bit instruction selecting an engine, shape, mode, and numeric parameters; StreamBeat: the value named ’stream beat’ in this block. Context: the function test_descriptor_program_layout, which handles test descriptor program layout.

Line 144: `clear_status_command(),` This is continuation line 3 of the 8-line logical statement that begins at source line 142. Its exact fragment is ‘clear_status_command(),‘. The important operands are clear_status_command: the 128-bit instruction selecting an engine, shape, mode, and numeric parameters. Read together, the complete operation is: This assigns ‘(ProgramRecord(clear_status_command(), (StreamBeat(0xAA, False), StreamBeat(0xBB, True)), 0,), ProgramRecord(clear_status_command(), (), 3),)‘ to ‘records ‘ in host memory. Here records means the number of descriptor records accepted since program start. The important operands are ProgramRecord: the value named ’program record’ in this block; clear_status_command: the 128-bit instruction selecting an engine, shape, mode, and numeric parameters; StreamBeat: the value named ’stream beat’ in this block. Context: the function test_descriptor_program_layout, which handles test descriptor program layout.

Line 145: `(StreamBeat(0xAA, False), StreamBeat(0xBB, True)),` This is continuation line 4 of the 8-line logical statement that begins at source line 142. Its exact fragment is ‘(StreamBeat(0xAA, False), StreamBeat(0xBB, True)),‘. The important operands are StreamBeat: the value named ’stream beat’ in this block. Read together, the complete operation is: This assigns ‘(ProgramRecord(clear_status_command(), (StreamBeat(0xAA, False), StreamBeat(0xBB, True)), 0,), ProgramRecord(clear_status_command(), (), 3),)‘ to ‘records ‘ in host memory. Here records means the number of descriptor records accepted since program start. The important operands are ProgramRecord: the value named ’program record’ in this block; clear_status_command: the 128-bit instruction selecting an engine, shape, mode, and numeric parameters; StreamBeat: the value named ’stream beat’ in this block. Context: the function test_descriptor_program_layout, which handles test descriptor program layout.

Line 146: `0,` This is continuation line 5 of the 8-line logical statement that begins at source line 142. Its exact fragment is ‘0,‘. The expression is a literal or structural operator and has no hidden software state. Read together, the complete operation is: This assigns ‘(ProgramRecord(clear_status_command(), (StreamBeat(0xAA, False), StreamBeat(0xBB, True)), 0,), ProgramRecord(clear_status_command(), (), 3),)‘ to ‘records ‘ in host memory. Here records means the number of descriptor records accepted since program start. The important operands are ProgramRecord: the value named ’program record’ in this block; clear_status_command: the 128-bit instruction selecting an engine, shape,

mode, and numeric parameters; StreamBeat: the value named 'stream beat' in this block. Context: the function test_descriptor_program_layout, which handles test descriptor program layout.

Line 147: `),` This is continuation line 6 of the 8-line logical statement that begins at source line 142. Its exact fragment is '),'. The expression is a literal or structural operator and has no hidden software state. Read together, the complete operation is: This assigns '(ProgramRecord(clear_status_command(), (StreamBeat(0xAA, False), StreamBeat(0xBB, True)), 0,), ProgramRecord(clear_status_command(), (), 3),)' to 'records ' in host memory. Here records means the number of descriptor records accepted since program start. The important operands are ProgramRecord: the value named 'program record' in this block; clear_status_command: the 128-bit instruction selecting an engine, shape, mode, and numeric parameters; StreamBeat: the value named 'stream beat' in this block. Context: the function test_descriptor_program_layout, which handles test descriptor program layout.

Line 148: `ProgramRecord(clear_status_command(), (), 3),` This is continuation line 7 of the 8-line logical statement that begins at source line 142. Its exact fragment is 'ProgramRecord(clear_status_command(), (), 3),'. The important operands are ProgramRecord: the value named 'program record' in this block; clear_status_command: the 128-bit instruction selecting an engine, shape, mode, and numeric parameters. Read together, the complete operation is: This assigns '(ProgramRecord(clear_status_command(), (StreamBeat(0xAA, False), StreamBeat(0xBB, True)), 0,), ProgramRecord(clear_status_command(), (), 3),)' to 'records ' in host memory. Here records means the number of descriptor records accepted since program start. The important operands are ProgramRecord: the value named 'program record' in this block; clear_status_command: the 128-bit instruction selecting an engine, shape, mode, and numeric parameters; StreamBeat: the value named 'stream beat' in this block. Context: the function test_descriptor_program_layout, which handles test descriptor program layout.

Line 149: `)` This is continuation line 8 of the 8-line logical statement that begins at source line 142. Its exact fragment is ')'. The expression is a literal or structural operator and has no hidden software state. Read together, the complete operation is: This assigns '(ProgramRecord(clear_status_command(), (StreamBeat(0xAA, False), StreamBeat(0xBB, True)), 0,), ProgramRecord(clear_status_command(), (), 3),)' to 'records ' in host memory. Here records means the number of descriptor records accepted since program start. The important operands are ProgramRecord: the value named 'program record' in this block; clear_status_command: the 128-bit instruction selecting an engine, shape, mode, and numeric parameters; StreamBeat: the value named 'stream beat' in this block. Context: the function test_descriptor_program_layout, which handles test descriptor program layout.

Line 150: `beats, outputs = pack_descriptor_program(records)` This assigns 'pack_descriptor_program(records)' to 'beats, outputs ' in host memory. Here beats means the value named 'beats' in this block. The important operands are pack_descriptor_program: a DMA record header plus one command and its declared payload; records: the number of descriptor records accepted since program start. Context: the function test_descriptor_program_layout, which handles test descriptor program layout.

Line 151: `self.assertEqual(outputs, 3)` This calls 'self.assertEqual' with 'outputs, 3' inside the function test_descriptor_prog which handles test descriptor program layout. The call advances the host-side job that checks neuraedge protocol behavior independently with Python assertions.

Line 152: `self.assertEqual(len(beats), 8)` This calls 'self.assertEqual' with 'len(beats), 8' inside the function test_descriptor_program_layout, which handles test descriptor program layout. The call advances the host-side job that checks neuraedge protocol behavior independently with Python assertions.

Line 153: `self.assertEqual(beats[0].data, 2)` This calls 'self.assertEqual' with 'beats[0].data, 2' inside the function test_descriptor_program_layout, which handles test descriptor program layout. The call advances the host-side job that checks neuraedge protocol behavior independently with Python assertions.

Line 154: `self.assertEqual(beats[5].data, (1 << 63) | (3 << 32))` This calls 'self.assertEqual' with 'beats[5].data, (1 << 63) | (3 << 32)' inside the function test_descriptor_program_layout, which handles test descriptor program layout. The call advances the host-side job that checks neuraedge protocol behavior independently with Python assertions.

Line 155: `self.assertEqual([beat.last for beat in beats], [False] * 7 + [True])` This calls ‘self.assertEqual‘ with ‘[beat.last for beat in beats], [False] * 7 + [True]‘ inside the function test_descriptor_program_layout, which handles test descriptor program layout. The call advances the host-side job that checks neuraedge protocol behavior independently with Python assertions.

Line 157: `def test_operator_stream_layouts(self):` This starts function test_operator_stream_layouts. Its indented body performs test operator stream layouts as part of the file that checks neuraedge protocol behavior independently with Python assertions; it runs only when called.

Line 158: `query = [index & 1 for index in range(256)]` This assigns ‘[index & 1 for index in range(256)]‘ to ‘query ‘ in host memory. Here query means the value named ’query’ in this block. The important operands are index: an integer selecting one tensor element, lane, bank, or state entry; for: the value named ’for’ in this block; in: the value named ’in’ in this block. Context: the function test_operator_stream_layouts, which handles test operator stream layouts.

Line 159: `key = [1 - bit for bit in query]` This assigns ‘[1 - bit for bit in query]‘ to ‘key ‘ in host memory. Here key means the value named ’key’ in this block. The important operands are bit: the value named ’bit’ in this block; for: the value named ’for’ in this block; in: the value named ’in’ in this block. Context: the function test_operator_stream_layouts, which handles test operator stream layouts.

Line 160: `alpha = pack_alpha_beats(query, key)` This assigns ‘pack_alpha_beats(query, key)‘ to ‘alpha ‘ in host memory. Here alpha means the programmable weight assigned to matching zero spikes in alpha-XNOR attention. The important operands are pack_alpha_beats: the programmable weight assigned to matching zero spikes in alpha-XNOR attention; query: the value named ’query’ in this block; key: the value named ’key’ in this block. Context: the function test_operator_stream_layouts, which handles test operator stream layouts.

Line 161: `self.assertEqual(len(alpha), 8)` This calls ‘self.assertEqual‘ with ‘len(alpha), 8‘ inside the function test_operator_stream_layouts, which handles test operator stream layouts. The call advances the host-side job that checks neuraedge protocol behavior independently with Python assertions.

Line 162: `self.assertEqual(alpha[0].data, 0xAAAAAAAAAAAAAAAA)` This calls ‘self.assertEqual‘ with ‘alpha[0].data, 0xAAAAAAAAAAAAAAAA‘ inside the function test_operator_stream_layouts, which handles test operator stream layouts. The call advances the host-side job that checks neuraedge protocol behavior independently with Python assertions.

Line 163: `self.assertEqual(alpha[4].data, 0x5555555555555555)` This calls ‘self.assertEqual‘ with ‘alpha[4].data, 0x5555555555555555‘ inside the function test_operator_stream_layouts, which handles test operator stream layouts. The call advances the host-side job that checks neuraedge protocol behavior independently with Python assertions.

Line 164: `self.assertTrue(alpha[-1].last)` This calls ‘self.assertTrue‘ with ‘alpha[-1].last‘ inside the function test_operator_stream_layouts, which handles test operator stream layouts. The call advances the host-side job that checks neuraedge protocol behavior independently with Python assertions.

Line 166: `vector = pack_vector_beats(range(-4, 4), range(10, 18), clamp_minimum=-7, clamp_maximum=8)` This assigns ‘pack_vector_beats(range(-4, 4), range(10, 18), clamp_minimum=-7, clamp_maximum=8)‘ to ‘vector ‘ in host memory. Here vector means the value named ’vector’ in this block. The important operands are pack_vector_beats: the value named ’pack vector beats’ in this block; range: the value named ’range’ in this block; clamp_minimum: the value named ’clamp minimum’ in this block. Context: the function test_operator_stream_layouts, which handles test operator stream layouts.

Line 167: `self.assertEqual(len(vector), 9)` This calls ‘self.assertEqual‘ with ‘len(vector), 9‘ inside the function test_operator_stream_layouts, which handles test operator stream layouts. The call advances the host-side job that checks neuraedge protocol behavior independently with Python assertions.

Line 168: `self.assertEqual(vector[0].data, 0x00000008FFFFFFF9)` This calls ‘self.assertEqual‘ with ‘vector[0].data, 0x00000008FFFFFFF9‘ inside the function test_operator_stream_layouts, which handles test operator stream layouts. The call advances the host-side job that checks neuraedge protocol behavior independently with Python assertions.

Line 169: `self.assertEqual(vector[1].data, 0xFFFFFFFDFFFFFFFC)` This calls ‘self.assertEqual‘ with ‘vector[1].data, 0xFFFFFFFDFFFFFFFC‘ inside the function test_operator_stream_layouts, which handles test operator stream layouts. The call advances the host-side job that checks neuraedge protocol behavior independently with Python assertions.

Line 170: `self.assertTrue(vector[-1].last)` This calls ‘self.assertTrue‘ with ‘vector[-1].last‘ inside the function test_operator_stream_layouts, which handles test operator stream layouts. The call advances the host-side job that checks neuraedge protocol behavior independently with Python assertions.

Line 172: `layernorm = pack_layernorm_beats([-1], [-2], [-3])` This assigns ‘pack_layernorm_beats([-1], [-2], [-3])‘ to ‘layernorm ‘ in host memory. Here layernorm means the value named ’layernorm’ in this block. The important operands are pack_layernorm_beats: the value named ’pack layernorm beats’ in this block. Context: the function test_operator_stream_layouts, which handles test operator stream layouts.

Line 173: `self.assertEqual(layernorm[0].data, 0xFFFDFFFFFEFFFFFF)` This calls ‘self.assertEqual‘ with ‘layernorm[0].data, 0xFFFDFFFFFEFFFFFF‘ inside the function test_operator_stream_layouts, which handles test operator stream layouts. The call advances the host-side job that checks neuraedge protocol behavior independently with Python assertions.

Line 174: `self.assertEqual(layernorm[1].data, 0xFF)` This calls ‘self.assertEqual‘ with ‘layernorm[1].data, 0xFF‘ inside the function test_operator_stream_layouts, which handles test operator stream layouts. The call advances the host-side job that checks neuraedge protocol behavior independently with Python assertions.

Line 175: `self.assertEqual([beat.last for beat in layernorm], [False, True])` This calls ‘self.assertEqual‘ with ‘[beat.last for beat in layernorm], [False, True]‘ inside the function test_operator_stream_layouts, which handles test operator stream layouts. The call advances the host-side job that checks neuraedge protocol behavior independently with Python assertions.

Line 176: `self.assertEqual(pack_softmax_beats([-1, 2])[0].data, 0xFFFFFF)` This calls ‘self.assertEqual‘ with ‘pack_softmax_beats([-1, 2])[0].data, 0xFFFFFF‘ inside the function test_operator_stream_layouts, which handles test operator stream layouts. The call advances the host-side job that checks neuraedge protocol behavior independently with Python assertions.

Line 178: `lif = pack_lif_beats(range(-16, 16))` This assigns ‘pack_lif_beats(range(-16, 16))‘ to ‘lif ‘ in host memory. Here lif means the value named ’lif’ in this block. The important operands are pack_lif_beats: the value named ’pack lif beats’ in this block; range: the value named ’range’ in this block. Context: the function test_operator_stream_layouts, which handles test operator stream layouts.

Line 179: `self.assertEqual(len(lif), 8)` This calls ‘self.assertEqual‘ with ‘len(lif), 8‘ inside the function test_operator_strea which handles test operator stream layouts. The call advances the host-side job that checks neuraedge protocol behavior independently with Python assertions.

Line 180: `self.assertEqual(lif[0].data, 0xFFF3FFF2FFF1FFF0)` This calls ‘self.assertEqual‘ with ‘lif[0].data, 0xFFF3FFF2FFF1FFF0‘ inside the function test_operator_stream_layouts, which handles test operator stream layouts. The call advances the host-side job that checks neuraedge protocol behavior independently with Python assertions.

Line 181: `optimizer = pack_optimizer_beats(range(-4, 4), range(-8, 0), range(8))` This assigns ‘pack_optimizer_be 4, 4), range(-8, 0), range(8))‘ to ‘optimizer ‘ in host memory. Here optimizer means the value named ’optimizer’ in this block. The important operands are pack_optimizer_beats: the value named ’pack optimizer beats’ in this block; range: the value named ’range’ in this block. Context: the function test_operator_stream_layouts, which handles test operator stream layouts.

Line 182: `self.assertEqual(len(optimizer), 8)` This calls ‘self.assertEqual‘ with ‘len(optimizer), 8‘ inside the function test_operator_stream_layouts, which handles test operator stream layouts. The call advances the host-side job that checks neuraedge protocol behavior independently with Python assertions.

Line 183: `self.assertEqual(optimizer[0].data, 0x000000FFFFF8FFFC)` This calls ‘self.assertEqual‘ with ‘optimizer[0].data, 0x000000FFFFF8FFFC‘ inside the function test_operator_stream_layouts, which handles test operator stream layouts. The call advances the host-side job that checks neuraedge protocol behavior independently with Python assertions.

Line 184: `self.assertTrue(optimizer[-1].last)` This calls ‘self.assertTrue‘ with ‘optimizer[-1].last‘ inside the function test_operator_stream_layouts, which handles test operator stream layouts. The call advances the host-side job that checks neuraedge protocol behavior independently with Python assertions.

Line 186: `load = pack_lut_load_beats([(7, -2), (8, 3)])` This assigns ‘pack_lut_load_beats([(7, -2), (8, 3)])‘ to ‘load ‘ in host memory. Here load means the value named ’load’ in this block. The important operands are pack_lut_load_beats: the value named ’pack lut load beats’ in this block. Context: the function test_operator_stream_layouts, which handles test operator stream layouts.

Line 187: `self.assertEqual(load[0].data, 0x00FFFE07)` This calls ‘self.assertEqual‘ with ‘load[0].data, 0x00FFFE07‘ inside the function test_operator_stream_layouts, which handles test operator stream layouts. The call advances the host-side job that checks neuraedge protocol behavior independently with Python assertions.

Line 188: `self.assertEqual([beat.last for beat in load], [False, True])` This calls ‘self.assertEqual‘ with ‘[beat.last for beat in load], [False, True]‘ inside the function test_operator_stream_layouts, which handles test operator stream layouts. The call advances the host-side job that checks neuraedge protocol behavior independently with Python assertions.

Line 189: `self.assertEqual(pack_lut_eval_beat(range(8))[0].data, 0x0706050403020100)` This calls ‘self.assertEqual‘ with ‘pack_lut_eval_beat(range(8))[0].data, 0x0706050403020100‘ inside the function test_operator_stream_layouts, which handles test operator stream layouts. The call advances the host-side job that checks neuraedge protocol behavior independently with Python assertions.

Line 191: `backward = pack_linear_backward_beats(` This statement continues through source line 195; the explanation uses the complete expression rather than only the first visual fragment. This assigns ‘pack_linear_backward_beats([[-128, -1, 0, 1], [127, 2, -3, 4]], [[-32768, -1, 32767], [1, 2, 3], [4, 5, 6], [7, 8, 9]], [[-32768, -1, 32767], [10, 11, 12]],)‘ to ‘backward ‘ in host memory. Here backward means the value named ’backward’ in this block. The important operands are pack_linear_backward_beats: the value named ’pack linear backward beats’ in this block. Context: the function test_operator_stream_layouts, which handles test operator stream layouts.

Line 192: `[[-128, -1, 0, 1], [127, 2, -3, 4]],` This is continuation line 2 of the 5-line logical statement that begins at source line 191. Its exact fragment is ‘[[-128, -1, 0, 1], [127, 2, -3, 4]],‘. The expression is a literal or structural operator and has no hidden software state. Read together, the complete operation is: This assigns ‘pack_linear_backward_beats([[-128, -1, 0, 1], [127, 2, -3, 4]], [[-32768, -1, 32767], [1, 2, 3], [4, 5, 6], [7, 8, 9]], [[-32768, -1, 32767], [10, 11, 12]],)‘ to ‘backward ‘ in host memory. Here backward means the value named ’backward’ in this block. The important operands are pack_linear_backward_beats: the value named ’pack linear backward beats’ in this block. Context: the function test_operator_stream_layouts, which handles test operator stream layouts.

Line 193: `[[-32768, -1, 32767], [1, 2, 3], [4, 5, 6], [7, 8, 9]],` This is continuation line 3 of the 5-line logical statement that begins at source line 191. Its exact fragment is ‘[[-32768, -1, 32767], [1, 2, 3], [4, 5, 6], [7, 8, 9]],‘. The expression is a literal or structural operator and has no hidden software state. Read together, the complete operation is: This assigns ‘pack_linear_backward_beats([[-128, -1, 0, 1], [127, 2, -3, 4]], [[-32768, -1, 32767], [1, 2, 3], [4, 5, 6], [7, 8, 9]], [[-32768, -1, 32767], [10, 11, 12]],)‘ to ‘backward ‘ in host memory. Here backward means the value named ’backward’ in this block. The important operands are pack_linear_backward_beats: the value named ’pack linear backward beats’ in this block. Context: the function test_operator_stream_layouts, which handles test operator stream layouts.

Line 194: `[[-32768, -1, 32767], [10, 11, 12]],` This is continuation line 4 of the 5-line logical statement that begins at source line 191. Its exact fragment is '[[-32768, -1, 32767], [10, 11, 12]],'. The expression is a literal or structural operator and has no hidden software state. Read together, the complete operation is: This assigns 'pack_linear_backward_beats([[-128, -1, 0, 1], [127, 2, -3, 4]], [[-32768, -1, 32767], [1, 2, 3], [4, 5, 6], [7, 8, 9]], [[-32768, -1, 32767], [10, 11, 12]],)' to 'backward ' in host memory. Here backward means the value named 'backward' in this block. The important operands are pack_linear_backward_beats: the value named 'pack linear backward beats' in this block. Context: the function test_operator_stream_layouts, which handles test operator stream layouts.

Line 195: `)` This is continuation line 5 of the 5-line logical statement that begins at source line 191. Its exact fragment is ')'. The expression is a literal or structural operator and has no hidden software state. Read together, the complete operation is: This assigns 'pack_linear_backward_beats([[-128, -1, 0, 1], [127, 2, -3, 4]], [[-32768, -1, 32767], [1, 2, 3], [4, 5, 6], [7, 8, 9]], [[-32768, -1, 32767], [10, 11, 12]],)' to 'backward ' in host memory. Here backward means the value named 'backward' in this block. The important operands are pack_linear_backward_beats: the value named 'pack linear backward beats' in this block. Context: the function test_operator_stream_layouts, which handles test operator stream layouts.

Line 196: `self.assertEqual(len(backward), 16)` This calls 'self.assertEqual' with 'len(backward), 16' inside the function test_operator_stream_layouts, which handles test operator stream layouts. The call advances the host-side job that checks neuraedge protocol behavior independently with Python assertions.

Line 197: `self.assertEqual(backward[0].data, 0x00010000FFFFFF80)` This calls 'self.assertEqual' with 'backward[0].data, 0x00010000FFFFFF80' inside the function test_operator_stream_layouts, which handles test operator stream layouts. The call advances the host-side job that checks neuraedge protocol behavior independently with Python assertions.

Line 198: `self.assertEqual(backward[1].data, 0)` This calls 'self.assertEqual' with 'backward[1].data, 0' inside the function test_operator_stream_layouts, which handles test operator stream layouts. The call advances the host-side job that checks neuraedge protocol behavior independently with Python assertions.

Line 199: `self.assertEqual(backward[2].data, 0x0004FFFD0002007F)` This calls 'self.assertEqual' with 'backward[2].data, 0x0004FFFD0002007F' inside the function test_operator_stream_layouts, which handles test operator stream layouts. The call advances the host-side job that checks neuraedge protocol behavior independently with Python assertions.

Line 200: `self.assertEqual(backward[4].data, 0x00007FFFFFFF8000)` This calls 'self.assertEqual' with 'backward[4].data, 0x00007FFFFFFF8000' inside the function test_operator_stream_layouts, which handles test operator stream layouts. The call advances the host-side job that checks neuraedge protocol behavior independently with Python assertions.

Line 201: `self.assertEqual(backward[5].data, 0)` This calls 'self.assertEqual' with 'backward[5].data, 0' inside the function test_operator_stream_layouts, which handles test operator stream layouts. The call advances the host-side job that checks neuraedge protocol behavior independently with Python assertions.

Line 202: `self.assertEqual([beat.last for beat in backward], [False] * 15 + [True])` This calls 'self.assertEqual' with '[beat.last for beat in backward], [False] * 15 + [True]' inside the function test_operator_stream_layouts, which handles test operator stream layouts. The call advances the host-side job that checks neuraedge protocol behavior independently with Python assertions.

Line 203: `input_only = pack_linear_backward_beats(` This statement continues through source line 208; the explanation uses the complete expression rather than only the first visual fragment. This assigns 'pack_linear_backward_beats([[-128, -1, 0, 1], [127, 2, -3, 4]], [[-32768, -1, 32767], [1, 2, 3], [4, 5, 6], [7, 8, 9]], [[-32768, -1, 32767], [10, 11, 12]], mode=LinearGradientMode.INPUT,)' to 'input_only ' in host memory. Here input_only means the value named 'input only' in this block. The important operands are pack_linear_backward_beats: the value named 'pack linear backward beats' in this block; mode: the value named 'mode' in this block; LinearGradientMode: the signed loss derivative used to

update a learned parameter. Context: the function test_operator_stream_layouts, which handles test operator stream layouts.

Line 204: `[[-128, -1, 0, 1], [127, 2, -3, 4]],` This is continuation line 2 of the 6-line logical statement that begins at source line 203. Line 215: `self.assertEqual(len(input_only), 12)` This calls ‘self.assertEqual‘ with ‘len(input_only), 12‘ inside the function test_operator_stream_layouts, which handles test operator stream layouts. The call advances the host-side job that checks neuraedge protocol behavior independently with Python assertions.

Line 216: `self.assertEqual(input_only[0].data, backward[4].data)` This calls ‘self.assertEqual‘ with ‘input_only[0].data, backward[4].data‘ inside the function test_operator_stream_layouts, which handles test operator stream layouts. The call advances the host-side job that checks neuraedge protocol behavior independently with Python assertions.

Line 217: `self.assertEqual(len(weight_only), 8)` This calls ‘self.assertEqual‘ with ‘len(weight_only), 8‘ inside the function test_operator_stream_layouts, which handles test operator stream layouts. The call advances the host-side job that checks neuraedge protocol behavior independently with Python assertions.

Line 218: `self.assertEqual(weight_only[0].data, backward[0].data)` This calls ‘self.assertEqual‘ with ‘weight_only[0].data, backward[0].data‘ inside the function test_operator_stream_layouts, which handles test operator stream layouts. The call advances the host-side job that checks neuraedge protocol behavior independently with Python assertions.

Line 220: `def test_result_decoders(self):` This starts function test_result_decoders. Its indented body performs test result decoders as part of the file that checks neuraedge protocol behavior independently with Python assertions; it runs only when called.

Line 221: `tensor_word = ((-7) & ((1 << 48) - 1)) | (5 << 48) | (12 << 52) | (1 << 58)` This assigns ‘((-7) & ((1 << 48) - 1)) | (5 << 48) | (12 << 52) | (1 << 58)‘ to ‘tensor_word ‘ in host memory. Here tensor_word means the value named ’tensor word’ in this block. The expression is a literal or structural operator and has no hidden software state. Context: the function test_result_decoders, which handles test result decoders.

Line 222: `self.assertEqual(unpack_tensor_result(tensor_word), (-7, 5, 12, True))` This calls ‘self.assertEqual‘ with ‘unpack_tensor_result(tensor_word), (-7, 5, 12, True)‘ inside the function test_result_decoders, which handles test result decoders. The call advances the host-side job that checks neuraedge protocol behavior independently with Python assertions.

Line 223: `self.assertEqual(unpack_alpha_result(11 | (12 << 18) | (13 << 27)), (11, 12, 13))` This calls ‘self.assertEqual‘ with ‘unpack_alpha_result(11 | (12 << 18) | (13 << 27)), (11, 12, 13)‘ inside the function test_result_decoders, which handles test result decoders. The call advances the host-side job that checks neuraedge protocol behavior independently with Python assertions.

Line 224: `self.assertEqual(unpack_vector_result([0xFFFFFFFF00000001, 0, 0, 0])[:2], (1, -1))` This calls ‘self.assertEqual‘ with ‘unpack_vector_result([0xFFFFFFFF00000001, 0, 0, 0])[:2], (1, -1)‘ inside the function test_result_decoders, which handles test result decoders. The call advances the host-side job that checks neuraedge protocol behavior independently with Python assertions.

Line 225: `self.assertEqual(unpack_layernorm_result(0xFFFFFFFF | (9 << 32) | (1 << 44)), (-1, 9, True))` This calls ‘self.assertEqual‘ with ‘unpack_layernorm_result(0xFFFFFFFF | (9 << 32) | (1 << 44)), (-1, 9, True)‘ inside the function test_result_decoders, which handles test result decoders. The call advances the host-side job that checks neuraedge protocol behavior independently with Python assertions.

Line 226: `self.assertEqual(unpack_softmax_result(123 | (7 << 16) | (1 << 25)), (123, 7, True))` This calls ‘self.assertEqual‘ with ‘unpack_softmax_result(123 | (7 << 16) | (1 << 25)), (123, 7, True)‘ inside the function test_result_decoders, which handles test result decoders. The call advances the host-side job that checks neuraedge protocol behavior independently with Python assertions.

Line 227: `self.assertEqual(unpack_lif_result(0x12345678ABCDEF01), (0xABCDEF01, 0x12345678))` This calls ‘self.assertEqual‘ with ‘unpack_lif_result(0x12345678ABCDEF01), (0xABCDEF01, 0x12345678)‘ inside the function test_result_decoders, which handles test result decoders. The call advances the host-side job that checks neuraedge protocol behavior independently with Python assertions.

Line 228: `expected_membranes = tuple(` This statement continues through source line 231; the explanation uses the complete expression rather than only the first visual fragment. Inside the function test_result_decoders, which handles test result decoders, this statement advances the host implementation that checks neuraedge protocol behavior independently with Python assertions. The important operands are expected_membranes: the persistent LIF neuron state carrying charge between timesteps; tuple: the value named 'tuple' in this block; lane: one parallel arithmetic element within a vector or tensor datapath.

Line 229: `(-1 if lane % 3 == 0 else (lane * 7919) % (1 << 23))` This is continuation line 2 of the 4-line logical statement that begins at source line 228. Its exact fragment is '(-1 if lane % 3 == 0 else (lane * 7919) % (1 << 23))'. The important operands are lane: one parallel arithmetic element within a vector or tensor datapath. Read together, the complete operation is: Inside the function test_result_decoders, which handles test result decoders, this statement advances the host implementation that checks neuraedge protocol behavior independently with Python assertions. The important operands are expected_membranes: the persistent LIF neuron state carrying charge between timesteps; tuple: the value named 'tuple' in this block; lane: one parallel arithmetic element within a vector or tensor datapath.

Line 230: `for lane in range(32)` This is continuation line 3 of the 4-line logical statement that begins at source line 228. Its exact fragment is 'for lane in range(32)'. The important operands are for: the value named 'for' in this block; lane: one parallel arithmetic element within a vector or tensor datapath; in: the value named 'in' in this block. Read together, the complete operation is: Inside the function test_result_decoders, which handles test result decoders, this statement advances the host implementation that checks neuraedge protocol behavior independently with Python assertions. The important operands are expected_membranes: the persistent LIF neuron state carrying charge between timesteps; tuple: the value named 'tuple' in this block; lane: one parallel arithmetic element within a vector or tensor datapath.

Line 231: `)` This is continuation line 4 of the 4-line logical statement that begins at source line 228. Its exact fragment is ')'. The expression is a literal or structural operator and has no hidden software state. Read together, the complete operation is: Inside the function test_result_decoders, which handles test result decoders, this statement advances the host implementation that checks neuraedge protocol behavior independently with Python assertions. The important operands are expected_membranes: the persistent LIF neuron state carrying charge between timesteps; tuple: the value named 'tuple' in this block; lane: one parallel arithmetic element within a vector or tensor datapath.

Line 232: `packed_membranes = sum(` This statement continues through source line 235; the explanation uses the complete expression rather than only the first visual fragment. This assigns 'sum((value & 0xFFFFFF) << (24 * lane) for lane, value in enumerate(expected_membranes))' to 'packed_membranes ' in host memory. Here packed_membranes means the persistent LIF neuron state carrying charge between timesteps. The important operands are sum: the value named 'sum' in this block; value: the value named 'value' in this block; lane: one parallel arithmetic element within a vector or tensor datapath. Context: the function test_result_decoders, which handles test result decoders.

Line 233: `(value & 0xFFFFFF) << (24 * lane)` This is continuation line 2 of the 4-line logical statement that begins at source line 232. Its exact fragment is '(value & 0xFFFFFF) << (24 * lane)'. The important operands are value: the value named 'value' in this block; lane: one parallel arithmetic element within a vector or tensor datapath. Read together, the complete operation is: This assigns 'sum((value & 0xFFFFFF) << (24 * lane) for lane, value in enumerate(expected_membranes))' to 'packed_membranes ' in host memory. Here packed_membranes means the persistent LIF neuron state carrying charge between timesteps. The important operands are sum: the value named 'sum' in this block; value: the value named 'value' in this block; lane: one parallel arithmetic element within a vector or tensor datapath. Context: the function test_result_decoders, which handles test result decoders.

Line 234: `for lane, value in enumerate(expected_membranes)` This is continuation line 3 of the 4-line logical statement that begins at source line 232. Its exact fragment is 'for lane, value in enumerate(expected_membranes)'. The important operands are for: the value named 'for' in this block; lane: one parallel arithmetic element within a vector or tensor datapath; value: the value named 'value' in this block. Read together, the complete operation is: This assigns 'sum((value & 0xFFFFFF) << (24 * lane) for lane, value in enumerate(expected_membranes))' to 'packed_membranes ' in host memory. Here packed_membranes means the persistent LIF neuron state carrying charge between timesteps. The important operands are sum: the value named 'sum' in this block; value: the value named 'value' in this block; lane: one parallel arithmetic element within a vector or tensor datapath. Context: the function test_result_decoders, which handles test result decoders.

Line 235: `)` This is continuation line 4 of the 4-line logical statement that begins at source line 232. Its exact fragment is ')'. The expression is a literal or structural operator and has no hidden software state. Read together, the complete operation is: This assigns 'sum((value & 0xFFFFFF) << (24 * lane) for lane, value in enumerate(expected_membranes))' to 'packed_membranes ' in host memory. Here packed_membranes means the persistent LIF neuron state carrying charge between timesteps. The important operands are sum: the value named 'sum' in this block; value: the value named 'value' in this block; lane: one parallel arithmetic element within a vector or tensor datapath. Context: the function test_result_decoders, which handles test result decoders.

Line 236: `trace_words = [0x12345678ABCDEF01]` This assigns '[0x12345678ABCDEF01]' to 'trace_words ' in host memory. Here trace_words means the value named 'trace words' in this block. The expression is a literal or structural operator and has no hidden software state. Context: the function test_result_decoders, which handles test result decoders.

Line 237: `trace_words.extend(` This statement continues through source line 240; the explanation uses the complete expression rather than only the first visual fragment. This calls 'trace_words.extend' with ' (packed_membranes >> (64 * index)) & 0xFFFFFFFFFFFFFFFF for index in range(12) ' inside the function test_result_decoders, which handles test result decoders. The call advances the host-side job that checks neuraedge protocol behavior independently with Python assertions.

Line 238: `(packed_membranes >> (64 * index)) & 0xFFFFFFFFFFFFFFFF` This is continuation line 2 of the 4-line logical statement that begins at source line 237. Its exact fragment is '(packed_membranes >> (64 * index)) & 0xFFFFFFFFFFFFFFFF'. The important operands are packed_membranes: the persistent LIF neuron state carrying charge between timesteps; index: an integer selecting one tensor element, lane, bank, or state entry. Read together, the complete operation is: This calls 'trace_words.extend' with ' (packed_membranes >> (64 * index)) & 0xFFFFFFFFFFFFFFFF for index in range(12) ' inside the function test_result_decoders, which handles test result decoders. The call advances the host-side job that checks neuraedge protocol behavior independently with Python assertions.

Line 239: `for index in range(12)` This is continuation line 3 of the 4-line logical statement that begins at source line 237. Its exact fragment is 'for index in range(12)'. The important operands are for: the value named 'for' in this block; index: an integer selecting one tensor element, lane, bank, or state entry; in: the value named 'in' in this block. Read together, the complete operation is: This calls 'trace_words.extend' with ' (packed_membranes >> (64 * index)) & 0xFFFFFFFFFFFFFFFF for index in range(12) ' inside the function test_result_decoders, which handles test result decoders. The call advances the host-side job that checks neuraedge protocol behavior independently with Python assertions.

Line 240: `)` This is continuation line 4 of the 4-line logical statement that begins at source line 237. Its exact fragment is ')'. The expression is a literal or structural operator and has no hidden software state. Read together, the complete operation is: This calls 'trace_words.extend' with ' (packed_membranes >> (64 * index)) & 0xFFFFFFFFFFFFFFFF for index in range(12) ' inside the function test_result_decoders, which handles test result decoders. The call advances the host-side job that checks neuraedge protocol behavior independently with Python assertions.

Line 241: `self.assertEqual(` This statement continues through source line 244; the explanation uses the complete expression rather than only the first visual fragment. This calls 'self.assertEqual' with ' unpack_lif_trace(trace_words), (0xABCDEF01, 0x12345678, expected_membranes), ' inside the function test_result_decoders, which handles test result decoders. The call advances the host-side job that checks neuraedge protocol behavior independently with Python assertions.

Line 242: `unpack_lif_trace(trace_words),` This is continuation line 2 of the 4-line logical statement that begins at source line 241. Its exact fragment is 'unpack_lif_trace(trace_words),'. The important operands are unpack_lif_trace: the value named 'unpack lif trace' in this block; trace_words: the value named 'trace words' in this block. Read together, the complete operation is: This calls 'self.assertEqual' with ' unpack_lif_trace(trace_words), (0xABCDEF01, 0x12345678, expected_membranes), ' inside the function test_result_decoders, which handles test result decoders. The call advances the host-side job that checks neuraedge protocol behavior independently with Python assertions.

Line 243: `(0xABCDEF01, 0x12345678, expected_membranes),` This is continuation line 3 of the 4-line logical statement that begins at source line 241. Its exact fragment is '(0xABCDEF01, 0x12345678, expected_membranes),'. The important operands are expected_membranes: the persistent LIF neuron state carrying charge between timesteps. Read together, the complete operation is: This calls 'self.assertEqual' with ' unpack_lif_trace(trace_words), (0xABCDEF01, 0x12345678, expected_membranes), ' inside the function test_result_decoders, which handles test result decoders. The call advances the host-side job that checks neuraedge protocol behavior independently with Python assertions.

Line 244: `)` This is continuation line 4 of the 4-line logical statement that begins at source line 241. Its exact fragment is ')'. The expression is a literal or structural operator and has no hidden software state. Read together, the complete operation is: This calls 'self.assertEqual' with ' unpack_lif_trace(trace_words), (0xABCDEF01, 0x12345678, expected_membranes), ' inside the function test_result_decoders, which handles test result decoders. The call advances the host-side job that checks neuraedge protocol behavior independently with Python assertions.

Line 245: `with self.assertRaises(ValueError):` This opens a managed resource scope for 'self.assertRaises(ValueError)' so files, tracing, or temporary state are finalized even if the function test_result_decoders, which handles test result decoders raises an error.

Line 246: `unpack_lif_trace(trace_words[:-1])` This calls 'unpack_lif_trace' with 'trace_words[:-1]' inside the function test_result_decoders, which handles test result decoders. The call advances the host-side job that checks neuraedge protocol behavior independently with Python assertions.

Line 247: `weights, velocities = unpack_optimizer_result([0xFFFFFF000001FFFF] * 8)` This assigns 'unpack_optimizer_ * 8)' to 'weights, velocities ' in host memory. Here weights means a learned coefficient multiplied by an activation. The important operands are unpack_optimizer_result: the value named 'unpack optimizer result' in this block. Context: the function test_result_decoders, which handles test result decoders.

Line 248: `self.assertEqual(weights[0], -1)` This calls 'self.assertEqual' with 'weights[0], -1' inside the function test_result_decoders, which handles test result decoders. The call advances the host-side job that checks neuraedge protocol behavior independently with Python assertions.

Line 249: `self.assertEqual(velocities[0], 1)` This calls 'self.assertEqual' with 'velocities[0], 1' inside the function test_result_decoders, which handles test result decoders. The call advances the host-side job that checks neuraedge protocol behavior independently with Python assertions.

Line 250: `self.assertEqual(unpack_lut_result([0x0003FFFE0001FFFF, 0]), (-1, 1, -2, 3, 0, 0, 0, 0))` This calls 'self.assertEqual' with 'unpack_lut_result([0x0003FFFE0001FFFF, 0]), (-1, 1, -2, 3, 0, 0, 0, 0)' inside the function test_result_decoders, which handles test result decoders. The call advances the host-side job that checks neuraedge protocol behavior independently with Python assertions.

Line 252: `expected_dx = ((-1, 2, -(1 << 31), (1 << 31) - 1), (9, -10, 11, -12))` This assigns '((-1, 2, -(1 << 31), (1 << 31) - 1), (9, -10, 11, -12))' to 'expected_dx ' in host memory. Here expected_dx means the value named 'expected dx' in this block. The expression is a literal or structural operator and has no hidden software state. Context: the function test_result_decoders, which handles test result decoders.

Line 253: `expected_dw = (` This statement continues through source line 258; the explanation uses the complete expression rather than only the first visual fragment. This assigns '((-1, 2, -3), ((1 << 23) - 1, -(1 << 23), 7), (8, 9, 10), (-11, -12, -13),)' to 'expected_dw ' in host memory. Here expected_dw means the value named 'expected dw' in this block. The expression is a literal or structural operator and has no hidden software state. Context: the function test_result_decoders, which handles test result decoders.

Line 254: `(-1, 2, -3),` This is continuation line 2 of the 6-line logical statement that begins at source line 253. Its exact fragment is '(-1, 2, -3),'. The expression is a literal or structural operator and has no hidden software state. Read together, the complete operation is: This assigns '((-1, 2, -3), ((1 << 23) - 1, -(1 << 23), 7), (8, 9, 10), (-11, -12, -13),)' to 'expected_dw ' in host memory. Here expected_dw means the value named 'expected dw' in this block. The expression

is a literal or structural operator and has no hidden software state. Context: the function test_result_decoders, which handles test result decoders.

Line 255: `((1 << 23) - 1, -(1 << 23), 7),` This is continuation line 3 of the 6-line logical statement that begins at source line 253. Its exact fragment is '((1 << 23) - 1, -(1 << 23), 7),'. The expression is a literal or structural operator and has no hidden software state. Read together, the complete operation is: This assigns '((-1, 2, -3), ((1 << 23) - 1, -(1 << 23), 7), (8, 9, 10), (-11, -12, -13),)' to 'expected_dw ' in host memory. Here expected_dw means the value named 'expected dw' in this block. The expression is a literal or structural operator and has no hidden software state. Context: the function test_result_decoders, which handles test result decoders.

Line 256: `(8, 9, 10),` This is continuation line 4 of the 6-line logical statement that begins at source line 253. Its exact fragment is '(8, 9, 10),'. The expression is a literal or structural operator and has no hidden software state. Read together, the complete operation is: This assigns '((-1, 2, -3), ((1 << 23) - 1, -(1 << 23), 7), (8, 9, 10), (-11, -12, -13),)' to 'expected_dw ' in host memory. Here expected_dw means the value named 'expected dw' in this block. The expression is a literal or structural operator and has no hidden software state. Context: the function test_result_decoders, which handles test result decoders.

Line 257: `(-11, -12, -13),` This is continuation line 5 of the 6-line logical statement that begins at source line 253. Its exact fragment is '(-11, -12, -13),'. The expression is a literal or structural operator and has no hidden software state. Read together, the complete operation is: This assigns '((-1, 2, -3), ((1 << 23) - 1, -(1 << 23), 7), (8, 9, 10), (-11, -12, -13),)' to 'expected_dw ' in host memory. Here expected_dw means the value named 'expected dw' in this block. The expression is a literal or structural operator and has no hidden software state. Context: the function test_result_decoders, which handles test result decoders.

Line 258: `)` This is continuation line 6 of the 6-line logical statement that begins at source line 253. Its exact fragment is ')'. The expression is a literal or structural operator and has no hidden software state. Read together, the complete operation is: This assigns '((-1, 2, -3), ((1 << 23) - 1, -(1 << 23), 7), (8, 9, 10), (-11, -12, -13),)' to 'expected_dw ' in host memory. Here expected_dw means the value named 'expected dw' in this block. The expression is a literal or structural operator and has no hidden software state. Context: the function test_result_decoders, which handles test result decoders.

Line 259: `backward_words = []` This assigns '[]' to 'backward_words ' in host memory. Here backward_words means the value named 'backward words' in this block. The expression is a literal or structural operator and has no hidden software state. Context: the function test_result_decoders, which handles test result decoders.

Line 260: `for row in expected_dx:` This iterates row over 'expected_dx'. Each iteration repeats the indented host operation, commonly once per layer, tile, timestep, or test case in the function test_result_decoders, which handles test result decoders.

Line 261: `padded = row + (0,) * (8 - len(row))` This assigns 'row + (0,) * (8 - len(row))' to 'padded ' in host memory. Here padded means the value named 'padded' in this block. The important operands are row: one output-row position processed by the tensor tile; len: the value named 'len' in this block. Context: the function test_result_decoders, which handles test result decoders.

Line 262: `backward_words.extend(` This statement continues through source line 266; the explanation uses the complete expression rather than only the first visual fragment. This calls 'backward_words.extend' with ' (padded[lane] & 0xFFFFFFFF) | ((padded[lane + 1] & 0xFFFFFFFF) << 32) for lane in range(0, 8, 2) ' inside the function test_result_decoders, which handles test result decoders. The call advances the host-side job that checks neuraedge protocol behavior independently with Python assertions.

Line 263: `(padded[lane] & 0xFFFFFFFF)` This is continuation line 2 of the 5-line logical statement that begins at source line 262. Its exact fragment is '(padded[lane] & 0xFFFFFFFF)'. The important operands are padded: the value named 'padded' in this block; lane: one parallel arithmetic element within a vector or tensor datapath. Read together, the complete operation is: This calls 'backward_words.extend' with ' (padded[lane] & 0xFFFFFFFF) | ((padded[lane + 1] & 0xFFFFFFFF) << 32) for lane in range(0, 8, 2) ' inside the function test_result_decoders, which handles test

result decoders. The call advances the host-side job that checks neuraedge protocol behavior independently with Python assertions.

Line 264: `| ((padded[lane + 1] & 0xFFFFFFFF) << 32)` This is continuation line 3 of the 5-line logical statement that begins at source line 262. Its exact fragment is '| ((padded[lane + 1] & 0xFFFFFFFF) << 32)'. The important operands are padded: the value named 'padded' in this block; lane: one parallel arithmetic element within a vector or tensor datapath. Read together, the complete operation is: This calls 'backward_words.extend' with ' (padded[lane] & 0xFFFFFFFF) | ((padded[lane + 1] & 0xFFFFFFFF) << 32) for lane in range(0, 8, 2) ' inside the function test_result_decoders, which handles test result decoders. The call advances the host-side job that checks neuraedge protocol behavior independently with Python assertions.

Line 265: `for lane in range(0, 8, 2)` This is continuation line 4 of the 5-line logical statement that begins at source line 262. Its exact fragment is 'for lane in range(0, 8, 2)'. The important operands are for: the value named 'for' in this block; lane: one parallel arithmetic element within a vector or tensor datapath; in: the value named 'in' in this block. Read together, the complete operation is: This calls 'backward_words.extend' with ' (padded[lane] & 0xFFFFFFFF) | ((padded[lane + 1] & 0xFFFFFFFF) << 32) for lane in range(0, 8, 2) ' inside the function test_result_decoders, which handles test result decoders. The call advances the host-side job that checks neuraedge protocol behavior independently with Python assertions.

Line 266: `)` This is continuation line 5 of the 5-line logical statement that begins at source line 262. Its exact fragment is ')'. The expression is a literal or structural operator and has no hidden software state. Read together, the complete operation is: This calls 'backward_words.extend' with ' (padded[lane] & 0xFFFFFFFF) | ((padded[lane + 1] & 0xFFFFFFFF) << 32) for lane in range(0, 8, 2) ' inside the function test_result_decoders, which handles test result decoders. The call advances the host-side job that checks neuraedge protocol behavior independently with Python assertions.

Line 267: `for row in expected_dw:` This iterates row over 'expected_dw'. Each iteration repeats the indented host operation, commonly once per layer, tile, timestep, or test case in the function test_result_decoders, which handles test result decoders.

Line 268: `padded = row + (0,) * (8 - len(row))` This assigns 'row + (0,) * (8 - len(row))' to 'padded ' in host memory. Here padded means the value named 'padded' in this block. The important operands are row: one output-row position processed by the tensor tile; len: the value named 'len' in this block. Context: the function test_result_decoders, which handles test result decoders.

Line 269: `packed = sum((value & 0xFFFFFF) << (24 * lane)` This statement continues through source line 270; the explanation uses the complete expression rather than only the first visual fragment. This assigns 'sum((value & 0xFFFFFF) << (24 * lane) for lane, value in enumerate(padded))' to 'packed ' in host memory. Here packed means the value named 'packed' in this block. The important operands are sum: the value named 'sum' in this block; value: the value named 'value' in this block; lane: one parallel arithmetic element within a vector or tensor datapath. Context: the function test_result_decoders, which handles test result decoders.

Line 270: `for lane, value in enumerate(padded))` This is continuation line 2 of the 2-line logical statement that begins at source line 269. Its exact fragment is 'for lane, value in enumerate(padded))'. The important operands are for: the value named 'for' in this block; lane: one parallel arithmetic element within a vector or tensor datapath; value: the value named 'value' in this block. Read together, the complete operation is: This assigns 'sum((value & 0xFFFFFF) << (24 * lane) for lane, value in enumerate(padded))' to 'packed ' in host memory. Here packed means the value named 'packed' in this block. The important operands are sum: the value named 'sum' in this block; value: the value named 'value' in this block; lane: one parallel arithmetic element within a vector or tensor datapath. Context: the function test_result_decoders, which handles test result decoders.

Line 271: `backward_words.extend(` This statement continues through source line 273; the explanation uses the complete expression rather than only the first visual fragment. This calls 'backward_words.extend' with ' (packed >> (64 * word)) & 0xFFFFFFFFFFFFFFFF for word in range(3) ' inside the function test_result_decoders, which handles test result decoders. The call advances the host-side job that checks neuraedge protocol behavior independently with Python assertions.

Line 272: `(packed >> (64 * word)) & 0xFFFFFFFFFFFFFFFF for word in range(3)` This is continuation line 2 of the 3-line logical statement that begins at source line 271. Its exact fragment is '(packed >> (64 * word)) & 0xFFFFFFFFFFFFFFFF for word in range(3)'. The important operands are packed: the value named 'packed' in this block; word: the value named 'word' in this block; for: the value named 'for' in this block. Read together, the complete operation is: This calls 'backward_words.extend' with ' (packed >> (64 * word)) & 0xFFFFFFFFFFFFFFFF for word in range(3) ' inside the function test_result_decoders, which handles test result decoders. The call advances the host-side job that checks neuraedge protocol behavior independently with Python assertions.

Line 273: `)` This is continuation line 3 of the 3-line logical statement that begins at source line 271. Its exact fragment is ')'. The expression is a literal or structural operator and has no hidden software state. Read together, the complete operation is: This calls 'backward_words.extend' with ' (packed >> (64 * word)) & 0xFFFFFFFFFFFFFFFF for word in range(3) ' inside the function test_result_decoders, which handles test result decoders. The call advances the host-side job that checks neuraedge protocol behavior independently with Python assertions.

Line 274: `self.assertEqual(` This statement continues through source line 277; the explanation uses the complete expression rather than only the first visual fragment. This calls 'self.assertEqual' with ' unpack_linear_backward_result(backward_wo 2, 4, 3), (expected_dx, expected_dw), ' inside the function test_result_decoders, which handles test result decoders. The call advances the host-side job that checks neuraedge protocol behavior independently with Python assertions.

Line 275: `unpack_linear_backward_result(backward_words, 2, 4, 3),` This is continuation line 2 of the 4-line logical statement that begins at source line 274. Its exact fragment is 'unpack_linear_backward_result(backward_words, 2, 4, 3),'. The important operands are unpack_linear_backward_result: the value named 'unpack linear backward result' in this block; backward_words: the value named 'backward words' in this block. Read together, the complete operation is: This calls 'self.assertEqual' with ' unpack_linear_backward_result(backward_words, 2, 4, 3), (expected_dx, expected_dw), ' inside the function test_result_decoders, which handles test result decoders. The call advances the host-side job that checks neuraedge protocol behavior independently with Python assertions.

Line 276: `(expected_dx, expected_dw),` This is continuation line 3 of the 4-line logical statement that begins at source line 274. Its exact fragment is '(expected_dx, expected_dw),'. The important operands are expected_dx: the value named 'expected dx' in this block; expected_dw: the value named 'expected dw' in this block. Read together, the complete operation is: This calls 'self.assertEqual' with ' unpack_linear_backward_result(backward_words, 2, 4, 3), (expected_dx, expected_dw), ' inside the function test_result_decoders, which handles test result decoders. The call advances the host-side job that checks neuraedge protocol behavior independently with Python assertions.

The call advances the host-side job that checks neuraedge protocol behavior independently with Python assertions.

Line 287: `),` This is continuation line 4 of the 6-line logical statement that begins at source line 284. Its exact fragment is '),'. The expression is a literal or structural operator and has no hidden software state. Read together, the complete operation is: This calls 'self.assertEqual' with ' unpack_linear_backward_result(backward_words[8:], 2, 4, 3,

mode=LinearGradientMode.WEIGHT), (), expected_dw), ‘ inside the function test_result_decoders, which handles test result decoders. The call advances the host-side job that checks neuraedge protocol behavior independently with Python assertions.

Line 288: `(), expected_dw),` This is continuation line 5 of the 6-line logical statement that begins at source line 284. Its exact fragment is ‘(), expected_dw),‘. The important operands are expected_dw: the value named ’expected dw’ in this block. Read together, the complete operation is: This calls ‘self.assertEqual‘ with ‘ unpack_linear_backward_result(backward_words[8:], 2, 4, 3, mode=LinearGradientMode.WEIGHT), (), expected_dw), ‘ inside the function test_result_decoders, which handles test result decoders. The call advances the host-side job that checks neuraedge protocol behavior independently with Python assertions.

Line 289: `)` This is continuation line 6 of the 6-line logical statement that begins at source line 284. Its exact fragment is ‘)‘. The expression is a literal or structural operator and has no hidden software state. Read together, the complete operation is: This calls ‘self.assertEqual‘ with ‘ unpack_linear_backward_result(backward_words[8:], 2, 4, 3, mode=LinearGradientMode.WEIGHT), (), expected_dw), ‘ inside the function test_result_decoders, which handles test result decoders. The call advances the host-side job that checks neuraedge protocol behavior independently with Python assertions.

Line 290: `with self.assertRaises(ValueError):` This opens a managed resource scope for ‘self.assertRaises(ValueError)‘ so files, tracing, or temporary state are finalized even if the function test_result_decoders, which handles test result decoders raises an error.

Line 291: `unpack_linear_backward_result(backward_words[:-1], 2, 4, 3)` This calls ‘unpack_linear_backward_result‘ with ‘backward_words[:-1], 2, 4, 3‘ inside the function test_result_decoders, which handles test result decoders. The call advances the host-side job that checks neuraedge protocol behavior independently with Python assertions.

Line 294: `if __name__ == "__main__":` This executes the following indented host-code branch only when ‘___name___ == "___main___"‘ is true. The important operands are ___name___: the value named ’name’ in this block; ___main___: the value named ’main’ in this block. Context: the file whose role is to checks neuraedge protocol behavior independently with Python assertions.

Line 295: `unittest.main()` This calls ‘unittest.main‘ with “ inside the file whose role is to checks neuraedge protocol behavior independently with Python assertions. The call advances the host-side job that checks neuraedge protocol behavior independently with Python assertions.

67 tests/test_neuraedge_pynq.py

Role in the complete system: checks neuraedge pynq behavior independently with Python assertions.

67.1 Beginner architecture map

Dataflow responsibility This file's end-to-end responsibility is to checks neuraedge pynq behavior independently with Python assertions.

Where it runs This is sequential host software. Python objects live in CPU memory; they become FPGA work only when the compiler packs a command or payload and the PYNQ driver transfers those bytes through AXI DMA or AXI-Lite.

Public structure Classes: FakeMmio, FakeBuffer, FakeChannel, FakeDma, PynqDriverTests. Functions: ___init___, read, write, ___new___, flush, invalidate, freebuffer, ___init___, transfer, wait, ___init___, make_driver, test_identity_and_m test_performance_snapshot_decodes_hardware_registers, test_receive_is_armed_before_submit_and_send, test_rejects_ test_descriptor_program_uses_one_dma_pair, test_descriptor_program_partitions_at_dma_packet_boundary. Each function annotation below names its enclosing function so an array operation is tied to the model, compiler, driver, test, or report phase that uses it.

Numeric and failure boundary Shapes, signedness, byte order, scaling, and saturation are part of the hardware contract. Validation exceptions are functional safety checks: rejecting malformed input before DMA is different from silently clipping, reshaping, or continuing with an incompatible artifact.

67.3 Line annotations

Line 1: `import unittest` This imports the named Python API so the file whose role is to checks neuraedge pynq behavior independently with Python assertions can use it explicitly. Imports execute on the host processor and create no FPGA hardware.

Line 3: `import numpy as np` This imports the named Python API so the file whose role is to checks neuraedge pynq behavior independently with Python assertions can use it explicitly. Imports execute on the host processor and create no FPGA hardware.

Line 5: `from neuraedge_protocol import ProgramRecord, StreamBeat, clear_status_command` This imports the named Python API so the file whose role is to checks neuraedge pynq behavior independently with Python assertions can use it explicitly. Imports execute on the host processor and create no FPGA hardware.

Line 6: `from neuraedge_pynq import NeuraEdgeDriver, NeuraEdgeHardwareError` This imports the named Python API so the file whose role is to checks neuraedge pynq behavior independently with Python assertions can use it explicitly. Imports execute on the host processor and create no FPGA hardware.

Line 9: `class FakeMmio:` This defines class FakeMmio, which groups data and methods for fake mmio. Instances exist in host memory and organize the flow that checks neuraedge pynq behavior independently with Python assertions.

Line 10: `def __init__(self, events, *, error=False):` This starts function ___init___. Its indented body performs init as part of the file that checks neuraedge pynq behavior independently with Python assertions; it runs only when called.

Line 11: `self.events = events` This assigns ‘events‘ to ‘self.events ‘ in host memory. Here events means the value named ’events’ in this block. The important operands are events: the value named ’events’ in this block. Context: the function ___init___, which handles init.

Line 12: `self.error = error` This assigns ‘error‘ to ‘self.error ‘ in host memory. Here error means the value named ’error’ in this block. The important operands are error: the value named ’error’ in this block. Context: the function ___init___, which handles init.

Line 13: `self.registers = {0x30: 0x00010007, 0x34: 0x4E455552,` This statement continues through source line 14; the explanation uses the complete expression rather than only the first visual fragment. This assigns ‘{0x30: 0x00010007, 0x34: 0x4E455552, 0x28: 200000000, 0x2C: 0x1FF, 0x04: 0}‘ to ‘self.registers ‘ in host memory. Here registers means the value named ’registers’ in this block. The expression is a literal or structural operator and has no hidden software state. Context: the function ___init___, which handles init.

Line 14: `0x28: 200000000, 0x2C: 0x1FF, 0x04: 0}` This is continuation line 2 of the 2-line logical statement that begins at source line 13. Its exact fragment is ‘0x28: 200000000, 0x2C: 0x1FF, 0x04: 0}‘. The expression is a literal or structural operator and has no hidden software state. Read together, the complete operation is: This assigns ‘{0x30: 0x00010007, 0x34: 0x4E455552, 0x28: 200000000, 0x2C: 0x1FF, 0x04: 0}‘ to ‘self.registers ‘ in host memory. Here registers means the value named ’registers’ in this block. The expression is a literal or structural operator and has no hidden software state. Context: the function ___init___, which handles init.

Line 16: `def read(self, address):` This starts function read. Its indented body performs read as part of the file that checks neuraedge pynq behavior independently with Python assertions; it runs only when called.

Line 17: `return self.registers.get(address, 0)` This returns ‘self.registers.get(address, 0)‘ to the caller of the function read, which handles read, ending this invocation. The important operands are registers: the value named ’registers’ in this block; get: the value named ’get’ in this block; address: the value named ’address’ in this block.

Line 19: `def write(self, address, value):` This starts function write. Its indented body performs write as part of the file that checks neuraedge pynq behavior independently with Python assertions; it runs only when called.

Line 20: `self.events.append(("mmio", address, value))` This calls ‘self.events.append‘ with ‘("mmio", address, value)‘ inside the function write, which handles write. The call advances the host-side job that checks neuraedge pynq behavior independently with Python assertions.

Line 21: `self.registers[address] = value` This assigns ‘value‘ to ‘self.registers[address] ‘ in host memory. Here registers means the value named ’registers’ in this block. The important operands are value: the value named ’value’ in this block. Context: the function write, which handles write.

Line 22: `if address == 0 and value & 0x5:` This executes the following indented host-code branch only when ‘address == 0 and value & 0x5‘ is true. The important operands are address: the value named ’address’ in this block; and: the value named ’and’ in this block; value: the value named ’value’ in this block. Context: the function write, which handles write.

Line 23: `self.registers[4] = 0x2 if self.error else 0x4` This assigns ‘0x2 if self.error else 0x4‘ to ‘self.registers[4] ‘ in host memory. Here registers means the value named ’registers’ in this block. The important operands are error: the value named ’error’ in this block. Context: the function write, which handles write.

Line 26: `class FakeBuffer(np.ndarray):` This defines class FakeBuffer, which groups data and methods for fake buffer. Instances exist in host memory and organize the flow that checks neuraedge pynq behavior independently with Python assertions.

Line 27: `def __new__(cls, shape, dtype):` This starts function ___new___. Its indented body performs new as part of the file that checks neuraedge pynq behavior independently with Python assertions; it runs only when called.

Line 28: `return np.zeros(shape, dtype=dtype).view(cls)` This returns ‘np.zeros(shape, dtype=dtype).view(cls)‘ to the caller of the function ___new___, which handles new, ending this invocation. The important operands are zeros: the value named ’zeros’ in this block; shape: the value named ’shape’ in this block; dtype: the value named ’dtype’ in this block.

Line 30: `def flush(self):` This starts function flush. Its indented body performs flush as part of the file that checks neuraedge pynq behavior independently with Python assertions; it runs only when called.

Line 31: `pass` Inside the function flush, which handles flush, this statement advances the host implementation that checks neuraedge pynq behavior independently with Python assertions. The important operands are pass: the value named ’pass’ in this block.

Line 33: `def invalidate(self):` This starts function invalidate. Its indented body performs invalidate as part of the file that checks neuraedge pynq behavior independently with Python assertions; it runs only when called.

Line 34: `pass` Inside the function invalidate, which handles invalidate, this statement advances the host implementation that checks neuraedge pynq behavior independently with Python assertions. The important operands are pass: the value named ’pass’ in this block.

Line 36: `def freebuffer(self):` This starts function freebuffer. Its indented body performs freebuffer as part of the file that checks neuraedge pynq behavior independently with Python assertions; it runs only when called.

Line 37: `self.freed = True` This assigns ‘True‘ to ‘self.freed ‘ in host memory. Here freed means the value named ’freed’ in this block. The expression is a literal or structural operator and has no hidden software state. Context: the function freebuffer, which handles freebuffer.

Line 40: `class FakeChannel:` This defines class FakeChannel, which groups data and methods for fake channel. Instances exist in host memory and organize the flow that checks neuraedge pynq behavior independently with Python assertions.

Line 41: `def __init__(self, events, name, receive_words=()):` This starts function ___init___. Its indented body performs init as part of the file that checks neuraedge pynq behavior independently with Python assertions; it runs only when called.

Line 42: `self.events = events` This assigns ‘events‘ to ‘self.events ‘ in host memory. Here events means the value named ’events’ in this block. The important operands are events: the value named ’events’ in this block. Context: the function ___init___, which handles init.

Line 43: `self.name = name` This assigns ‘name‘ to ‘self.name ‘ in host memory. Here name means the value named ’name’ in this block. The important operands are name: the value named ’name’ in this block. Context: the function ___init___, which handles init.

Line 44: `self.receive_words = receive_words` This assigns ‘receive_words‘ to ‘self.receive_words ‘ in host memory. Here receive_words means the value named ’receive words’ in this block. The important operands are receive_words: the value named ’receive words’ in this block. Context: the function ___init___, which handles init.

Line 45: `self.idle = True` This assigns ‘True‘ to ‘self.idle ‘ in host memory. Here idle means the value named ’idle’ in this block. The expression is a literal or structural operator and has no hidden software state. Context: the function ___init___, which handles init.

Line 47: `def transfer(self, buffer, nbytes):` This starts function transfer. Its indented body performs transfer as part of the file that checks neuraedge pynq behavior independently with Python assertions; it runs only when called.

Line 48: `self.events.append((self.name, "transfer", nbytes))` This calls ‘self.events.append‘ with ‘(self.name, "transfer", nbytes)‘ inside the function transfer, which handles transfer. The call advances the host-side job that checks neuraedge pynq behavior independently with Python assertions.

Line 49: `if self.name == "recv":` This executes the following indented host-code branch only when ‘self.name == "recv"‘ is true. The important operands are name: the value named ’name’ in this block; recv: the value named ’recv’ in this block. Context: the function transfer, which handles transfer.

Line 50: `buffer[:len(self.receive_words)] = self.receive_words` This assigns ‘self.receive_words‘ to ‘buffer[‘ in host memory. Here buffer means local storage that decouples producer and consumer timing. The important operands are receive_words: the value named ’receive words’ in this block. Context: the function transfer, which handles transfer.

Line 52: `def wait(self):` This starts function wait. Its indented body performs wait as part of the file that checks neuraedge pynq behavior independently with Python assertions; it runs only when called.

Line 53: `self.events.append((self.name, "wait"))` This calls ‘self.events.append‘ with ‘(self.name, "wait")‘ inside the function wait, which handles wait. The call advances the host-side job that checks neuraedge pynq behavior independently with Python assertions.

Line 56: `class FakeDma:` This defines class FakeDma, which groups data and methods for fake dma. Instances exist in host memory and organize the flow that checks neuraedge pynq behavior independently with Python assertions.

Line 57: `def __init__(self, events, receive_words=()):` This starts function ___init___. Its indented body performs init as part of the file that checks neuraedge pynq behavior independently with Python assertions; it runs only when called.

Line 58: `self.sendchannel = FakeChannel(events, "send")` This assigns ‘FakeChannel(events, "send")‘ to ‘self.sendchannel ‘ in host memory. Here sendchannel means the value named ’sendchannel’ in this block. The important operands are FakeChannel: the value named ’fake channel’ in this block; events: the value named ’events’ in this block; send: the value named ’send’ in this block. Context: the function ___init___, which handles init.

Line 59: `self.recvchannel = FakeChannel(events, "recv", receive_words)` This assigns ‘FakeChannel(events, "recv", receive_words)‘ to ‘self.recvchannel ‘ in host memory. Here recvchannel means the value named ’recvchannel’ in this block. The important operands are FakeChannel: the value named ’fake channel’ in this block; events: the value named ’events’ in this block; recv: the value named ’recv’ in this block. Context: the function ___init___, which handles init.

Line 62: `class PynqDriverTests(unittest.TestCase):` This defines class PynqDriverTests, which groups data and methods for pynq driver tests. Instances exist in host memory and organize the flow that checks neuraedge pynq behavior independently with Python assertions.

Line 63: `def make_driver(self, *, receive_words=(), error=False):` This starts function make_driver. Its indented body performs make driver as part of the file that checks neuraedge pynq behavior independently with Python assertions; it runs only when called.

Line 64: `events = []` This assigns ‘[]‘ to ‘events ‘ in host memory. Here events means the value named ’events’ in this block. The expression is a literal or structural operator and has no hidden software state. Context: the function make_driver, which handles make driver.

Line 65: `mmio = FakeMmio(events, error=error)` This assigns ‘FakeMmio(events, error=error)‘ to ‘mmio ‘ in host memory. Here mmio means the value named ’mmio’ in this block. The important operands are FakeMmio: the value named ’fake mmio’ in this block; events: the value named ’events’ in this block; error: the value named ’error’ in this block. Context: the function make_driver, which handles make driver.

Line 66: `dma = FakeDma(events, receive_words)` This assigns ‘FakeDma(events, receive_words)‘ to ‘dma ‘ in host memory. Here dma means the direct-memory-access engine moving contiguous buffers between DDR and FPGA logic. The important operands are FakeDma: the direct-memory-access engine moving contiguous buffers between DDR and FPGA logic; events: the value named ’events’ in this block; receive_words: the value named ’receive words’ in this block. Context: the function make_driver, which handles make driver.

Line 67: `driver = NeuraEdgeDriver(mmio, dma, lambda *, shape, dtype: FakeBuffer(shape, dtype))` This assigns ‘NeuraEdgeDriver(mmio, dma, lambda *, shape, dtype: FakeBuffer(shape, dtype))‘ to ‘driver ‘ in host memory. Here driver means the value named ’driver’ in this block. The important operands are NeuraEdgeDriver: the value named ’neura edge driver’ in this block; mmio: the value named ’mmio’ in this block; dma: the direct-memory-access engine moving contiguous buffers between DDR and FPGA logic. Context: the function make_driver, which handles make driver.

Line 68: `return driver, events` This returns ‘driver, events‘ to the caller of the function make_driver, which handles make driver, ending this invocation. The important operands are driver: the value named ’driver’ in this block; events: the value named ’events’ in this block.

Line 70: `def test_identity_and_metadata(self):` This starts function test_identity_and_metadata. Its indented body performs test identity and metadata as part of the file that checks neuraedge pynq behavior independently with Python assertions; it runs only when called.

Line 71: `driver, _ = self.make_driver()` This assigns ‘self.make_driver()‘ to ‘driver, _ ‘ in host memory. Here driver means the value named ’driver’ in this block. The important operands are make_driver: the value named ’make driver’ in this block. Context: the function test_identity_and_metadata, which handles test identity and metadata.

Line 72: `self.assertEqual(driver.target_clock_hz, 200000000)` This calls ‘self.assertEqual‘ with ‘driver.target_clock_hz, 200000000‘ inside the function test_identity_and_metadata, which handles test identity and metadata. The call advances the host-side job that checks neuraedge pynq behavior independently with Python assertions.

Line 73: `self.assertEqual(driver.capabilities, 0x1FF)` This calls ‘self.assertEqual‘ with ‘driver.capabilities, 0x1FF‘ inside the function test_identity_and_metadata, which handles test identity and metadata. The call advances the host-side job that checks neuraedge pynq behavior independently with Python assertions.

Line 75: `def test_performance_snapshot_decodes_hardware_registers(self):` This starts function test_performance_sna
Its indented body performs test performance snapshot decodes hardware registers as part of the file that checks neuraedge pynq behavior independently with Python assertions; it runs only when called.

Line 76: `driver, _ = self.make_driver()` This assigns ‘self.make_driver()‘ to ‘driver, _ ‘ in host memory. Here driver means the value named ’driver’ in this block. The important operands are make_driver: the value named ’make driver’ in this block. Context: the function test_performance_snapshot_decodes_hardware_registers, which handles test performance snapshot decodes hardware registers.

Line 77: `driver.mmio.registers.update({` This statement continues through source line 101; the explanation uses the complete expression rather than only the first visual fragment. This calls ‘driver.mmio.registers.update‘ with ‘{ 0x38: (29 << 16) | 31, 0x3C: 17, 0x40: 1234, 0x44: 14, 0x48: 0x89ABCDEF, 0x4C: 0x01234567, 0x50: 0x76543210, 0x54: 0xFEDCBA98, 0x58: 222, 0x5C: 0xFFFFFFF9, 0x60: 81, 0x64: 9, 0x68: 333, 0x6C: 0xFFFFFFF5, 0x70: 0xABCDEF, 0x74: 0x11111111, 0x78: 0x22222222, 0x7C: 44, 0x80: 256, 0x84: 0x12345678, 0x88: 0x87654321, 0x94: 19, 0x98: 9876, }‘ inside the function test_performance_snapshot_decodes_hardware_registers, which handles test performance snapshot decodes hardware registers. The call advances the host-side job that checks neuraedge pynq behavior independently with Python assertions.

Line 78: `0x38: (29 << 16) | 31,` This is continuation line 2 of the 25-line logical statement that begins at source line 77. Its exact fragment is ‘0x38: (29 << 16) | 31,‘. The expression is a literal or structural operator and has no hidden software state. Read together, the complete operation is: This calls ‘driver.mmio.registers.update‘ with ‘{ 0x38:

(29 << 16) | 31, 0x3C: 17, 0x40: 1234, 0x44: 14, 0x48: 0x89ABCDEF, 0x4C: 0x01234567, 0x50: 0x76543210, 0x54: 0xFEDCBA98, 0x58: 222, 0x5C: 0xFFFFFFF9, 0x60: 81, 0x64: 9, 0x68: 333, 0x6C: 0xFFFFFFF5, 0x70: 0xABCDEF, 0x74: 0x11111111, 0x78: 0x22222222, 0x7C: 44, 0x80: 256, 0x84: 0x12345678, 0x88: 0x87654321, 0x94: 19, 0x98: 9876, }‘ inside the function test_performance_snapshot_decodes_hardware_registers, which handles test performance snapshot decodes hardware registers. The call advances the host-side job that checks neuraedge pynq behavior independently with Python assertions.

Line 79: `0x3C: 17,` This is continuation line 3 of the 25-line logical statement that begins at source line 77. Its exact fragment is ‘0x3C: 17,‘. The expression is a literal or structural operator and has no hidden software state. Read together, the complete operation is: This calls ‘driver.mmio.registers.update‘ with ‘{ 0x38: (29 << 16) | 31, 0x3C: 17, 0x40: 1234, 0x44: 14, 0x48: 0x89ABCDEF, 0x4C: 0x01234567, 0x50: 0x76543210, 0x54: 0xFEDCBA98, 0x58: 222, 0x5C: 0xFFFFFFF9, 0x60: 81, 0x64: 9, 0x68: 333, 0x6C: 0xFFFFFFF5, 0x70: 0xABCDEF, 0x74: 0x11111111, 0x78: 0x22222222, 0x7C: 44, 0x80: 256, 0x84: 0x12345678, 0x88: 0x87654321, 0x94: 19, 0x98: 9876, }‘ inside the function test_performance_snapshot_decodes_hardware_registers, which handles test performance snapshot decodes hardware registers. The call advances the host-side job that checks neuraedge pynq behavior independently with Python assertions.

Line 80: `0x40: 1234,` This is continuation line 4 of the 25-line logical statement that begins at source line 77. Its exact fragment is ‘0x40: 1234,‘. The expression is a literal or structural operator and has no hidden software state. Read together, the complete operation is: This calls ‘driver.mmio.registers.update‘ with ‘{ 0x38: (29 << 16) | 31, 0x3C: 17, 0x40: 1234, 0x44: 14, 0x48: 0x89ABCDEF, 0x4C: 0x01234567, 0x50: 0x76543210, 0x54: 0xFEDCBA98, 0x58: 222, 0x5C: 0xFFFFFFF9, 0x60: 81, 0x64: 9, 0x68: 333, 0x6C: 0xFFFFFFF5, 0x70: 0xABCDEF, 0x74: 0x11111111, 0x78: 0x22222222, 0x7C: 44, 0x80: 256, 0x84: 0x12345678, 0x88: 0x87654321, 0x94: 19, 0x98: 9876, }‘ inside the function test_performance_snapshot_decodes_hardware_registers, which handles test performance snapshot decodes hardware registers. The call advances the host-side job that checks neuraedge pynq behavior independently with Python assertions.

Line 81: `0x44: 14,` This is continuation line 5 of the 25-line logical statement that begins at source line 77. Its exact fragment is ‘0x44: 14,‘. The expression is a literal or structural operator and has no hidden software state. Read together, the complete operation is: This calls ‘driver.mmio.registers.update‘ with ‘{ 0x38: (29 << 16) | 31, 0x3C: 17, 0x40: 1234, 0x44: 14, 0x48: 0x89ABCDEF, 0x4C: 0x01234567, 0x50: 0x76543210, 0x54: 0xFEDCBA98, 0x58: 222, 0x5C: 0xFFFFFFF9, 0x60: 81, 0x64: 9, 0x68: 333, 0x6C: 0xFFFFFFF5, 0x70: 0xABCDEF, 0x74: 0x11111111, 0x78: 0x22222222, 0x7C: 44, 0x80: 256, 0x84: 0x12345678, 0x88: 0x87654321, 0x94: 19, 0x98: 9876, }‘ inside the function test_performance_snapshot_decodes_hardware_registers, which handles test performance snapshot decodes hardware registers. The call advances the host-side job that checks neuraedge pynq behavior independently with Python assertions.

Line 82: `0x48: 0x89ABCDEF,` This is continuation line 6 of the 25-line logical statement that begins at source line 77. Its exact fragment is ‘0x48: 0x89ABCDEF,‘. The expression is a literal or structural operator and has no hidden software state. Read together, the complete operation is: This calls ‘driver.mmio.registers.update‘ with ‘{ 0x38: (29 << 16) | 31, 0x3C: 17, 0x40: 1234, 0x44: 14, 0x48: 0x89ABCDEF, 0x4C: 0x01234567, 0x50: 0x76543210, 0x54: 0xFEDCBA98, 0x58: 222, 0x5C: 0xFFFFFFF9, 0x60: 81, 0x64: 9, 0x68: 333, 0x6C: 0xFFFFFFF5, 0x70: 0xABCDEF, 0x74: 0x11111111, 0x78: 0x22222222, 0x7C: 44, 0x80: 256, 0x84: 0x12345678, 0x88: 0x87654321, 0x94: 19, 0x98: 9876, }‘ inside the function test_performance_snapshot_decodes_hardware_registers, which handles test performance snapshot decodes hardware registers. The call advances the host-side job that checks neuraedge pynq behavior independently with Python assertions.

Line 83: `0x4C: 0x01234567,` This is continuation line 7 of the 25-line logical statement that begins at source line 77. Its exact fragment is ‘0x4C: 0x01234567,‘. The expression is a literal or structural operator and has no hidden software state. Read together, the complete operation is: This calls ‘driver.mmio.registers.update‘ with ‘{ 0x38: (29 << 16) | 31, 0x3C: 17, 0x40: 1234, 0x44: 14, 0x48: 0x89ABCDEF, 0x4C: 0x01234567, 0x50: 0x76543210, 0x54: 0xFEDCBA98, 0x58: 222, 0x5C: 0xFFFFFFF9, 0x60: 81, 0x64: 9, 0x68: 333, 0x6C: 0xFFFFFFF5, 0x70: 0xABCDEF, 0x74: 0x11111111, 0x78: 0x22222222, 0x7C: 44, 0x80: 256, 0x84: 0x12345678, 0x88: 0x87654321, 0x94: 19, 0x98: 9876, }‘ inside the function test_performance_snapshot_decodes_hardware_registers, which handles test performance snapshot decodes hardware registers. The call advances the host-side job that checks neuraedge pynq behavior independently with Python assertions.

Line 84: `0x50: 0x76543210,` This is continuation line 8 of the 25-line logical statement that begins at source line 77. Its exact fragment is ‘0x50: 0x76543210,‘. Line 101: `})` This is continuation line 25 of the 25-line logical statement that begins at source line 77. Its exact fragment is '})'. The expression is a literal or structural operator and has no hidden software state. Read together, the complete operation is: This calls 'driver.mmio.registers.update' with '{ 0x38: (29 << 16) | 31, 0x3C: 17, 0x40: 1234, 0x44: 14, 0x48: 0x89ABCDEF, 0x4C: 0x01234567, 0x50: 0x76543210, 0x54: 0xFEDCBA98, 0x58: 222, 0x5C: 0xFFFFFFF9, 0x60: 81, 0x64: 9, 0x68: 333, 0x6C: 0xFFFFFFF5, 0x70: 0xABCDEF, 0x74: 0x11111111, 0x78: 0x22222222, 0x7C: 44, 0x80: 256, 0x84: 0x12345678, 0x88: 0x87654321, 0x94: 19, 0x98: 9876, }' inside the function test_performance_snapshot_decodes_hardware_registers, which handles test performance snapshot decodes hardware registers. The call advances the host-side job that checks neuraedge pynq behavior independently with Python assertions.

Line 102: `snapshot = driver.performance_snapshot()` This assigns 'driver.performance_snapshot()' to 'snapshot ' in host memory. Here snapshot means the value named 'snapshot' in this block. The important operands are driver: the value named 'driver' in this block; performance_snapshot: the value named 'performance snapshot' in this block. Context: the function test_performance_snapshot_decodes_hardware_registers, which handles test performance snapshot decodes hardware registers.

Line 103: `self.assertEqual(snapshot.tensor_loaded_activations, 31)` This calls 'self.assertEqual' with 'snapshot.tensor_loaded_activations, 31' inside the function test_performance_snapshot_decodes_hardware_registers, which handles test performance snapshot decodes hardware registers. The call advances the host-side job that checks neuraedge pynq behavior independently with Python assertions.

Line 104: `self.assertEqual(snapshot.tensor_loaded_weights, 29)` This calls ‘self.assertEqual‘ with ‘snapshot.tensor_load 29‘ inside the function test_performance_snapshot_decodes_hardware_registers, which handles test performance snapshot decodes hardware registers. The call advances the host-side job that checks neuraedge pynq behavior independently with Python assertions.

Line 105: `self.assertEqual(snapshot.tensor_active_issues, 17)` This calls ‘self.assertEqual‘ with ‘snapshot.tensor_active 17‘ inside the function test_performance_snapshot_decodes_hardware_registers, which handles test performance snapshot decodes hardware registers. The call advances the host-side job that checks neuraedge pynq behavior independently with Python assertions.

Line 106: `self.assertEqual(snapshot.dense_macs, 0x0123456789ABCDEF)` This calls ‘self.assertEqual‘ with ‘snapshot.dense_macs, 0x0123456789ABCDEF‘ inside the function test_performance_snapshot_decodes_hardware_registers, which handles test performance snapshot decodes hardware registers. The call advances the host-side job that checks neuraedge pynq behavior independently with Python assertions.

Line 107: `self.assertEqual(snapshot.spike_adds, 0xFEDCBA9876543210)` This calls ‘self.assertEqual‘ with ‘snapshot.spike_adds, 0xFEDCBA9876543210‘ inside the function test_performance_snapshot_decodes_hardware_registers, which handles test performance snapshot decodes hardware registers. The call advances the host-side job that checks neuraedge pynq behavior independently with Python assertions.

Line 108: `self.assertEqual(snapshot.layernorm_mean, -7)` This calls ‘self.assertEqual‘ with ‘snapshot.layernorm_mean, -7‘ inside the function test_performance_snapshot_decodes_hardware_registers, which handles test performance snapshot decodes hardware registers. The call advances the host-side job that checks neuraedge pynq behavior independently with Python assertions.

Line 109: `self.assertEqual(snapshot.softmax_maximum, -11)` This calls ‘self.assertEqual‘ with ‘snapshot.softmax_maximu -11‘ inside the function test_performance_snapshot_decodes_hardware_registers, which handles test performance snapshot decodes hardware registers. The call advances the host-side job that checks neuraedge pynq behavior independently with Python assertions.

Line 110: `self.assertEqual(snapshot.lif_total_spikes, 0x2222222211111111)` This calls ‘self.assertEqual‘ with ‘snapshot.lif_total_spikes, 0x2222222211111111‘ inside the function test_performance_snapshot_decodes_hardware_registers, which handles test performance snapshot decodes hardware registers. The call advances the host-side job that checks neuraedge pynq behavior independently with Python assertions.

Line 111: `self.assertEqual(snapshot.lut_loaded_entries, 256)` This calls ‘self.assertEqual‘ with ‘snapshot.lut_loaded_en 256‘ inside the function test_performance_snapshot_decodes_hardware_registers, which handles test performance snapshot decodes hardware registers. The call advances the host-side job that checks neuraedge pynq behavior independently with Python assertions.

Line 112: `self.assertEqual(snapshot.training_tiles, 19)` This calls ‘self.assertEqual‘ with ‘snapshot.training_tiles, 19‘ inside the function test_performance_snapshot_decodes_hardware_registers, which handles test performance snapshot decodes hardware registers. The call advances the host-side job that checks neuraedge pynq behavior independently with Python assertions.

Line 113: `self.assertEqual(snapshot.training_cycles, 9876)` This calls ‘self.assertEqual‘ with ‘snapshot.training_cycles, 9876‘ inside the function test_performance_snapshot_decodes_hardware_registers, which handles test performance snapshot decodes hardware registers. The call advances the host-side job that checks neuraedge pynq behavior independently with Python assertions.

Line 115: `def test_receive_is_armed_before_submit_and_send(self):` This starts function test_receive_is_armed_before Its indented body performs test receive is armed before submit and send as part of the file that checks neuraedge pynq behavior independently with Python assertions; it runs only when called.

Line 116: `driver, events = self.make_driver(receive_words=(0x1234, 0x5678))` This assigns ‘self.make_driver(receive_ 0x5678))‘ to ‘driver, events ‘ in host memory. Here driver means the value named ’driver’ in this block. The important operands are make_driver: the value named ’make driver’ in this block; receive_words: the value named ’receive words’ in this block. Context: the function test_receive_is_armed_before_submit_and_send, which handles test receive is armed before submit and send.

Line 117: `results = driver.execute(` This statement continues through source line 121; the explanation uses the complete expression rather than only the first visual fragment. This assigns ‘driver.execute(clear_status_command(), [StreamBeat(1, False), StreamBeat(2, True)], output_beats=2,)‘ to ‘results ‘ in host memory. Here results means the value named ’results’ in this block. The important operands are driver: the value named ’driver’ in this block; execute: the value named ’execute’ in this block; clear_status_command: the 128-bit instruction selecting an engine, shape, mode, and numeric parameters. Context: the function test_receive_is_armed_before_submit_and_send, which handles test receive is armed before submit and send.

Line 118: `clear_status_command(),` This is continuation line 2 of the 5-line logical statement that begins at source line 117. Its exact fragment is ‘clear_status_command(),‘. The important operands are clear_status_command: the 128-bit instruction selecting an engine, shape, mode, and numeric parameters. Read together, the complete operation is: This assigns ‘driver.execute(clear_status_command(), [StreamBeat(1, False), StreamBeat(2, True)], output_beats=2,)‘ to ‘results ‘ in host memory. Here results means the value named ’results’ in this block. The important operands are driver: the value named ’driver’ in this block; execute: the value named ’execute’ in this block; clear_status_command: the 128-bit instruction selecting an engine, shape, mode, and numeric parameters. Context: the function test_receive_is_armed_before_submit_and_send, which handles test receive is armed before submit and send.

Line 119: `[StreamBeat(1, False), StreamBeat(2, True)],` This is continuation line 3 of the 5-line logical statement that begins at source line 117. Its exact fragment is ‘[StreamBeat(1, False), StreamBeat(2, True)],‘. The important operands are StreamBeat: the value named ’stream beat’ in this block. Read together, the complete operation is: This assigns ‘driver.execute(clear_status_command(), [StreamBeat(1, False), StreamBeat(2, True)], output_beats=2,)‘ to ‘results ‘ in host memory. Here results means the value named ’results’ in this block. The important operands are driver: the value named ’driver’ in this block; execute: the value named ’execute’ in this block; clear_status_command: the 128-bit instruction selecting an engine, shape, mode, and numeric parameters. Context: the function test_receive_is_armed_before_submit_and_send, which handles test receive is armed before submit and send.

Line 120: `output_beats=2,` This is continuation line 4 of the 5-line logical statement that begins at source line 117. Its exact fragment is ‘output_beats=2,‘. The important operands are output_beats: the value named ’output beats’ in this block. Read together, the complete operation is: This assigns ‘driver.execute(clear_status_command(), [StreamBeat(1, False), StreamBeat(2, True)], output_beats=2,)‘ to ‘results ‘ in host memory. Here results means the value named ’results’ in this block. The important operands are driver: the value named ’driver’ in this block; execute: the value named ’execute’ in this block; clear_status_command: the 128-bit instruction selecting an engine, shape, mode, and numeric parameters. Context: the function test_receive_is_armed_before_submit_and_send, which handles test receive is armed before submit and send.

Line 121: `)` This is continuation line 5 of the 5-line logical statement that begins at source line 117. Its exact fragment is ‘)‘. The expression is a literal or structural operator and has no hidden software state. Read together, the complete operation is: This assigns ‘driver.execute(clear_status_command(), [StreamBeat(1, False), StreamBeat(2, True)], output_beats=2,)‘ to ‘results ‘ in host memory. Here results means the value named ’results’ in this block. The important operands are driver: the value named ’driver’ in this block; execute: the value named ’execute’ in this block; clear_status_command: the 128-bit instruction selecting an engine, shape, mode, and numeric parameters. Context: the function test_receive_is_armed_before_submit_and_send, which handles test receive is armed before submit and send.

Line 122: `self.assertEqual(results, (0x1234, 0x5678))` This calls ‘self.assertEqual‘ with ‘results, (0x1234, 0x5678)‘ inside the function test_receive_is_armed_before_submit_and_send, which handles test receive is armed before submit and send. The call advances the host-side job that checks neuraedge pynq behavior independently with Python assertions.

Line 123: `receive_index = events.index(("recv", "transfer", 16))` This assigns ‘events.index(("recv", "transfer", 16))‘ to ‘receive_index ‘ in host memory. Here receive_index means an integer selecting one tensor element, lane, bank, or state entry. The important operands are events: the value named ’events’ in this block; index: an integer selecting one tensor element, lane, bank, or state entry; recv: the value named ’recv’ in this block. Context: the function test_receive_is_armed_before_submit_and_send, which handles test receive is armed before submit and send.

Line 124: `submit_index = next(index for index, event in enumerate(events)` This statement continues through source line 125; the explanation uses the complete expression rather than only the first visual fragment. Inside the function test_receive_is_armed_before_submit_and_send, which handles test receive is armed before submit and send, this statement advances the host implementation that checks neuraedge pynq behavior independently with Python assertions. The important operands are submit_index: an integer selecting one tensor element, lane, bank, or state entry; next: the value named ’next’ in this block; index: an integer selecting one tensor element, lane, bank, or state entry.

Line 125: `if event[0] == "mmio" and event[1] == 0 and event[2] & 1)` This is continuation line 2 of the 2-line logical statement that begins at source line 124. Its exact fragment is ‘if event[0] == "mmio" and event[1] == 0 and event[2] & 1)‘. The important operands are event: the value named ’event’ in this block; mmio: the value named ’mmio’ in this block; and: the value named ’and’ in this block. Read together, the complete operation is: Inside the function test_receive_is_armed_before_submit_and_send, which handles test receive is armed before submit and send, this statement advances the host implementation that checks neuraedge pynq behavior independently with Python assertions. The important operands are submit_index: an integer selecting one tensor element, lane, bank, or state entry; next: the value named ’next’ in this block; index: an integer selecting one tensor element, lane, bank, or state entry.

Line 126: `send_index = events.index(("send", "transfer", 16))` This assigns ‘events.index(("send", "transfer", 16))‘ to ‘send_index ‘ in host memory. Here send_index means an integer selecting one tensor element, lane, bank, or state entry. The important operands are events: the value named ’events’ in this block; index: an integer selecting one tensor element, lane, bank, or state entry; send: the value named ’send’ in this block. Context: the function test_receive_is_armed_before_submit_and_send, which handles test receive is armed before submit and send.

Line 127: `self.assertLess(receive_index, submit_index)` This calls ‘self.assertLess‘ with ‘receive_index, submit_index‘ inside the function test_receive_is_armed_before_submit_and_send, which handles test receive is armed before submit and send. The call advances the host-side job that checks neuraedge pynq behavior independently with Python assertions.

Line 128: `self.assertLess(submit_index, send_index)` This calls ‘self.assertLess‘ with ‘submit_index, send_index‘ inside the function test_receive_is_armed_before_submit_and_send, which handles test receive is armed before submit and send. The call advances the host-side job that checks neuraedge pynq behavior independently with Python assertions.

Line 130: `def test_rejects_bad_last_and_hardware_error(self):` This starts function test_rejects_bad_last_and_hardw Its indented body performs test rejects bad last and hardware error as part of the file that checks neuraedge pynq behavior independently with Python assertions; it runs only when called.

Line 131: `driver, _ = self.make_driver()` This assigns ‘self.make_driver()‘ to ‘driver, _ ‘ in host memory. Here driver means the value named ’driver’ in this block. The important operands are make_driver: the value named ’make driver’ in this block. Context: the function test_rejects_bad_last_and_hardware_error, which handles test rejects bad last and hardware error.

Line 132: `with self.assertRaises(ValueError):` This opens a managed resource scope for ‘self.assertRaises(ValueError)‘ so files, tracing, or temporary state are finalized even if the function test_rejects_bad_last_and_hardware_error, which handles test rejects bad last and hardware error raises an error.

Line 133: `driver.execute(clear_status_command(), [StreamBeat(1, False)])` This calls ‘driver.execute‘ with ‘clear_status_command(), [StreamBeat(1, False)]‘ inside the function test_rejects_bad_last_and_hardware_error, which handles test rejects bad last and hardware error. The call advances the host-side job that checks neuraedge pynq behavior independently with Python assertions.

Line 134: `driver, _ = self.make_driver(error=True)` This assigns ‘self.make_driver(error=True)‘ to ‘driver, _ ‘ in host memory. Here driver means the value named ’driver’ in this block. The important operands are make_driver: the value named ’make driver’ in this block; error: the value named ’error’ in this block. Context: the function test_rejects_bad_last_and_hardware_error, which handles test rejects bad last and hardware error.

Line 135: `with self.assertRaises(NeuraEdgeHardwareError):` This opens a managed resource scope for ‘self.assertRaises(Ne so files, tracing, or temporary state are finalized even if the function test_rejects_bad_last_and_hardware_error, which handles test rejects bad last and hardware error raises an error.

Line 136: `driver.execute(clear_status_command())` This calls ‘driver.execute‘ with ‘clear_status_command()‘ inside the function test_rejects_bad_last_and_hardware_error, which handles test rejects bad last and hardware error. The call advances the host-side job that checks neuraedge pynq behavior independently with Python assertions.

Line 138: `def test_descriptor_program_uses_one_dma_pair(self):` This starts function test_descriptor_program_uses_o Its indented body performs test descriptor program uses one dma pair as part of the file that checks neuraedge pynq behavior independently with Python assertions; it runs only when called.

Line 139: `driver, events = self.make_driver(receive_words=(0xAA, 0xBB))` This assigns ‘self.make_driver(receive_word 0xBB))‘ to ‘driver, events ‘ in host memory. Here driver means the value named ’driver’ in this block. The important operands are make_driver: the value named ’make driver’ in this block; receive_words: the value named ’receive words’ in this block. Context: the function test_descriptor_program_uses_one_dma_pair, which handles test descriptor program uses one dma pair.

Line 140: `driver.mmio.registers[0x8C] = 2` This assigns ‘2‘ to ‘driver.mmio.registers[0x8C] ‘ in host memory. Here registers means the value named ’registers’ in this block. The expression is a literal or structural operator and has no hidden software state. Context: the function test_descriptor_program_uses_one_dma_pair, which handles test descriptor program uses one dma pair.

Line 141: `records = (` This statement continues through source line 148; the explanation uses the complete expression rather than only the first visual fragment. This assigns ‘(ProgramRecord(clear_status_command(), (StreamBeat(0x11, False), StreamBeat(0x22, True)), 0,), ProgramRecord(clear_status_command(), (), 2),)‘ to ‘records ‘ in host memory. Here records means the number of descriptor records accepted since program start. The important operands are ProgramRecord: the value named ’program record’ in this block; clear_status_command: the 128-bit instruction selecting an engine, shape, mode, and numeric parameters; StreamBeat: the value named ’stream beat’ in this block. Context: the function test_descriptor_program_uses_one_dma_pair, which handles test descriptor program uses one dma pair.

Line 142: `ProgramRecord(` This is continuation line 2 of the 8-line logical statement that begins at source line 141. Its exact fragment is ‘ProgramRecord(‘. The important operands are ProgramRecord: the value named ’program record’ in this block. Read together, the complete operation is: This assigns ‘(ProgramRecord(clear_status_command(), (StreamBeat(0x11, False), StreamBeat(0x22, True)), 0,), ProgramRecord(clear_status_command(), (), 2),)‘ to ‘records ‘ in host memory. Here records means the number of descriptor records accepted since program start. The important operands are ProgramRecord: the value named ’program record’ in this block; clear_status_command: the 128-bit instruction selecting an engine, shape, mode, and numeric parameters; StreamBeat: the value named ’stream beat’ in this block. Context: the function test_descriptor_program_uses_one_dma_pair, which handles test descriptor program uses one dma pair.

Line 143: `clear_status_command(),` This is continuation line 3 of the 8-line logical statement that begins at source line 141. Its exact fragment is ‘clear_status_command(),‘. The important operands are clear_status_command: the 128-bit instruction selecting an engine, shape, mode, and numeric parameters. Read together, the complete operation is: This assigns ‘(ProgramRecord(clear_status_command(), (StreamBeat(0x11, False), StreamBeat(0x22, True)), 0,), ProgramRecord(clear_status_command(), (), 2),)‘ to ‘records ‘ in host memory. Here records means the number of descriptor records accepted since program start. The important operands are ProgramRecord: the value named ’program record’ in this block; clear_status_command: the 128-bit instruction selecting an engine, shape, mode, and numeric parameters; StreamBeat: the value named ’stream beat’ in this block. Context: the function test_descriptor_program_uses_one_dma_pair, which handles test descriptor program uses one dma pair.

Line 144: `(StreamBeat(0x11, False), StreamBeat(0x22, True)),` This is continuation line 4 of the 8-line logical statement that begins at source line 141. Its exact fragment is ‘(StreamBeat(0x11, False), StreamBeat(0x22, True)),‘. The important operands are StreamBeat: the value named ’stream beat’ in this block. Read together, the complete operation is: This assigns ‘(ProgramRecord(clear_status_command(), (StreamBeat(0x11, False), StreamBeat(0x22, True)), 0,), ProgramRecord(clear_status_command(), (), 2),)‘ to ‘records ‘ in host memory. Here records means the number of descriptor records accepted since program start. The important operands are ProgramRecord: the value named ’program record’ in this block; clear_status_command: the 128-bit instruction selecting an engine, shape, mode, and numeric parameters; StreamBeat: the value named ’stream beat’ in this block. Context: the function test_descriptor_program_uses_one_dma_pair, which handles test descriptor program uses one dma pair.

Line 145: `0,` This is continuation line 5 of the 8-line logical statement that begins at source line 141. Its exact fragment is ‘0,‘. The expression is a literal or structural operator and has no hidden software state. Read together, the complete operation is: This assigns ‘(ProgramRecord(clear_status_command(), (StreamBeat(0x11, False), StreamBeat(0x22, True)), 0,), ProgramRecord(clear_status_command(), (), 2),)‘ to ‘records ‘ in host memory. Here records means the number of descriptor records accepted since program start. The important operands are ProgramRecord: the value named ’program record’ in this block; clear_status_command: the 128-bit instruction selecting an engine, shape, mode, and numeric parameters; StreamBeat: the value named ’stream beat’ in this block. Context: the function test_descriptor_program_uses_one_dma_pair, which handles test descriptor program uses one dma pair.

Line 146: `),` This is continuation line 6 of the 8-line logical statement that begins at source line 141. Its exact fragment is ‘),‘. The expression is a literal or structural operator and has no hidden software state. Read together, the complete operation is: This assigns ‘(ProgramRecord(clear_status_command(), (StreamBeat(0x11, False), StreamBeat(0x22, True)), 0,), ProgramRecord(clear_status_command(), (), 2),)‘ to ‘records ‘ in host memory. Here records means the number of descriptor records accepted since program start. The important operands are ProgramRecord: the value named ’program record’ in this block; clear_status_command: the 128-bit instruction selecting an engine, shape, mode, and numeric parameters; StreamBeat: the value named ’stream beat’ in this block. Context: the function test_descriptor_program_uses_one_dma_pair, which handles test descriptor program uses one dma pair.

Line 147: `ProgramRecord(clear_status_command(), (), 2),` This is continuation line 7 of the 8-line logical statement that begins at source line 141. Its exact fragment is ‘ProgramRecord(clear_status_command(), (), 2),‘. The important operands are ProgramRecord: the value named ’program record’ in this block; clear_status_command: the 128-bit instruction selecting an engine, shape, mode, and numeric parameters. Read together, the complete operation is: This assigns ‘(ProgramRecord(clear_status_command(), (StreamBeat(0x11, False), StreamBeat(0x22, True)), 0,), ProgramRecord(clear_status_command(), (), 2),)‘ to ‘records ‘ in host memory. Here records means the number of descriptor records accepted since program start. The important operands are ProgramRecord: the value named ’program record’ in this block; clear_status_command: the 128-bit instruction selecting an engine, shape, mode, and numeric parameters; StreamBeat: the value named ’stream beat’ in this block. Context: the function test_descriptor_program_uses_one_dma_pair, which handles test descriptor program uses one dma pair.

Line 148: `)` This is continuation line 8 of the 8-line logical statement that begins at source line 141. Its exact fragment is ‘)‘. The expression is a literal or structural operator and has no hidden software state. Read together, the complete operation is: This assigns ‘(ProgramRecord(clear_status_command(), (StreamBeat(0x11, False), StreamBeat(0x22, True)), 0,), ProgramRecord(clear_status_command(), (), 2),)‘ to ‘records ‘ in host memory. Here records means the number of descriptor records accepted since program start. The important operands are ProgramRecord: the value named ’program record’ in this block; clear_status_command: the 128-bit instruction selecting an engine, shape, mode, and numeric parameters; StreamBeat: the value named ’stream beat’ in this block. Context: the function test_descriptor_program_uses_one_dma_pair, which handles test descriptor program uses one dma pair.

Line 149: `result = driver.execute_program(records)` This assigns ‘driver.execute_program(records)‘ to ‘result ‘ in host memory. Here result means the value named ’result’ in this block. The important operands are driver: the value named ’driver’ in this block; execute_program: the value named ’execute program’ in this block; records: the number of descriptor records accepted since program start. Context: the function test_descriptor_program_uses_one_dma_pair, which handles test descriptor program uses one dma pair.

Line 150: `self.assertEqual(result, (0xAA, 0xBB))` This calls ‘self.assertEqual‘ with ‘result, (0xAA, 0xBB)‘ inside the function test_descriptor_program_uses_one_dma_pair, which handles test descriptor program uses one dma pair.

The call advances the host-side job that checks neuraedge pynq behavior independently with Python assertions.

Line 151: `self.assertIn(("recv", "transfer", 16), events)` This calls ‘self.assertIn‘ with ‘("recv", "transfer", 16), events‘ inside the function test_descriptor_program_uses_one_dma_pair, which handles test descriptor program uses one dma pair. The call advances the host-side job that checks neuraedge pynq behavior independently with Python assertions.

Line 152: `self.assertIn(("send", "transfer", 64), events)` This calls ‘self.assertIn‘ with ‘("send", "transfer", 64), events‘ inside the function test_descriptor_program_uses_one_dma_pair, which handles test descriptor program uses one dma pair. The call advances the host-side job that checks neuraedge pynq behavior independently with Python assertions.

Line 153: `self.assertIn(("mmio", 0x90, 2), events)` This calls ‘self.assertIn‘ with ‘("mmio", 0x90, 2), events‘ inside the function test_descriptor_program_uses_one_dma_pair, which handles test descriptor program uses one dma pair. The call advances the host-side job that checks neuraedge pynq behavior independently with Python assertions.

Line 154: `self.assertTrue(any(event[0] == "mmio" and event[1] == 0` This statement continues through source line 155; the explanation uses the complete expression rather than only the first visual fragment. This calls ‘self.assertTrue‘ with ‘any(event[0] == "mmio" and event[1] == 0 and event[2] & 4 for event in events)‘ inside the function test_descriptor_program_u which handles test descriptor program uses one dma pair. The call advances the host-side job that checks neuraedge pynq behavior independently with Python assertions.

Line 155: `and event[2] & 4 for event in events))` This is continuation line 2 of the 2-line logical statement that begins at source line 154. Its exact fragment is ‘and event[2] & 4 for event in events))‘. The important operands are and: the value named ’and’ in this block; event: the value named ’event’ in this block; for: the value named ’for’ in this block. Read together, the complete operation is: This calls ‘self.assertTrue‘ with ‘any(event[0] == "mmio" and event[1] == 0 and event[2] & 4 for event in events)‘ inside the function test_descriptor_program_uses_one_dma_pair, which handles test descriptor program uses one dma pair. The call advances the host-side job that checks neuraedge pynq behavior independently with Python assertions.

Line 157: `def test_descriptor_program_partitions_at_dma_packet_boundary(self):` This starts function test_descriptor Its indented body performs test descriptor program partitions at dma packet boundary as part of the file that checks neuraedge pynq behavior independently with Python assertions; it runs only when called.

Line 158: `driver, events = self.make_driver(receive_words=(0xAA,))` This assigns ‘self.make_driver(receive_words=(0x to ‘driver, events ‘ in host memory. Here driver means the value named ’driver’ in this block. The important operands are make_driver: the value named ’make driver’ in this block; receive_words: the value named ’receive words’ in this block. Context: the function test_descriptor_program_partitions_at_dma_packet_boundary, which handles test descriptor program partitions at dma packet boundary.

Line 159: `driver.MAX_DMA_TRANSFER_BYTES = 32` This assigns ‘32‘ to ‘driver.MAX_DMA_TRANSFER_BYTES ‘ in host memory. Here MAX_DMA_TRANSFER_BYTES means the direct-memory-access engine moving contiguous buffers between DDR and FPGA logic. The expression is a literal or structural operator and has no hidden software state. Context: the function test_descriptor_program_partitions_at_dma_packet_boundary, which handles test descriptor program partitions at dma packet boundary.

Line 160: `driver.mmio.registers[0x8C] = 1` This assigns ‘1‘ to ‘driver.mmio.registers[0x8C] ‘ in host memory. Here registers means the value named ’registers’ in this block. The expression is a literal or structural operator and has no hidden software state. Context: the function test_descriptor_program_partitions_at_dma_packet_boundary, which handles test descriptor program partitions at dma packet boundary.

Line 161: `records = (` This statement continues through source line 164; the explanation uses the complete expression rather than only the first visual fragment. This assigns ‘(ProgramRecord(clear_status_command(), (), 1), ProgramRecord(clear_status_command(), (), 1),)‘ to ‘records ‘ in host memory. Here records means the number of descriptor

records accepted since program start. The important operands are ProgramRecord: the value named 'program record' in this block; clear_status_command: the 128-bit instruction selecting an engine, shape, mode, and numeric parameters. Context: the function test_descriptor_program_partitions_at_dma_packet_boundary, which handles test descriptor program partitions at dma packet boundary.

Line 162: `ProgramRecord(clear_status_command(), (), 1),` This is continuation line 2 of the 4-line logical statement that begins at source line 161. Its exact fragment is 'ProgramRecord(clear_status_command(), (), 1),'. The important operands are ProgramRecord: the value named 'program record' in this block; clear_status_command: the 128-bit instruction selecting an engine, shape, mode, and numeric parameters. Read together, the complete operation is: This assigns '(ProgramRecord(clear_status_command(), (), 1), ProgramRecord(clear_status_command(), (), 1),)' to 'records ' in host memory. Here records means the number of descriptor records accepted since program start. The important operands are ProgramRecord: the value named 'program record' in this block; clear_status_command: the 128-bit instruction selecting an engine, shape, mode, and numeric parameters. Context: the function test_descriptor_program_partitions_at which handles test descriptor program partitions at dma packet boundary.

Line 163: `ProgramRecord(clear_status_command(), (), 1),` This is continuation line 3 of the 4-line logical statement that begins at source line 161. Its exact fragment is 'ProgramRecord(clear_status_command(), (), 1),'. The important operands are ProgramRecord: the value named 'program record' in this block; clear_status_command: the 128-bit instruction selecting an engine, shape, mode, and numeric parameters. Read together, the complete operation is: This assigns '(ProgramRecord(clear_status_command(), (), 1), ProgramRecord(clear_status_command(), (), 1),)' to 'records ' in host memory. Here records means the number of descriptor records accepted since program start. The important operands are ProgramRecord: the value named 'program record' in this block; clear_status_command: the 128-bit instruction selecting an engine, shape, mode, and numeric parameters. Context: the function test_descriptor_program_partitions_at which handles test descriptor program partitions at dma packet boundary.

Line 164: `)` This is continuation line 4 of the 4-line logical statement that begins at source line 161. Its exact fragment is ')'. The expression is a literal or structural operator and has no hidden software state. Read together, the complete operation is: This assigns '(ProgramRecord(clear_status_command(), (), 1), ProgramRecord(clear_status_command(), (), 1),)' to 'records ' in host memory. Here records means the number of descriptor records accepted since program start. The important operands are ProgramRecord: the value named 'program record' in this block; clear_status_command: the 128-bit instruction selecting an engine, shape, mode, and numeric parameters. Context: the function test_descriptor_program_part which handles test descriptor program partitions at dma packet boundary.

Line 165: `result = driver.execute_program(records)` This assigns 'driver.execute_program(records)' to 'result ' in host memory. Here result means the value named 'result' in this block. The important operands are driver: the value named 'driver' in this block; execute_program: the value named 'execute program' in this block; records: the number of descriptor records accepted since program start. Context: the function test_descriptor_program_partitions_at_dma_packet_bou which handles test descriptor program partitions at dma packet boundary.

Line 166: `self.assertEqual(result, (0xAA, 0xAA))` This calls 'self.assertEqual' with 'result, (0xAA, 0xAA)' inside the function test_descriptor_program_partitions_at_dma_packet_boundary, which handles test descriptor program partitions at dma packet boundary. The call advances the host-side job that checks neuraedge pynq behavior independently with Python assertions.

Line 167: `self.assertEqual(events.count(("send", "transfer", 24)), 2)` This calls 'self.assertEqual' with 'events.count(("send", "transfer", 24)), 2' inside the function test_descriptor_program_partitions_at_dma_packet_boundary, which handles test descriptor program partitions at dma packet boundary. The call advances the host-side job that checks neuraedge pynq behavior independently with Python assertions.

Line 168: `self.assertEqual(events.count(("recv", "transfer", 8)), 2)` This calls 'self.assertEqual' with 'events.count(("recv", "transfer", 8)), 2' inside the function test_descriptor_program_partitions_at_dma_packet_boundary, which handles test descriptor program partitions at dma packet boundary. The call advances the host-side job that checks neuraedge pynq behavior independently with Python assertions.

Line 171: `if __name__ == "__main__":` This executes the following indented host-code branch only when ‘___name___ == "___main___"‘ is true. The important operands are ___name___: the value named ’name’ in this block; ___main___: the value named ’main’ in this block. Context: the file whose role is to checks neuraedge pynq behavior independently with Python assertions.

Line 172: `unittest.main()` This calls ‘unittest.main‘ with “ inside the file whose role is to checks neuraedge pynq behavior independently with Python assertions. The call advances the host-side job that checks neuraedge pynq behavior independently with Python assertions.

68 tests/test_neuraedge_training.py

Role in the complete system: checks neuraedge training behavior independently with Python assertions.

68.1 Beginner architecture map

Dataflow responsibility This file's end-to-end responsibility is to checks neuraedge training behavior independently with Python assertions.

Where it runs This is sequential host software. Python objects live in CPU memory; they become FPGA work only when the compiler packs a command or payload and the PYNQ driver transfers those bytes through AXI DMA or AXI-Lite.

Public structure Classes: BackwardRtlEmulator, FabricOperatorEmulator, FullTrainingEmulator, TrainingCompilerTests. Functions: _signed, ___init___, _round_and_clip, _decode, _pack_dx, _pack_dw, execute, execute_program, ___init___, execute, ___init___, execute, execute_program, setUp, test_arbitrary_linear_shape_uses_exact_ test_affine_augmentation_returns_exact_bias_gradient, test_grouped_convolution_backward_and_fabric_col2im, test_arbitrary_parameter_sgdw_and_int8_projection_run_in_fabric, test_rejects_misaligned_or_out_of_range_operar test_lif_bptt_fabric_schedule_matches_fixed_point_recurrence, test_maxpool_backward_matches_first_winner_and_o test_real_spikingformer_manifest_has_no_training_coverage_holes. Each function annotation below names its enclosing function so an array operation is tied to the model, compiler, driver, test, or report phase that uses it.

Numeric and failure boundary Shapes, signedness, byte order, scaling, and saturation are part of the hardware contract. Validation exceptions are functional safety checks: rejecting malformed input before DMA is different from silently clipping, reshaping, or continuing with an incompatible artifact.

Line 22: `execute_lif_bptt,` This is continuation line 6 of the 14-line logical statement that begins at source line 17. Its exact fragment is 'execute_lif_bptt,'. The important operands are execute_lif_bptt: the value named 'execute lif bptt' in this block. Read together, the complete operation is: This imports the named Python API so the file whose role is to checks neuraedge training behavior independently with Python assertions can use it explicitly. Imports execute on the host processor and create no FPGA hardware.

Line 23: `execute_int8_weight_projection,` This is continuation line 7 of the 14-line logical statement that begins at source line 17. Its exact fragment is 'execute_int8_weight_projection,'. The important operands are execute_int8_weight_projection: a learned coefficient multiplied by an activation. Read together, the complete operation is: This imports the named Python API so the file whose role is to checks neuraedge training behavior independently with Python assertions can use it explicitly. Imports execute on the host processor and create no FPGA hardware.

Line 24: `execute_maxpool2d_backward,` This is continuation line 8 of the 14-line logical statement that begins at source line 17. Its exact fragment is 'execute_maxpool2d_backward,'. The important operands are execute_maxpool2d_backward: the value named 'execute maxpool2d backward' in this block. Read together, the complete operation is: This imports the named Python API so the file whose role is to checks neuraedge training behavior independently with Python assertions can use it explicitly. Imports execute on the host processor and create no FPGA hardware.

Line 25: `execute_sgdw_update,` This is continuation line 9 of the 14-line logical statement that begins at source line 17. Its exact fragment is 'execute_sgdw_update,'. The important operands are execute_sgdw_update: the value named 'execute sgdw update' in this block. Read together, the complete operation is: This imports the named Python API so the file whose role is to checks neuraedge training behavior independently with Python assertions can use it explicitly. Imports execute on the host processor and create no FPGA hardware.

Line 26: `lif_bptt_fixed,` This is continuation line 10 of the 14-line logical statement that begins at source line 17. Its exact fragment is 'lif_bptt_fixed,'. The important operands are lif_bptt_fixed: the value named 'lif bptt fixed' in this block. Read together, the complete operation is: This imports the named Python API so the file whose role is to checks neuraedge training behavior independently with Python assertions can use it explicitly. Imports execute on the host processor and create no FPGA hardware.

Line 27: `maxpool2d_backward_fixed,` This is continuation line 11 of the 14-line logical statement that begins at source line 17. Its exact fragment is 'maxpool2d_backward_fixed,'. The important operands are maxpool2d_backward_fixed: the value named 'maxpool2d backward fixed' in this block. Read together, the complete operation is: This imports the named Python API so the file whose role is to checks neuraedge training behavior independently with Python assertions can use it explicitly. Imports execute on the host processor and create no FPGA hardware.

Line 28: `sigmoid_surrogate_lut_q15,` This is continuation line 12 of the 14-line logical statement that begins at source line 17. Its exact fragment is 'sigmoid_surrogate_lut_q15,'. The important operands are sigmoid_surrogate_lut_q15: the value named 'sigmoid surrogate lut q15' in this block. Read together, the complete operation is: This imports the named Python API so the file whose role is to checks neuraedge training behavior independently with Python assertions can use it explicitly. Imports execute on the host processor and create no FPGA hardware.

Line 29: `surrogate_lut_addresses,` This is continuation line 13 of the 14-line logical statement that begins at source line 17. Its exact fragment is 'surrogate_lut_addresses,'. The important operands are surrogate_lut_addresses: the value named 'surrogate lut addresses' in this block. Read together, the complete operation is: This imports the named Python API so the file whose role is to checks neuraedge training behavior independently with Python assertions can use it explicitly. Imports execute on the host processor and create no FPGA hardware.

Line 30: `)` This is continuation line 14 of the 14-line logical statement that begins at source line 17. Its exact fragment is ')'. The expression is a literal or structural operator and has no hidden software state. Read together, the complete operation is: This imports the named Python API so the file whose role is to checks neuraedge training behavior independently with Python assertions can use it explicitly. Imports execute on the host processor and create no FPGA hardware.

Line 31: `from tests.test_neuraedge_compiler import TensorTransactionEmulator` This imports the named Python API so the file whose role is to checks neuraedge training behavior independently with Python assertions can use it explicitly. Imports execute on the host processor and create no FPGA hardware.

Line 34: `def _signed(value: int, bits: int) -> int:` This starts function _signed. Its indented body performs signed as part of the file that checks neuraedge training behavior independently with Python assertions; it runs only when called.

Line 35: `masked = value & ((1 << bits) - 1)` This assigns 'value & ((1 << bits) - 1)' to 'masked ' in host memory. Here masked means the value named 'masked' in this block. The important operands are value: the value named 'value' in this block; bits: the value named 'bits' in this block. Context: the function _signed, which handles signed.

Line 36: `return masked - (1 << bits) if masked & (1 << (bits - 1)) else masked` This returns 'masked - (1 << bits) if masked & (1 << (bits - 1)) else masked' to the caller of the function _signed, which handles signed, ending this invocation. The important operands are masked: the value named 'masked' in this block; bits: the value named 'bits' in this block.

Line 39: `class BackwardRtlEmulator:` This defines class BackwardRtlEmulator, which groups data and methods for backward rtl emulator. Instances exist in host memory and organize the flow that checks neuraedge training behavior independently with Python assertions.

Line 40: `"""Independent command-level model of retained raw gradient sums."""` This is executable documentation attached to the class BackwardRtlEmulator, which handles backward rtl emulator. It states the intended contract that tests and callers should enforce, but the text itself does not transform data or issue hardware work.

Line 42: `def __init__(self) -> None:` This starts function ___init___. Its indented body performs init as part of the file that checks neuraedge training behavior independently with Python assertions; it runs only when called.

Line 43: `self.input_accumulator: np.ndarray | None = None` This assigns 'None' to 'self.input_accumulator' in host memory. Here input_accumulator means a widened running sum that prevents intermediate overflow. The important operands are None: the value named 'none' in this block. Context: the function ___init___, which handles init.

Line 44: `self.weight_accumulator: np.ndarray | None = None` This assigns 'None' to 'self.weight_accumulator' in host memory. Here weight_accumulator means a learned coefficient multiplied by an activation. The important operands are None: the value named 'none' in this block. Context: the function ___init___, which handles init.

Line 46: `@staticmethod` This decorator changes how the following class or function is constructed. '@staticmethod' is applied at import time on the host and is part of the class BackwardRtlEmulator, which handles backward rtl emulator; it creates no FPGA circuit by itself.

Line 47: `def _round_and_clip(values: np.ndarray, shift: int, bits: int) -> np.ndarray:` This starts function _round_and_clip. Its indented body performs round and clip as part of the file that checks neuraedge training behavior independently with Python assertions; it runs only when called.

Line 48: `return saturate_signed(round_shift_signed(values, shift), bits)` This returns 'saturate_signed(round_shift_ shift), bits)' to the caller of the function _round_and_clip, which handles round and clip, ending this invocation. The important operands are saturate_signed: the value named 'saturate signed' in this block; round_shift_signed: the value named 'round shift signed' in this block; values: the value named 'values' in this block.

Line 50: `@staticmethod` This decorator changes how the following class or function is constructed. '@staticmethod' is applied at import time on the host and is part of the class BackwardRtlEmulator, which handles backward rtl emulator; it creates no FPGA circuit by itself.

Line 51: `def _decode(command, beats):` This starts function _decode. Its indented body performs decode as part of the file that checks neuraedge training behavior independently with Python assertions; it runs only when called.

Line 52: `value = command.value` This assigns 'command.value' to 'value ' in host memory. Here value means the value named 'value' in this block. The important operands are command: the 128-bit instruction selecting an engine, shape, mode, and numeric parameters; value: the value named 'value' in this block. Context: the function _decode, which handles decode.

Line 53: `rows = (value >> 4) & 0xF` This assigns '(value >> 4) & 0xF' to 'rows ' in host memory. Here rows means one output-row position processed by the tensor tile. The important operands are value: the value named 'value' in this block. Context: the function _decode, which handles decode.

Line 54: `inputs = (value >> 8) & 0xF` This assigns '(value >> 8) & 0xF' to 'inputs ' in host memory. Here inputs means the value named 'inputs' in this block. The important operands are value: the value named 'value' in this block. Context: the function _decode, which handles decode.

Line 55: `outputs = (value >> 12) & 0xF` This assigns '(value >> 12) & 0xF' to 'outputs ' in host memory. Here outputs means the value named 'outputs' in this block. The important operands are value: the value named 'value' in this block. Context: the function _decode, which handles decode.

Line 56: `mode = LinearGradientMode((value >> 26) & 0x3)` This assigns 'LinearGradientMode((value >> 26) & 0x3)' to 'mode ' in host memory. Here mode means the value named 'mode' in this block. The important operands are LinearGradientMode: the signed loss derivative used to update a learned parameter; value: the value named 'value' in this block. Context: the function _decode, which handles decode.

Line 57: `words = [beat.data for beat in beats]` This assigns ‘[beat.data for beat in beats]‘ to ‘words ‘ in host memory. Here words means the value named ’words’ in this block. The important operands are beat: the value named ’beat’ in this block; data: the value named ’data’ in this block; for: the value named ’for’ in this block. Context: the function _decode, which handles decode.

Line 58: `cursor = 0` This assigns ‘0‘ to ‘cursor ‘ in host memory. Here cursor means the value named ’cursor’ in this block. The expression is a literal or structural operator and has no hidden software state. Context: the function _decode, which handles decode.

Line 59: `x = np.zeros((rows, inputs), dtype=np.int64)` This assigns ‘np.zeros((rows, inputs), dtype=np.int64)‘ to ‘x ‘ in host memory. Here x means the value named ’x’ in this block. The important operands are zeros: the value named ’zeros’ in this block; rows: one output-row position processed by the tensor tile; inputs: the value named ’inputs’ in this block. Context: the function _decode, which handles decode.

Line 60: `w = np.zeros((inputs, outputs), dtype=np.int64)` This assigns ‘np.zeros((inputs, outputs), dtype=np.int64)‘ to ‘w ‘ in host memory. Here w means the value named ’w’ in this block. The important operands are zeros: the value named ’zeros’ in this block; inputs: the value named ’inputs’ in this block; outputs: the value named ’outputs’ in this block. Context: the function _decode, which handles decode.

Line 61: `if mode != LinearGradientMode.INPUT:` This executes the following indented host-code branch only when ‘mode != LinearGradientMode.INPUT‘ is true. The important operands are mode: the value named ’mode’ in this block; LinearGradientMode: the signed loss derivative used to update a learned parameter; INPUT: the value named ’input’ in this block. Context: the function _decode, which handles decode.

Line 62: `for row in range(rows):` This iterates row over ‘range(rows)‘. Each iteration repeats the indented host operation, commonly once per layer, tile, timestep, or test case in the function _decode, which handles decode.

Line 63: `packed = words[cursor] | (words[cursor + 1] << 64)` This assigns ‘words[cursor] | (words[cursor + 1] << 64)‘ to ‘packed ‘ in host memory. Here packed means the value named ’packed’ in this block. The important operands are words: the value named ’words’ in this block; cursor: the value named ’cursor’ in this block. Context: the function _decode, which handles decode.

Line 64: `cursor += 2` Inside the function _decode, which handles decode, this statement advances the host implementation that checks neuraedge training behavior independently with Python assertions. The important operands are cursor: the value named ’cursor’ in this block.

Line 65: `for lane in range(inputs):` This iterates lane over ‘range(inputs)‘. Each iteration repeats the indented host operation, commonly once per layer, tile, timestep, or test case in the function _decode, which handles decode.

Line 66: `x[row, lane] = _signed(packed >> (16 * lane), 16)` This assigns ‘_signed(packed >> (16 * lane), 16)‘ to ‘x[row, lane] ‘ in host memory. Here x means the value named ’x’ in this block. The important operands are _signed: the value named ’signed’ in this block; packed: the value named ’packed’ in this block; lane: one parallel arithmetic element within a vector or tensor datapath. Context: the function _decode, which handles decode.

Line 67: `if mode != LinearGradientMode.WEIGHT:` This executes the following indented host-code branch only when ‘mode != LinearGradientMode.WEIGHT‘ is true. The important operands are mode: the value named ’mode’ in this block; LinearGradientMode: the signed loss derivative used to update a learned parameter; WEIGHT: a learned coefficient multiplied by an activation. Context: the function _decode, which handles decode.

Line 68: `for row in range(inputs):` This iterates row over ‘range(inputs)‘. Each iteration repeats the indented host operation, commonly once per layer, tile, timestep, or test case in the function _decode, which handles decode.

Line 69: `packed = words[cursor] | (words[cursor + 1] << 64)` This assigns ‘words[cursor] | (words[cursor + 1] << 64)‘ to ‘packed ‘ in host memory. Here packed means the value named ’packed’ in this block. The important operands are words: the value named ’words’ in this block; cursor: the value named ’cursor’ in this block. Context: the function _decode, which handles decode.

Line 70: `cursor += 2` Inside the function _decode, which handles decode, this statement advances the host implementation that checks neuraedge training behavior independently with Python assertions. The important operands are cursor: the value named ’cursor’ in this block.

Line 71: `for lane in range(outputs):` This iterates lane over ‘range(outputs)‘. Each iteration repeats the indented host operation, commonly once per layer, tile, timestep, or test case in the function _decode, which handles decode.

Line 72: `w[row, lane] = _signed(packed >> (16 * lane), 16)` This assigns ‘_signed(packed >> (16 * lane), 16)‘ to ‘w[row, lane] ‘ in host memory. Here w means the value named ’w’ in this block. The important operands are _signed: the value named ’signed’ in this block; packed: the value named ’packed’ in this block; lane: one parallel arithmetic element within a vector or tensor datapath. Context: the function _decode, which handles decode.

Line 73: `dy = np.zeros((rows, outputs), dtype=np.int64)` This assigns ‘np.zeros((rows, outputs), dtype=np.int64)‘ to ‘dy ‘ in host memory. Here dy means the value named ’dy’ in this block. The important operands are zeros: the value named ’zeros’ in this block; rows: one output-row position processed by the tensor tile; outputs: the value named ’outputs’ in this block. Context: the function _decode, which handles decode.

Line 74: `for row in range(rows):` This iterates row over ‘range(rows)‘. Each iteration repeats the indented host operation, commonly once per layer, tile, timestep, or test case in the function _decode, which handles decode.

Line 75: `packed = words[cursor] | (words[cursor + 1] << 64)` This assigns ‘words[cursor] | (words[cursor + 1] << 64)‘ to ‘packed ‘ in host memory. Here packed means the value named ’packed’ in this block. The important operands are words: the value named ’words’ in this block; cursor: the value named ’cursor’ in this block. Context: the function _decode, which handles decode.

Line 76: `cursor += 2` Inside the function _decode, which handles decode, this statement advances the host implementation that checks neuraedge training behavior independently with Python assertions. The important operands are cursor: the value named ’cursor’ in this block.

Line 77: `for lane in range(outputs):` This iterates lane over ‘range(outputs)‘. Each iteration repeats the indented host operation, commonly once per layer, tile, timestep, or test case in the function _decode, which handles decode.

Line 78: `dy[row, lane] = _signed(packed >> (16 * lane), 16)` This assigns ‘_signed(packed >> (16 * lane), 16)‘ to ‘dy[row, lane] ‘ in host memory. Here dy means the value named ’dy’ in this block. The important operands are _signed: the value named ’signed’ in this block; packed: the value named ’packed’ in this block; lane: one parallel arithmetic element within a vector or tensor datapath. Context: the function _decode, which handles decode.

Line 79: `if cursor != len(words):` This executes the following indented host-code branch only when ‘cursor != len(words)‘ is true. The important operands are cursor: the value named ’cursor’ in this block; len: the value named ’len’ in this block; words: the value named ’words’ in this block. Context: the function _decode, which handles decode.

Line 80: `raise AssertionError("compiler emitted an unexpected backward stream length")` This rejects an invalid state by raising ‘AssertionError("compiler emitted an unexpected backward stream length")‘. Failing before DMA prevents malformed shapes or artifacts from silently becoming hardware results.

Line 81: `return rows, inputs, outputs, mode, x, w, dy` This returns ‘rows, inputs, outputs, mode, x, w, dy‘ to the caller of the function _decode, which handles decode, ending this invocation. The important operands are rows: one output-row position processed by the tensor tile; inputs: the value named ’inputs’ in this block; outputs: the value named ’outputs’ in this block.

Line 83: `@staticmethod` This decorator changes how the following class or function is constructed. ‘@staticmethod‘ is applied at import time on the host and is part of the class BackwardRtlEmulator, which handles backward rtl emulator; it creates no FPGA circuit by itself.

Line 84: `def _pack_dx(values: np.ndarray) -> tuple[int, ...]:` This starts function _pack_dx. Its indented body performs pack dx as part of the file that checks neuraedge training behavior independently with Python assertions; it runs only when called.

Line 85: `words: list[int] = []` This assigns ‘[]‘ to ‘words‘ in host memory. Here words means the value named ’words’ in this block. The expression is a literal or structural operator and has no hidden software state. Context: the function _pack_dx, which handles pack dx.

Line 86: `for row in values:` This iterates row over ‘values‘. Each iteration repeats the indented host operation, commonly once per layer, tile, timestep, or test case in the function _pack_dx, which handles pack dx.

Line 87: `padded = list(map(int, row)) + [0] * (8 - len(row))` This assigns ‘list(map(int, row)) + [0] * (8 - len(row))‘ to ‘padded ‘ in host memory. Here padded means the value named ’padded’ in this block. The important operands are list: the value named ’list’ in this block; map: the value named ’map’ in this block; row: one output-row position processed by the tensor tile. Context: the function _pack_dx, which handles pack dx.

Line 88: `for lane in range(0, 8, 2):` This iterates lane over ‘range(0, 8, 2)‘. Each iteration repeats the indented host operation, commonly once per layer, tile, timestep, or test case in the function _pack_dx, which handles pack dx.

Line 89: `words.append(` This statement continues through source line 92; the explanation uses the complete expression rather than only the first visual fragment. This calls ‘words.append‘ with ‘ (padded[lane] & 0xFFFFFFFF) | ((padded[lane + 1] & 0xFFFFFFFF) << 32) ‘ inside the function _pack_dx, which handles pack dx. The call advances the host-side job that checks neuraedge training behavior independently with Python assertions.

Line 90: `(padded[lane] & 0xFFFFFFFF)` This is continuation line 2 of the 4-line logical statement that begins at source line 89. Its exact fragment is ‘(padded[lane] & 0xFFFFFFFF)‘. The important operands are padded: the value named ’padded’ in this block; lane: one parallel arithmetic element within a vector or tensor datapath. Read together, the complete operation is: This calls ‘words.append‘ with ‘ (padded[lane] & 0xFFFFFFFF) | ((padded[lane + 1] & 0xFFFFFFFF) << 32) ‘ inside the function _pack_dx, which handles pack dx. The call advances the host-side job that checks neuraedge training behavior independently with Python assertions.

Line 91: `| ((padded[lane + 1] & 0xFFFFFFFF) << 32)` This is continuation line 3 of the 4-line logical statement that begins at source line 89. Its exact fragment is ‘| ((padded[lane + 1] & 0xFFFFFFFF) << 32)‘. The important operands are padded: the value named ’padded’ in this block; lane: one parallel arithmetic element within a vector or tensor datapath. Read together, the complete operation is: This calls ‘words.append‘ with ‘ (padded[lane] & 0xFFFFFFFF) | ((padded[lane + 1] & 0xFFFFFFFF) << 32) ‘ inside the function _pack_dx, which handles pack dx. The call advances the host-side job that checks neuraedge training behavior independently with Python assertions.

Line 92: `)` This is continuation line 4 of the 4-line logical statement that begins at source line 89. Its exact fragment is ‘)‘. The expression is a literal or structural operator and has no hidden software state. Read together, the complete operation is: This calls ‘words.append‘ with ‘ (padded[lane] & 0xFFFFFFFF) | ((padded[lane + 1] & 0xFFFFFFFF) << 32) ‘ inside the function _pack_dx, which handles pack dx. The call advances the host-side job that checks neuraedge training behavior independently with Python assertions.

Line 93: `return tuple(words)` This returns ‘tuple(words)‘ to the caller of the function _pack_dx, which handles pack dx, ending this invocation. The important operands are tuple: the value named ’tuple’ in this block; words: the value named ’words’ in this block.

Line 95: `@staticmethod` This decorator changes how the following class or function is constructed. ‘@staticmethod‘ is applied at import time on the host and is part of the class BackwardRtlEmulator, which handles backward rtl emulator; it creates no FPGA circuit by itself.

Line 96: `def _pack_dw(values: np.ndarray) -> tuple[int, ...]:` This starts function _pack_dw. Its indented body performs pack dw as part of the file that checks neuraedge training behavior independently with Python assertions; it runs only when called.

Line 97: `words: list[int] = []` This assigns '[]' to 'words' in host memory. Here words means the value named 'words' in this block. The expression is a literal or structural operator and has no hidden software state. Context: the function _pack_dw, which handles pack dw.

Line 98: `for row in values:` This iterates row over 'values'. Each iteration repeats the indented host operation, commonly once per layer, tile, timestep, or test case in the function _pack_dw, which handles pack dw.

Line 99: `padded = list(map(int, row)) + [0] * (8 - len(row))` This assigns 'list(map(int, row)) + [0] * (8 - len(row))' to 'padded ' in host memory. Here padded means the value named 'padded' in this block. The important operands are list: the value named 'list' in this block; map: the value named 'map' in this block; row: one output-row position processed by the tensor tile. Context: the function _pack_dw, which handles pack dw.

Line 100: `packed = sum(` This statement continues through source line 103; the explanation uses the complete expression rather than only the first visual fragment. This assigns 'sum((item & 0xFFFFFF) << (24 * lane) for lane, item in enumerate(padded))' to 'packed ' in host memory. Here packed means the value named 'packed' in this block. The important operands are sum: the value named 'sum' in this block; item: the value named 'item' in this block; lane: one parallel arithmetic element within a vector or tensor datapath. Context: the function _pack_dw, which handles pack dw.

Line 101: `(item & 0xFFFFFF) << (24 * lane)` This is continuation line 2 of the 4-line logical statement that begins at source line 100. Its exact fragment is '(item & 0xFFFFFF) << (24 * lane)'. The important operands are item: the value named 'item' in this block; lane: one parallel arithmetic element within a vector or tensor datapath. Read together, the complete operation is: This assigns 'sum((item & 0xFFFFFF) << (24 * lane) for lane, item in enumerate(padded))' to 'packed ' in host memory. Here packed means the value named 'packed' in this block. The important operands are sum: the value named 'sum' in this block; item: the value named 'item' in this block; lane: one parallel arithmetic element within a vector or tensor datapath. Context: the function _pack_dw, which handles pack dw.

Line 102: `for lane, item in enumerate(padded)` This is continuation line 3 of the 4-line logical statement that begins at source line 100. Its exact fragment is 'for lane, item in enumerate(padded)'. The important operands are for: the value named 'for' in this block; lane: one parallel arithmetic element within a vector or tensor datapath; item: the value named 'item' in this block. Read together, the complete operation is: This assigns 'sum((item & 0xFFFFFF) << (24 * lane) for lane, item in enumerate(padded))' to 'packed ' in host memory. Here packed means the value named 'packed' in this block. The important operands are sum: the value named 'sum' in this block; item: the value named 'item' in this block; lane: one parallel arithmetic element within a vector or tensor datapath. Context: the function _pack_dw, which handles pack dw.

Line 103: `)` This is continuation line 4 of the 4-line logical statement that begins at source line 100. Its exact fragment is ')'. The expression is a literal or structural operator and has no hidden software state. Read together, the complete operation is: This assigns 'sum((item & 0xFFFFFF) << (24 * lane) for lane, item in enumerate(padded))' to 'packed ' in host memory. Here packed means the value named 'packed' in this block. The important operands are sum: the value named 'sum' in this block; item: the value named 'item' in this block; lane: one parallel arithmetic element within a vector or tensor datapath. Context: the function _pack_dw, which handles pack dw.

Line 104: `words.extend(` This statement continues through source line 106; the explanation uses the complete expression rather than only the first visual fragment. This calls 'words.extend' with ' (packed >> (64 * word)) & 0xFFFFFFFFFFFFFFFF for word in range(3) ' inside the function _pack_dw, which handles pack dw. The call advances the host-side job that checks neuraedge training behavior independently with Python assertions.

Line 105: `(packed >> (64 * word)) & 0xFFFFFFFFFFFFFFFF for word in range(3)` This is continuation line 2 of the 3-line logical statement that begins at source line 104. Its exact fragment is '(packed >> (64 * word)) & 0xFFFFFFFFFFFFFFFF for word in range(3)'. The important operands are packed: the value named 'packed' in

this block; word: the value named 'word' in this block; for: the value named 'for' in this block. Read together, the complete operation is: This calls 'words.extend' with ' (packed >> (64 * word)) & 0xFFFFFFFFFFFFFFFF for word in range(3) ' inside the function _pack_dw, which handles pack dw. The call advances the host-side job that checks neuraedge training behavior independently with Python assertions.

Line 106: `)` This is continuation line 3 of the 3-line logical statement that begins at source line 104. Its exact fragment is ')'. The expression is a literal or structural operator and has no hidden software state. Read together, the complete operation is: This calls 'words.extend' with ' (packed >> (64 * word)) & 0xFFFFFFFFFFFFFFFF for word in range(3) ' inside the function _pack_dw, which handles pack dw. The call advances the host-side job that checks neuraedge training behavior independently with Python assertions.

Line 107: `return tuple(words)` This returns 'tuple(words)' to the caller of the function _pack_dw, which handles pack dw, ending this invocation. The important operands are tuple: the value named 'tuple' in this block; words: the value named 'words' in this block.

Line 109: `def execute(` This starts function execute. Its indented body performs execute as part of the file that checks neuraedge training behavior independently with Python assertions; it runs only when called.

Line 110: `self,` Inside the function execute, which handles execute, this statement advances the host implementation that checks neuraedge training behavior independently with Python assertions. The expression is a literal or structural operator and has no hidden software state.

Line 111: `command,` Inside the function execute, which handles execute, this statement advances the host implementation that checks neuraedge training behavior independently with Python assertions. The important operands are command: the 128-bit instruction selecting an engine, shape, mode, and numeric parameters.

Line 112: `input_beats=(),` This assigns '(),' to 'input_beats' in host memory. Here input_beats means the value named 'input beats' in this block. The expression is a literal or structural operator and has no hidden software state. Context: the function execute, which handles execute.

Line 113: `*,` Inside the function execute, which handles execute, this statement advances the host implementation that checks neuraedge training behavior independently with Python assertions. The expression is a literal or structural operator and has no hidden software state.

Line 114: `output_beats=0,` This assigns '0,' to 'output_beats' in host memory. Here output_beats means the value named 'output beats' in this block. The expression is a literal or structural operator and has no hidden software state. Context: the function execute, which handles execute.

Line 115: `timeout_seconds=5.0,` This assigns '5.0,' to 'timeout_seconds' in host memory. Here timeout_seconds means the value named 'timeout seconds' in this block. The expression is a literal or structural operator and has no hidden software state. Context: the function execute, which handles execute.

Line 116: `) -> tuple[int, ...]:` Inside the function execute, which handles execute, this statement advances the host implementation that checks neuraedge training behavior independently with Python assertions. The important operands are tuple: the value named 'tuple' in this block.

Line 117: `del timeout_seconds` Inside the function execute, which handles execute, this statement advances the host implementation that checks neuraedge training behavior independently with Python assertions. The important operands are del: the value named 'del' in this block; timeout_seconds: the value named 'timeout seconds' in this block.

Line 118: `rows, inputs, outputs, mode, x, w, dy = self._decode(command, input_beats)` This assigns ‘self._decode(co input_beats)‘ to ‘rows, inputs, outputs, mode, x, w, dy ‘ in host memory. Here rows means one output-row position processed by the tensor tile. The important operands are _decode: the value named ’decode’ in this block; command: the 128-bit instruction selecting an engine, shape, mode, and numeric parameters; input_beats: the value named ’input beats’ in this block. Context: the function execute, which handles execute.

Line 119: `accumulate = bool((command.value >> 28) & 1)` This assigns ‘bool((command.value >> 28) & 1)‘ to ‘accumulate ‘ in host memory. Here accumulate means the value named ’accumulate’ in this block. The important operands are bool: the value named ’bool’ in this block; command: the 128-bit instruction selecting an engine, shape, mode, and numeric parameters; value: the value named ’value’ in this block. Context: the function execute, which handles execute.

Line 120: `suppress = bool((command.value >> 29) & 1)` This assigns ‘bool((command.value >> 29) & 1)‘ to ‘suppress ‘ in host memory. Here suppress means the value named ’suppress’ in this block. The important operands are bool: the value named ’bool’ in this block; command: the 128-bit instruction selecting an engine, shape, mode, and numeric parameters; value: the value named ’value’ in this block. Context: the function execute, which handles execute.

Line 121: `dx_shift = (command.value >> 16) & 0x1F` This assigns ‘(command.value >> 16) & 0x1F‘ to ‘dx_shift ‘ in host memory. Here dx_shift means the value named ’dx shift’ in this block. The important operands are command: the 128-bit instruction selecting an engine, shape, mode, and numeric parameters; value: the value named ’value’ in this block. Context: the function execute, which handles execute.

Line 122: `dw_shift = (command.value >> 21) & 0x1F` This assigns ‘(command.value >> 21) & 0x1F‘ to ‘dw_shift ‘ in host memory. Here dw_shift means the value named ’dw shift’ in this block. The important operands are command: the 128-bit instruction selecting an engine, shape, mode, and numeric parameters; value: the value named ’value’ in this block. Context: the function execute, which handles execute.

Line 123: `result: tuple[int, ...]` Inside the function execute, which handles execute, this statement advances the host implementation that checks neuraedge training behavior independently with Python assertions. The important operands are result: the value named ’result’ in this block; tuple: the value named ’tuple’ in this block.

Line 124: `if mode == LinearGradientMode.INPUT:` This executes the following indented host-code branch only when ‘mode == LinearGradientMode.INPUT‘ is true. The important operands are mode: the value named ’mode’ in this block; LinearGradientMode: the signed loss derivative used to update a learned parameter; INPUT: the value named ’input’ in this block. Context: the function execute, which handles execute.

Line 125: `partial = np.zeros((rows, inputs), dtype=np.int64)` This assigns ‘np.zeros((rows, inputs), dtype=np.int64)‘ to ‘partial ‘ in host memory. Here partial means the value named ’partial’ in this block. The important operands are zeros: the value named ’zeros’ in this block; rows: one output-row position processed by the tensor tile; inputs: the value named ’inputs’ in this block. Context: the function execute, which handles execute.

Line 126: `for row in range(rows):` This iterates row over ‘range(rows)‘. Each iteration repeats the indented host operation, commonly once per layer, tile, timestep, or test case in the function execute, which handles execute.

Line 127: `for input_index in range(inputs):` This iterates input_index over ‘range(inputs)‘. Each iteration repeats the indented host operation, commonly once per layer, tile, timestep, or test case in the function execute, which handles execute.

Line 128: `partial[row, input_index] = sum(` This statement continues through source line 131; the explanation uses the complete expression rather than only the first visual fragment. This assigns ‘sum(int(dy[row, output]) * int(w[input_index, output]) for output in range(outputs))‘ to ‘partial[row, input_index] ‘ in host memory. Here partial means the value named ’partial’ in this block. The important operands are sum: the value named ’sum’ in this block; dy: the value named ’dy’ in this block; row: one output-row position processed by the tensor tile. Context: the function execute, which handles execute.

Line 129: `int(dy[row, output]) * int(w[input_index, output])` This is continuation line 2 of the 4-line logical statement that begins at source line 128. Its exact fragment is ‘int(dy[row, output]) * int(w[input_index, output])‘. The important operands are dy: the value named ’dy’ in this block; row: one output-row position processed by the tensor tile; output: the value named ’output’ in this block. Read together, the complete operation is: This assigns ‘sum(int(dy[row, output]) * int(w[input_index, output]) for output in range(outputs))‘ to ‘partial[row, input_index] ‘ in host memory. Here partial means the value named ’partial’ in this block. The important operands are sum: the value named ’sum’ in this block; dy: the value named ’dy’ in this block; row: one output-row position processed by the tensor tile. Context: the function execute, which handles execute.

Line 130: `for output in range(outputs)` This is continuation line 3 of the 4-line logical statement that begins at source line 128. Its exact fragment is ‘for output in range(outputs)‘. The important operands are for: the value named ’for’ in this block; output: the value named ’output’ in this block; in: the value named ’in’ in this block. Read together, the complete operation is: This assigns ‘sum(int(dy[row, output]) * int(w[input_index, output]) for output in range(outputs))‘ to ‘partial[row, input_index] ‘ in host memory. Here partial means the value named ’partial’ in this block. The important operands are sum: the value named ’sum’ in this block; dy: the value named ’dy’ in this block; row: one output-row position processed by the tensor tile. Context: the function execute, which handles execute.

Line 131: `)` This is continuation line 4 of the 4-line logical statement that begins at source line 128. Its exact fragment is ‘)‘. The expression is a literal or structural operator and has no hidden software state. Read together, the complete operation is: This assigns ‘sum(int(dy[row, output]) * int(w[input_index, output]) for output in range(outputs))‘ to ‘partial[row, input_index] ‘ in host memory. Here partial means the value named ’partial’ in this block. The important operands are sum: the value named ’sum’ in this block; dy: the value named ’dy’ in this block; row: one output-row position processed by the tensor tile. Context: the function execute, which handles execute.

Line 132: `if accumulate:` This executes the following indented host-code branch only when ‘accumulate‘ is true. The important operands are accumulate: the value named ’accumulate’ in this block. Context: the function execute, which handles execute.

Line 133: `if self.input_accumulator is None:` This executes the following indented host-code branch only when ‘self.input_accumulator is None‘ is true. The important operands are input_accumulator: a widened running sum that prevents intermediate overflow; is: the value named ’is’ in this block; None: the value named ’none’ in this block. Context: the function execute, which handles execute.

Line 134: `raise AssertionError("input accumulation began without retained state")` This rejects an invalid state by raising ‘AssertionError("input accumulation began without retained state")‘. Failing before DMA prevents malformed shapes or artifacts from silently becoming hardware results.

Line 135: `self.input_accumulator += partial` Inside the function execute, which handles execute, this statement advances the host implementation that checks neuraedge training behavior independently with Python assertions. The important operands are input_accumulator: a widened running sum that prevents intermediate overflow; partial: the value named ’partial’ in this block.

Line 136: `else:` This begins the alternative host-code branch when the preceding condition was false, still inside the function execute, which handles execute.

Line 137: `self.input_accumulator = partial` This assigns ‘partial‘ to ‘self.input_accumulator ‘ in host memory. Here input_accumulator means a widened running sum that prevents intermediate overflow. The important operands are partial: the value named ’partial’ in this block. Context: the function execute, which handles execute.

Line 138: `if suppress:` This executes the following indented host-code branch only when ‘suppress‘ is true. The important operands are suppress: the value named ’suppress’ in this block. Context: the function execute, which handles execute.

Line 139: `result = ()` This assigns '()' to 'result ' in host memory. Here result means the value named 'result' in this block. The expression is a literal or structural operator and has no hidden software state. Context: the function execute, which handles execute.

Line 140: `else:` This begins the alternative host-code branch when the preceding condition was false, still inside the function execute, which handles execute.

Line 141: `result = self._pack_dx(` This statement continues through source line 143; the explanation uses the complete expression rather than only the first visual fragment. This assigns 'self._pack_dx(self._round_and_clip(self.input_accumulat dx_shift, 32))' to 'result ' in host memory. Here result means the value named 'result' in this block. The important operands are _pack_dx: the value named 'pack dx' in this block; _round_and_clip: the value named 'round and clip' in this block; input_accumulator: a widened running sum that prevents intermediate overflow. Context: the function execute, which handles execute.

Line 142: `self._round_and_clip(self.input_accumulator, dx_shift, 32)` This is continuation line 2 of the 3-line logical statement that begins at source line 141. Its exact fragment is 'self._round_and_clip(self.input_accumulator, dx_shift, 32)'. The important operands are _round_and_clip: the value named 'round and clip' in this block; input_accumulator: a widened running sum that prevents intermediate overflow; dx_shift: the value named 'dx shift' in this block. Read together, the complete operation is: This assigns 'self._pack_dx(self._round_and_clip(self.input_accumulator, dx_shift, 32))' to 'result ' in host memory. Here result means the value named 'result' in this block. The important operands are _pack_dx: the value named 'pack dx' in this block; _round_and_clip: the value named 'round and clip' in this block; input_accumulator: a widened running sum that prevents intermediate overflow. Context: the function execute, which handles execute.

Line 143: `)` This is continuation line 3 of the 3-line logical statement that begins at source line 141. Its exact fragment is ')'. The expression is a literal or structural operator and has no hidden software state. Read together, the complete operation is: This assigns 'self._pack_dx(self._round_and_clip(self.input_accumulator, dx_shift, 32))' to 'result ' in host memory. Here result means the value named 'result' in this block. The important operands are _pack_dx: the value named 'pack dx' in this block; _round_and_clip: the value named 'round and clip' in this block; input_accumulator: a widened running sum that prevents intermediate overflow. Context: the function execute, which handles execute.

Line 144: `self.input_accumulator = None` This assigns 'None' to 'self.input_accumulator ' in host memory. Here input_accumulator means a widened running sum that prevents intermediate overflow. The important operands are None: the value named 'none' in this block. Context: the function execute, which handles execute.

Line 145: `elif mode == LinearGradientMode.WEIGHT:` This executes the following indented host-code branch only when 'mode == LinearGradientMode.WEIGHT' is true. The important operands are mode: the value named 'mode' in this block; LinearGradientMode: the signed loss derivative used to update a learned parameter; WEIGHT: a learned coefficient multiplied by an activation. Context: the function execute, which handles execute.

Line 146: `partial = np.zeros((inputs, outputs), dtype=np.int64)` This assigns 'np.zeros((inputs, outputs), dtype=np.int64)' to 'partial ' in host memory. Here partial means the value named 'partial' in this block. The important operands are zeros: the value named 'zeros' in this block; inputs: the value named 'inputs' in this block; outputs: the value named 'outputs' in this block. Context: the function execute, which handles execute.

Line 147: `for input_index in range(inputs):` This iterates input_index over 'range(inputs)'. Each iteration repeats the indented host operation, commonly once per layer, tile, timestep, or test case in the function execute, which handles execute.

Line 148: `for output in range(outputs):` This iterates output over 'range(outputs)'. Each iteration repeats the indented host operation, commonly once per layer, tile, timestep, or test case in the function execute, which handles execute.

Line 149: `partial[input_index, output] = sum(` This statement continues through source line 152; the explanation uses the complete expression rather than only the first visual fragment. This assigns ‘sum(int(x[row, input_index]) * int(dy[row, output]) for row in range(rows))‘ to ‘partial[input_index, output] ‘ in host memory. Here partial means the value named ’partial’ in this block. The important operands are sum: the value named ’sum’ in this block; x: the value named ’x’ in this block; row: one output-row position processed by the tensor tile. Context: the function execute, which handles execute.

Line 150: `int(x[row, input_index]) * int(dy[row, output])` This is continuation line 2 of the 4-line logical statement that begins at source line 149. Its exact fragment is ‘int(x[row, input_index]) * int(dy[row, output])‘. The important operands are x: the value named ’x’ in this block; row: one output-row position processed by the tensor tile; input_index: an integer selecting one tensor element, lane, bank, or state entry. Read together, the complete operation is: This assigns ‘sum(int(x[row, input_index]) * int(dy[row, output]) for row in range(rows))‘ to ‘partial[input_index, output] ‘ in host memory. Here partial means the value named ’partial’ in this block. The important operands are sum: the value named ’sum’ in this block; x: the value named ’x’ in this block; row: one output-row position processed by the tensor tile. Context: the function execute, which handles execute.

Line 151: `for row in range(rows)` This is continuation line 3 of the 4-line logical statement that begins at source line 149. Its exact fragment is ‘for row in range(rows)‘. The important operands are for: the value named ’for’ in this block; row: one output-row position processed by the tensor tile; in: the value named ’in’ in this block. Read together, the complete operation is: This assigns ‘sum(int(x[row, input_index]) * int(dy[row, output]) for row in range(rows))‘ to ‘partial[input_index, output] ‘ in host memory. Here partial means the value named ’partial’ in this block. The important operands are sum: the value named ’sum’ in this block; x: the value named ’x’ in this block; row: one output-row position processed by the tensor tile. Context: the function execute, which handles execute.

Line 152: `)` This is continuation line 4 of the 4-line logical statement that begins at source line 149. Its exact fragment is ‘)‘. The expression is a literal or structural operator and has no hidden software state. Read together, the complete operation is: This assigns ‘sum(int(x[row, input_index]) * int(dy[row, output]) for row in range(rows))‘ to ‘partial[input_index, output] ‘ in host memory. Here partial means the value named ’partial’ in this block. The important operands are sum: the value named ’sum’ in this block; x: the value named ’x’ in this block; row: one output-row position processed by the tensor tile. Context: the function execute, which handles execute.

Line 153: `if accumulate:` This executes the following indented host-code branch only when ‘accumulate‘ is true. The important operands are accumulate: the value named ’accumulate’ in this block. Context: the function execute, which handles execute.

Line 154: `if self.weight_accumulator is None:` This executes the following indented host-code branch only when ‘self.weight_accumulator is None‘ is true. The important operands are weight_accumulator: a learned coefficient multiplied by an activation; is: the value named ’is’ in this block; None: the value named ’none’ in this block. Context: the function execute, which handles execute.

Line 155: `raise AssertionError("weight accumulation began without retained state")` This rejects an invalid state by raising ‘AssertionError("weight accumulation began without retained state")‘. Failing before DMA prevents malformed shapes or artifacts from silently becoming hardware results.

Line 156: `self.weight_accumulator += partial` Inside the function execute, which handles execute, this statement advances the host implementation that checks neuraedge training behavior independently with Python assertions. The important operands are weight_accumulator: a learned coefficient multiplied by an activation; partial: the value named ’partial’ in this block.

Line 157: `else:` This begins the alternative host-code branch when the preceding condition was false, still inside the function execute, which handles execute.

Line 158: `self.weight_accumulator = partial` This assigns ‘partial‘ to ‘self.weight_accumulator ‘ in host memory. Here weight_accumulator means a learned coefficient multiplied by an activation. The important operands are partial: the value named ’partial’ in this block. Context: the function execute, which handles execute.

Line 159: `if suppress:` This executes the following indented host-code branch only when ‘suppress‘ is true. The important operands are suppress: the value named ’suppress’ in this block. Context: the function execute, which handles execute.

Line 160: `result = ()` This assigns ‘()‘ to ‘result ‘ in host memory. Here result means the value named ’result’ in this block. The expression is a literal or structural operator and has no hidden software state. Context: the function execute, which handles execute.

Line 161: `else:` This begins the alternative host-code branch when the preceding condition was false, still inside the function execute, which handles execute.

Line 162: `result = self._pack_dw(` This statement continues through source line 164; the explanation uses the complete expression rather than only the first visual fragment. This assigns ‘self._pack_dw(self._round_and_clip(self.weight_accumula dw_shift, 24))‘ to ‘result ‘ in host memory. Here result means the value named ’result’ in this block. The important operands are _pack_dw: the value named ’pack dw’ in this block; _round_and_clip: the value named ’round and clip’ in this block; weight_accumulator: a learned coefficient multiplied by an activation. Context: the function execute, which handles execute.

Line 163: `self._round_and_clip(self.weight_accumulator, dw_shift, 24)` This is continuation line 2 of the 3-line logical statement that begins at source line 162. Its exact fragment is ‘self._round_and_clip(self.weight_accumulator, dw_shift, 24)‘. The important operands are _round_and_clip: the value named ’round and clip’ in this block; weight_accumulator: a learned coefficient multiplied by an activation; dw_shift: the value named ’dw shift’ in this block. Read together, the complete operation is: This assigns ‘self._pack_dw(self._round_and_clip(self.weight_accumulator, dw_shift, 24))‘ to ‘result ‘ in host memory. Here result means the value named ’result’ in this block. The important operands are _pack_dw: the value named ’pack dw’ in this block; _round_and_clip: the value named ’round and clip’ in this block; weight_accumulator: a learned coefficient multiplied by an activation. Context: the function execute, which handles execute.

Line 164: `)` This is continuation line 3 of the 3-line logical statement that begins at source line 162. Its exact fragment is ‘)‘. The expression is a literal or structural operator and has no hidden software state. Read together, the complete operation is: This assigns ‘self._pack_dw(self._round_and_clip(self.weight_accumulator, dw_shift, 24))‘ to ‘result ‘ in host memory. Here result means the value named ’result’ in this block. The important operands are _pack_dw: the value named ’pack dw’ in this block; _round_and_clip: the value named ’round and clip’ in this block; weight_accumulator: a learned coefficient multiplied by an activation. Context: the function execute, which handles execute.

Line 165: `self.weight_accumulator = None` This assigns ‘None‘ to ‘self.weight_accumulator ‘ in host memory. Here weight_accumulator means a learned coefficient multiplied by an activation. The important operands are None: the value named ’none’ in this block. Context: the function execute, which handles execute.

Line 166: `else:` This begins the alternative host-code branch when the preceding condition was false, still inside the function execute, which handles execute.

Line 167: `raise AssertionError("the tiled compiler must use one-gradient passes")` This rejects an invalid state by raising ‘AssertionError("the tiled compiler must use one-gradient passes")‘. Failing before DMA prevents malformed shapes or artifacts from silently becoming hardware results.

Line 168: `if len(result) != output_beats:` This executes the following indented host-code branch only when ‘len(result) != output_beats‘ is true. The important operands are len: the value named ’len’ in this block; result: the value named ’result’ in this block; output_beats: the value named ’output beats’ in this block. Context: the function execute, which handles execute.

Line 169: `raise AssertionError(f"emulator produced {len(result)} words, expected {output_beats}")` This rejects an invalid state by raising ‘AssertionError(f"emulator produced {len(result)} words, expected {output_beats}")‘. Failing before DMA prevents malformed shapes or artifacts from silently becoming hardware results.

Line 170: `return result` This returns ‘result‘ to the caller of the function execute, which handles execute, ending this invocation. The important operands are result: the value named ’result’ in this block.

Line 172: `def execute_program(self, records, *, timeout_seconds=30.0) -> tuple[int, ...]:` This starts function execute_program. Its indented body performs execute program as part of the file that checks neuraedge training behavior independently with Python assertions; it runs only when called.

Line 173: `del timeout_seconds` Inside the function execute_program, which handles execute program, this statement advances the host implementation that checks neuraedge training behavior independently with Python assertions. The important operands are del: the value named ’del’ in this block; timeout_seconds: the value named ’timeout seconds’ in this block.

Line 174: `output: list[int] = []` This assigns ‘[]‘ to ‘output‘ in host memory. Here output means the value named ’output’ in this block. The expression is a literal or structural operator and has no hidden software state. Context: the function execute_program, which handles execute program.

Line 175: `for record in records:` This iterates record over ‘records‘. Each iteration repeats the indented host operation, commonly once per layer, tile, timestep, or test case in the function execute_program, which handles execute program.

Line 176: `output.extend(self.execute(` This statement continues through source line 180; the explanation uses the complete expression rather than only the first visual fragment. This calls ‘output.extend‘ with ‘self.execute(record.command, record.input_beats, output_beats=record.output_beats,)‘ inside the function execute_program, which handles execute program. The call advances the host-side job that checks neuraedge training behavior independently with Python assertions.

Line 177: `record.command,` This is continuation line 2 of the 5-line logical statement that begins at source line 176. Its exact fragment is ‘record.command,‘. The important operands are record: the value named ’record’ in this block; command: the 128-bit instruction selecting an engine, shape, mode, and numeric parameters. Read together, the complete operation is: This calls ‘output.extend‘ with ‘self.execute(record.command, record.input_beats, output_beats=record.output_beats,)‘ inside the function execute_program, which handles execute program. The call advances the host-side job that checks neuraedge training behavior independently with Python assertions.

Line 178: `record.input_beats,` This is continuation line 3 of the 5-line logical statement that begins at source line 176. Its exact fragment is ‘record.input_beats,‘. The important operands are record: the value named ’record’ in this block; input_beats: the value named ’input beats’ in this block. Read together, the complete operation is: This calls ‘output.extend‘ with ‘self.execute(record.command, record.input_beats, output_beats=record.output_beats,)‘ inside the function execute_program, which handles execute program. The call advances the host-side job that checks neuraedge training behavior independently with Python assertions.

Line 179: `output_beats=record.output_beats,` This is continuation line 4 of the 5-line logical statement that begins at source line 176. Its exact fragment is ‘output_beats=record.output_beats,‘. The important operands are output_beats: the value named ’output beats’ in this block; record: the value named ’record’ in this block. Read together, the complete operation is: This calls ‘output.extend‘ with ‘self.execute(record.command, record.input_beats, output_beats=record.output_beats,)‘ inside the function execute_program, which handles execute program. The call advances the host-side job that checks neuraedge training behavior independently with Python assertions.

Line 180: `))` This is continuation line 5 of the 5-line logical statement that begins at source line 176. Its exact fragment is ‘))‘. The expression is a literal or structural operator and has no hidden software state. Read together, the complete operation is: This calls ‘output.extend‘ with ‘self.execute(record.command, record.input_beats, output_beats=record.output_beats,)‘ inside the function execute_program, which handles execute program. The call advances the host-side job that checks neuraedge training behavior independently with Python assertions.

Line 181: `return tuple(output)` This returns ‘tuple(output)‘ to the caller of the function execute_program, which handles execute program, ending this invocation. The important operands are tuple: the value named ’tuple’ in this block; output: the value named ’output’ in this block.

Line 184: `class FabricOperatorEmulator:` This defines class FabricOperatorEmulator, which groups data and methods for fabric operator emulator. Instances exist in host memory and organize the flow that checks neuraedge training behavior independently with Python assertions.

Line 185: `def __init__(self) -> None:` This starts function ___init___. Its indented body performs init as part of the file that checks neuraedge training behavior independently with Python assertions; it runs only when called.

Line 186: `self.lut = np.zeros(256, dtype=np.int64)` This assigns ‘np.zeros(256, dtype=np.int64)‘ to ‘self.lut ‘ in host memory. Here lut means the value named ’lut’ in this block. The important operands are zeros: the value named ’zeros’ in this block; dtype: the value named ’dtype’ in this block; int64: the value named ’int64’ in this block. Context: the function ___init___, which handles init.

Line 187: `self.lif_membrane = np.zeros(32, dtype=np.int64)` This assigns ‘np.zeros(32, dtype=np.int64)‘ to ‘self.lif_membrane ‘ in host memory. Here lif_membrane means the persistent LIF neuron state carrying charge between timesteps. The important operands are zeros: the value named ’zeros’ in this block; dtype: the value named ’dtype’ in this block; int64: the value named ’int64’ in this block. Context: the function ___init___, which handles init.

Line 188: `self.lif_timestep = 0` This assigns ‘0‘ to ‘self.lif_timestep ‘ in host memory. Here lif_timestep means one discrete SNN update instant. The expression is a literal or structural operator and has no hidden software state. Context: the function ___init___, which handles init.

Line 189: `self.command_count = 0` This assigns ‘0‘ to ‘self.command_count ‘ in host memory. Here command_count means the 128-bit instruction selecting an engine, shape, mode, and numeric parameters. The expression is a literal or structural operator and has no hidden software state. Context: the function ___init___, which handles init.

Line 191: `def execute(` This starts function execute. Its indented body performs execute as part of the file that checks neuraedge training behavior independently with Python assertions; it runs only when called.

Line 192: `self,` Inside the function execute, which handles execute, this statement advances the host implementation that checks neuraedge training behavior independently with Python assertions. The expression is a literal or structural operator and has no hidden software state.

Line 193: `command,` Inside the function execute, which handles execute, this statement advances the host implementation that checks neuraedge training behavior independently with Python assertions. The important operands are command: the 128-bit instruction selecting an engine, shape, mode, and numeric parameters.

Line 194: `input_beats=(),` This assigns ‘(),‘ to ‘input_beats‘ in host memory. Here input_beats means the value named ’input beats’ in this block. The expression is a literal or structural operator and has no hidden software state. Context: the function execute, which handles execute.

Line 195: `*,` Inside the function execute, which handles execute, this statement advances the host implementation that checks neuraedge training behavior independently with Python assertions. The expression is a literal or structural operator and has no hidden software state.

Line 196: `output_beats=0,` This assigns ‘0,‘ to ‘output_beats‘ in host memory. Here output_beats means the value named ’output beats’ in this block. The expression is a literal or structural operator and has no hidden software state. Context: the function execute, which handles execute.

Line 197: `timeout_seconds=5.0,` This assigns ‘5.0,‘ to ‘timeout_seconds‘ in host memory. Here timeout_seconds means the value named ’timeout seconds’ in this block. The expression is a literal or structural operator and has no hidden software state. Context: the function execute, which handles execute.

Line 198: `) -> tuple[int, ...]:` Inside the function execute, which handles execute, this statement advances the host implementation that checks neuraedge training behavior independently with Python assertions. The important operands are tuple: the value named ’tuple’ in this block.

Line 199: `del timeout_seconds` Inside the function execute, which handles execute, this statement advances the host implementation that checks neuraedge training behavior independently with Python assertions. The important operands are del: the value named ’del’ in this block; timeout_seconds: the value named ’timeout seconds’ in this block.

Line 200: `self.command_count += 1` Inside the function execute, which handles execute, this statement advances the host implementation that checks neuraedge training behavior independently with Python assertions. The important operands are command_count: the 128-bit instruction selecting an engine, shape, mode, and numeric parameters.

Line 201: `words = [beat.data for beat in input_beats]` This assigns ‘[beat.data for beat in input_beats]‘ to ‘words ‘ in host memory. Here words means the value named ’words’ in this block. The important operands are beat: the value named ’beat’ in this block; data: the value named ’data’ in this block; for: the value named ’for’ in this block. Context: the function execute, which handles execute.

Line 202: `if command.opcode == Opcode.ACTIVATION_LUT:` This executes the following indented host-code branch only when ‘command.opcode == Opcode.ACTIVATION_LUT‘ is true. The important operands are command: the 128-bit instruction selecting an engine, shape, mode, and numeric parameters; opcode: the value named ’opcode’ in this block; Opcode: the value named ’opcode’ in this block. Context: the function execute, which handles execute.

Line 203: `suboperation = (command.value >> 4) & 0xF` This assigns ‘(command.value >> 4) & 0xF‘ to ‘suboperation ‘ in host memory. Here suboperation means the value named ’suboperation’ in this block. The important operands are command: the 128-bit instruction selecting an engine, shape, mode, and numeric parameters; value: the value named ’value’ in this block. Context: the function execute, which handles execute.

Line 204: `if suboperation == 1:` This executes the following indented host-code branch only when ‘suboperation == 1‘ is true. The important operands are suboperation: the value named ’suboperation’ in this block. Context: the function execute, which handles execute.

Line 205: `for word in words:` This iterates word over ‘words‘. Each iteration repeats the indented host operation, commonly once per layer, tile, timestep, or test case in the function execute, which handles execute.

Line 206: `self.lut[word & 0xFF] = _signed(word >> 8, 16)` Inside the function execute, which handles execute, this statement advances the host implementation that checks neuraedge training behavior independently with Python assertions. The important operands are lut: the value named ’lut’ in this block; word: the value named ’word’ in this block; _signed: the value named ’signed’ in this block.

Line 207: `result: tuple[int, ...] = ()` This assigns ‘()‘ to ‘result‘ in host memory. Here result means the value named ’result’ in this block. The expression is a literal or structural operator and has no hidden software state. Context: the function execute, which handles execute.

Line 208: `elif suboperation == 2:` This executes the following indented host-code branch only when ‘suboperation == 2‘ is true. The important operands are suboperation: the value named ’suboperation’ in this block. Context: the function execute, which handles execute.

Line 209: `indices = [(words[0] >> (8 * lane)) & 0xFF for lane in range(8)]` This assigns ‘[(words[0] >> (8 * lane)) & 0xFF for lane in range(8)]‘ to ‘indices ‘ in host memory. Here indices means the value named ’indices’ in this block. The important operands are words: the value named ’words’ in this block; lane: one parallel arithmetic element within a vector or tensor datapath; for: the value named ’for’ in this block. Context: the function execute, which handles execute.

Line 210: `values = [int(self.lut[index]) for index in indices]` This assigns ‘[int(self.lut[index]) for index in indices]‘ to ‘values ‘ in host memory. Here values means the value named ’values’ in this block. The important operands are lut: the value named ’lut’ in this block; index: an integer selecting one tensor element, lane, bank, or state entry; for: the value named ’for’ in this block. Context: the function execute, which handles execute.

Line 211: `result = tuple(` This statement continues through source line 215; the explanation uses the complete expression rather than only the first visual fragment. This assigns ‘tuple(sum((values[word * 4 + lane] & 0xFFFF) << (16 * lane) for lane in range(4)) for word in range(2))‘ to ‘result ‘ in host memory. Here result means the value named ’result’ in this block. The important operands are tuple: the value named ’tuple’ in this block; sum: the value named ’sum’ in this block; values: the value named ’values’ in this block. Context: the function execute, which handles execute.

Line 212: `sum((values[word * 4 + lane] & 0xFFFF) << (16 * lane)` This is continuation line 2 of the 5-line logical statement that begins at source line 211. Its exact fragment is ‘sum((values[word * 4 + lane] & 0xFFFF) << (16 * lane)‘. The important operands are sum: the value named ’sum’ in this block; values: the value named ’values’ in this block; word: the value named ’word’ in this block. Read together, the complete operation is: This assigns ‘tuple(sum((values[word * 4 + lane] & 0xFFFF) << (16 * lane) for lane in range(4)) for word in range(2))‘ to ‘result ‘ in host memory. Here result means the value named ’result’ in this block. The important operands are tuple: the value named ’tuple’ in this block; sum: the value named ’sum’ in this block; values: the value named ’values’ in this block. Context: the function execute, which handles execute.

Line 213: `for lane in range(4))` This is continuation line 3 of the 5-line logical statement that begins at source line 211. Its exact fragment is ‘for lane in range(4))‘. The important operands are for: the value named ’for’ in this block; lane: one parallel arithmetic element within a vector or tensor datapath; in: the value named ’in’ in this block. Read together, the complete operation is: This assigns ‘tuple(sum((values[word * 4 + lane] & 0xFFFF) << (16 * lane) for lane in range(4)) for word in range(2))‘ to ‘result ‘ in host memory. Here result means the value named ’result’ in this block. The important operands are tuple: the value named ’tuple’ in this block; sum: the value named ’sum’ in this block; values: the value named ’values’ in this block. Context: the function execute, which handles execute.

Line 214: `for word in range(2)` This is continuation line 4 of the 5-line logical statement that begins at source line 211. Its exact fragment is ‘for word in range(2)‘. The important operands are for: the value named ’for’ in this block; word: the value named ’word’ in this block; in: the value named ’in’ in this block. Read together, the complete operation is: This assigns ‘tuple(sum((values[word * 4 + lane] & 0xFFFF) << (16 * lane) for lane in range(4)) for word in range(2))‘ to ‘result ‘ in host memory. Here result means the value named ’result’ in this block. The important operands are tuple: the value named ’tuple’ in this block; sum: the value named ’sum’ in this block; values: the value named ’values’ in this block. Context: the function execute, which handles execute.

Line 215: `)` This is continuation line 5 of the 5-line logical statement that begins at source line 211. Its exact fragment is ‘)‘. The expression is a literal or structural operator and has no hidden software state. Read together, the complete operation is: This assigns ‘tuple(sum((values[word * 4 + lane] & 0xFFFF) << (16 * lane) for lane in range(4)) for word in range(2))‘ to ‘result ‘ in host memory. Here result means the value named ’result’ in this block. The important operands are tuple: the value named ’tuple’ in this block; sum: the value named ’sum’ in this block; values: the value named ’values’ in this block. Context: the function execute, which handles execute.

Line 216: `else:` This begins the alternative host-code branch when the preceding condition was false, still inside the function execute, which handles execute.

Line 217: `self.lut.fill(0)` This calls ‘self.lut.fill‘ with ‘0‘ inside the function execute, which handles execute. The call advances the host-side job that checks neuraedge training behavior independently with Python assertions.

Line 218: `result = ()` This assigns '()' to 'result ' in host memory. Here result means the value named 'result' in this block. The expression is a literal or structural operator and has no hidden software state. Context: the function execute, which handles execute.

Line 219: `elif command.opcode == Opcode.VECTOR_ALU:` This executes the following indented host-code branch only when 'command.opcode == Opcode.VECTOR_ALU' is true. The important operands are command: the 128-bit instruction selecting an engine, shape, mode, and numeric parameters; opcode: the value named 'opcode' in this block; Opcode: the value named 'opcode' in this block. Context: the function execute, which handles execute.

Line 220: `operation = VectorOperation((command.value >> 4) & 0xF)` This assigns 'VectorOperation((command.value >> 4) & 0xF)' to 'operation ' in host memory. Here operation means the value named 'operation' in this block. The important operands are VectorOperation: the value named 'vector operation' in this block; command: the 128-bit instruction selecting an engine, shape, mode, and numeric parameters; value: the value named 'value' in this block. Context: the function execute, which handles execute.

Line 221: `multiplier = _signed(command.value >> 8, 16)` This assigns '_signed(command.value >> 8, 16)' to 'multiplier ' in host memory. Here multiplier means the value named 'multiplier' in this block. The important operands are _signed: the value named 'signed' in this block; command: the 128-bit instruction selecting an engine, shape, mode, and numeric parameters; value: the value named 'value' in this block. Context: the function execute, which handles execute.

Line 222: `shift_bits = (command.value >> 24) & 0x1F` This assigns '(command.value >> 24) & 0x1F' to 'shift_bits ' in host memory. Here shift_bits means the value named 'shift bits' in this block. The important operands are command: the 128-bit instruction selecting an engine, shape, mode, and numeric parameters; value: the value named 'value' in this block. Context: the function execute, which handles execute.

Line 223: `right_shift = _signed(shift_bits, 5) if operation == VectorOperation.FLEX_REQUANTIZE else shift_bits` Inside the function execute, which handles execute, this statement advances the host implementation that checks neuraedge training behavior independently with Python assertions. The important operands are right_shift: the value named 'right shift' in this block; _signed: the value named 'signed' in this block; shift_bits: the value named 'shift bits' in this block.

Line 224: `output_zero_point = _signed(command.value >> 29, 16)` This assigns '_signed(command.value >> 29, 16)' to 'output_zero_point ' in host memory. Here output_zero_point means the integer code representing real numeric zero in affine quantization. The important operands are _signed: the value named 'signed' in this block; command: the 128-bit instruction selecting an engine, shape, mode, and numeric parameters; value: the value named 'value' in this block. Context: the function execute, which handles execute.

Line 225: `threshold = _signed(command.value >> 45, 32)` This assigns '_signed(command.value >> 45, 32)' to 'threshold ' in host memory. Here threshold means the membrane level at which a neuron emits a spike. The important operands are _signed: the value named 'signed' in this block; command: the 128-bit instruction selecting an engine, shape, mode, and numeric parameters; value: the value named 'value' in this block. Context: the function execute, which handles execute.

Line 226: `surrogate_window = (command.value >> 77) & 0xFFFFFFFF` This assigns '(command.value >> 77) & 0xFFFFFFFF' to 'surrogate_window ' in host memory. Here surrogate_window means the value named 'surrogate window' in this block. The important operands are command: the 128-bit instruction selecting an engine, shape, mode, and numeric parameters; value: the value named 'value' in this block. Context: the function execute, which handles execute.

Line 227: `clamp_minimum = _signed(words[0], 32)` This assigns '_signed(words[0], 32)' to 'clamp_minimum ' in host memory. Here clamp_minimum means the value named 'clamp minimum' in this block. The important operands are _signed: the value named 'signed' in this block; words: the value named 'words' in this block. Context: the function execute, which handles execute.

Line 228: `clamp_maximum = _signed(words[0] >> 32, 32)` This assigns '_signed(words[0] >> 32, 32)' to 'clamp_maximum ' in host memory. Here clamp_maximum means the value named 'clamp maximum' in this block. The important operands are _signed: the value named 'signed' in this block; words: the value named 'words' in this block. Context: the function execute, which handles execute.

Line 229: `operand_a = np.array([` This statement continues through source line 232; the explanation uses the complete expression rather than only the first visual fragment. This assigns 'np.array([_signed(words[1 + lane // 2] >> (32 * (lane % 2)), 32) for lane in range(8)], dtype=np.int64)' to 'operand_a ' in host memory. Here operand_a means the value named 'operand a' in this block. The important operands are array: the value named 'array' in this block; _signed: the value named 'signed' in this block; words: the value named 'words' in this block. Context: the function execute, which handles execute.

Line 230: `_signed(words[1 + lane // 2] >> (32 * (lane % 2)), 32)` This is continuation line 2 of the 4-line logical statement that begins at source line 229. Its exact fragment is '_signed(words[1 + lane // 2] >> (32 * (lane % 2)), 32)'. The important operands are _signed: the value named 'signed' in this block; words: the value named 'words' in this block; lane: one parallel arithmetic element within a vector or tensor datapath. Read together, the complete operation is: This assigns 'np.array([_signed(words[1 + lane // 2] >> (32 * (lane % 2)), 32) for lane in range(8)], dtype=np.int64)' to 'operand_a ' in host memory. Here operand_a means the value named 'operand a' in this block. The important operands are array: the value named 'array' in this block; _signed: the value named 'signed' in this block; words: the value named 'words' in this block. Context: the function execute, which handles execute.

Line 231: `for lane in range(8)` This is continuation line 3 of the 4-line logical statement that begins at source line 229. Its exact fragment is 'for lane in range(8)'. The important operands are for: the value named 'for' in this block; lane: one parallel arithmetic element within a vector or tensor datapath; in: the value named 'in' in this block. Read together, the complete operation is: This assigns 'np.array([_signed(words[1 + lane // 2] >> (32 * (lane % 2)), 32) for lane in range(8)], dtype=np.int64)' to 'operand_a ' in host memory. Here operand_a means the value named 'operand a' in this block. The important operands are array: the value named 'array' in this block; _signed: the value named 'signed' in this block; words: the value named 'words' in this block. Context: the function execute, which handles execute.

Line 232: `], dtype=np.int64)` This is continuation line 4 of the 4-line logical statement that begins at source line 229. Its exact fragment is '], dtype=np.int64)'. The important operands are dtype: the value named 'dtype' in this block; int64: the value named 'int64' in this block. Read together, the complete operation is: This assigns 'np.array([_signed(words[1 + lane // 2] >> (32 * (lane % 2)), 32) for lane in range(8)], dtype=np.int64)' to 'operand_a ' in host memory. Here operand_a means the value named 'operand a' in this block. The important operands are array: the value named 'array' in this block; _signed: the value named 'signed' in this block; words: the value named 'words' in this block. Context: the function execute, which handles execute.

Line 233: `operand_b = np.array([` This statement continues through source line 236; the explanation uses the complete expression rather than only the first visual fragment. This assigns 'np.array([_signed(words[5 + lane // 2] >> (32 * (lane % 2)), 32) for lane in range(8)], dtype=np.int64)' to 'operand_b ' in host memory. Here operand_b means the value named 'operand b' in this block. The important operands are array: the value named 'array' in this block; _signed: the value named 'signed' in this block; words: the value named 'words' in this block. Context: the function execute, which handles execute.

Line 234: `_signed(words[5 + lane // 2] >> (32 * (lane % 2)), 32)` This is continuation line 2 of the 4-line logical statement that begins at source line 233. Its exact fragment is '_signed(words[5 + lane // 2] >> (32 * (lane % 2)), 32)'. The important operands are _signed: the value named 'signed' in this block; words: the value named 'words' in this block; lane: one parallel arithmetic element within a vector or tensor datapath. Read together, the complete operation is: This assigns 'np.array([_signed(words[5 + lane // 2] >> (32 * (lane % 2)), 32) for lane in range(8)], dtype=np.int64)' to 'operand_b ' in host memory. Here operand_b means the value named 'operand b' in this block. The important operands are array: the value named 'array' in this block; _signed: the value named 'signed' in this block; words: the value named 'words' in this block. Context: the function execute, which handles execute.

Line 235: `for lane in range(8)` This is continuation line 3 of the 4-line logical statement that begins at source line 233. Its exact fragment is 'for lane in range(8)'. The important operands are for: the value named 'for' in this block; lane: one parallel arithmetic element within a vector or tensor datapath; in: the value named 'in' in this block. Read together,

the complete operation is: This assigns ‘np.array([_signed(words[5 + lane // 2] >> (32 * (lane % 2)), 32) for lane in range(8)], dtype=np.int64)‘ to ‘operand_b ‘ in host memory. Here operand_b means the value named ’operand b’ in this block. The important operands are array: the value named ’array’ in this block; _signed: the value named ’signed’ in this block; words: the value named ’words’ in this block. Context: the function execute, which handles execute.

Line 236: `], dtype=np.int64)` This is continuation line 4 of the 4-line logical statement that begins at source line 233. Its exact fragment is ‘], dtype=np.int64)‘. The important operands are dtype: the value named ’dtype’ in this block; int64: the value named ’int64’ in this block. Read together, the complete operation is: This assigns ‘np.array([_signed(words[5 + lane // 2] >> (32 * (lane % 2)), 32) for lane in range(8)], dtype=np.int64)‘ to ‘operand_b ‘ in host memory. Here operand_b means the value named ’operand b’ in this block. The important operands are array: the value named ’array’ in this block; _signed: the value named ’signed’ in this block; words: the value named ’words’ in this block. Context: the function execute, which handles execute.

Line 237: `values = vector_alu(` This statement continues through source line 248; the explanation uses the complete expression rather than only the first visual fragment. This assigns ‘vector_alu(operation, operand_a, operand_b, multiplier_q15=multiplier, right_shift=right_shift, output_zero_point=output_zero_point, threshold=threshold, surrogate_window=surrogate_window, clamp_minimum=clamp_minimum, clamp_maximum=clamp_maximum,)‘ to ‘values ‘ in host memory. Here values means the value named ’values’ in this block. The important operands are vector_alu: the value named ’vector alu’ in this block; operation: the value named ’operation’ in this block; operand_a: the value named ’operand a’ in this block. Context: the function execute, which handles execute.

Line 238: `operation,` This is continuation line 2 of the 12-line logical statement that begins at source line 237. Its exact fragment is ‘operation,‘. The important operands are operation: the value named ’operation’ in this block. Read together, the complete operation is: This assigns ‘vector_alu(operation, operand_a, operand_b, multiplier_q15=multiplier, right_shift=right_shift, output_zero_point=output_zero_point, threshold=threshold, surrogate_window=surrogate_window, clamp_minimum=clamp_minimum, clamp_maximum=clamp_maximum,)‘ to ‘values ‘ in host memory. Here values means the value named ’values’ in this block. The important operands are vector_alu: the value named ’vector alu’ in this block; operation: the value named ’operation’ in this block; operand_a: the value named ’operand a’ in this block. Context: the function execute, which handles execute.

Line 239: `operand_a,` This is continuation line 3 of the 12-line logical statement that begins at source line 237. Its exact fragment is ‘operand_a,‘. The important operands are operand_a: the value named ’operand a’ in this block. Read together, the complete operation is: This assigns ‘vector_alu(operation, operand_a, operand_b, multiplier_q15=multiplier, right_shift=right_shift, output_zero_point=output_zero_point, threshold=threshold, surrogate_window=surrogate_window, clamp_minimum=clamp_minimum, clamp_maximum=clamp_maximum,)‘ to ‘values ‘ in host memory. Here values means the value named ’values’ in this block. The important operands are vector_alu: the value named ’vector alu’ in this block; operation: the value named ’operation’ in this block; operand_a: the value named ’operand a’ in this block. Context: the function execute, which handles execute.

Line 240: `operand_b,` This is continuation line 4 of the 12-line logical statement that begins at source line 237. Its exact fragment is ‘operand_b,‘. The important operands are operand_b: the value named ’operand b’ in this block. Read together, the complete operation is: This assigns ‘vector_alu(operation, operand_a, operand_b, multiplier_q15=multiplier, right_shift=right_shift, output_zero_point=output_zero_point, threshold=threshold, surrogate_window=surrogate_window, clamp_minimum=clamp_minimum, clamp_maximum=clamp_maximum,)‘ to ‘values ‘ in host memory. Here values means the value named ’values’ in this block. The important operands are vector_alu: the value named ’vector alu’ in this block; operation: the value named ’operation’ in this block; operand_a: the value named ’operand a’ in this block. Context: the function execute, which handles execute.

Line 241: `multiplier_q15=multiplier,` This is continuation line 5 of the 12-line logical statement that begins at source line 237. Its exact fragment is ‘multiplier_q15=multiplier,‘. The important operands are multiplier_q15: the value named ’multiplier q15’ in this block; multiplier: the value named ’multiplier’ in this block. Read together, the complete operation is: This assigns ‘vector_alu(operation, operand_a, operand_b, multiplier_q15=multiplier, right_shift=right_shift, output_zero_point=output_zero_point, threshold=threshold, surrogate_window=surrogate_window, clamp_minimum=clamp_minimum, clamp_maximum=clamp_maximum,)‘ to ‘values ‘ in host memory. Here values means the value named ’values’ in this block. The important operands are vector_alu: the value named ’vector alu’ in

this block; operation: the value named 'operation' in this block; operand_a: the value named 'operand a' in this block. Context: the function execute, which handles execute.

Line 242: `right_shift=right_shift,` This is continuation line 6 of the 12-line logical statement that begins at source line 237. Its exact fragment is 'right_shift=right_shift,'. The important operands are right_shift: the value named 'right shift' in this block. Read together, the complete operation is: This assigns 'vector_alu(operation, operand_a, operand_b, multiplier_q15=multiplier, right_shift=right_shift, output_zero_point=output_zero_point, threshold=threshold, surrogate_window=surrogate_window, clamp_minimum=clamp_minimum, clamp_maximum=clamp_maximum,)' to 'values ' in host memory. Here values means the value named 'values' in this block. The important operands are vector_alu: the value named 'vector alu' in this block; operation: the value named 'operation' in this block; operand_a: the value named 'operand a' in this block. Context: the function execute, which handles execute.

Line 243: `output_zero_point=output_zero_point,` This is continuation line 7 of the 12-line logical statement that begins at source line 237. Its exact fragment is 'output_zero_point=output_zero_point,'. The important operands are output_zero_point: the integer code representing real numeric zero in affine quantization. Read together, the complete operation is: This assigns 'vector_alu(operation, operand_a, operand_b, multiplier_q15=multiplier, right_shift=right_shift, output_zero_point=output_zero_point, threshold=threshold, surrogate_window=surrogate_window, clamp_minimum=clamp_
clamp_maximum=clamp_maximum,)' to 'values ' in host memory. Here values means the value named 'values' in this block. The important operands are vector_alu: the value named 'vector alu' in this block; operation: the value named 'operation' in this block; operand_a: the value named 'operand a' in this block. Context: the function execute, which handles execute.

Line 244: `threshold=threshold,` This is continuation line 8 of the 12-line logical statement that begins at source line 237. Its exact fragment is 'threshold=threshold,'. The important operands are threshold: the membrane level at which a neuron emits a spike. Read together, the complete operation is: This assigns 'vector_alu(operation, operand_a, operand_b, multiplier_q15=multiplier, right_shift=right_shift, output_zero_point=output_zero_point, threshold=threshold, surrogate_window=surrogate_window, clamp_minimum=clamp_minimum, clamp_maximum=clamp_max
)' to 'values ' in host memory. Here values means the value named 'values' in this block. The important operands are vector_alu: the value named 'vector alu' in this block; operation: the value named 'operation' in this block; operand_a: the value named 'operand a' in this block. Context: the function execute, which handles execute.

Line 245: `surrogate_window=surrogate_window,` This is continuation line 9 of the 12-line logical statement that begins at source line 237. Its exact fragment is 'surrogate_window=surrogate_window,'. The important operands are surrogate_window: the value named 'surrogate window' in this block. Read together, the complete operation is: This assigns 'vector_alu(operation, operand_a, operand_b, multiplier_q15=multiplier, right_shift=right_shift, output_zero_point=output_zero_point, threshold=threshold, surrogate_window=surrogate_window, clamp_minimum=clamp_min
clamp_maximum=clamp_maximum,)' to 'values ' in host memory. Here values means the value named 'values' in this block. The important operands are vector_alu: the value named 'vector alu' in this block; operation: the value named 'operation' in this block; operand_a: the value named 'operand a' in this block. Context: the function execute, which handles execute.

Line 246: `clamp_minimum=clamp_minimum,` This is continuation line 10 of the 12-line logical statement that begins at source line 237. Its exact fragment is 'clamp_minimum=clamp_minimum,'. The important operands are clamp_minimum: the value named 'clamp minimum' in this block. Read together, the complete operation is: This assigns 'vector_alu(operation, operand_a, operand_b, multiplier_q15=multiplier, right_shift=right_shift, output_zero_point=output_z
threshold=threshold, surrogate_window=surrogate_window, clamp_minimum=clamp_minimum, clamp_maximum=clamp_max
)' to 'values ' in host memory. Here values means the value named 'values' in this block. The important operands are vector_alu: the value named 'vector alu' in this block; operation: the value named 'operation' in this block; operand_a: the value named 'operand a' in this block. Context: the function execute, which handles execute.

Line 247: `clamp_maximum=clamp_maximum,` This is continuation line 11 of the 12-line logical statement that begins at source line 237. Its exact fragment is 'clamp_maximum=clamp_maximum,'. The important operands are clamp_maximum: the value named 'clamp maximum' in this block. Read together, the complete operation is: This assigns 'vector_alu(operation, operand_a, operand_b, multiplier_q15=multiplier, right_shift=right_shift, output_zero_point=outp
threshold=threshold, surrogate_window=surrogate_window, clamp_minimum=clamp_minimum, clamp_maximum=clamp_max
)' to 'values ' in host memory. Here values means the value named 'values' in this block. The important operands are

vector_alu: the value named 'vector alu' in this block; operation: the value named 'operation' in this block; operand_a: the value named 'operand a' in this block. Context: the function execute, which handles execute.

Line 248: `)` This is continuation line 12 of the 12-line logical statement that begins at source line 237. Its exact fragment is ')'. The expression is a literal or structural operator and has no hidden software state. Read together, the complete operation is: This assigns 'vector_alu(operation, operand_a, operand_b, multiplier_q15=multiplier, right_shift=right_shift, output_zero_point=output_zero_point, threshold=threshold, surrogate_window=surrogate_window, clamp_minimum=clamp_minimum, clamp_maximum=clamp_maximum,)' to 'values ' in host memory. Here values means the value named 'values' in this block. The important operands are vector_alu: the value named 'vector alu' in this block; operation: the value named 'operation' in this block; operand_a: the value named 'operand a' in this block. Context: the function execute, which handles execute.

Line 249: `result = tuple(` This statement continues through source line 253; the explanation uses the complete expression rather than only the first visual fragment. This assigns 'tuple((int(values[lane]) & 0xFFFFFFFF) | ((int(values[lane + 1]) & 0xFFFFFFFF) << 32) for lane in range(0, 8, 2))' to 'result ' in host memory. Here result means the value named 'result' in this block. The important operands are tuple: the value named 'tuple' in this block; values: the value named 'values' in this block; lane: one parallel arithmetic element within a vector or tensor datapath. Context: the function execute, which handles execute.

Line 250: `(int(values[lane]) & 0xFFFFFFFF)` This is continuation line 2 of the 5-line logical statement that begins at source line 249. Its exact fragment is '(int(values[lane]) & 0xFFFFFFFF)'. The important operands are values: the value named 'values' in this block; lane: one parallel arithmetic element within a vector or tensor datapath. Read together, the complete operation is: This assigns 'tuple((int(values[lane]) & 0xFFFFFFFF) | ((int(values[lane + 1]) & 0xFFFFFFFF) << 32) for lane in range(0, 8, 2))' to 'result ' in host memory. Here result means the value named 'result' in this block. The important operands are tuple: the value named 'tuple' in this block; values: the value named 'values' in this block; lane: one parallel arithmetic element within a vector or tensor datapath. Context: the function execute, which handles execute.

Line 251: `| ((int(values[lane + 1]) & 0xFFFFFFFF) << 32)` This is continuation line 3 of the 5-line logical statement that begins at source line 249. Its exact fragment is '| ((int(values[lane + 1]) & 0xFFFFFFFF) << 32)'. The important operands are values: the value named 'values' in this block; lane: one parallel arithmetic element within a vector or tensor datapath. Read together, the complete operation is: This assigns 'tuple((int(values[lane]) & 0xFFFFFFFF) | ((int(values[lane + 1]) & 0xFFFFFFFF) << 32) for lane in range(0, 8, 2))' to 'result ' in host memory. Here result means the value named 'result' in this block. The important operands are tuple: the value named 'tuple' in this block; values: the value named 'values' in this block; lane: one parallel arithmetic element within a vector or tensor datapath. Context: the function execute, which handles execute.

Line 252: `for lane in range(0, 8, 2)` This is continuation line 4 of the 5-line logical statement that begins at source line 249. Its exact fragment is 'for lane in range(0, 8, 2)'. The important operands are for: the value named 'for' in this block; lane: one parallel arithmetic element within a vector or tensor datapath; in: the value named 'in' in this block. Read together, the complete operation is: This assigns 'tuple((int(values[lane]) & 0xFFFFFFFF) | ((int(values[lane + 1]) & 0xFFFFFFFF) << 32) for lane in range(0, 8, 2))' to 'result ' in host memory. Here result means the value named 'result' in this block. The important operands are tuple: the value named 'tuple' in this block; values: the value named 'values' in this block; lane: one parallel arithmetic element within a vector or tensor datapath. Context: the function execute, which handles execute.

Line 253: `)` This is continuation line 5 of the 5-line logical statement that begins at source line 249. Its exact fragment is ')'. The expression is a literal or structural operator and has no hidden software state. Read together, the complete operation is: This assigns 'tuple((int(values[lane]) & 0xFFFFFFFF) | ((int(values[lane + 1]) & 0xFFFFFFFF) << 32) for lane in range(0, 8, 2))' to 'result ' in host memory. Here result means the value named 'result' in this block. The important operands are tuple: the value named 'tuple' in this block; values: the value named 'values' in this block; lane: one parallel arithmetic element within a vector or tensor datapath. Context: the function execute, which handles execute.

Line 254: `elif command.opcode == Opcode.SGD_UPDATE:` This executes the following indented host-code branch only when 'command.opcode == Opcode.SGD_UPDATE' is true. The important operands are command: the 128-bit

instruction selecting an engine, shape, mode, and numeric parameters; opcode: the value named 'opcode' in this block; Opcode: the value named 'opcode' in this block. Context: the function execute, which handles execute.

Line 255: `weights = np.array([_signed(word, 16) for word in words], dtype=np.int64)` This assigns 'np.array([_signe 16) for word in words], dtype=np.int64)' to 'weights ' in host memory. Here weights means a learned coefficient multiplied by an activation. The important operands are array: the value named 'array' in this block; _signed: the value named 'signed' in this block; word: the value named 'word' in this block. Context: the function execute, which handles execute.

Line 256: `gradients = np.array([_signed(word >> 16, 24) for word in words], dtype=np.int64)` This assigns 'np.array([_signed(word >> 16, 24) for word in words], dtype=np.int64)' to 'gradients ' in host memory. Here gradients means the signed loss derivative used to update a learned parameter. The important operands are array: the value named 'array' in this block; _signed: the value named 'signed' in this block; word: the value named 'word' in this block. Context: the function execute, which handles execute.

Line 257: `velocities = np.array([_signed(word >> 40, 24) for word in words], dtype=np.int64)` This assigns 'np.array([_signed(word >> 40, 24) for word in words], dtype=np.int64)' to 'velocities ' in host memory. Here velocities means the value named 'velocities' in this block. The important operands are array: the value named 'array' in this block; _signed: the value named 'signed' in this block; word: the value named 'word' in this block. Context: the function execute, which handles execute.

Line 258: `learning_rate = (command.value >> 4) & 0x3FFFF` This assigns '(command.value >> 4) & 0x3FFFF' to 'learning_rate ' in host memory. Here learning_rate means the fixed-point multiplier controlling update magnitude. The important operands are command: the 128-bit instruction selecting an engine, shape, mode, and numeric parameters; value: the value named 'value' in this block. Context: the function execute, which handles execute.

Line 259: `momentum = (command.value >> 22) & 0x1FFFF` This assigns '(command.value >> 22) & 0x1FFFF' to 'momentum ' in host memory. Here momentum means the value named 'momentum' in this block. The important operands are command: the 128-bit instruction selecting an engine, shape, mode, and numeric parameters; value: the value named 'value' in this block. Context: the function execute, which handles execute.

Line 260: `weight_decay = (command.value >> 39) & 0x1FFFF` This assigns '(command.value >> 39) & 0x1FFFF' to 'weight_decay ' in host memory. Here weight_decay means a learned coefficient multiplied by an activation. The important operands are command: the 128-bit instruction selecting an engine, shape, mode, and numeric parameters; value: the value named 'value' in this block. Context: the function execute, which handles execute.

Line 261: `update_right_shift = (command.value >> 56) & 0x1F` This assigns '(command.value >> 56) & 0x1F' to 'update_right_shift ' in host memory. Here update_right_shift means the value named 'update right shift' in this block. The important operands are command: the 128-bit instruction selecting an engine, shape, mode, and numeric parameters; value: the value named 'value' in this block. Context: the function execute, which handles execute.

Line 262: `updated_weight, updated_velocity = sgd_momentum_step(` This statement continues through source line 270; the explanation uses the complete expression rather than only the first visual fragment. This assigns 'sgd_momentum_step(weights, gradients, velocities, learning_rate, momentum, weight_decay, update_right_shift,)' to 'updated_weight, updated_velocity ' in host memory. Here updated_weight means a learned coefficient multiplied by an activation. The important operands are sgd_momentum_step: the value named 'sgd momentum step' in this block; weights: a learned coefficient multiplied by an activation; gradients: the signed loss derivative used to update a learned parameter. Context: the function execute, which handles execute.

Line 263: `weights,` This is continuation line 2 of the 9-line logical statement that begins at source line 262. Its exact fragment is 'weights,'. The important operands are weights: a learned coefficient multiplied by an activation. Read together, the complete operation is: This assigns 'sgd_momentum_step(weights, gradients, velocities, learning_rate, momentum, weight_decay, update_right_shift,)' to 'updated_weight, updated_velocity ' in host memory. Here updated_weight means a learned coefficient multiplied by an activation. The important operands are sgd_momentum_step: the value named 'sgd momentum step' in this block; weights: a learned coefficient multiplied by an activation; gradients: the signed loss derivative used to update a learned parameter. Context: the function execute, which handles execute.

Line 264: `gradients,` This is continuation line 3 of the 9-line logical statement that begins at source line 262. Its exact fragment is 'gradients,'. The important operands are gradients: the signed loss derivative used to update a learned parameter. Read together, the complete operation is: This assigns 'sgd_momentum_step(weights, gradients, velocities, learning_rate, momentum, weight_decay, update_right_shift,)' to 'updated_weight, updated_velocity ' in host memory. Here updated_weight means a learned coefficient multiplied by an activation. The important operands are sgd_momentum_step: the value named 'sgd momentum step' in this block; weights: a learned coefficient multiplied by an activation; gradients: the signed loss derivative used to update a learned parameter. Context: the function execute, which handles execute.

Line 265: `velocities,` This is continuation line 4 of the 9-line logical statement that begins at source line 262. Its exact fragment is 'velocities,'. The important operands are velocities: the value named 'velocities' in this block. Read together, the complete operation is: This assigns 'sgd_momentum_step(weights, gradients, velocities, learning_rate, momentum, weight_decay, update_right_shift,)' to 'updated_weight, updated_velocity ' in host memory. Here updated_weight means a learned coefficient multiplied by an activation. The important operands are sgd_momentum_step: the value named 'sgd momentum step' in this block; weights: a learned coefficient multiplied by an activation; gradients: the signed loss derivative used to update a learned parameter. Context: the function execute, which handles execute.

Line 266: `learning_rate,` This is continuation line 5 of the 9-line logical statement that begins at source line 262. Its exact fragment is 'learning_rate,'. The important operands are learning_rate: the fixed-point multiplier controlling update magnitude. Read together, the complete operation is: This assigns 'sgd_momentum_step(weights, gradients, velocities, learning_rate, momentum, weight_decay, update_right_shift,)' to 'updated_weight, updated_velocity ' in host memory. Here updated_weight means a learned coefficient multiplied by an activation. The important operands are sgd_momentum_step: the value named 'sgd momentum step' in this block; weights: a learned coefficient multiplied by an activation; gradients: the signed loss derivative used to update a learned parameter. Context: the function execute, which handles execute.

Line 267: `momentum,` This is continuation line 6 of the 9-line logical statement that begins at source line 262. Its exact fragment is 'momentum,'. The important operands are momentum: the value named 'momentum' in this block. Read together, the complete operation is: This assigns 'sgd_momentum_step(weights, gradients, velocities, learning_rate, momentum, weight_decay, update_right_shift,)' to 'updated_weight, updated_velocity ' in host memory. Here updated_weight means a learned coefficient multiplied by an activation. The important operands are sgd_momentum_step: the value named 'sgd momentum step' in this block; weights: a learned coefficient multiplied by an activation; gradients: the signed loss derivative used to update a learned parameter. Context: the function execute, which handles execute.

Line 268: `weight_decay,` This is continuation line 7 of the 9-line logical statement that begins at source line 262. Its exact fragment is 'weight_decay,'. The important operands are weight_decay: a learned coefficient multiplied by an activation. Read together, the complete operation is: This assigns 'sgd_momentum_step(weights, gradients, velocities, learning_rate, momentum, weight_decay, update_right_shift,)' to 'updated_weight, updated_velocity ' in host memory. Here updated_weight means a learned coefficient multiplied by an activation. The important operands are sgd_momentum_step: the value named 'sgd momentum step' in this block; weights: a learned coefficient multiplied by an activation; gradients: the signed loss derivative used to update a learned parameter. Context: the function execute, which handles execute.

Line 269: `update_right_shift,` This is continuation line 8 of the 9-line logical statement that begins at source line 262. Its exact fragment is 'update_right_shift,'. The important operands are update_right_shift: the value named 'update right shift' in this block. Read together, the complete operation is: This assigns 'sgd_momentum_step(weights, gradients, velocities, learning_rate, momentum, weight_decay, update_right_shift,)' to 'updated_weight, updated_velocity ' in host memory. Here updated_weight means a learned coefficient multiplied by an activation. The important operands are sgd_momentum_step: the value named 'sgd momentum step' in this block; weights: a learned coefficient multiplied by an activation; gradients: the signed loss derivative used to update a learned parameter. Context: the function execute, which handles execute.

Line 270: `)` This is continuation line 9 of the 9-line logical statement that begins at source line 262. Its exact fragment is ')'. The expression is a literal or structural operator and has no hidden software state. Read together, the complete operation is: This assigns 'sgd_momentum_step(weights, gradients, velocities, learning_rate, momentum, weight_decay, update_right_shift,)' to 'updated_weight, updated_velocity ' in host memory. Here updated_weight

means a learned coefficient multiplied by an activation. The important operands are sgd_momentum_step: the value named 'sgd momentum step' in this block; weights: a learned coefficient multiplied by an activation; gradients: the signed loss derivative used to update a learned parameter. Context: the function execute, which handles execute.

Line 271: `result = tuple(` This statement continues through source line 275; the explanation uses the complete expression rather than only the first visual fragment. This assigns 'tuple((int(updated_weight[lane]) & 0xFFFF) | ((int(updated_velocity[lane]) & 0xFFFFFF) << 16) for lane in range(8))' to 'result ' in host memory. Here result means the value named 'result' in this block. The important operands are tuple: the value named 'tuple' in this block; updated_weight: a learned coefficient multiplied by an activation; lane: one parallel arithmetic element within a vector or tensor datapath. Context: the function execute, which handles execute.

Line 272: `(int(updated_weight[lane]) & 0xFFFF)` This is continuation line 2 of the 5-line logical statement that begins at source line 271. Its exact fragment is '(int(updated_weight[lane]) & 0xFFFF)'. The important operands are updated_weight: a learned coefficient multiplied by an activation; lane: one parallel arithmetic element within a vector or tensor datapath. Read together, the complete operation is: This assigns 'tuple((int(updated_weight[lane]) & 0xFFFF) | ((int(updated_velocity[lane]) & 0xFFFFFF) << 16) for lane in range(8))' to 'result ' in host memory. Here result means the value named 'result' in this block. The important operands are tuple: the value named 'tuple' in this block; updated_weight: a learned coefficient multiplied by an activation; lane: one parallel arithmetic element within a vector or tensor datapath. Context: the function execute, which handles execute.

Line 273: `| ((int(updated_velocity[lane]) & 0xFFFFFF) << 16)` This is continuation line 3 of the 5-line logical statement that begins at source line 271. Its exact fragment is '| ((int(updated_velocity[lane]) & 0xFFFFFF) << 16)'. The important operands are updated_velocity: the momentum history retained by the SGD optimizer; lane: one parallel arithmetic element within a vector or tensor datapath. Read together, the complete operation is: This assigns 'tuple((int(updated_weight[lane]) & 0xFFFF) | ((int(updated_velocity[lane]) & 0xFFFFFF) << 16) for lane in range(8))' to 'result ' in host memory. Here result means the value named 'result' in this block. The important operands are tuple: the value named 'tuple' in this block; updated_weight: a learned coefficient multiplied by an activation; lane: one parallel arithmetic element within a vector or tensor datapath. Context: the function execute, which handles execute.

Line 274: `for lane in range(8)` This is continuation line 4 of the 5-line logical statement that begins at source line 271. Its exact fragment is 'for lane in range(8)'. The important operands are for: the value named 'for' in this block; lane: one parallel arithmetic element within a vector or tensor datapath; in: the value named 'in' in this block. Read together, the complete operation is: This assigns 'tuple((int(updated_weight[lane]) & 0xFFFF) | ((int(updated_velocity[lane]) & 0xFFFFFF) << 16) for lane in range(8))' to 'result ' in host memory. Here result means the value named 'result' in this block. The important operands are tuple: the value named 'tuple' in this block; updated_weight: a learned coefficient multiplied by an activation; lane: one parallel arithmetic element within a vector or tensor datapath. Context: the function execute, which handles execute.

Line 275: `)` This is continuation line 5 of the 5-line logical statement that begins at source line 271. Its exact fragment is ')'. The expression is a literal or structural operator and has no hidden software state. Read together, the complete operation is: This assigns 'tuple((int(updated_weight[lane]) & 0xFFFF) | ((int(updated_velocity[lane]) & 0xFFFFFF) << 16) for lane in range(8))' to 'result ' in host memory. Here result means the value named 'result' in this block. The important operands are tuple: the value named 'tuple' in this block; updated_weight: a learned coefficient multiplied by an activation; lane: one parallel arithmetic element within a vector or tensor datapath. Context: the function execute, which handles execute.

Line 276: `elif command.opcode == Opcode.LOG_SOFTMAX:` This executes the following indented host-code branch only when 'command.opcode == Opcode.LOG_SOFTMAX' is true. The important operands are command: the 128-bit instruction selecting an engine, shape, mode, and numeric parameters; opcode: the value named 'opcode' in this block; Opcode: the value named 'opcode' in this block. Context: the function execute, which handles execute.

Line 277: `count = (command.value >> 4) & 0x1FF` This assigns '(command.value >> 4) & 0x1FF' to 'count ' in host memory. Here count means the value named 'count' in this block. The important operands are command: the 128-bit instruction selecting an engine, shape, mode, and numeric parameters; value: the value named 'value' in this block. Context: the function execute, which handles execute.

Line 278: `difference_shift = (command.value >> 13) & 0x1F` This assigns ‘(command.value >> 13) & 0x1F‘ to ‘difference_shift ‘ in host memory. Here difference_shift means the value named ’difference shift’ in this block. The important operands are command: the 128-bit instruction selecting an engine, shape, mode, and numeric parameters; value: the value named ’value’ in this block. Context: the function execute, which handles execute.

Line 279: `scores = np.asarray(` This statement continues through source line 280; the explanation uses the complete expression rather than only the first visual fragment. This assigns ‘np.asarray([_signed(word, 24) for word in words[:count]], dtype=np.int64)‘ to ‘scores ‘ in host memory. Here scores means the value named ’scores’ in this block. The important operands are asarray: the value named ’asarray’ in this block; _signed: the value named ’signed’ in this block; word: the value named ’word’ in this block. Context: the function execute, which handles execute.

Line 280: `[_signed(word, 24) for word in words[:count]], dtype=np.int64)` This is continuation line 2 of the 2-line logical statement that begins at source line 279. Its exact fragment is ‘[_signed(word, 24) for word in words[:count]], dtype=np.int64)‘. The important operands are _signed: the value named ’signed’ in this block; word: the value named ’word’ in this block; for: the value named ’for’ in this block. Read together, the complete operation is: This assigns ‘np.asarray([_signed(word, 24) for word in words[:count]], dtype=np.int64)‘ to ‘scores ‘ in host memory. Here scores means the value named ’scores’ in this block. The important operands are asarray: the value named ’asarray’ in this block; _signed: the value named ’signed’ in this block; word: the value named ’word’ in this block. Context: the function execute, which handles execute.

Line 281: `probabilities = log_int_softmax_q15(scores, difference_shift)` This assigns ‘log_int_softmax_q15(scores, difference_shift)‘ to ‘probabilities ‘ in host memory. Here probabilities means the value named ’probabilities’ in this block. The important operands are log_int_softmax_q15: the value named ’log int softmax q15’ in this block; scores: the value named ’scores’ in this block; difference_shift: the value named ’difference shift’ in this block. Context: the function execute, which handles execute.

Line 282: `result = tuple(` This statement continues through source line 287; the explanation uses the complete expression rather than only the first visual fragment. Inside the function execute, which handles execute, this statement advances the host implementation that checks neuraedge training behavior independently with Python assertions. The important operands are result: the value named ’result’ in this block; tuple: the value named ’tuple’ in this block; probabilities: the value named ’probabilities’ in this block.

Line 283: `int(probabilities[index])` This is continuation line 2 of the 6-line logical statement that begins at source line 282. Its exact fragment is ‘int(probabilities[index])‘. The important operands are probabilities: the value named ’probabilities’ in this block; index: an integer selecting one tensor element, lane, bank, or state entry. Read together, the complete operation is: Inside the function execute, which handles execute, this statement advances the host implementation that checks neuraedge training behavior independently with Python assertions. The important operands are result: the value named ’result’ in this block; tuple: the value named ’tuple’ in this block; probabilities: the value named ’probabilities’ in this block.

Line 284: `| (index << 16)` This is continuation line 3 of the 6-line logical statement that begins at source line 282. Its exact fragment is ‘| (index << 16)‘. The important operands are index: an integer selecting one tensor element, lane, bank, or state entry. Read together, the complete operation is: Inside the function execute, which handles execute, this statement advances the host implementation that checks neuraedge training behavior independently with Python assertions. The important operands are result: the value named ’result’ in this block; tuple: the value named ’tuple’ in this block; probabilities: the value named ’probabilities’ in this block.

Line 285: `| (int(index == count - 1) << 25)` This is continuation line 4 of the 6-line logical statement that begins at source line 282. Its exact fragment is ‘| (int(index == count - 1) << 25)‘. The important operands are index: an integer selecting one tensor element, lane, bank, or state entry; count: the value named ’count’ in this block. Read together, the complete operation is: Inside the function execute, which handles execute, this statement advances the host implementation that checks neuraedge training behavior independently with Python assertions. The important operands are result: the value named ’result’ in this block; tuple: the value named ’tuple’ in this block; probabilities: the value named ’probabilities’ in this block.

Line 286: `for index in range(count)` This is continuation line 5 of the 6-line logical statement that begins at source line 282. Its exact fragment is 'for index in range(count)'. The important operands are for: the value named 'for' in this block; index: an integer selecting one tensor element, lane, bank, or state entry; in: the value named 'in' in this block. Read together, the complete operation is: Inside the function execute, which handles execute, this statement advances the host implementation that checks neuraedge training behavior independently with Python assertions. The important operands are result: the value named 'result' in this block; tuple: the value named 'tuple' in this block; probabilities: the value named 'probabilities' in this block.

Line 287: `)` This is continuation line 6 of the 6-line logical statement that begins at source line 282. Its exact fragment is ')'. The expression is a literal or structural operator and has no hidden software state. Read together, the complete operation is: Inside the function execute, which handles execute, this statement advances the host implementation that checks neuraedge training behavior independently with Python assertions. The important operands are result: the value named 'result' in this block; tuple: the value named 'tuple' in this block; probabilities: the value named 'probabilities' in this block.

Line 288: `elif command.opcode == Opcode.LIF_STEP:` This executes the following indented host-code branch only when 'command.opcode == Opcode.LIF_STEP' is true. The important operands are command: the 128-bit instruction selecting an engine, shape, mode, and numeric parameters; opcode: the value named 'opcode' in this block; Opcode: the value named 'opcode' in this block. Context: the function execute, which handles execute.

Line 289: `leak_shift = (command.value >> 4) & 0x1F` This assigns '(command.value >> 4) & 0x1F' to 'leak_shift ' in host memory. Here leak_shift means the retained fraction of prior membrane state. The important operands are command: the 128-bit instruction selecting an engine, shape, mode, and numeric parameters; value: the value named 'value' in this block. Context: the function execute, which handles execute.

Line 290: `threshold = _signed(command.value >> 9, 24)` This assigns '_signed(command.value >> 9, 24)' to 'threshold ' in host memory. Here threshold means the membrane level at which a neuron emits a spike. The important operands are _signed: the value named 'signed' in this block; command: the 128-bit instruction selecting an engine, shape, mode, and numeric parameters; value: the value named 'value' in this block. Context: the function execute, which handles execute.

Line 291: `reset = _signed(command.value >> 33, 24)` This assigns '_signed(command.value >> 33, 24)' to 'reset ' in host memory. Here reset means the value named 'reset' in this block. The important operands are _signed: the value named 'signed' in this block; command: the 128-bit instruction selecting an engine, shape, mode, and numeric parameters; value: the value named 'value' in this block. Context: the function execute, which handles execute.

Line 292: `if (command.value >> 57) & 1:` This executes the following indented host-code branch only when '(command.value >> 57) & 1' is true. The important operands are command: the 128-bit instruction selecting an engine, shape, mode, and numeric parameters; value: the value named 'value' in this block. Context: the function execute, which handles execute.

Line 293: `self.lif_membrane.fill(reset)` This calls 'self.lif_membrane.fill' with 'reset' inside the function execute, which handles execute. The call advances the host-side job that checks neuraedge training behavior independently with Python assertions.

Line 294: `self.lif_timestep = 0` This assigns '0' to 'self.lif_timestep ' in host memory. Here lif_timestep means one discrete SNN update instant. The expression is a literal or structural operator and has no hidden software state. Context: the function execute, which handles execute.

Line 295: `currents = np.asarray([` This statement continues through source line 298; the explanation uses the complete expression rather than only the first visual fragment. This assigns 'np.asarray([_signed(word >> (16 * lane), 16) for word in words for lane in range(4)], dtype=np.int64)' to 'currents ' in host memory. Here currents means the value named 'currents' in this block. The important operands are asarray: the value named 'asarray' in this block; _signed: the value named 'signed' in this block; word: the value named 'word' in this block. Context: the function execute, which handles execute.

Line 296: `_signed(word >> (16 * lane), 16)` This is continuation line 2 of the 4-line logical statement that begins at source line 295. Its exact fragment is '_signed(word >> (16 * lane), 16)'. The important operands are _signed: the value named 'signed' in this block; word: the value named 'word' in this block; lane: one parallel arithmetic element within a vector or tensor datapath. Read together, the complete operation is: This assigns 'np.asarray([_signed(word >> (16 * lane), 16) for word in words for lane in range(4)], dtype=np.int64)' to 'currents ' in host memory. Here currents means the value named 'currents' in this block. The important operands are asarray: the value named 'asarray' in this block; _signed: the value named 'signed' in this block; word: the value named 'word' in this block. Context: the function execute, which handles execute.

Line 297: `for word in words for lane in range(4)` This is continuation line 3 of the 4-line logical statement that begins at source line 295. Its exact fragment is 'for word in words for lane in range(4)'. The important operands are for: the value named 'for' in this block; word: the value named 'word' in this block; in: the value named 'in' in this block. Read together, the complete operation is: This assigns 'np.asarray([_signed(word >> (16 * lane), 16) for word in words for lane in range(4)], dtype=np.int64)' to 'currents ' in host memory. Here currents means the value named 'currents' in this block. The important operands are asarray: the value named 'asarray' in this block; _signed: the value named 'signed' in this block; word: the value named 'word' in this block. Context: the function execute, which handles execute.

Line 298: `], dtype=np.int64)` This is continuation line 4 of the 4-line logical statement that begins at source line 295. Its exact fragment is '], dtype=np.int64)'. The important operands are dtype: the value named 'dtype' in this block; int64: the value named 'int64' in this block. Read together, the complete operation is: This assigns 'np.asarray([_signed(word >> (16 * lane), 16) for word in words for lane in range(4)], dtype=np.int64)' to 'currents ' in host memory. Here currents means the value named 'currents' in this block. The important operands are asarray: the value named 'asarray' in this block; _signed: the value named 'signed' in this block; word: the value named 'word' in this block. Context: the function execute, which handles execute.

Line 299: `self.lif_membrane = saturate_signed(` This statement continues through source line 302; the explanation uses the complete expression rather than only the first visual fragment. This assigns 'saturate_signed(self.lif_membrane - (self.lif_membrane >> leak_shift) + currents, 24,)' to 'self.lif_membrane ' in host memory. Here lif_membrane means the persistent LIF neuron state carrying charge between timesteps. The important operands are saturate_signed: the value named 'saturate signed' in this block; lif_membrane: the persistent LIF neuron state carrying charge between timesteps; leak_shift: the retained fraction of prior membrane state. Context: the function execute, which handles execute.

Line 300: `self.lif_membrane - (self.lif_membrane >> leak_shift) + currents,` This is continuation line 2 of the 4-line logical statement that begins at source line 299. Its exact fragment is 'self.lif_membrane - (self.lif_membrane >> leak_shift) + currents,'. The important operands are lif_membrane: the persistent LIF neuron state carrying charge between timesteps; leak_shift: the retained fraction of prior membrane state; currents: the value named 'currents' in this block. Read together, the complete operation is: This assigns 'saturate_signed(self.lif_membrane - (self.lif_membrane >> leak_shift) + currents, 24,)' to 'self.lif_membrane ' in host memory. Here lif_membrane means the persistent LIF neuron state carrying charge between timesteps. The important operands are saturate_signed: the value named 'saturate signed' in this block; lif_membrane: the persistent LIF neuron state carrying charge between timesteps; leak_shift: the retained fraction of prior membrane state. Context: the function execute, which handles execute.

Line 301: `24,` This is continuation line 3 of the 4-line logical statement that begins at source line 299. Its exact fragment is '24,'. The expression is a literal or structural operator and has no hidden software state. Read together, the complete operation is: This assigns 'saturate_signed(self.lif_membrane - (self.lif_membrane >> leak_shift) + currents, 24,)' to 'self.lif_membrane ' in host memory. Here lif_membrane means the persistent LIF neuron state carrying charge between timesteps. The important operands are saturate_signed: the value named 'saturate signed' in this block; lif_membrane: the persistent LIF neuron state carrying charge between timesteps; leak_shift: the retained fraction of prior membrane state. Context: the function execute, which handles execute.

Line 302: `)` This is continuation line 4 of the 4-line logical statement that begins at source line 299. Its exact fragment is ')'. The expression is a literal or structural operator and has no hidden software state. Read together, the complete operation is: This assigns 'saturate_signed(self.lif_membrane - (self.lif_membrane >> leak_shift) + currents, 24,)' to 'self.lif_membrane ' in host memory. Here lif_membrane means the persistent LIF neuron state carrying charge between timesteps. The important operands are saturate_signed: the value named 'saturate signed' in this block; lif_membrane:

the persistent LIF neuron state carrying charge between timesteps; leak_shift: the retained fraction of prior membrane state. Context: the function execute, which handles execute.

Line 303: `pre_reset = self.lif_membrane.copy()` This assigns ‘self.lif_membrane.copy()‘ to ‘pre_reset ‘ in host memory. Here pre_reset means the value named ’pre reset’ in this block. The important operands are lif_membrane: the persistent LIF neuron state carrying charge between timesteps; copy: the value named ’copy’ in this block. Context: the function execute, which handles execute.

Line 304: `fired = pre_reset >= threshold` Inside the function execute, which handles execute, this statement advances the host implementation that checks neuraedge training behavior independently with Python assertions. The important operands are fired: the value named ’fired’ in this block; pre_reset: the value named ’pre reset’ in this block; threshold: the membrane level at which a neuron emits a spike.

Line 305: `self.lif_membrane = np.where(fired, reset, pre_reset)` This assigns ‘np.where(fired, reset, pre_reset)‘ to ‘self.lif_membrane ‘ in host memory. Here lif_membrane means the persistent LIF neuron state carrying charge between timesteps. The important operands are where: the value named ’where’ in this block; fired: the value named ’fired’ in this block; reset: the value named ’reset’ in this block. Context: the function execute, which handles execute.

Line 306: `self.lif_timestep += 1` Inside the function execute, which handles execute, this statement advances the host implementation that checks neuraedge training behavior independently with Python assertions. The important operands are lif_timestep: one discrete SNN update instant.

Line 307: `spike_word = sum(int(fired[lane]) << lane for lane in range(32))` This assigns ‘sum(int(fired[lane]) << lane for lane in range(32))‘ to ‘spike_word ‘ in host memory. Here spike_word means a binary event produced when a neuron crosses its threshold. The important operands are sum: the value named ’sum’ in this block; fired: the value named ’fired’ in this block; lane: one parallel arithmetic element within a vector or tensor datapath. Context: the function execute, which handles execute.

Line 308: `output = [spike_word | (self.lif_timestep << 32)]` This assigns ‘[spike_word | (self.lif_timestep << 32)]‘ to ‘output ‘ in host memory. Here output means the value named ’output’ in this block. The important operands are spike_word: a binary event produced when a neuron crosses its threshold; lif_timestep: one discrete SNN update instant. Context: the function execute, which handles execute.

Line 309: `if (command.value >> 58) & 1:` This executes the following indented host-code branch only when ‘(command.value >> 58) & 1‘ is true. The important operands are command: the 128-bit instruction selecting an engine, shape, mode, and numeric parameters; value: the value named ’value’ in this block. Context: the function execute, which handles execute.

Line 310: `packed = sum(` This statement continues through source line 313; the explanation uses the complete expression rather than only the first visual fragment. This assigns ‘sum((int(pre_reset[lane]) & 0xFFFFFF) << (24 * lane) for lane in range(32))‘ to ‘packed ‘ in host memory. Here packed means the value named ’packed’ in this block. The important operands are sum: the value named ’sum’ in this block; pre_reset: the value named ’pre reset’ in this block; lane: one parallel arithmetic element within a vector or tensor datapath. Context: the function execute, which handles execute.

Line 311: `(int(pre_reset[lane]) & 0xFFFFFF) << (24 * lane)` This is continuation line 2 of the 4-line logical statement that begins at source line 310. Its exact fragment is ‘(int(pre_reset[lane]) & 0xFFFFFF) << (24 * lane)‘. The important operands are pre_reset: the value named ’pre reset’ in this block; lane: one parallel arithmetic element within a vector or tensor datapath. Read together, the complete operation is: This assigns ‘sum((int(pre_reset[lane]) & 0xFFFFFF) << (24 * lane) for lane in range(32))‘ to ‘packed ‘ in host memory. Here packed means the value named ’packed’ in this block. The important operands are sum: the value named ’sum’ in this block; pre_reset: the value named ’pre reset’ in this block; lane: one parallel arithmetic element within a vector or tensor datapath. Context: the function execute, which handles execute.

Line 312: `for lane in range(32)` This is continuation line 3 of the 4-line logical statement that begins at source line 310. Its exact fragment is ‘for lane in range(32)‘. The important operands are for: the value named ’for’ in this block; lane: one parallel arithmetic element within a vector or tensor datapath; in: the value named ’in’ in this block. Read together, the complete operation is: This assigns ‘sum((int(pre_reset[lane]) & 0xFFFFFF) << (24 * lane) for lane in range(32))‘ to ‘packed ‘ in host memory. Here packed means the value named ’packed’ in this block. The important operands are sum: the value named ’sum’ in this block; pre_reset: the value named ’pre reset’ in this block; lane: one parallel arithmetic element within a vector or tensor datapath. Context: the function execute, which handles execute.

Line 313: `)` This is continuation line 4 of the 4-line logical statement that begins at source line 310. Its exact fragment is ‘)‘. The expression is a literal or structural operator and has no hidden software state. Read together, the complete operation is: This assigns ‘sum((int(pre_reset[lane]) & 0xFFFFFF) << (24 * lane) for lane in range(32))‘ to ‘packed ‘ in host memory. Here packed means the value named ’packed’ in this block. The important operands are sum: the value named ’sum’ in this block; pre_reset: the value named ’pre reset’ in this block; lane: one parallel arithmetic element within a vector or tensor datapath. Context: the function execute, which handles execute.

Line 314: `output.extend(` This statement continues through source line 317; the explanation uses the complete expression rather than only the first visual fragment. This calls ‘output.extend‘ with ‘ (packed >> (64 * word)) & 0xFFFFFFFFFFFFFFFF for word in range(12) ‘ inside the function execute, which handles execute. The call advances the host-side job that checks neuraedge training behavior independently with Python assertions.

Line 315: `(packed >> (64 * word)) & 0xFFFFFFFFFFFFFFFF` This is continuation line 2 of the 4-line logical statement that begins at source line 314. Its exact fragment is ‘(packed >> (64 * word)) & 0xFFFFFFFFFFFFFFFF‘. The important operands are packed: the value named ’packed’ in this block; word: the value named ’word’ in this block. Read together, the complete operation is: This calls ‘output.extend‘ with ‘ (packed >> (64 * word)) & 0xFFFFFFFFFFFFFFFF for word in range(12) ‘ inside the function execute, which handles execute. The call advances the host-side job that checks neuraedge training behavior independently with Python assertions.

Line 316: `for word in range(12)` This is continuation line 3 of the 4-line logical statement that begins at source line 314. Its exact fragment is ‘for word in range(12)‘. The important operands are for: the value named ’for’ in this block; word: the value named ’word’ in this block; in: the value named ’in’ in this block. Read together, the complete operation is: This calls ‘output.extend‘ with ‘ (packed >> (64 * word)) & 0xFFFFFFFFFFFFFFFF for word in range(12) ‘ inside the function execute, which handles execute. The call advances the host-side job that checks neuraedge training behavior independently with Python assertions.

Line 317: `)` This is continuation line 4 of the 4-line logical statement that begins at source line 314. Its exact fragment is ‘)‘. The expression is a literal or structural operator and has no hidden software state. Read together, the complete operation is: This calls ‘output.extend‘ with ‘ (packed >> (64 * word)) & 0xFFFFFFFFFFFFFFFF for word in range(12) ‘ inside the function execute, which handles execute. The call advances the host-side job that checks neuraedge training behavior independently with Python assertions.

Line 318: `result = tuple(output)` This assigns ‘tuple(output)‘ to ‘result ‘ in host memory. Here result means the value named ’result’ in this block. The important operands are tuple: the value named ’tuple’ in this block; output: the value named ’output’ in this block. Context: the function execute, which handles execute.

Line 319: `elif command.opcode == Opcode.CLEAR_STATUS:` This executes the following indented host-code branch only when ‘command.opcode == Opcode.CLEAR_STATUS‘ is true. The important operands are command: the 128-bit instruction selecting an engine, shape, mode, and numeric parameters; opcode: the value named ’opcode’ in this block; Opcode: the value named ’opcode’ in this block. Context: the function execute, which handles execute.

Line 320: `result = ()` This assigns ‘()‘ to ‘result ‘ in host memory. Here result means the value named ’result’ in this block. The expression is a literal or structural operator and has no hidden software state. Context: the function execute, which handles execute.

Line 321: `else:` This begins the alternative host-code branch when the preceding condition was false, still inside the function execute, which handles execute.

Line 322: `raise AssertionError(f"unexpected fabric opcode {command.opcode}")` This rejects an invalid state by raising ‘AssertionError(f"unexpected fabric opcode {command.opcode}")‘. Failing before DMA prevents malformed shapes or artifacts from silently becoming hardware results.

Line 323: `if len(result) != output_beats:` This executes the following indented host-code branch only when ‘len(result) != output_beats‘ is true. The important operands are len: the value named ’len’ in this block; result: the value named ’result’ in this block; output_beats: the value named ’output beats’ in this block. Context: the function execute, which handles execute.

Line 324: `raise AssertionError(f"fabric emulator returned {len(result)} words, expected {output_beats}")` This rejects an invalid state by raising ‘AssertionError(f"fabric emulator returned {len(result)} words, expected {output_beats}")‘. Failing before DMA prevents malformed shapes or artifacts from silently becoming hardware results.

Line 325: `return result` This returns ‘result‘ to the caller of the function execute, which handles execute, ending this invocation. The important operands are result: the value named ’result’ in this block.

Line 328: `class FullTrainingEmulator:` This defines class FullTrainingEmulator, which groups data and methods for full training emulator. Instances exist in host memory and organize the flow that checks neuraedge training behavior independently with Python assertions.

Line 329: `def __init__(self) -> None:` This starts function ___init___. Its indented body performs init as part of the file that checks neuraedge training behavior independently with Python assertions; it runs only when called.

Line 330: `self.backward = BackwardRtlEmulator()` This assigns ‘BackwardRtlEmulator()‘ to ‘self.backward ‘ in host memory. Here backward means the value named ’backward’ in this block. The important operands are BackwardRtlEmulator: the value named ’backward rtl emulator’ in this block. Context: the function ___init___, which handles init.

Line 331: `self.fabric = FabricOperatorEmulator()` This assigns ‘FabricOperatorEmulator()‘ to ‘self.fabric ‘ in host memory. Here fabric means the value named ’fabric’ in this block. The important operands are FabricOperatorEmulator: the value named ’fabric operator emulator’ in this block. Context: the function ___init___, which handles init.

Line 332: `self.tensor = TensorTransactionEmulator()` This assigns ‘TensorTransactionEmulator()‘ to ‘self.tensor ‘ in host memory. Here tensor means the value named ’tensor’ in this block. The important operands are TensorTransactionEmulator: the value named ’tensor transaction emulator’ in this block. Context: the function ___init___, which handles init.

Line 334: `def execute(self, command, input_beats=(), *, output_beats=0, timeout_seconds=5.0):` This starts function execute. Its indented body performs execute as part of the file that checks neuraedge training behavior independently with Python assertions; it runs only when called.

Line 335: `if command.opcode == Opcode.TRAIN_LINEAR_BACKWARD:` This executes the following indented host-code branch only when ‘command.opcode == Opcode.TRAIN_LINEAR_BACKWARD‘ is true. The important operands are command: the 128-bit instruction selecting an engine, shape, mode, and numeric parameters; opcode: the value named ’opcode’ in this block; Opcode: the value named ’opcode’ in this block. Context: the function execute, which handles execute.

Line 336: `return self.backward.execute(` This statement continues through source line 341; the explanation uses the complete expression rather than only the first visual fragment. This returns ‘self.backward.execute(command, input_beats, output_beats=output_beats, timeout_seconds=timeout_seconds,)‘ to the caller of the function execute, which handles execute, ending this invocation. The important operands are backward: the value named ’backward’ in this block; execute: the value named ’execute’ in this block; command: the 128-bit instruction selecting an engine, shape, mode, and numeric parameters.

Line 337: `command,` This is continuation line 2 of the 6-line logical statement that begins at source line 336. Its exact fragment is 'command,'. The important operands are command: the 128-bit instruction selecting an engine, shape, mode, and numeric parameters. Read together, the complete operation is: This returns 'self.backward.execute(command, input_beats, output_beats=output_beats, timeout_seconds=timeout_seconds,)' to the caller of the function execute, which handles execute, ending this invocation. The important operands are backward: the value named 'backward' in this block; execute: the value named 'execute' in this block; command: the 128-bit instruction selecting an engine, shape, mode, and numeric parameters.

Line 338: `input_beats,` This is continuation line 3 of the 6-line logical statement that begins at source line 336. Its exact fragment is 'input_beats,'. The important operands are input_beats: the value named 'input beats' in this block. Read together, the complete operation is: This returns 'self.backward.execute(command, input_beats, output_beats=output_beats, timeout_seconds=timeout_seconds,)' to the caller of the function execute, which handles execute, ending this invocation. The important operands are backward: the value named 'backward' in this block; execute: the value named 'execute' in this block; command: the 128-bit instruction selecting an engine, shape, mode, and numeric parameters.

Line 339: `output_beats=output_beats,` This is continuation line 4 of the 6-line logical statement that begins at source line 336. Its exact fragment is 'output_beats=output_beats,'. The important operands are output_beats: the value named 'output beats' in this block. Read together, the complete operation is: This returns 'self.backward.execute(command, input_beats, output_beats=output_beats, timeout_seconds=timeout_seconds,)' to the caller of the function execute, which handles execute, ending this invocation. The important operands are backward: the value named 'backward' in this block; execute: the value named 'execute' in this block; command: the 128-bit instruction selecting an engine, shape, mode, and numeric parameters.

Line 340: `timeout_seconds=timeout_seconds,` This is continuation line 5 of the 6-line logical statement that begins at source line 336. Its exact fragment is 'timeout_seconds=timeout_seconds,'. The important operands are timeout_seconds: the value named 'timeout seconds' in this block. Read together, the complete operation is: This returns 'self.backward.execute(command, input_beats, output_beats=output_beats, timeout_seconds=timeout_seconds,)' to the caller of the function execute, which handles execute, ending this invocation. The important operands are backward: the value named 'backward' in this block; execute: the value named 'execute' in this block; command: the 128-bit instruction selecting an engine, shape, mode, and numeric parameters.

Line 341: `)` This is continuation line 6 of the 6-line logical statement that begins at source line 336. Its exact fragment is ')'. The expression is a literal or structural operator and has no hidden software state. Read together, the complete operation is: This returns 'self.backward.execute(command, input_beats, output_beats=output_beats, timeout_seconds=timeout_seconds,)' to the caller of the function execute, which handles execute, ending this invocation. The important operands are backward: the value named 'backward' in this block; execute: the value named 'execute' in this block; command: the 128-bit instruction selecting an engine, shape, mode, and numeric parameters.

Line 342: `if command.opcode in {` This line opens or closes a multi-line Python expression inside the function execute, which handles execute; the neighboring lines supply its arguments or elements.

Line 343: `Opcode.LOAD_ACTIVATIONS,` Inside the function execute, which handles execute, this statement advances the host implementation that checks neuraedge training behavior independently with Python assertions. The important operands are Opcode: the value named 'opcode' in this block; LOAD_ACTIVATIONS: an input feature value consumed by a neuron or multiply-accumulate operation.

Line 344: `Opcode.LOAD_WEIGHTS_OUTER,` Inside the function execute, which handles execute, this statement advances the host implementation that checks neuraedge training behavior independently with Python assertions. The important operands are Opcode: the value named 'opcode' in this block; LOAD_WEIGHTS_OUTER: a learned coefficient multiplied by an activation.

Line 345: `Opcode.LOAD_WEIGHTS_DOT8,` Inside the function execute, which handles execute, this statement advances the host implementation that checks neuraedge training behavior independently with Python assertions. The important operands are Opcode: the value named 'opcode' in this block; LOAD_WEIGHTS_DOT8: a learned coefficient multiplied by an activation.

Line 346: `Opcode.COMPUTE_DENSE_OUTER,` Inside the function execute, which handles execute, this statement advances the host implementation that checks neuraedge training behavior independently with Python assertions. The important operands are Opcode: the value named 'opcode' in this block; COMPUTE_DENSE_OUTER: the value named 'compute dense outer' in this block.

Line 347: `Opcode.COMPUTE_DENSE_DOT8,` Inside the function execute, which handles execute, this statement advances the host implementation that checks neuraedge training behavior independently with Python assertions. The important operands are Opcode: the value named 'opcode' in this block; COMPUTE_DENSE_DOT8: the value named 'compute dense dot8' in this block.

Line 348: `Opcode.COMPUTE_BINARY,` Inside the function execute, which handles execute, this statement advances the host implementation that checks neuraedge training behavior independently with Python assertions. The important operands are Opcode: the value named 'opcode' in this block; COMPUTE_BINARY: the value named 'compute binary' in this block.

Line 349: `Opcode.COMPUTE_TERNARY,` Inside the function execute, which handles execute, this statement advances the host implementation that checks neuraedge training behavior independently with Python assertions. The important operands are Opcode: the value named 'opcode' in this block; COMPUTE_TERNARY: the value named 'compute ternary' in this block.

Line 350: `}:` Inside the function execute, which handles execute, this statement advances the host implementation that checks neuraedge training behavior independently with Python assertions. The expression is a literal or structural operator and has no hidden software state.

Line 351: `return self.tensor.execute(` This statement continues through source line 356; the explanation uses the complete expression rather than only the first visual fragment. This returns ‘self.tensor.execute(command, input_beats, output_beats=output_beats, timeout_seconds=timeout_seconds,)‘ to the caller of the function execute, which handles execute, ending this invocation. The important operands are tensor: the value named 'tensor' in this block; execute: the value named 'execute' in this block; command: the 128-bit instruction selecting an engine, shape, mode, and numeric parameters.

Line 352: `command,` This is continuation line 2 of the 6-line logical statement that begins at source line 351. Its exact fragment is ‘command,‘. The important operands are command: the 128-bit instruction selecting an engine, shape, mode, and numeric parameters. Read together, the complete operation is: This returns ‘self.tensor.execute(command, input_beats, output_beats=output_beats, timeout_seconds=timeout_seconds,)‘ to the caller of the function execute, which handles execute, ending this invocation. The important operands are tensor: the value named 'tensor' in this block; execute: the value named 'execute' in this block; command: the 128-bit instruction selecting an engine, shape, mode, and numeric parameters.

Line 353: `input_beats,` This is continuation line 3 of the 6-line logical statement that begins at source line 351. Its exact fragment is ‘input_beats,‘. The important operands are input_beats: the value named 'input beats' in this block. Read together, the complete operation is: This returns ‘self.tensor.execute(command, input_beats, output_beats=output_beats, timeout_seconds=timeout_seconds,)‘ to the caller of the function execute, which handles execute, ending this invocation. The important operands are tensor: the value named 'tensor' in this block; execute: the value named 'execute' in this block; command: the 128-bit instruction selecting an engine, shape, mode, and numeric parameters.

Line 354: `output_beats=output_beats,` This is continuation line 4 of the 6-line logical statement that begins at source line 351. Its exact fragment is ‘output_beats=output_beats,‘. The important operands are output_beats: the value named 'output beats' in this block. Read together, the complete operation is: This returns ‘self.tensor.execute(command, input_beats, output_beats=output_beats, timeout_seconds=timeout_seconds,)‘ to the caller of the function execute, which handles execute, ending this invocation. The important operands are tensor: the value named 'tensor' in this block; execute: the value named 'execute' in this block; command: the 128-bit instruction selecting an engine, shape, mode, and numeric parameters.

Line 355: `timeout_seconds=timeout_seconds,` This is continuation line 5 of the 6-line logical statement that begins at source line 351. Its exact fragment is ‘timeout_seconds=timeout_seconds,‘. The important operands are timeout_seconds: the value named ’timeout seconds’ in this block. Read together, the complete operation is: This returns ‘self.tensor.execute(command, input_beats, output_beats=output_beats, timeout_seconds=timeout_seconds,)‘ to the caller of the function execute, which handles execute, ending this invocation. The important operands are tensor: the value named ’tensor’ in this block; execute: the value named ’execute’ in this block; command: the 128-bit instruction selecting an engine, shape, mode, and numeric parameters.

Line 356: `)` This is continuation line 6 of the 6-line logical statement that begins at source line 351. Its exact fragment is ‘)‘. The expression is a literal or structural operator and has no hidden software state. Read together, the complete operation is: This returns ‘self.tensor.execute(command, input_beats, output_beats=output_beats, timeout_seconds=timeout_seconds,)‘ to the caller of the function execute, which handles execute, ending this invocation. The important operands are tensor: the value named ’tensor’ in this block; execute: the value named ’execute’ in this block; command: the 128-bit instruction selecting an engine, shape, mode, and numeric parameters.

Line 357: `return self.fabric.execute(` This statement continues through source line 362; the explanation uses the complete expression rather than only the first visual fragment. This returns ‘self.fabric.execute(command, input_beats, output_beats=output_beats, timeout_seconds=timeout_seconds,)‘ to the caller of the function execute, which handles execute, ending this invocation. The important operands are fabric: the value named ’fabric’ in this block; execute: the value named ’execute’ in this block; command: the 128-bit instruction selecting an engine, shape, mode, and numeric parameters.

Line 358: `command,` This is continuation line 2 of the 6-line logical statement that begins at source line 357. Its exact fragment is ‘command,‘. The important operands are command: the 128-bit instruction selecting an engine, shape, mode, and numeric parameters. Read together, the complete operation is: This returns ‘self.fabric.execute(command, input_beats, output_beats=output_beats, timeout_seconds=timeout_seconds,)‘ to the caller of the function execute, which handles execute, ending this invocation. The important operands are fabric: the value named ’fabric’ in this block; execute: the value named ’execute’ in this block; command: the 128-bit instruction selecting an engine, shape, mode, and numeric parameters.

Line 359: `input_beats,` This is continuation line 3 of the 6-line logical statement that begins at source line 357. Its exact fragment is ‘input_beats,‘. The important operands are input_beats: the value named ’input beats’ in this block. Read together, the complete operation is: This returns ‘self.fabric.execute(command, input_beats, output_beats=output_beats, timeout_seconds=timeout_seconds,)‘ to the caller of the function execute, which handles execute, ending this invocation. The important operands are fabric: the value named ’fabric’ in this block; execute: the value named ’execute’ in this block; command: the 128-bit instruction selecting an engine, shape, mode, and numeric parameters.

Line 360: `output_beats=output_beats,` This is continuation line 4 of the 6-line logical statement that begins at source line 357. Its exact fragment is ‘output_beats=output_beats,‘. The important operands are output_beats: the value named ’output beats’ in this block. Read together, the complete operation is: This returns ‘self.fabric.execute(command, input_beats, output_beats=output_beats, timeout_seconds=timeout_seconds,)‘ to the caller of the function execute, which handles execute, ending this invocation. The important operands are fabric: the value named ’fabric’ in this block; execute: the value named ’execute’ in this block; command: the 128-bit instruction selecting an engine, shape, mode, and numeric parameters.

Line 361: `timeout_seconds=timeout_seconds,` This is continuation line 5 of the 6-line logical statement that begins at source line 357. Its exact fragment is ‘timeout_seconds=timeout_seconds,‘. The important operands are timeout_seconds: the value named ’timeout seconds’ in this block. Read together, the complete operation is: This returns ‘self.fabric.execute(command, input_beats, output_beats=output_beats, timeout_seconds=timeout_seconds,)‘ to the caller of the function execute, which handles execute, ending this invocation. The important operands are fabric: the value named ’fabric’ in this block; execute: the value named ’execute’ in this block; command: the 128-bit instruction selecting an engine, shape, mode, and numeric parameters.

Line 362: `)` This is continuation line 6 of the 6-line logical statement that begins at source line 357. Its exact fragment is ‘)‘. The expression is a literal or structural operator and has no hidden software state. Read together, the

complete operation is: This returns ‘self.fabric.execute(command, input_beats, output_beats=output_beats, timeout_seconds=timeout_seconds,)‘ to the caller of the function execute, which handles execute, ending this invocation. The important operands are fabric: the value named ’fabric’ in this block; execute: the value named ’execute’ in this block; command: the 128-bit instruction selecting an engine, shape, mode, and numeric parameters.

Line 364: `def execute_program(self, records, *, timeout_seconds=30.0) -> tuple[int, ...]:` This starts function execute_program. Its indented body performs execute program as part of the file that checks neuraedge training behavior independently with Python assertions; it runs only when called.

Line 365: `output: list[int] = []` This assigns ‘[]‘ to ‘output‘ in host memory. Here output means the value named ’output’ in this block. The expression is a literal or structural operator and has no hidden software state. Context: the function execute_program, which handles execute program.

Line 366: `for record in records:` This iterates record over ‘records‘. Each iteration repeats the indented host operation, commonly once per layer, tile, timestep, or test case in the function execute_program, which handles execute program.

Line 367: `output.extend(self.execute(` This statement continues through source line 372; the explanation uses the complete expression rather than only the first visual fragment. This calls ‘output.extend‘ with ‘self.execute(record.command, record.input_beats, output_beats=record.output_beats, timeout_seconds=timeout_seconds,)‘ inside the function execute_program, which handles execute program. The call advances the host-side job that checks neuraedge training behavior independently with Python assertions.

Line 368: `record.command,` This is continuation line 2 of the 6-line logical statement that begins at source line 367. Its exact fragment is ‘record.command,‘. The important operands are record: the value named ’record’ in this block; command: the 128-bit instruction selecting an engine, shape, mode, and numeric parameters. Read together, the complete operation is: This calls ‘output.extend‘ with ‘self.execute(record.command, record.input_beats, output_beats=record.output_beats, timeout_seconds=timeout_seconds,)‘ inside the function execute_program, which handles execute program. The call advances the host-side job that checks neuraedge training behavior independently with Python assertions.

Line 369: `record.input_beats,` This is continuation line 3 of the 6-line logical statement that begins at source line 367. Its exact fragment is ‘record.input_beats,‘. The important operands are record: the value named ’record’ in this block; input_beats: the value named ’input beats’ in this block. Read together, the complete operation is: This calls ‘output.extend‘ with ‘self.execute(record.command, record.input_beats, output_beats=record.output_beats, timeout_seconds=timeout_seconds,)‘ inside the function execute_program, which handles execute program. The call advances the host-side job that checks neuraedge training behavior independently with Python assertions.

Line 370: `output_beats=record.output_beats,` This is continuation line 4 of the 6-line logical statement that begins at source line 367. Its exact fragment is ‘output_beats=record.output_beats,‘. The important operands are output_beats: the value named ’output beats’ in this block; record: the value named ’record’ in this block. Read together, the complete operation is: This calls ‘output.extend‘ with ‘self.execute(record.command, record.input_beats, output_beats=record.output_beats, timeout_seconds=timeout_seconds,)‘ inside the function execute_program, which handles execute program. The call advances the host-side job that checks neuraedge training behavior independently with Python assertions.

Line 371: `timeout_seconds=timeout_seconds,` This is continuation line 5 of the 6-line logical statement that begins at source line 367. Its exact fragment is ‘timeout_seconds=timeout_seconds,‘. The important operands are timeout_seconds: the value named ’timeout seconds’ in this block. Read together, the complete operation is: This calls ‘output.extend‘ with ‘self.execute(record.command, record.input_beats, output_beats=record.output_beats, timeout_seconds=timeout_seconds,)‘ inside the function execute_program, which handles execute program. The call advances the host-side job that checks neuraedge training behavior independently with Python assertions.

Line 372: `))` This is continuation line 6 of the 6-line logical statement that begins at source line 367. Its exact fragment is ‘))‘. The expression is a literal or structural operator and has no hidden software state. Read together, the complete operation is: This calls ‘output.extend‘ with ‘self.execute(record.command, record.input_beats, output_beats=record.output_beats, timeout_seconds=timeout_seconds,)‘ inside the function execute_program, which handles execute program. The call advances the host-side job that checks neuraedge training behavior independently with Python assertions.

Line 373: `return tuple(output)` This returns ‘tuple(output)‘ to the caller of the function execute_program, which handles execute program, ending this invocation. The important operands are tuple: the value named ’tuple’ in this block; output: the value named ’output’ in this block.

Line 376: `class TrainingCompilerTests(unittest.TestCase):` This defines class TrainingCompilerTests, which groups data and methods for training compiler tests. Instances exist in host memory and organize the flow that checks neuraedge training behavior independently with Python assertions.

Line 377: `def setUp(self) -> None:` This starts function setUp. Its indented body performs set up as part of the file that checks neuraedge training behavior independently with Python assertions; it runs only when called.

Line 378: `self.rng = np.random.default_rng(20260713)` This assigns ‘np.random.default_rng(20260713)‘ to ‘self.rng ‘ in host memory. Here rng means the value named ’rng’ in this block. The important operands are random: the value named ’random’ in this block; default_rng: the value named ’default rng’ in this block. Context: the function setUp, which handles set up.

Line 380: `def test_arbitrary_linear_shape_uses_exact_two_pass_accumulation(self) -> None:` This starts function test_arbitrary_linear_shape_uses_exact_two_pass_accumulation. Its indented body performs test arbitrary linear shape uses exact two pass accumulation as part of the file that checks neuraedge training behavior independently with Python assertions; it runs only when called.

Line 381: `x = self.rng.integers(-128, 128, size=(13, 11), dtype=np.int64)` This assigns ‘self.rng.integers(-128, 128, size=(13, 11), dtype=np.int64)‘ to ‘x ‘ in host memory. Here x means the value named ’x’ in this block. The important operands are rng: the value named ’rng’ in this block; integers: the value named ’integers’ in this block; size: the value named ’size’ in this block. Context: the function test_arbitrary_linear_shape_uses_exact_two_pass_accumulation, which handles test arbitrary linear shape uses exact two pass accumulation.

Line 382: `w = self.rng.integers(-32768, 32768, size=(11, 17), dtype=np.int64)` This assigns ‘self.rng.integers(-32768, 32768, size=(11, 17), dtype=np.int64)‘ to ‘w ‘ in host memory. Here w means the value named ’w’ in this block. The important operands are rng: the value named ’rng’ in this block; integers: the value named ’integers’ in this block; size: the value named ’size’ in this block. Context: the function test_arbitrary_linear_shape_uses_exact_two_pass_accumulation, which handles test arbitrary linear shape uses exact two pass accumulation.

Line 383: `dy = self.rng.integers(-32768, 32768, size=(13, 17), dtype=np.int64)` This assigns ‘self.rng.integers(-32768, 32768, size=(13, 17), dtype=np.int64)‘ to ‘dy ‘ in host memory. Here dy means the value named ’dy’ in this block. The important operands are rng: the value named ’rng’ in this block; integers: the value named ’integers’ in this block; size: the value named ’size’ in this block. Context: the function test_arbitrary_linear_shape_uses_exact_two_pass_accumulation which handles test arbitrary linear shape uses exact two pass accumulation.

Line 384: `program = compile_linear_backward(` This statement continues through source line 390; the explanation uses the complete expression rather than only the first visual fragment. This assigns ‘compile_linear_backward(x, w, dy, input_gradient_shift=4, weight_gradient_shift=3,)‘ to ‘program ‘ in host memory. Here program means the value named ’program’ in this block. The important operands are compile_linear_backward: the value named ’compile linear backward’ in this block; x: the value named ’x’ in this block; w: the value named ’w’ in this block. Context: the function test_arbitrary_linear_shape_uses_exact_two_pass_accumulation, which handles test arbitrary linear shape uses exact two pass accumulation.

Line 385: `x,` This is continuation line 2 of the 7-line logical statement that begins at source line 384. Its exact fragment is ‘x,‘. The important operands are x: the value named ’x’ in this block. Read together, the complete operation is: This assigns ‘compile_linear_backward(x, w, dy, input_gradient_shift=4, weight_gradient_shift=3,)‘ to ‘program ‘ in host memory. Here program means the value named ’program’ in this block. The important operands are compile_linear_backward: the value named ’compile linear backward’ in this block; x: the value named ’x’ in this block; w: the value named ’w’ in this block. Context: the function test_arbitrary_linear_shape_uses_exact_two_pass_accumulation, which handles test arbitrary linear shape uses exact two pass accumulation.

Line 386: `w,` This is continuation line 3 of the 7-line logical statement that begins at source line 384. Its exact fragment is ‘w,‘. The important operands are w: the value named ’w’ in this block. Read together, the complete operation is: This assigns ‘compile_linear_backward(x, w, dy, input_gradient_shift=4, weight_gradient_shift=3,)‘ to ‘program ‘ in host memory. Here program means the value named ’program’ in this block. The important operands are compile_linear_backward: the value named ’compile linear backward’ in this block; x: the value named ’x’ in this block; w: the value named ’w’ in this block. Context: the function test_arbitrary_linear_shape_uses_exact_two_pass_accumulation, which handles test arbitrary linear shape uses exact two pass accumulation.

Line 387: `dy,` This is continuation line 4 of the 7-line logical statement that begins at source line 384. Its exact fragment is ‘dy,‘. The important operands are dy: the value named ’dy’ in this block. Read together, the complete operation is: This assigns ‘compile_linear_backward(x, w, dy, input_gradient_shift=4, weight_gradient_shift=3,)‘ to ‘program ‘ in host memory. Here program means the value named ’program’ in this block. The important operands are compile_linear_backward: the value named ’compile linear backward’ in this block; x: the value named ’x’ in this block; w: the value named ’w’ in this block. Context: the function test_arbitrary_linear_shape_uses_exact_two_pass_accumulation, which handles test arbitrary linear shape uses exact two pass accumulation.

Line 388: `input_gradient_shift=4,` This is continuation line 5 of the 7-line logical statement that begins at source line 384. Its exact fragment is ‘input_gradient_shift=4,‘. The important operands are input_gradient_shift: the signed loss derivative used to update a learned parameter. Read together, the complete operation is: This assigns ‘compile_linear_backward(x, w, dy, input_gradient_shift=4, weight_gradient_shift=3,)‘ to ‘program ‘ in host memory. Here program means the value named ’program’ in this block. The important operands are compile_linear_backward: the value named ’compile linear backward’ in this block; x: the value named ’x’ in this block; w: the value named ’w’ in this block. Context: the function test_arbitrary_linear_shape_uses_exact_two_pass_accumulation, which handles test arbitrary linear shape uses exact two pass accumulation.

Line 389: `weight_gradient_shift=3,` This is continuation line 6 of the 7-line logical statement that begins at source line 384. Its exact fragment is ‘weight_gradient_shift=3,‘. The important operands are weight_gradient_shift: a learned coefficient multiplied by an activation. Read together, the complete operation is: This assigns ‘compile_linear_backward(x, w, dy, input_gradient_shift=4, weight_gradient_shift=3,)‘ to ‘program ‘ in host memory. Here program means the value named ’program’ in this block. The important operands are compile_linear_backward: the value named ’compile linear backward’ in this block; x: the value named ’x’ in this block; w: the value named ’w’ in this block. Context: the function test_arbitrary_linear_shape_uses_exact_two_pass_accumulation, which handles test arbitrary linear shape uses exact two pass accumulation.

Line 390: `)` This is continuation line 7 of the 7-line logical statement that begins at source line 384. Its exact fragment is ‘)‘. The expression is a literal or structural operator and has no hidden software state. Read together, the complete operation is: This assigns ‘compile_linear_backward(x, w, dy, input_gradient_shift=4, weight_gradient_shift=3,)‘ to ‘program ‘ in host memory. Here program means the value named ’program’ in this block. The important operands are compile_linear_backward: the value named ’compile linear backward’ in this block; x: the value named ’x’ in this block; w: the value named ’w’ in this block. Context: the function test_arbitrary_linear_shape_uses_exact_two_pass_accumulation, which handles test arbitrary linear shape uses exact two pass accumulation.

Line 391: `self.assertEqual(program.shape, (13, 11, 17))` This calls ‘self.assertEqual‘ with ‘program.shape, (13, 11, 17)‘ inside the function test_arbitrary_linear_shape_uses_exact_two_pass_accumulation, which handles test arbitrary linear shape uses exact two pass accumulation. The call advances the host-side job that checks neuraedge training behavior independently with Python assertions.

Line 392: `self.assertEqual(program.partial_tile_count, 24)` This calls ‘self.assertEqual‘ with ‘program.partial_tile_coun 24‘ inside the function test_arbitrary_linear_shape_uses_exact_two_pass_accumulation, which handles test arbitrary linear shape uses exact two pass accumulation. The call advances the host-side job that checks neuraedge training behavior independently with Python assertions.

Line 393: `self.assertEqual(program.mathematical_multiplications, 2 * 13 * 11 * 17)` This calls ‘self.assertEqual‘ with ‘program.mathematical_multiplications, 2 * 13 * 11 * 17‘ inside the function test_arbitrary_linear_shape_uses_exact_two_p which handles test arbitrary linear shape uses exact two pass accumulation. The call advances the host-side job that checks neuraedge training behavior independently with Python assertions.

Line 394: `self.assertEqual(sum(` This statement continues through source line 397; the explanation uses the complete expression rather than only the first visual fragment. This calls ‘self.assertEqual‘ with ‘sum(instruction.mode == LinearGradientMode.INPUT for instruction in program.instructions), 12‘ inside the function test_arbitrary_linear_shape_uses_ex which handles test arbitrary linear shape uses exact two pass accumulation. The call advances the host-side job that checks neuraedge training behavior independently with Python assertions.

Line 395: `instruction.mode == LinearGradientMode.INPUT` This is continuation line 2 of the 4-line logical statement that begins at source line 394. Its exact fragment is ‘instruction.mode == LinearGradientMode.INPUT‘. The important operands are instruction: the value named ’instruction’ in this block; mode: the value named ’mode’ in this block; LinearGradientMode: the signed loss derivative used to update a learned parameter. Read together, the complete operation is: This calls ‘self.assertEqual‘ with ‘sum(instruction.mode == LinearGradientMode.INPUT for instruction in program.instructions), 12‘ inside the function test_arbitrary_linear_shape_uses_exact_two_pass_accumulation, which handles test arbitrary linear shape uses exact two pass accumulation. The call advances the host-side job that checks neuraedge training behavior independently with Python assertions.

Line 396: `for instruction in program.instructions` This is continuation line 3 of the 4-line logical statement that begins at source line 394. Its exact fragment is ‘for instruction in program.instructions‘. The important operands are for: the value named ’for’ in this block; instruction: the value named ’instruction’ in this block; in: the value named ’in’ in this block. Read together, the complete operation is: This calls ‘self.assertEqual‘ with ‘sum(instruction.mode == LinearGradientMode.INPUT for instruction in program.instructions), 12‘ inside the function test_arbitrary_linear_shape_uses_exact_two_ which handles test arbitrary linear shape uses exact two pass accumulation. The call advances the host-side job that checks neuraedge training behavior independently with Python assertions.

Line 397: `), 12)` This is continuation line 4 of the 4-line logical statement that begins at source line 394. Its exact fragment is ‘), 12)‘. The expression is a literal or structural operator and has no hidden software state. Read together, the complete operation is: This calls ‘self.assertEqual‘ with ‘sum(instruction.mode == LinearGradientMode.INPUT for instruction in program.instructions), 12‘ inside the function test_arbitrary_linear_shape_uses_exact_two_pass_accumulation, which handles test arbitrary linear shape uses exact two pass accumulation. The call advances the host-side job that checks neuraedge training behavior independently with Python assertions.

Line 398: `self.assertEqual(sum(` This statement continues through source line 401; the explanation uses the complete expression rather than only the first visual fragment. This calls ‘self.assertEqual‘ with ‘sum(instruction.mode == LinearGradientMode.WEIGHT for instruction in program.instructions), 12‘ inside the function test_arbitrary_linear_shape_uses_ which handles test arbitrary linear shape uses exact two pass accumulation. The call advances the host-side job that checks neuraedge training behavior independently with Python assertions.

Line 399: `instruction.mode == LinearGradientMode.WEIGHT` This is continuation line 2 of the 4-line logical statement that begins at source line 398. Its exact fragment is ‘instruction.mode == LinearGradientMode.WEIGHT‘. The important operands are instruction: the value named ’instruction’ in this block; mode: the value named ’mode’ in this block; LinearGradientMode: the signed loss derivative used to update a learned parameter. Read together, the complete operation is: This calls ‘self.assertEqual‘ with ‘sum(instruction.mode == LinearGradientMode.WEIGHT for instruction in program.instructions), 12‘ inside the function test_arbitrary_linear_shape_uses_exact_two_pass_accumulation, which handles test arbitrary linear shape uses exact two pass accumulation. The call advances the host-side job that checks neuraedge training behavior independently with Python assertions.

Line 400: `for instruction in program.instructions` This is continuation line 3 of the 4-line logical statement that begins at source line 398. Its exact fragment is 'for instruction in program.instructions'. The important operands are for: the value named 'for' in this block; instruction: the value named 'instruction' in this block; in: the value named 'in' in this block. Read together, the complete operation is: This calls 'self.assertEqual' with 'sum(instruction.mode == LinearGradientMode.WEIGHT for instruction in program.instructions), 12' inside the function test_arbitrary_linear_shape_uses_exact_two which handles test arbitrary linear shape uses exact two pass accumulation. The call advances the host-side job that checks neuraedge training behavior independently with Python assertions.

Line 401: `), 12)` This is continuation line 4 of the 4-line logical statement that begins at source line 398. Its exact fragment is '), 12)'. The expression is a literal or structural operator and has no hidden software state. Read together, the complete operation is: This calls 'self.assertEqual' with 'sum(instruction.mode == LinearGradientMode.WEIGHT for instruction in program.instructions), 12' inside the function test_arbitrary_linear_shape_uses_exact_two_pass_accumulation, which handles test arbitrary linear shape uses exact two pass accumulation. The call advances the host-side job that checks neuraedge training behavior independently with Python assertions.

Line 402: `for instruction in program.instructions:` This iterates instruction over 'program.instructions'. Each iteration repeats the indented host operation, commonly once per layer, tile, timestep, or test case in the function test_arbitrary_linear_shape_uses_exact_two_pass_accumulation, which handles test arbitrary linear shape uses exact two pass accumulation.

Line 403: `self.assertEqual(` This statement continues through source line 406; the explanation uses the complete expression rather than only the first visual fragment. This calls 'self.assertEqual' with ' instruction.record.output_beats == 0, instruction.suppress_output, ' inside the function test_arbitrary_linear_shape_uses_exact_two_pass_accumulation, which handles test arbitrary linear shape uses exact two pass accumulation. The call advances the host-side job that checks neuraedge training behavior independently with Python assertions.

Line 404: `instruction.record.output_beats == 0,` This is continuation line 2 of the 4-line logical statement that begins at source line 403. Its exact fragment is 'instruction.record.output_beats == 0,'. The important operands are instruction: the value named 'instruction' in this block; record: the value named 'record' in this block; output_beats: the value named 'output beats' in this block. Read together, the complete operation is: This calls 'self.assertEqual' with ' instruction.record.output_beats == 0, instruction.suppress_output, ' inside the function test_arbitrary_linear_shape_uses_exact_t which handles test arbitrary linear shape uses exact two pass accumulation. The call advances the host-side job that checks neuraedge training behavior independently with Python assertions.

Line 405: `instruction.suppress_output,` This is continuation line 3 of the 4-line logical statement that begins at source line 403. Its exact fragment is 'instruction.suppress_output,'. The important operands are instruction: the value named 'instruction' in this block; suppress_output: the value named 'suppress output' in this block. Read together, the complete operation is: This calls 'self.assertEqual' with ' instruction.record.output_beats == 0, instruction.suppress_output, ' inside the function test_arbitrary_linear_shape_uses_exact_two_pass_accumulation, which handles test arbitrary linear shape uses exact two pass accumulation. The call advances the host-side job that checks neuraedge training behavior independently with Python assertions.

Line 406: `)` This is continuation line 4 of the 4-line logical statement that begins at source line 403. Its exact fragment is ')'. The expression is a literal or structural operator and has no hidden software state. Read together, the complete operation is: This calls 'self.assertEqual' with ' instruction.record.output_beats == 0, instruction.suppress_output, ' inside the function test_arbitrary_linear_shape_uses_exact_two_pass_accumulation, which handles test arbitrary linear shape uses exact two pass accumulation. The call advances the host-side job that checks neuraedge training behavior independently with Python assertions.

Line 407: `self.assertEqual(` This statement continues through source line 410; the explanation uses the complete expression rather than only the first visual fragment. This calls 'self.assertEqual' with ' bool((instruction.record.command.value >> 28) & 1), instruction.accumulate, ' inside the function test_arbitrary_linear_shape_uses_exact_two_pass_accumulation, which handles test arbitrary linear shape uses exact two pass accumulation. The call advances the host-side job that checks neuraedge training behavior independently with Python assertions.

Line 408: `bool((instruction.record.command.value >> 28) & 1),` This is continuation line 2 of the 4-line logical statement that begins at source line 407. Its exact fragment is 'bool((instruction.record.command.value >> 28) & 1),'. The important operands are bool: the value named 'bool' in this block; instruction: the value named 'instruction' in this block; record: the value named 'record' in this block. Read together, the complete operation is: This calls 'self.assertEqual' with ' bool((instruction.record.command.value >> 28) & 1), instruction.accumulate, ' inside the function test_arbitrary_linear_shape_uses_exact_two_pass_accumulation, which handles test arbitrary linear shape uses exact two pass accumulation. The call advances the host-side job that checks neuraedge training behavior independently with Python assertions.

Line 409: `instruction.accumulate,` This is continuation line 3 of the 4-line logical statement that begins at source line 407. Its exact fragment is 'instruction.accumulate,'. The important operands are instruction: the value named 'instruction' in this block; accumulate: the value named 'accumulate' in this block. Read together, the complete operation is: This calls 'self.assertEqual' with ' bool((instruction.record.command.value >> 28) & 1), instruction.accumulate, ' inside the function test_arbitrary_linear_shape_uses_exact_two_pass_accumulation, which handles test arbitrary linear shape uses exact two pass accumulation. The call advances the host-side job that checks neuraedge training behavior independently with Python assertions.

Line 410: `)` This is continuation line 4 of the 4-line logical statement that begins at source line 407. Its exact fragment is ')'. The expression is a literal or structural operator and has no hidden software state. Read together, the complete operation is: This calls 'self.assertEqual' with ' bool((instruction.record.command.value >> 28) & 1), instruction.accumulate, ' inside the function test_arbitrary_linear_shape_uses_exact_two_pass_accumulation, which handles test arbitrary linear shape uses exact two pass accumulation. The call advances the host-side job that checks neuraedge training behavior independently with Python assertions.

Line 412: `expected_dx = saturate_signed(round_shift_signed(dy @ w.T, 4), 32)` This assigns 'saturate_signed(round_ @ w.T, 4), 32)' to 'expected_dx ' in host memory. Here expected_dx means the value named 'expected dx' in this block. The important operands are saturate_signed: the value named 'saturate signed' in this block; round_shift_signed: the value named 'round shift signed' in this block; dy: the value named 'dy' in this block. Context: the function test_arbitrary_linear_shape_uses_exact_two_pass_accumulation, which handles test arbitrary linear shape uses exact two pass accumulation.

Line 413: `expected_dw = saturate_signed(round_shift_signed(x.T @ dy, 3), 24)` This assigns 'saturate_signed(round_ @ dy, 3), 24)' to 'expected_dw ' in host memory. Here expected_dw means the value named 'expected dw' in this block. The important operands are saturate_signed: the value named 'saturate signed' in this block; round_shift_signed: the value named 'round shift signed' in this block; x: the value named 'x' in this block. Context: the function test_arbitrary_linear_shape_uses_exact_two_pass_accumulation, which handles test arbitrary linear shape uses exact two pass accumulation.

Line 414: `got_dx, got_dw = program.execute(BackwardRtlEmulator())` This assigns 'program.execute(BackwardRtlEmulat to 'got_dx, got_dw ' in host memory. Here got_dx means the value named 'got dx' in this block. The important operands are program: the value named 'program' in this block; execute: the value named 'execute' in this block; BackwardRtlEmulator: the value named 'backward rtl emulator' in this block. Context: the function test_arbitrary_linear_shape_uses_exact_two_ which handles test arbitrary linear shape uses exact two pass accumulation.

Line 415: `np.testing.assert_array_equal(got_dx, expected_dx)` This calls 'np.testing.assert_array_equal' with 'got_dx, expected_dx' inside the function test_arbitrary_linear_shape_uses_exact_two_pass_accumulation, which handles test arbitrary linear shape uses exact two pass accumulation. The call advances the host-side job that checks neuraedge training behavior independently with Python assertions.

Line 416: `np.testing.assert_array_equal(got_dw, expected_dw)` This calls 'np.testing.assert_array_equal' with 'got_dw, expected_dw' inside the function test_arbitrary_linear_shape_uses_exact_two_pass_accumulation, which handles test arbitrary linear shape uses exact two pass accumulation. The call advances the host-side job that checks neuraedge training behavior independently with Python assertions.

Line 417: `got_dx, got_dw = program.execute_batched(BackwardRtlEmulator())` This assigns ‘program.execute_batched(B to ‘got_dx, got_dw ‘ in host memory. Here got_dx means the value named ’got dx’ in this block. The important operands are program: the value named ’program’ in this block; execute_batched: the value named ’execute batched’ in this block; BackwardRtlEmulator: the value named ’backward rtl emulator’ in this block. Context: the function test_arbitrary_linear_shape_uses_exact_two_pass_accumulation, which handles test arbitrary linear shape uses exact two pass accumulation.

Line 418: `np.testing.assert_array_equal(got_dx, expected_dx)` This calls ‘np.testing.assert_array_equal‘ with ‘got_dx, expected_dx‘ inside the function test_arbitrary_linear_shape_uses_exact_two_pass_accumulation, which handles test arbitrary linear shape uses exact two pass accumulation. The call advances the host-side job that checks neuraedge training behavior independently with Python assertions.

Line 419: `np.testing.assert_array_equal(got_dw, expected_dw)` This calls ‘np.testing.assert_array_equal‘ with ‘got_dw, expected_dw‘ inside the function test_arbitrary_linear_shape_uses_exact_two_pass_accumulation, which handles test arbitrary linear shape uses exact two pass accumulation. The call advances the host-side job that checks neuraedge training behavior independently with Python assertions.

Line 421: `def test_affine_augmentation_returns_exact_bias_gradient(self) -> None:` This starts function test_affine_augmentation_returns_exact_bias_gradient. Its indented body performs test affine augmentation returns exact bias gradient as part of the file that checks neuraedge training behavior independently with Python assertions; it runs only when called.

Line 422: `x = self.rng.integers(-32, 33, size=(9, 10), dtype=np.int64)` This assigns ‘self.rng.integers(-32, 33, size=(9, 10), dtype=np.int64)‘ to ‘x ‘ in host memory. Here x means the value named ’x’ in this block. The important operands are rng: the value named ’rng’ in this block; integers: the value named ’integers’ in this block; size: the value named ’size’ in this block. Context: the function test_affine_augmentation_returns_exact_bias_gradient, which handles test affine augmentation returns exact bias gradient.

Line 423: `w = self.rng.integers(-2000, 2001, size=(10, 7), dtype=np.int64)` This assigns ‘self.rng.integers(-2000, 2001, size=(10, 7), dtype=np.int64)‘ to ‘w ‘ in host memory. Here w means the value named ’w’ in this block. The important operands are rng: the value named ’rng’ in this block; integers: the value named ’integers’ in this block; size: the value named ’size’ in this block. Context: the function test_affine_augmentation_returns_exact_bias_gradient, which handles test affine augmentation returns exact bias gradient.

Line 424: `bias = self.rng.integers(-3000, 3001, size=7, dtype=np.int64)` This assigns ‘self.rng.integers(-3000, 3001, size=7, dtype=np.int64)‘ to ‘bias ‘ in host memory. Here bias means an additive learned offset applied after accumulation. The important operands are rng: the value named ’rng’ in this block; integers: the value named ’integers’ in this block; size: the value named ’size’ in this block. Context: the function test_affine_augmentation_returns_exact_bias_gradient which handles test affine augmentation returns exact bias gradient.

Line 425: `dy = self.rng.integers(-1000, 1001, size=(9, 7), dtype=np.int64)` This assigns ‘self.rng.integers(-1000, 1001, size=(9, 7), dtype=np.int64)‘ to ‘dy ‘ in host memory. Here dy means the value named ’dy’ in this block. The important operands are rng: the value named ’rng’ in this block; integers: the value named ’integers’ in this block; size: the value named ’size’ in this block. Context: the function test_affine_augmentation_returns_exact_bias_gradient, which handles test affine augmentation returns exact bias gradient.

Line 426: `program = compile_affine_backward(` This statement continues through source line 433; the explanation uses the complete expression rather than only the first visual fragment. This assigns ‘compile_affine_backward(x, w, bias, dy, input_gradient_shift=2, weight_gradient_shift=1,)‘ to ‘program ‘ in host memory. Here program means the value named ’program’ in this block. The important operands are compile_affine_backward: the value named ’compile affine backward’ in this block; x: the value named ’x’ in this block; w: the value named ’w’ in this block. Context: the function test_affine_augmentation_returns_exact_bias_gradient, which handles test affine augmentation returns exact bias gradient.

Line 427: `x,` This is continuation line 2 of the 8-line logical statement that begins at source line 426. Its exact fragment is ‘x,‘. The important operands are x: the value named ’x’ in this block. Read together, the complete operation is: This assigns ‘compile_affine_backward(x, w, bias, dy, input_gradient_shift=2, weight_gradient_shift=1,)‘ to ‘program ‘ in host memory. Here program means the value named ’program’ in this block. The important operands are compile_affine_backward: the value named ’compile affine backward’ in this block; x: the value named ’x’ in this block; w: the value named ’w’ in this block. Context: the function test_affine_augmentation_returns_exact_bias_gradient, which handles test affine augmentation returns exact bias gradient.

Line 428: `w,` This is continuation line 3 of the 8-line logical statement that begins at source line 426. Its exact fragment is ‘w,‘. The important operands are w: the value named ’w’ in this block. Read together, the complete operation is: This assigns ‘compile_affine_backward(x, w, bias, dy, input_gradient_shift=2, weight_gradient_shift=1,)‘ to ‘program ‘ in host memory. Here program means the value named ’program’ in this block. The important operands are compile_affine_backward: the value named ’compile affine backward’ in this block; x: the value named ’x’ in this block; w: the value named ’w’ in this block. Context: the function test_affine_augmentation_returns_exact_bias_gradient, which handles test affine augmentation returns exact bias gradient.

Line 429: `bias,` This is continuation line 4 of the 8-line logical statement that begins at source line 426. Its exact fragment is ‘bias,‘. The important operands are bias: an additive learned offset applied after accumulation. Read together, the complete operation is: This assigns ‘compile_affine_backward(x, w, bias, dy, input_gradient_shift=2, weight_gradient_shift=1,)‘ to ‘program ‘ in host memory. Here program means the value named ’program’ in this block. The important operands are compile_affine_backward: the value named ’compile affine backward’ in this block; x: the value named ’x’ in this block; w: the value named ’w’ in this block. Context: the function test_affine_augmentation_returns_exact_ which handles test affine augmentation returns exact bias gradient.

Line 430: `dy,` This is continuation line 5 of the 8-line logical statement that begins at source line 426. Its exact fragment is ‘dy,‘. The important operands are dy: the value named ’dy’ in this block. Read together, the complete operation is: This assigns ‘compile_affine_backward(x, w, bias, dy, input_gradient_shift=2, weight_gradient_shift=1,)‘ to ‘program ‘ in host memory. Here program means the value named ’program’ in this block. The important operands are compile_affine_backward: the value named ’compile affine backward’ in this block; x: the value named ’x’ in this block; w: the value named ’w’ in this block. Context: the function test_affine_augmentation_returns_exact_bias_gradient, which handles test affine augmentation returns exact bias gradient.

Line 431: `input_gradient_shift=2,` This is continuation line 6 of the 8-line logical statement that begins at source line 426. Its exact fragment is ‘input_gradient_shift=2,‘. The important operands are input_gradient_shift: the signed loss derivative used to update a learned parameter. Read together, the complete operation is: This assigns ‘compile_affine_backward(x, w, bias, dy, input_gradient_shift=2, weight_gradient_shift=1,)‘ to ‘program ‘ in host memory. Here program means the value named ’program’ in this block. The important operands are compile_affine_backward: the value named ’compile affine backward’ in this block; x: the value named ’x’ in this block; w: the value named ’w’ in this block. Context: the function test_affine_augmentation_returns_exact_bias_gradient, which handles test affine augmentation returns exact bias gradient.

Line 432: `weight_gradient_shift=1,` This is continuation line 7 of the 8-line logical statement that begins at source line 426. Its exact fragment is ‘weight_gradient_shift=1,‘. The important operands are weight_gradient_shift: a learned coefficient multiplied by an activation. Read together, the complete operation is: This assigns ‘compile_affine_backward(x, w, bias, dy, input_gradient_shift=2, weight_gradient_shift=1,)‘ to ‘program ‘ in host memory. Here program means the value named ’program’ in this block. The important operands are compile_affine_backward: the value named ’compile affine backward’ in this block; x: the value named ’x’ in this block; w: the value named ’w’ in this block. Context: the function test_affine_augmentation_returns_exact_bias_gradient, which handles test affine augmentation returns exact bias gradient.

Line 433: `)` This is continuation line 8 of the 8-line logical statement that begins at source line 426. Its exact fragment is ‘)‘. The expression is a literal or structural operator and has no hidden software state. Read together, the complete operation is: This assigns ‘compile_affine_backward(x, w, bias, dy, input_gradient_shift=2, weight_gradient_shift=1,)‘ to ‘program ‘ in host memory. Here program means the value named ’program’ in this block. The important operands are compile_affine_backward: the value named ’compile affine backward’ in this block; x: the value named ’x’ in this block;

w: the value named 'w' in this block. Context: the function test_affine_augmentation_returns_exact_bias_gradient, which handles test affine augmentation returns exact bias gradient.

Line 434: `got_dx, got_dw, got_db = program.execute_batched(BackwardRtlEmulator())` This assigns 'program.execute_ to 'got_dx, got_dw, got_db ' in host memory. Here got_dx means the value named 'got dx' in this block. The important operands are program: the value named 'program' in this block; execute_batched: the value named 'execute batched' in this block; BackwardRtlEmulator: the value named 'backward rtl emulator' in this block. Context: the function test_affine_augmentation_returns_exact_bias_gradient, which handles test affine augmentation returns exact bias gradient.

Line 435: `np.testing.assert_array_equal(` This statement continues through source line 438; the explanation uses the complete expression rather than only the first visual fragment. This calls 'np.testing.assert_array_equal' with ' got_dx, saturate_signed(round_shift_signed(dy @ w.T, 2), 32), ' inside the function test_affine_augmentation_returns_exact_bia which handles test affine augmentation returns exact bias gradient. The call advances the host-side job that checks neuraedge training behavior independently with Python assertions.

Line 436: `got_dx,` This is continuation line 2 of the 4-line logical statement that begins at source line 435. Its exact fragment is 'got_dx,'. The important operands are got_dx: the value named 'got dx' in this block. Read together, the complete operation is: This calls 'np.testing.assert_array_equal' with ' got_dx, saturate_signed(round_shift_signed(dy @ w.T, 2), 32), ' inside the function test_affine_augmentation_returns_exact_bias_gradient, which handles test affine augmentation returns exact bias gradient. The call advances the host-side job that checks neuraedge training behavior independently with Python assertions.

Line 437: `saturate_signed(round_shift_signed(dy @ w.T, 2), 32),` This is continuation line 3 of the 4-line logical statement that begins at source line 435. Its exact fragment is 'saturate_signed(round_shift_signed(dy @ w.T, 2), 32),'. The important operands are saturate_signed: the value named 'saturate signed' in this block; round_shift_signed: the value named 'round shift signed' in this block; dy: the value named 'dy' in this block. Read together, the complete operation is: This calls 'np.testing.assert_array_equal' with ' got_dx, saturate_signed(round_shift_signed(dy @ w.T, 2), 32), ' inside the function test_affine_augmentation_returns_exact_bias_gradient, which handles test affine augmentation returns exact bias gradient. The call advances the host-side job that checks neuraedge training behavior independently with Python assertions.

Line 438: `)` This is continuation line 4 of the 4-line logical statement that begins at source line 435. Its exact fragment is ')'. The expression is a literal or structural operator and has no hidden software state. Read together, the complete operation is: This calls 'np.testing.assert_array_equal' with ' got_dx, saturate_signed(round_shift_signed(dy @ w.T, 2), 32), ' inside the function test_affine_augmentation_returns_exact_bias_gradient, which handles test affine augmentation returns exact bias gradient. The call advances the host-side job that checks neuraedge training behavior independently with Python assertions.

Line 439: `np.testing.assert_array_equal(` This statement continues through source line 442; the explanation uses the complete expression rather than only the first visual fragment. This calls 'np.testing.assert_array_equal' with ' got_dw, saturate_signed(round_shift_signed(x.T @ dy, 1), 24), ' inside the function test_affine_augmentation_returns_exact_bia which handles test affine augmentation returns exact bias gradient. The call advances the host-side job that checks neuraedge training behavior independently with Python assertions.

Line 440: `got_dw,` This is continuation line 2 of the 4-line logical statement that begins at source line 439. Its exact fragment is 'got_dw,'. The important operands are got_dw: the value named 'got dw' in this block. Read together, the complete operation is: This calls 'np.testing.assert_array_equal' with ' got_dw, saturate_signed(round_shift_signed(x.T @ dy, 1), 24), ' inside the function test_affine_augmentation_returns_exact_bias_gradient, which handles test affine augmentation returns exact bias gradient. The call advances the host-side job that checks neuraedge training behavior independently with Python assertions.

Line 441: `saturate_signed(round_shift_signed(x.T @ dy, 1), 24),` This is continuation line 3 of the 4-line logical statement that begins at source line 439. Its exact fragment is 'saturate_signed(round_shift_signed(x.T @ dy, 1), 24),'. The important operands are saturate_signed: the value named 'saturate signed' in this block; round_shift_signed:

the value named 'round shift signed' in this block; x: the value named 'x' in this block. Read together, the complete operation is: This calls 'np.testing.assert_array_equal' with ' got_dw, saturate_signed(round_shift_signed(x.T @ dy, 1), 24), ' inside the function test_affine_augmentation_returns_exact_bias_gradient, which handles test affine augmentation returns exact bias gradient. The call advances the host-side job that checks neuraedge training behavior independently with Python assertions.

Line 442: `)` This is continuation line 4 of the 4-line logical statement that begins at source line 439. Its exact fragment is ')'. The expression is a literal or structural operator and has no hidden software state. Read together, the complete operation is: This calls 'np.testing.assert_array_equal' with ' got_dw, saturate_signed(round_shift_signed(x.T @ dy, 1), 24), ' inside the function test_affine_augmentation_returns_exact_bias_gradient, which handles test affine augmentation returns exact bias gradient. The call advances the host-side job that checks neuraedge training behavior independently with Python assertions.

Line 443: `np.testing.assert_array_equal(` This statement continues through source line 446; the explanation uses the complete expression rather than only the first visual fragment. This calls 'np.testing.assert_array_equal' with ' got_db, saturate_signed(round_shift_signed(dy.sum(axis=0), 1), 24), ' inside the function test_affine_augmentation_returns_exa which handles test affine augmentation returns exact bias gradient. The call advances the host-side job that checks neuraedge training behavior independently with Python assertions.

Line 444: `got_db,` This is continuation line 2 of the 4-line logical statement that begins at source line 443. Its exact fragment is 'got_db,'. The important operands are got_db: the value named 'got db' in this block. Read together, the complete operation is: This calls 'np.testing.assert_array_equal' with ' got_db, saturate_signed(round_shift_signed(dy.sum(axis= 1), 24), ' inside the function test_affine_augmentation_returns_exact_bias_gradient, which handles test affine augmentation returns exact bias gradient. The call advances the host-side job that checks neuraedge training behavior independently with Python assertions.

Line 445: `saturate_signed(round_shift_signed(dy.sum(axis=0), 1), 24),` This is continuation line 3 of the 4-line logical statement that begins at source line 443. Its exact fragment is 'saturate_signed(round_shift_signed(dy.sum(axis=0), 1), 24),'. The important operands are saturate_signed: the value named 'saturate signed' in this block; round_shift_signed: the value named 'round shift signed' in this block; dy: the value named 'dy' in this block. Read together, the complete operation is: This calls 'np.testing.assert_array_equal' with ' got_db, saturate_signed(round_shift_signed(dy.sum(axis=0), 1), 24), ' inside the function test_affine_augmentation_returns_exact_bias_gradient, which handles test affine augmentation returns exact bias gradient. The call advances the host-side job that checks neuraedge training behavior independently with Python assertions.

Line 446: `)` This is continuation line 4 of the 4-line logical statement that begins at source line 443. Its exact fragment is ')'. The expression is a literal or structural operator and has no hidden software state. Read together, the complete operation is: This calls 'np.testing.assert_array_equal' with ' got_db, saturate_signed(round_shift_signed(dy.sum(axis=0), 1), 24), ' inside the function test_affine_augmentation_returns_exact_bias_gradient, which handles test affine augmentation returns exact bias gradient. The call advances the host-side job that checks neuraedge training behavior independently with Python assertions.

Line 448: `def test_grouped_convolution_backward_and_fabric_col2im(self) -> None:` This starts function test_grouped_convolution_backward_and_fabric_col2im. Its indented body performs test grouped convolution backward and fabric col2im as part of the file that checks neuraedge training behavior independently with Python assertions; it runs only when called.

Line 449: `x = self.rng.integers(-8, 9, size=(1, 4, 4, 5), dtype=np.int64)` This assigns 'self.rng.integers(-8, 9, size=(1, 4, 4, 5), dtype=np.int64)' to 'x ' in host memory. Here x means the value named 'x' in this block. The important operands are rng: the value named 'rng' in this block; integers: the value named 'integers' in this block; size: the value named 'size' in this block. Context: the function test_grouped_convolution_backward_and_fabric_col2im, which handles test grouped convolution backward and fabric col2im.

Line 450: `w = self.rng.integers(-20, 21, size=(4, 2, 3, 3), dtype=np.int64)` This assigns 'self.rng.integers(-20, 21, size=(4, 2, 3, 3), dtype=np.int64)' to 'w ' in host memory. Here w means the value named 'w' in this block. The

important operands are rng: the value named 'rng' in this block; integers: the value named 'integers' in this block; size: the value named 'size' in this block. Context: the function test_grouped_convolution_backward_and_fabric_col2im, which handles test grouped convolution backward and fabric col2im.

Line 451: `bias = self.rng.integers(-30, 31, size=4, dtype=np.int64)` This assigns 'self.rng.integers(-30, 31, size=4, dtype=np.int64)' to 'bias ' in host memory. Here bias means an additive learned offset applied after accumulation. The important operands are rng: the value named 'rng' in this block; integers: the value named 'integers' in this block; size: the value named 'size' in this block. Context: the function test_grouped_convolution_backward_and_fabric_col2im, which handles test grouped convolution backward and fabric col2im.

Line 452: `dy = self.rng.integers(-12, 13, size=(1, 4, 2, 3), dtype=np.int64)` This assigns 'self.rng.integers(-12, 13, size=(1, 4, 2, 3), dtype=np.int64)' to 'dy ' in host memory. Context: the function test_grouped_convolution_backward_and_fabric_col2im, which handles test grouped convolution backward and fabric col2im.

Line 455: `w,` This is continuation line 3 of the 9-line logical statement that begins at source line 453. Its exact fragment is 'w,'. The important operands are w: the value named 'w' in this block. Read together, the complete operation is: This assigns 'compile_conv2d_backward(x, w, bias, dy, stride=2, padding=1, groups=2,)' to 'program ' in host memory. Here program means the value named 'program' in this block. The important operands are compile_conv2d_backward: the value named 'compile conv2d backward' in this block; x: the value named 'x' in this block; w: the value named 'w' in this block. Context: the function test_grouped_convolution_backward_and_fabric_col2im, which handles test grouped convolution backward and fabric col2im.

Line 456: `bias,` This is continuation line 4 of the 9-line logical statement that begins at source line 453. Its exact fragment is 'bias,'. The important operands are bias: an additive learned offset applied after accumulation. Read together, the complete operation is: This assigns 'compile_conv2d_backward(x, w, bias, dy, stride=2, padding=1, groups=2,)' to 'program ' in host memory. Here program means the value named 'program' in this block. The important operands are compile_conv2d_backward: the value named 'compile conv2d backward' in this block; x: the value named 'x' in this block; w: the value named 'w' in this block. Context: the function test_grouped_convolution_backward_and_fabric_col2im, which handles test grouped convolution backward and fabric col2im.

Line 457: `dy,` This is continuation line 5 of the 9-line logical statement that begins at source line 453. Its exact fragment is 'dy,'. The important operands are dy: the value named 'dy' in this block. Read together, the complete operation is: This assigns 'compile_conv2d_backward(x, w, bias, dy, stride=2, padding=1, groups=2,)' to 'program ' in host memory. Here program means the value named 'program' in this block. The important operands are compile_conv2d_backward: the value named 'compile conv2d backward' in this block; x: the value named 'x' in this block; w: the value named 'w' in this block. Context: the function test_grouped_convolution_backward_and_fabric_col2im, which handles test grouped convolution backward and fabric col2im.

Line 458: `stride=2,` This is continuation line 6 of the 9-line logical statement that begins at source line 453. Its exact fragment is ‘stride=2,‘. The important operands are stride: the value named ’stride’ in this block. Read together, the complete operation is: This assigns ‘compile_conv2d_backward(x, w, bias, dy, stride=2, padding=1, groups=2,)‘ to ‘program ‘ in host memory. Here program means the value named ’program’ in this block. The important operands are compile_conv2d_backward: the value named ’compile conv2d backward’ in this block; x: the value named ’x’ in this block; w: the value named ’w’ in this block. Context: the function test_grouped_convolution_backward_and_fabric_col2im, which handles test grouped convolution backward and fabric col2im.

Line 459: `padding=1,` This is continuation line 7 of the 9-line logical statement that begins at source line 453. Its exact fragment is ‘padding=1,‘. The important operands are padding: the value named ’padding’ in this block. Read together, the complete operation is: This assigns ‘compile_conv2d_backward(x, w, bias, dy, stride=2, padding=1, groups=2,)‘ to ‘program ‘ in host memory. Here program means the value named ’program’ in this block. The important operands are compile_conv2d_backward: the value named ’compile conv2d backward’ in this block; x: the value named ’x’ in this block; w: the value named ’w’ in this block. Context: the function test_grouped_convolution_backward_and_fabric_col2im, which handles test grouped convolution backward and fabric col2im.

Line 460: `groups=2,` This is continuation line 8 of the 9-line logical statement that begins at source line 453. Its exact fragment is ‘groups=2,‘. The important operands are groups: the value named ’groups’ in this block. Read together, the complete operation is: This assigns ‘compile_conv2d_backward(x, w, bias, dy, stride=2, padding=1, groups=2,)‘ to ‘program ‘ in host memory. Here program means the value named ’program’ in this block. The important operands are compile_conv2d_backward: the value named ’compile conv2d backward’ in this block; x: the value named ’x’ in this block; w: the value named ’w’ in this block. Context: the function test_grouped_convolution_backward_and_fabric_col2im, which handles test grouped convolution backward and fabric col2im.

Line 461: `)` This is continuation line 9 of the 9-line logical statement that begins at source line 453. Its exact fragment is ‘)‘. The expression is a literal or structural operator and has no hidden software state. Read together, the complete operation is: This assigns ‘compile_conv2d_backward(x, w, bias, dy, stride=2, padding=1, groups=2,)‘ to ‘program ‘ in host memory. Here program means the value named ’program’ in this block. The important operands are compile_conv2d_backward: the value named ’compile conv2d backward’ in this block; x: the value named ’x’ in this block; w: the value named ’w’ in this block. Context: the function test_grouped_convolution_backward_and_fabric_col2im, which handles test grouped convolution backward and fabric col2im.

Line 462: `self.assertEqual(program.output_shape, (1, 4, 2, 3))` This calls ‘self.assertEqual‘ with ‘program.output_shap (1, 4, 2, 3)‘ inside the function test_grouped_convolution_backward_and_fabric_col2im, which handles test grouped convolution backward and fabric col2im. The call advances the host-side job that checks neuraedge training behavior independently with Python assertions.

Line 463: `self.assertEqual(program.partial_tile_count, 12)` This calls ‘self.assertEqual‘ with ‘program.partial_tile_coun 12‘ inside the function test_grouped_convolution_backward_and_fabric_col2im, which handles test grouped convolution backward and fabric col2im. The call advances the host-side job that checks neuraedge training behavior independently with Python assertions.

Line 464: `got_dx, got_dw, got_db = program.execute_batched(FullTrainingEmulator())` This assigns ‘program.execute_batched(FullTrainingEmulator())‘ to ‘got_dx, got_dw, got_db ‘ in host memory. Here got_dx means the value named ’got dx’ in this block. The important operands are program: the value named ’program’ in this block; execute_batched: the value named ’execute batched’ in this block; FullTrainingEmulator: the value named ’full training emulator’ in this block. Context: the function test_grouped_convolution_backward_and_fabric_col2im, which handles test grouped convolution backward and fabric col2im.

Line 466: `expected_dx = np.zeros_like(x)` This assigns ‘np.zeros_like(x)‘ to ‘expected_dx ‘ in host memory. Here expected_dx means the value named ’expected dx’ in this block. The important operands are zeros_like: the value named ’zeros like’ in this block; x: the value named ’x’ in this block. Context: the function test_grouped_convolution_backward_and_fabr which handles test grouped convolution backward and fabric col2im.

Line 467: `expected_dw = np.zeros_like(w)` This assigns ‘np.zeros_like(w)‘ to ‘expected_dw ‘ in host memory. Here expected_dw means the value named ’expected dw’ in this block. The important operands are zeros_like: the value named ’zeros like’ in this block; w: the value named ’w’ in this block. Context: the function test_grouped_convolution_backward_a which handles test grouped convolution backward and fabric col2im.

Line 468: `expected_db = np.zeros_like(bias)` This assigns ‘np.zeros_like(bias)‘ to ‘expected_db ‘ in host memory. Here expected_db means the value named ’expected db’ in this block. The important operands are zeros_like: the value named ’zeros like’ in this block; bias: an additive learned offset applied after accumulation. Context: the function test_grouped_convolution_backward_and_fabric_col2im, which handles test grouped convolution backward and fabric col2im.

Line 469: `for output_channel in range(4):` This iterates output_channel over ‘range(4)‘. Each iteration repeats the indented host operation, commonly once per layer, tile, timestep, or test case in the function test_grouped_convolution_backwar which handles test grouped convolution backward and fabric col2im.

Line 470: `group = output_channel // 2` This assigns ‘output_channel // 2‘ to ‘group ‘ in host memory. Here group means the value named ’group’ in this block. The important operands are output_channel: the value named ’output channel’ in this block. Context: the function test_grouped_convolution_backward_and_fabric_col2im, which handles test grouped convolution backward and fabric col2im.

Line 471: `input_start = group * 2` This assigns ‘group * 2‘ to ‘input_start ‘ in host memory. Here input_start means the value named ’input start’ in this block. The important operands are group: the value named ’group’ in this block. Context: the function test_grouped_convolution_backward_and_fabric_col2im, which handles test grouped convolution backward and fabric col2im.

Line 472: `for output_y in range(2):` This iterates output_y over ‘range(2)‘. Each iteration repeats the indented host operation, commonly once per layer, tile, timestep, or test case in the function test_grouped_convolution_backward_and_fabri which handles test grouped convolution backward and fabric col2im.

Line 473: `for output_x in range(3):` This iterates output_x over ‘range(3)‘. Each iteration repeats the indented host operation, commonly once per layer, tile, timestep, or test case in the function test_grouped_convolution_backward_and_fabri which handles test grouped convolution backward and fabric col2im.

Line 474: `gradient = int(dy[0, output_channel, output_y, output_x])` This assigns ‘int(dy[0, output_channel, output_y, output_x])‘ to ‘gradient ‘ in host memory. Here gradient means the signed loss derivative used to update a learned parameter. The important operands are dy: the value named ’dy’ in this block; output_channel: the value named ’output channel’ in this block; output_y: the value named ’output y’ in this block. Context: the function test_grouped_convolution_backward_and_fabric_col2im, which handles test grouped convolution backward and fabric col2im.

Line 475: `expected_db[output_channel] += gradient` Inside the function test_grouped_convolution_backward_and_fabric which handles test grouped convolution backward and fabric col2im, this statement advances the host implementation that checks neuraedge training behavior independently with Python assertions. The important operands are expected_db: the value named ’expected db’ in this block; output_channel: the value named ’output channel’ in this block; gradient: the signed loss derivative used to update a learned parameter.

Line 476: `for local_input in range(2):` This iterates local_input over ‘range(2)‘. Each iteration repeats the indented host operation, commonly once per layer, tile, timestep, or test case in the function test_grouped_convolution_backward_an which handles test grouped convolution backward and fabric col2im.

Line 477: `for kernel_y in range(3):` This iterates kernel_y over ‘range(3)‘. Each iteration repeats the indented host operation, commonly once per layer, tile, timestep, or test case in the function test_grouped_convolution_backward_and_fabri which handles test grouped convolution backward and fabric col2im.

Line 478: `input_y = output_y * 2 - 1 + kernel_y` This assigns ‘output_y * 2 - 1 + kernel_y‘ to ‘input_y ‘ in host memory. Here input_y means the value named ’input y’ in this block. The important operands are output_y: the value named ’output y’ in this block; kernel_y: the value named ’kernel y’ in this block. Context: the function test_grouped_convolution_backward_and_fabric_col2im, which handles test grouped convolution backward and fabric col2im.

Line 479: `for kernel_x in range(3):` This iterates kernel_x over ‘range(3)‘. Each iteration repeats the indented host operation, commonly once per layer, tile, timestep, or test case in the function test_grouped_convolution_backward_and_fabri which handles test grouped convolution backward and fabric col2im.

Line 480: `input_x = output_x * 2 - 1 + kernel_x` This assigns ‘output_x * 2 - 1 + kernel_x‘ to ‘input_x ‘ in host memory. Here input_x means the value named ’input x’ in this block. The important operands are output_x: the value named ’output x’ in this block; kernel_x: the value named ’kernel x’ in this block. Context: the function test_grouped_convolution_backward_and_fabric_col2im, which handles test grouped convolution backward and fabric col2im.

Line 481: `if 0 <= input_y < 4 and 0 <= input_x < 5:` This executes the following indented host-code branch only when ‘0 <= input_y < 4 and 0 <= input_x < 5‘ is true. The important operands are input_y: the value named ’input y’ in this block; and: the value named ’and’ in this block; input_x: the value named ’input x’ in this block. Context: the function test_grouped_convolution_backward_and_fabric_col2im, which handles test grouped convolution backward and fabric col2im.

Line 482: `expected_dw[output_channel, local_input, kernel_y, kernel_x] += (` This statement continues through source line 485; the explanation uses the complete expression rather than only the first visual fragment. Inside the function test_grouped_convolution_backward_and_fabric_col2im, which handles test grouped convolution backward and fabric col2im, this statement advances the host implementation that checks neuraedge training behavior independently with Python assertions. The important operands are expected_dw: the value named ’expected dw’ in this block; output_channel: the value named ’output channel’ in this block; local_input: the value named ’local input’ in this block.

Line 483: `int(x[0, input_start + local_input, input_y, input_x])` This is continuation line 2 of the 4-line logical statement that begins at source line 482. Its exact fragment is ‘int(x[0, input_start + local_input, input_y, input_x])‘. The important operands are x: the value named ’x’ in this block; input_start: the value named ’input start’ in this block; local_input: the value named ’local input’ in this block. Read together, the complete operation is: Inside the function test_grouped_convolution_backward_and_fabric_col2im, which handles test grouped convolution backward and fabric col2im, this statement advances the host implementation that checks neuraedge training behavior independently with Python assertions. The important operands are expected_dw: the value named ’expected dw’ in this block; output_channel: the value named ’output channel’ in this block; local_input: the value named ’local input’ in this block.

Line 484: `* gradient` This is continuation line 3 of the 4-line logical statement that begins at source line 482. Its exact fragment is ‘* gradient‘. The important operands are gradient: the signed loss derivative used to update a learned parameter. Read together, the complete operation is: Inside the function test_grouped_convolution_backward_and_fabric_col2im, which handles test grouped convolution backward and fabric col2im, this statement advances the host implementation that checks neuraedge training behavior independently with Python assertions. The important operands are expected_dw: the value named ’expected dw’ in this block; output_channel: the value named ’output channel’ in this block; local_input: the value named ’local input’ in this block.

Line 485: `)` This is continuation line 4 of the 4-line logical statement that begins at source line 482. Its exact fragment is ‘)‘. The expression is a literal or structural operator and has no hidden software state. Read together, the complete operation is: Inside the function test_grouped_convolution_backward_and_fabric_col2im, which handles test grouped convolution backward and fabric col2im, this statement advances the host implementation that checks neuraedge training behavior independently with Python assertions. The important operands are expected_dw: the value named ’expected dw’ in this block; output_channel: the value named ’output channel’ in this block; local_input: the value named ’local input’ in this block.

Line 486: `expected_dx[0, input_start + local_input, input_y, input_x] += (` This statement continues through source line 489; the explanation uses the complete expression rather than only the first visual fragment. Inside the function test_grouped_convolution_backward_and_fabric_col2im, which handles test grouped convolution backward and fabric col2im, this statement advances the host implementation that checks neuraedge training behavior independently with Python assertions. The important operands are expected_dx: the value named 'expected dx' in this block; input_start: the value named 'input start' in this block; local_input: the value named 'local input' in this block.

Line 487: `int(w[output_channel, local_input, kernel_y, kernel_x])` This is continuation line 2 of the 4-line logical statement that begins at source line 486. Its exact fragment is 'int(w[output_channel, local_input, kernel_y, kernel_x])'. The important operands are w: the value named 'w' in this block; output_channel: the value named 'output channel' in this block; local_input: the value named 'local input' in this block. Read together, the complete operation is: Inside the function test_grouped_convolution_backward_and_fabric_col2im, which handles test grouped convolution backward and fabric col2im, this statement advances the host implementation that checks neuraedge training behavior independently with Python assertions. The important operands are expected_dx: the value named 'expected dx' in this block; input_start: the value named 'input start' in this block; local_input: the value named 'local input' in this block.

Line 488: `* gradient` This is continuation line 3 of the 4-line logical statement that begins at source line 486. Its exact fragment is '* gradient'. The important operands are gradient: the signed loss derivative used to update a learned parameter. Read together, the complete operation is: Inside the function test_grouped_convolution_backward_and_fabric_col2im, which handles test grouped convolution backward and fabric col2im, this statement advances the host implementation that checks neuraedge training behavior independently with Python assertions. The important operands are expected_dx: the value named 'expected dx' in this block; input_start: the value named 'input start' in this block; local_input: the value named 'local input' in this block.

Line 489: `)` This is continuation line 4 of the 4-line logical statement that begins at source line 486. Its exact fragment is ')'. The expression is a literal or structural operator and has no hidden software state. Read together, the complete operation is: Inside the function test_grouped_convolution_backward_and_fabric_col2im, which handles test grouped convolution backward and fabric col2im, this statement advances the host implementation that checks neuraedge training behavior independently with Python assertions. The important operands are expected_dx: the value named 'expected dx' in this block; input_start: the value named 'input start' in this block; local_input: the value named 'local input' in this block.

Line 490: `np.testing.assert_array_equal(got_dx, expected_dx)` This calls 'np.testing.assert_array_equal' with 'got_dx, expected_dx' inside the function test_grouped_convolution_backward_and_fabric_col2im, which handles test grouped convolution backward and fabric col2im. The call advances the host-side job that checks neuraedge training behavior independently with Python assertions.

Line 491: `np.testing.assert_array_equal(got_dw, expected_dw)` This calls 'np.testing.assert_array_equal' with 'got_dw, expected_dw' inside the function test_grouped_convolution_backward_and_fabric_col2im, which handles test grouped convolution backward and fabric col2im. The call advances the host-side job that checks neuraedge training behavior independently with Python assertions.

Line 492: `np.testing.assert_array_equal(got_db, expected_db)` This calls 'np.testing.assert_array_equal' with 'got_db, expected_db' inside the function test_grouped_convolution_backward_and_fabric_col2im, which handles test grouped convolution backward and fabric col2im. The call advances the host-side job that checks neuraedge training behavior independently with Python assertions.

Line 494: `def test_arbitrary_parameter_sgdw_and_int8_projection_run_in_fabric(self) -> None:` This starts function test_arbitrary_parameter_sgdw_and_int8_projection_run_in_fabric. Its indented body performs test arbitrary parameter sgdw and int8 projection run in fabric as part of the file that checks neuraedge training behavior independently with Python assertions; it runs only when called.

Line 495: `weights = self.rng.integers(-500, 501, size=(3, 11), dtype=np.int64)` This assigns 'self.rng.integers(-500, 501, size=(3, 11), dtype=np.int64)' to 'weights ' in host memory. Here weights means a learned coefficient multiplied by an activation. The important operands are rng: the value named 'rng' in this block; integers: the value named 'integers'

in this block; size: the value named 'size' in this block. Context: the function test_arbitrary_parameter_sgdw_and_int8_projectio which handles test arbitrary parameter sgdw and int8 projection run in fabric.

Line 496: `gradients = self.rng.integers(-(1 << 20), 1 << 20, size=(3, 11), dtype=np.int64)` This assigns 'self.rng.integers(-(1 << 20), 1 << 20, size=(3, 11), dtype=np.int64)' to 'gradients ' in host memory. Here gradients means the signed loss derivative used to update a learned parameter. The important operands are rng: the value named 'rng' in this block; integers: the value named 'integers' in this block; size: the value named 'size' in this block. Context: the function test_arbitrary_parameter_sgdw_and_int8_projection_run_in_fabric, which handles test arbitrary parameter sgdw and int8 projection run in fabric.

Line 497: `velocities = self.rng.integers(-(1 << 20), 1 << 20, size=(3, 11), dtype=np.int64)` This assigns 'self.rng.integers(-(1 << 20), 1 << 20, size=(3, 11), dtype=np.int64)' to 'velocities ' in host memory. Here velocities means the value named 'velocities' in this block. The important operands are rng: the value named 'rng' in this block; integers: the value named 'integers' in this block; size: the value named 'size' in this block. Context: the function test_arbitrary_parameter_sgdw_and_int8_projection_run_in_fabric, which handles test arbitrary parameter sgdw and int8 projection run in fabric.

Line 498: `expected_weight, expected_velocity = sgd_momentum_step(` This statement continues through source line 505; the explanation uses the complete expression rather than only the first visual fragment. This assigns 'sgd_momentum_step(weights, gradients, velocities, 655, 58982, 66,)' to 'expected_weight, expected_velocity ' in host memory. Here expected_weight means a learned coefficient multiplied by an activation. The important operands are sgd_momentum_step: the value named 'sgd momentum step' in this block; weights: a learned coefficient multiplied by an activation; gradients: the signed loss derivative used to update a learned parameter. Context: the function test_arbitrary_parameter_sgdw_and_int8_pr which handles test arbitrary parameter sgdw and int8 projection run in fabric.

Line 499: `weights,` This is continuation line 2 of the 8-line logical statement that begins at source line 498. Its exact fragment is 'weights,'. The important operands are weights: a learned coefficient multiplied by an activation. Read together, the complete operation is: This assigns 'sgd_momentum_step(weights, gradients, velocities, 655, 58982, 66,)' to 'expected_weight, expected_velocity ' in host memory. Here expected_weight means a learned coefficient multiplied by an activation. The important operands are sgd_momentum_step: the value named 'sgd momentum step' in this block; weights: a learned coefficient multiplied by an activation; gradients: the signed loss derivative used to update a learned parameter. Context: the function test_arbitrary_parameter_sgdw_and_int8_projection_run_in_fabric, which handles test arbitrary parameter sgdw and int8 projection run in fabric.

Line 500: `gradients,` This is continuation line 3 of the 8-line logical statement that begins at source line 498. Its exact fragment is 'gradients,'. The important operands are gradients: the signed loss derivative used to update a learned parameter. Read together, the complete operation is: This assigns 'sgd_momentum_step(weights, gradients, velocities, 655, 58982, 66,)' to 'expected_weight, expected_velocity ' in host memory. Here expected_weight means a learned coefficient multiplied by an activation. The important operands are sgd_momentum_step: the value named 'sgd momentum step' in this block; weights: a learned coefficient multiplied by an activation; gradients: the signed loss derivative used to update a learned parameter. Context: the function test_arbitrary_parameter_sgdw_and_int8_projection_run_in_fabric, which handles test arbitrary parameter sgdw and int8 projection run in fabric.

Line 501: `velocities,` This is continuation line 4 of the 8-line logical statement that begins at source line 498. Its exact fragment is 'velocities,'. The important operands are velocities: the value named 'velocities' in this block. Read together, the complete operation is: This assigns 'sgd_momentum_step(weights, gradients, velocities, 655, 58982, 66,)' to 'expected_weight, expected_velocity ' in host memory. Here expected_weight means a learned coefficient multiplied by an activation. The important operands are sgd_momentum_step: the value named 'sgd momentum step' in this block; weights: a learned coefficient multiplied by an activation; gradients: the signed loss derivative used to update a learned parameter. Context: the function test_arbitrary_parameter_sgdw_and_int8_projection_run_in_fabric, which handles test arbitrary parameter sgdw and int8 projection run in fabric.

Line 502: `655,` This is continuation line 5 of the 8-line logical statement that begins at source line 498. Its exact fragment is '655,'. The expression is a literal or structural operator and has no hidden software state. Read together, the complete operation is: This assigns 'sgd_momentum_step(weights, gradients, velocities, 655, 58982, 66,)' to 'expected_weight, expected_velocity ' in host memory. Here expected_weight means a learned coefficient multiplied

by an activation. The important operands are sgd_momentum_step: the value named 'sgd momentum step' in this block; weights: a learned coefficient multiplied by an activation; gradients: the signed loss derivative used to update a learned parameter. Context: the function test_arbitrary_parameter_sgdw_and_int8_projection_run_in_fabric, which handles test arbitrary parameter sgdw and int8 projection run in fabric.

Line 503: `58982,` This is continuation line 6 of the 8-line logical statement that begins at source line 498. Its exact fragment is '58982,'. The expression is a literal or structural operator and has no hidden software state. Read together, the complete operation is: This assigns 'sgd_momentum_step(weights, gradients, velocities, 655, 58982, 66,)' to 'expected_weight, expected_velocity ' in host memory. Here expected_weight means a learned coefficient multiplied by an activation. The important operands are sgd_momentum_step: the value named 'sgd momentum step' in this block; weights: a learned coefficient multiplied by an activation; gradients: the signed loss derivative used to update a learned parameter. Context: the function test_arbitrary_parameter_sgdw_and_int8_projection_run_in_fabric, which handles test arbitrary parameter sgdw and int8 projection run in fabric.

Line 504: `66,` This is continuation line 7 of the 8-line logical statement that begins at source line 498. Its exact fragment is '66,'. The expression is a literal or structural operator and has no hidden software state. Read together, the complete operation is: This assigns 'sgd_momentum_step(weights, gradients, velocities, 655, 58982, 66,)' to 'expected_weight, expected_velocity ' in host memory. Here expected_weight means a learned coefficient multiplied by an activation. The important operands are sgd_momentum_step: the value named 'sgd momentum step' in this block; weights: a learned coefficient multiplied by an activation; gradients: the signed loss derivative used to update a learned parameter. Context: the function test_arbitrary_parameter_sgdw_and_int8_projection_run_in_fabric, which handles test arbitrary parameter sgdw and int8 projection run in fabric.

Line 505: `)` This is continuation line 8 of the 8-line logical statement that begins at source line 498. Its exact fragment is ')'. The expression is a literal or structural operator and has no hidden software state. Read together, the complete operation is: This assigns 'sgd_momentum_step(weights, gradients, velocities, 655, 58982, 66,)' to 'expected_weight, expected_velocity ' in host memory. Here expected_weight means a learned coefficient multiplied by an activation. The important operands are sgd_momentum_step: the value named 'sgd momentum step' in this block; weights: a learned coefficient multiplied by an activation; gradients: the signed loss derivative used to update a learned parameter. Context: the function test_arbitrary_parameter_sgdw_and_int8_projection_run_in_fabric, which handles test arbitrary parameter sgdw and int8 projection run in fabric.

Line 506: `emulator = FabricOperatorEmulator()` This assigns 'FabricOperatorEmulator()' to 'emulator ' in host memory. Here emulator means the value named 'emulator' in this block. The important operands are FabricOperatorEmulator: the value named 'fabric operator emulator' in this block. Context: the function test_arbitrary_parameter_sgdw_and_int8_ which handles test arbitrary parameter sgdw and int8 projection run in fabric.

Line 507: `got_weight, got_velocity = execute_sgdw_update(` This statement continues through source line 515; the explanation uses the complete expression rather than only the first visual fragment. This assigns 'execute_sgdw_update(emulator, weights, gradients, velocities, learning_rate_q16=655, momentum_q16=58982, weight_decay_q16=66,)' to 'got_weight, got_velocity ' in host memory. Here got_weight means a learned coefficient multiplied by an activation. The important operands are execute_sgdw_update: the value named 'execute sgdw update' in this block; emulator: the value named 'emulator' in this block; weights: a learned coefficient multiplied by an activation. Context: the function test_arbitrary_parameter_sgdw_and_int8_projection_run_in_fabric, which handles test arbitrary parameter sgdw and int8 projection run in fabric.

Line 508: `emulator,` This is continuation line 2 of the 9-line logical statement that begins at source line 507. Its exact fragment is 'emulator,'. The important operands are emulator: the value named 'emulator' in this block. Read together, the complete operation is: This assigns 'execute_sgdw_update(emulator, weights, gradients, velocities, learning_rate_q16=655, momentum_q16=58982, weight_decay_q16=66,)' to 'got_weight, got_velocity ' in host memory. Here got_weight means a learned coefficient multiplied by an activation. The important operands are execute_sgdw_update: the value named 'execute sgdw update' in this block; emulator: the value named 'emulator' in this block; weights: a learned coefficient multiplied by an activation. Context: the function test_arbitrary_parameter_sgdw_and_int8_ which handles test arbitrary parameter sgdw and int8 projection run in fabric.

Line 509: `weights,` This is continuation line 3 of the 9-line logical statement that begins at source line 507. Its exact fragment is ‘weights,‘. The important operands are weights: a learned coefficient multiplied by an activation. Read together, the complete operation is: This assigns ‘execute_sgdw_update(emulator, weights, gradients, velocities, learning_rate_q16=655, momentum_q16=58982, weight_decay_q16=66,)‘ to ‘got_weight, got_velocity ‘ in host memory. Here got_weight means a learned coefficient multiplied by an activation. The important operands are execute_sgdw_update: the value named ’execute sgdw update’ in this block; emulator: the value named ’emulator’ in this block; weights: a learned coefficient multiplied by an activation. Context: the function test_arbitrary_parameter_sgdw_and_int8_ which handles test arbitrary parameter sgdw and int8 projection run in fabric.

Line 510: `gradients,` This is continuation line 4 of the 9-line logical statement that begins at source line 507. Its exact fragment is ‘gradients,‘. The important operands are gradients: the signed loss derivative used to update a learned parameter. Read together, the complete operation is: This assigns ‘execute_sgdw_update(emulator, weights, gradients, velocities, learning_rate_q16=655, momentum_q16=58982, weight_decay_q16=66,)‘ to ‘got_weight, got_velocity ‘ in host memory. Here got_weight means a learned coefficient multiplied by an activation. The important operands are execute_sgdw_update: the value named ’execute sgdw update’ in this block; emulator: the value named ’emulator’ in this block; weights: a learned coefficient multiplied by an activation. Context: the function test_arbitrary_parameter_sgdw_and_int8_ which handles test arbitrary parameter sgdw and int8 projection run in fabric.

Line 511: `velocities,` This is continuation line 5 of the 9-line logical statement that begins at source line 507. Its exact fragment is ‘velocities,‘. The important operands are velocities: the value named ’velocities’ in this block. Read together, the complete operation is: This assigns ‘execute_sgdw_update(emulator, weights, gradients, velocities, learning_rate_q16=655, momentum_q16=58982, weight_decay_q16=66,)‘ to ‘got_weight, got_velocity ‘ in host memory. Here got_weight means a learned coefficient multiplied by an activation. The important operands are execute_sgdw_update: the value named ’execute sgdw update’ in this block; emulator: the value named ’emulator’ in this block; weights: a learned coefficient multiplied by an activation. Context: the function test_arbitrary_parameter_sgdw_and_int8_ which handles test arbitrary parameter sgdw and int8 projection run in fabric.

Line 512: `learning_rate_q16=655,` This is continuation line 6 of the 9-line logical statement that begins at source line 507. Its exact fragment is ‘learning_rate_q16=655,‘. The important operands are learning_rate_q16: the fixed-point multiplier controlling update magnitude. Read together, the complete operation is: This assigns ‘execute_sgdw_update(emulator, weights, gradients, velocities, learning_rate_q16=655, momentum_q16=58982, weight_decay_q16=66,)‘ to ‘got_weight, got_velocity ‘ in host memory. Here got_weight means a learned coefficient multiplied by an activation. The important operands are execute_sgdw_update: the value named ’execute sgdw update’ in this block; emulator: the value named ’emulator’ in this block; weights: a learned coefficient multiplied by an activation. Context: the function test_arbitrary_parameter_sgdw_and_int8_projection_run_in_fabric, which handles test arbitrary parameter sgdw and int8 projection run in fabric.

Line 513: `momentum_q16=58982,` This is continuation line 7 of the 9-line logical statement that begins at source line 507. Its exact fragment is ‘momentum_q16=58982,‘. The important operands are momentum_q16: the value named ’momentum q16’ in this block. Read together, the complete operation is: This assigns ‘execute_sgdw_update(emulator, weights, gradients, velocities, learning_rate_q16=655, momentum_q16=58982, weight_decay_q16=66,)‘ to ‘got_weight, got_velocity ‘ in host memory. Here got_weight means a learned coefficient multiplied by an activation. The important operands are execute_sgdw_update: the value named ’execute sgdw update’ in this block; emulator: the value named ’emulator’ in this block; weights: a learned coefficient multiplied by an activation. Context: the function test_arbitrary_parameter_sgdw_and_int8_projection_run_in_fabric, which handles test arbitrary parameter sgdw and int8 projection run in fabric.

Line 514: `weight_decay_q16=66,` This is continuation line 8 of the 9-line logical statement that begins at source line 507. Its exact fragment is ‘weight_decay_q16=66,‘. The important operands are weight_decay_q16: a learned coefficient multiplied by an activation. Read together, the complete operation is: This assigns ‘execute_sgdw_update(emulator, weights, gradients, velocities, learning_rate_q16=655, momentum_q16=58982, weight_decay_q16=66,)‘ to ‘got_weight, got_velocity ‘ in host memory. Here got_weight means a learned coefficient multiplied by an activation. The important operands are execute_sgdw_update: the value named ’execute sgdw update’ in this block; emulator: the value named ’emulator’ in this block; weights: a learned coefficient multiplied by an activation. Context: the function test_arbitrary_parameter_sgdw_and_int8_projection_run_in_fabric, which handles test arbitrary parameter sgdw and int8 projection run in fabric.

Line 515: `)` This is continuation line 9 of the 9-line logical statement that begins at source line 507. Its exact fragment is ')'. The expression is a literal or structural operator and has no hidden software state. Read together, the complete operation is: This assigns 'execute_sgdw_update(emulator, weights, gradients, velocities, learning_rate_q16=655, momentum_q16=58982, weight_decay_q16=66,)' to 'got_weight, got_velocity ' in host memory. Here got_weight means a learned coefficient multiplied by an activation. The important operands are execute_sgdw_update: the value named 'execute sgdw update' in this block; emulator: the value named 'emulator' in this block; weights: a learned coefficient multiplied by an activation. Context: the function test_arbitrary_parameter_sgdw_and_int8_projection_run_in_fabric, which handles test arbitrary parameter sgdw and int8 projection run in fabric.

Line 516: `np.testing.assert_array_equal(got_weight, expected_weight)` This calls 'np.testing.assert_array_equal' with 'got_weight, expected_weight' inside the function test_arbitrary_parameter_sgdw_and_int8_projection_run_in_fabric, which handles test arbitrary parameter sgdw and int8 projection run in fabric. The call advances the host-side job that checks neuraedge training behavior independently with Python assertions.

Line 517: `np.testing.assert_array_equal(got_velocity, expected_velocity)` This calls 'np.testing.assert_array_equal' with 'got_velocity, expected_velocity' inside the function test_arbitrary_parameter_sgdw_and_int8_projection_run_in_fabric, which handles test arbitrary parameter sgdw and int8 projection run in fabric. The call advances the host-side job that checks neuraedge training behavior independently with Python assertions.

Line 518: `projected = execute_int8_weight_projection(emulator, got_weight)` This assigns 'execute_int8_weight_proj got_weight)' to 'projected ' in host memory. Here projected means the value named 'projected' in this block. The important operands are execute_int8_weight_projection: a learned coefficient multiplied by an activation; emulator: the value named 'emulator' in this block; got_weight: a learned coefficient multiplied by an activation. Context: the function test_arbitrary_parameter_sgdw_and_int8_projection_run_in_fabric, which handles test arbitrary parameter sgdw and int8 projection run in fabric.

Line 519: `np.testing.assert_array_equal(projected, np.clip(got_weight, -128, 127).astype(np.int8))` This calls 'np.testing.assert_array_equal' with 'projected, np.clip(got_weight, -128, 127).astype(np.int8)' inside the function test_arbitrary_parameter_sgdw_and_int8_projection_run_in_fabric, which handles test arbitrary parameter sgdw and int8 projection run in fabric. The call advances the host-side job that checks neuraedge training behavior independently with Python assertions.

Line 520: `self.assertEqual(emulator.command_count, 10)` This calls 'self.assertEqual' with 'emulator.command_count, 10' inside the function test_arbitrary_parameter_sgdw_and_int8_projection_run_in_fabric, which handles test arbitrary parameter sgdw and int8 projection run in fabric. The call advances the host-side job that checks neuraedge training behavior independently with Python assertions.

Line 522: `def test_rejects_misaligned_or_out_of_range_operands(self) -> None:` This starts function test_rejects_mis Its indented body performs test rejects misaligned or out of range operands as part of the file that checks neuraedge training behavior independently with Python assertions; it runs only when called.

Line 523: `with self.assertRaises(ValueError):` This opens a managed resource scope for 'self.assertRaises(ValueError)' so files, tracing, or temporary state are finalized even if the function test_rejects_misaligned_or_out_of_range_operands, which handles test rejects misaligned or out of range operands raises an error.

Line 524: `compile_linear_backward(np.zeros((2, 3)), np.zeros((4, 5)), np.zeros((2, 5)))` This calls 'compile_linear_backward' with 'np.zeros((2, 3)), np.zeros((4, 5)), np.zeros((2, 5))' inside the function test_rejects_misaligned_or_out_ which handles test rejects misaligned or out of range operands. The call advances the host-side job that checks neuraedge training behavior independently with Python assertions.

Line 525: `with self.assertRaises(ValueError):` This opens a managed resource scope for 'self.assertRaises(ValueError)' so files, tracing, or temporary state are finalized even if the function test_rejects_misaligned_or_out_of_range_operands, which handles test rejects misaligned or out of range operands raises an error.

Line 526: `compile_linear_backward(np.array([[32768]]), np.array([[1]]), np.array([[1]]))` This calls ‘compile_linear_backward‘ with ‘np.array([[32768]]), np.array([[1]]), np.array([[1]])‘ inside the function test_rejects_misaligned_or_out which handles test rejects misaligned or out of range operands. The call advances the host-side job that checks neuraedge training behavior independently with Python assertions.

Line 527: `with self.assertRaises(ValueError):` This opens a managed resource scope for ‘self.assertRaises(ValueError)‘ so files, tracing, or temporary state are finalized even if the function test_rejects_misaligned_or_out_of_range_operands, which handles test rejects misaligned or out of range operands raises an error.

Line 528: `compile_affine_backward(` This statement continues through source line 533; the explanation uses the complete expression rather than only the first visual fragment. This calls ‘compile_affine_backward‘ with ‘ np.zeros((1, 1), dtype=np.int64), np.zeros((1, 2), dtype=np.int64), np.zeros(3, dtype=np.int64), np.zeros((1, 2), dtype=np.int64), ‘ inside the function test_rejects_misaligned_or_out_of_range_operands, which handles test rejects misaligned or out of range operands. The call advances the host-side job that checks neuraedge training behavior independently with Python assertions.

Line 529: `np.zeros((1, 1), dtype=np.int64),` This is continuation line 2 of the 6-line logical statement that begins at source line 528. Its exact fragment is ‘np.zeros((1, 1), dtype=np.int64),‘. The important operands are zeros: the value named ’zeros’ in this block; dtype: the value named ’dtype’ in this block; int64: the value named ’int64’ in this block. Read together, the complete operation is: This calls ‘compile_affine_backward‘ with ‘ np.zeros((1, 1), dtype=np.int64), np.zeros((1, 2), dtype=np.int64), np.zeros(3, dtype=np.int64), np.zeros((1, 2), dtype=np.int64), ‘ inside the function test_rejects_misaligned_or_out_of_range_operands, which handles test rejects misaligned or out of range operands. The call advances the host-side job that checks neuraedge training behavior independently with Python assertions.

Line 530: `np.zeros((1, 2), dtype=np.int64),` This is continuation line 3 of the 6-line logical statement that begins at source line 528. Its exact fragment is ‘np.zeros((1, 2), dtype=np.int64),‘. The important operands are zeros: the value named ’zeros’ in this block; dtype: the value named ’dtype’ in this block; int64: the value named ’int64’ in this block. Read together, the complete operation is: This calls ‘compile_affine_backward‘ with ‘ np.zeros((1, 1), dtype=np.int64), np.zeros((1, 2), dtype=np.int64), np.zeros(3, dtype=np.int64), np.zeros((1, 2), dtype=np.int64), ‘ inside the function test_rejects_misaligned_or_out_of_range_operands, which handles test rejects misaligned or out of range operands. The call advances the host-side job that checks neuraedge training behavior independently with Python assertions.

Line 531: `np.zeros(3, dtype=np.int64),` This is continuation line 4 of the 6-line logical statement that begins at source line 528. Its exact fragment is ‘np.zeros(3, dtype=np.int64),‘. The important operands are zeros: the value named ’zeros’ in this block; dtype: the value named ’dtype’ in this block; int64: the value named ’int64’ in this block. Read together, the complete operation is: This calls ‘compile_affine_backward‘ with ‘ np.zeros((1, 1), dtype=np.int64), np.zeros((1, 2), dtype=np.int64), np.zeros(3, dtype=np.int64), np.zeros((1, 2), dtype=np.int64), ‘ inside the function test_rejects_misaligned_or_out_of_range_operands, which handles test rejects misaligned or out of range operands. The call advances the host-side job that checks neuraedge training behavior independently with Python assertions.

Line 532: `np.zeros((1, 2), dtype=np.int64),` This is continuation line 5 of the 6-line logical statement that begins at source line 528. Its exact fragment is ‘np.zeros((1, 2), dtype=np.int64),‘. The important operands are zeros: the value named ’zeros’ in this block; dtype: the value named ’dtype’ in this block; int64: the value named ’int64’ in this block. Read together, the complete operation is: This calls ‘compile_affine_backward‘ with ‘ np.zeros((1, 1), dtype=np.int64), np.zeros((1, 2), dtype=np.int64), np.zeros(3, dtype=np.int64), np.zeros((1, 2), dtype=np.int64), ‘ inside the function test_rejects_misaligned_or_out_of_range_operands, which handles test rejects misaligned or out of range operands. The call advances the host-side job that checks neuraedge training behavior independently with Python assertions.

Line 533: `)` This is continuation line 6 of the 6-line logical statement that begins at source line 528. Its exact fragment is ‘)‘. The expression is a literal or structural operator and has no hidden software state. Read together, the complete operation is: This calls ‘compile_affine_backward‘ with ‘ np.zeros((1, 1), dtype=np.int64), np.zeros((1, 2), dtype=np.int64), np.zeros(3, dtype=np.int64), np.zeros((1, 2), dtype=np.int64), ‘ inside the function test_rejects_misaligned_or_out_of_range_ope which handles test rejects misaligned or out of range operands. The call advances the host-side job that checks neuraedge training behavior independently with Python assertions.

Line 535: `def test_lif_bptt_fabric_schedule_matches_fixed_point_recurrence(self) -> None:` This starts function test_lif_bptt_fabric_schedule_matches_fixed_point_recurrence. Its indented body performs test lif bptt fabric schedule matches fixed point recurrence as part of the file that checks neuraedge training behavior independently with Python assertions; it runs only when called.

Line 536: `time_steps = 4` This assigns '4' to 'time_steps ' in host memory. Here time_steps means the value named 'time steps' in this block. The expression is a literal or structural operator and has no hidden software state. Context: the function test_lif_bptt_fabric_schedule_matches_fixed_point_recurrence, which handles test lif bptt fabric schedule matches fixed point recurrence.

Line 537: `neurons = 19` This assigns '19' to 'neurons ' in host memory. Here neurons means the value named 'neurons' in this block. The expression is a literal or structural operator and has no hidden software state. Context: the function test_lif_bptt_fabric_schedule_matches_fixed_point_recurrence, which handles test lif bptt fabric schedule matches fixed point recurrence.

Line 538: `threshold = 1 << 10` This assigns '1 << 10' to 'threshold ' in host memory. Here threshold means the membrane level at which a neuron emits a spike. The expression is a literal or structural operator and has no hidden software state. Context: the function test_lif_bptt_fabric_schedule_matches_fixed_point_recurrence, which handles test lif bptt fabric schedule matches fixed point recurrence.

Line 539: `membrane = self.rng.integers(` This statement continues through source line 544; the explanation uses the complete expression rather than only the first visual fragment. This assigns 'self.rng.integers(threshold - 4096, threshold + 4097, size=(time_steps, neurons), dtype=np.int64,)' to 'membrane ' in host memory. Here membrane means the persistent LIF neuron state carrying charge between timesteps. The important operands are rng: the value named 'rng' in this block; integers: the value named 'integers' in this block; threshold: the membrane level at which a neuron emits a spike. Context: the function test_lif_bptt_fabric_schedule_matches_fixed_point_recurrence, which handles test lif bptt fabric schedule matches fixed point recurrence.

Line 540: `threshold - 4096,` This is continuation line 2 of the 6-line logical statement that begins at source line 539. Its exact fragment is 'threshold - 4096,'. The important operands are threshold: the membrane level at which a neuron emits a spike. Read together, the complete operation is: This assigns 'self.rng.integers(threshold - 4096, threshold + 4097, size=(time_steps, neurons), dtype=np.int64,)' to 'membrane ' in host memory. Here membrane means the persistent LIF neuron state carrying charge between timesteps. The important operands are rng: the value named 'rng' in this block; integers: the value named 'integers' in this block; threshold: the membrane level at which a neuron emits a spike. Context: the function test_lif_bptt_fabric_schedule_matches_fixed_point_recurrence, which handles test lif bptt fabric schedule matches fixed point recurrence.

Line 541: `threshold + 4097,` This is continuation line 3 of the 6-line logical statement that begins at source line 539. Its exact fragment is 'threshold + 4097,'. The important operands are threshold: the membrane level at which a neuron emits a spike. Read together, the complete operation is: This assigns 'self.rng.integers(threshold - 4096, threshold + 4097, size=(time_steps, neurons), dtype=np.int64,)' to 'membrane ' in host memory. Here membrane means the persistent LIF neuron state carrying charge between timesteps. The important operands are rng: the value named 'rng' in this block; integers: the value named 'integers' in this block; threshold: the membrane level at which a neuron emits a spike. Context: the function test_lif_bptt_fabric_schedule_matches_fixed_point_recurrence, which handles test lif bptt fabric schedule matches fixed point recurrence.

Line 542: `size=(time_steps, neurons),` This is continuation line 4 of the 6-line logical statement that begins at source line 539. Its exact fragment is 'size=(time_steps, neurons),'. The important operands are size: the value named 'size' in this block; time_steps: the value named 'time steps' in this block; neurons: the value named 'neurons' in this block. Read together, the complete operation is: This assigns 'self.rng.integers(threshold - 4096, threshold + 4097, size=(time_steps, neurons), dtype=np.int64,)' to 'membrane ' in host memory. Here membrane means the persistent LIF neuron state carrying charge between timesteps. The important operands are rng: the value named 'rng' in this block; integers: the value named 'integers' in this block; threshold: the membrane level at which a neuron emits a spike. Context: the function test_lif_bptt_fabric_schedule_matches_fixed_point_recurrence, which handles test lif bptt fabric schedule matches fixed point recurrence.

Line 543: `dtype=np.int64,` This is continuation line 5 of the 6-line logical statement that begins at source line 539. Its exact fragment is 'dtype=np.int64,'. The important operands are dtype: the value named 'dtype' in this block; int64: the value named 'int64' in this block. Read together, the complete operation is: This assigns 'self.rng.integers(threshold - 4096, threshold + 4097, size=(time_steps, neurons), dtype=np.int64,)' to 'membrane ' in host memory. Here membrane means the persistent LIF neuron state carrying charge between timesteps. The important operands are rng: the value named 'rng' in this block; integers: the value named 'integers' in this block; threshold: the membrane level at which a neuron emits a spike. Context: the function test_lif_bptt_fabric_schedule_matches_fixed_point_recurrence, which handles test lif bptt fabric schedule matches fixed point recurrence.

Line 544: `)` This is continuation line 6 of the 6-line logical statement that begins at source line 539. Its exact fragment is ')'. The expression is a literal or structural operator and has no hidden software state. Read together, the complete operation is: This assigns 'self.rng.integers(threshold - 4096, threshold + 4097, size=(time_steps, neurons), dtype=np.int64,)' to 'membrane ' in host memory. Here membrane means the persistent LIF neuron state carrying charge between timesteps. The important operands are rng: the value named 'rng' in this block; integers: the value named 'integers' in this block; threshold: the membrane level at which a neuron emits a spike. Context: the function test_lif_bptt_fabric_schedule_matches_fixed_point_recurrence, which handles test lif bptt fabric schedule matches fixed point recurrence.

Line 545: `spikes = (membrane >= threshold).astype(np.int64)` Inside the function test_lif_bptt_fabric_schedule_matche which handles test lif bptt fabric schedule matches fixed point recurrence, this statement advances the host implementation that checks neuraedge training behavior independently with Python assertions. The important operands are spikes: a binary event produced when a neuron crosses its threshold; membrane: the persistent LIF neuron state carrying charge between timesteps; threshold: the membrane level at which a neuron emits a spike.

Line 546: `grad_spikes = self.rng.integers(` This statement continues through source line 548; the explanation uses the complete expression rather than only the first visual fragment. This assigns 'self.rng.integers(-(1 << 20), 1 << 20, size=(time_steps, neurons), dtype=np.int64)' to 'grad_spikes ' in host memory. Here grad_spikes means a binary event produced when a neuron crosses its threshold. The important operands are rng: the value named 'rng' in this block; integers: the value named 'integers' in this block; size: the value named 'size' in this block. Context: the function test_lif_bptt_fabric_schedule_matches_fixed_point_recurrence, which handles test lif bptt fabric schedule matches fixed point recurrence.

Line 547: `-(1 << 20), 1 << 20, size=(time_steps, neurons), dtype=np.int64` This is continuation line 2 of the 3-line logical statement that begins at source line 546. Its exact fragment is '-(1 << 20), 1 << 20, size=(time_steps, neurons), dtype=np.int64'. The important operands are size: the value named 'size' in this block; time_steps: the value named 'time steps' in this block; neurons: the value named 'neurons' in this block. Read together, the complete operation is: This assigns 'self.rng.integers(-(1 << 20), 1 << 20, size=(time_steps, neurons), dtype=np.int64)' to 'grad_spikes ' in host memory. Here grad_spikes means a binary event produced when a neuron crosses its threshold. The important operands are rng: the value named 'rng' in this block; integers: the value named 'integers' in this block; size: the value named 'size' in this block. Line 548: `)` This is continuation line 3 of the 3-line logical statement that begins at source line 546. Its exact fragment is ')'. The expression is a literal or structural operator and has no hidden software state. Read together, the complete operation is: This assigns 'self.rng.integers(-(1 << 20), 1 << 20, size=(time_steps, neurons), dtype=np.int64)' to 'grad_spikes ' in host memory. Here grad_spikes means a binary event produced when a neuron crosses its threshold. The important operands are rng: the value named 'rng' in this block; integers: the value named 'integers' in this block; size: the value named 'size' in this block. Context: the function test_lif_bptt_fabric_schedule_matches_fixed_point_recurrence, which handles test lif bptt fabric schedule matches fixed point recurrence.

Line 549: `grad_membrane = self.rng.integers(` This statement continues through source line 551; the explanation uses the complete expression rather than only the first visual fragment. This assigns 'self.rng.integers(-(1 << 18), 1 << 18, size=(time_steps, neurons), dtype=np.int64)' to 'grad_membrane ' in host memory. Here grad_membrane means the persistent LIF neuron state carrying charge between timesteps. The important operands are rng: the value named 'rng' in this block; integers: the value named 'integers' in this block; size: the value named 'size' in this block. Context:

the function test_lif_bptt_fabric_schedule_matches_fixed_point_recurrence, which handles test lif bptt fabric schedule matches fixed point recurrence.

Line 550: `-(1 << 18), 1 << 18, size=(time_steps, neurons), dtype=np.int64` This is continuation line 2 of the 3-line logical statement that begins at source line 549. Its exact fragment is '-(1 << 18), 1 << 18, size=(time_steps, neurons), dtype=np.int64'. The important operands are size: the value named 'size' in this block; time_steps: the value named 'time steps' in this block; neurons: the value named 'neurons' in this block. Read together, the complete operation is: This assigns 'self.rng.integers(-(1 << 18), 1 << 18, size=(time_steps, neurons), dtype=np.int64)' to 'grad_membrane ' in host memory. Here grad_membrane means the persistent LIF neuron state carrying charge between timesteps. The important operands are rng: the value named 'rng' in this block; integers: the value named 'integers' in this block; size: the value named 'size' in this block. Context: the function test_lif_bptt_fabric_schedule_matches_fixed_point_recurr which handles test lif bptt fabric schedule matches fixed point recurrence.

Line 551: `)` This is continuation line 3 of the 3-line logical statement that begins at source line 549. Its exact fragment is ')'. The expression is a literal or structural operator and has no hidden software state. Read together, the complete operation is: This assigns 'self.rng.integers(-(1 << 18), 1 << 18, size=(time_steps, neurons), dtype=np.int64)' to 'grad_membrane ' in host memory. Here grad_membrane means the persistent LIF neuron state carrying charge between timesteps. The important operands are rng: the value named 'rng' in this block; integers: the value named 'integers' in this block; size: the value named 'size' in this block. Context: the function test_lif_bptt_fabric_schedule_matches_fixed_point_recurrence, which handles test lif bptt fabric schedule matches fixed point recurrence.

Line 552: `table, address_shift = sigmoid_surrogate_lut_q15()` This assigns 'sigmoid_surrogate_lut_q15()' to 'table, address_shift ' in host memory. Here table means the value named 'table' in this block. The important operands are sigmoid_surrogate_lut_q15: the value named 'sigmoid surrogate lut q15' in this block. Context: the function test_lif_bptt_fabric_schedule_matches_fixed_point_recurrence, which handles test lif bptt fabric schedule matches fixed point recurrence.

Line 553: `self.assertEqual(int(table[128]), 32767)` This calls 'self.assertEqual' with 'int(table[128]), 32767' inside the function test_lif_bptt_fabric_schedule_matches_fixed_point_recurrence, which handles test lif bptt fabric schedule matches fixed point recurrence. The call advances the host-side job that checks neuraedge training behavior independently with Python assertions.

Line 554: `addresses = surrogate_lut_addresses(membrane, threshold, address_shift)` This assigns 'surrogate_lut_addresses(membrane, threshold, address_shift)' to 'addresses ' in host memory. Here addresses means the value named 'addresses' in this block. The important operands are surrogate_lut_addresses: the value named 'surrogate lut addresses' in this block; membrane: the persistent LIF neuron state carrying charge between timesteps; threshold: the membrane level at which a neuron emits a spike. Context: the function test_lif_bptt_fabric_schedule_matches_fixed_point_recurrence which handles test lif bptt fabric schedule matches fixed point recurrence.

Line 555: `self.assertTrue(np.all(addresses >= 0))` This calls 'self.assertTrue' with 'np.all(addresses >= 0)' inside the function test_lif_bptt_fabric_schedule_matches_fixed_point_recurrence, which handles test lif bptt fabric schedule matches fixed point recurrence. The call advances the host-side job that checks neuraedge training behavior independently with Python assertions.

Line 556: `self.assertTrue(np.all(addresses <= 255))` This calls 'self.assertTrue' with 'np.all(addresses <= 255)' inside the function test_lif_bptt_fabric_schedule_matches_fixed_point_recurrence, which handles test lif bptt fabric schedule matches fixed point recurrence. The call advances the host-side job that checks neuraedge training behavior independently with Python assertions.

Line 557: `expected_input, expected_h = lif_bptt_fixed(` This statement continues through source line 565; the explanation uses the complete expression rather than only the first visual fragment. This assigns 'lif_bptt_fixed(membrane, spikes, grad_spikes, threshold=threshold, membrane_gradients=grad_membrane, surrogate_table_q15=table, surrogate_address_shift=address_shift,)' to 'expected_input, expected_h ' in host memory. Here expected_input means the value named 'expected input' in this block. The important operands are lif_bptt_fixed: the value named 'lif

bptt fixed' in this block; membrane: the persistent LIF neuron state carrying charge between timesteps; spikes: a binary event produced when a neuron crosses its threshold. Context: the function test_lif_bptt_fabric_schedule_matches_fixed_point_re which handles test lif bptt fabric schedule matches fixed point recurrence.

Line 558: `membrane,` This is continuation line 2 of the 9-line logical statement that begins at source line 557. Its exact fragment is 'membrane,'. The important operands are membrane: the persistent LIF neuron state carrying charge between timesteps. Read together, the complete operation is: This assigns 'lif_bptt_fixed(membrane, spikes, grad_spikes, threshold=threshold, membrane_gradients=grad_membrane, surrogate_table_q15=table, surrogate_address_shift=address_shift,)' to 'expected_input, expected_h ' in host memory. Here expected_input means the value named 'expected input' in this block. The important operands are lif_bptt_fixed: the value named 'lif bptt fixed' in this block; membrane: the persistent LIF neuron state carrying charge between timesteps; spikes: a binary event produced when a neuron crosses its threshold. Context: the function test_lif_bptt_fabric_schedule_matches_fixed_point_recurrence, which handles test lif bptt fabric schedule matches fixed point recurrence.

Line 559: `spikes,` This is continuation line 3 of the 9-line logical statement that begins at source line 557. Its exact fragment is 'spikes,'. The important operands are spikes: a binary event produced when a neuron crosses its threshold. Read together, the complete operation is: This assigns 'lif_bptt_fixed(membrane, spikes, grad_spikes, threshold=threshold, membrane_gradients=grad_membrane, surrogate_table_q15=table, surrogate_address_shift=address_shift,)' to 'expected_input, expected_h ' in host memory. Here expected_input means the value named 'expected input' in this block. The important operands are lif_bptt_fixed: the value named 'lif bptt fixed' in this block; membrane: the persistent LIF neuron state carrying charge between timesteps; spikes: a binary event produced when a neuron crosses its threshold. Context: the function test_lif_bptt_fabric_schedule_matches_fixed_point_recurrence, which handles test lif bptt fabric schedule matches fixed point recurrence.

Line 560: `grad_spikes,` This is continuation line 4 of the 9-line logical statement that begins at source line 557. Its exact fragment is 'grad_spikes,'. The important operands are grad_spikes: a binary event produced when a neuron crosses its threshold. Read together, the complete operation is: This assigns 'lif_bptt_fixed(membrane, spikes, grad_spikes, threshold=threshold, membrane_gradients=grad_membrane, surrogate_table_q15=table, surrogate_address_shift=address_shift,)' to 'expected_input, expected_h ' in host memory. Here expected_input means the value named 'expected input' in this block. The important operands are lif_bptt_fixed: the value named 'lif bptt fixed' in this block; membrane: the persistent LIF neuron state carrying charge between timesteps; spikes: a binary event produced when a neuron crosses its threshold. Context: the function test_lif_bptt_fabric_schedule_matches_fixed_point_recurrence, which handles test lif bptt fabric schedule matches fixed point recurrence.

Line 561: `threshold=threshold,` This is continuation line 5 of the 9-line logical statement that begins at source line 557. Its exact fragment is 'threshold=threshold,'. The important operands are threshold: the membrane level at which a neuron emits a spike. Read together, the complete operation is: This assigns 'lif_bptt_fixed(membrane, spikes, grad_spikes, threshold=threshold, membrane_gradients=grad_membrane, surrogate_table_q15=table, surrogate_address_shift=address_shift,)' to 'expected_input, expected_h ' in host memory. Here expected_input means the value named 'expected input' in this block. Context: the function test_lif_bptt_fabric_schedule_matches_fixed_point_recurrence, which handles test lif bptt fabric schedule matches fixed point recurrence.

Line 562: `membrane_gradients=grad_membrane,` This is continuation line 6 of the 9-line logical statement that begins at source line 557. Its exact fragment is 'membrane_gradients=grad_membrane,'. The important operands are membrane_gradients: the persistent LIF neuron state carrying charge between timesteps; grad_membrane: the persistent LIF neuron state carrying charge between timesteps. Read together, the complete operation is: This assigns 'lif_bptt_fixed(membrane, spikes, grad_spikes, threshold=threshold, membrane_gradients=grad_membrane, surrogate_table_q15=table, surrogate_address_shift=address_shift,)' to 'expected_input, expected_h ' in host memory. Here expected_input means the value named 'expected input' in this block. The important operands are lif_bptt_fixed: the value named 'lif bptt fixed' in this block; membrane: the persistent LIF neuron state carrying charge between timesteps; spikes: a binary event produced when a neuron crosses its threshold. Context: the function test_lif_bptt_fabric_schedule which handles test lif bptt fabric schedule matches fixed point recurrence.

Line 563: `surrogate_table_q15=table,` This is continuation line 7 of the 9-line logical statement that begins at source line 557. Its exact fragment is 'surrogate_table_q15=table,'. The important operands are surrogate_table_q15: the value named 'surrogate table q15' in this block; table: the value named 'table' in this block. Read together, the complete operation is: This assigns 'lif_bptt_fixed(membrane, spikes, grad_spikes, threshold=threshold, membrane_gradients=grad_membrane, surrogate_table_q15=table, surrogate_address_shift=address_shift,)' to 'expected_input, expected_h ' in host memory. Here expected_input means the value named 'expected input' in this block. The important operands are lif_bptt_fixed: the value named 'lif bptt fixed' in this block; membrane: the persistent LIF neuron state carrying charge between timesteps; spikes: a binary event produced when a neuron crosses its threshold. Context: the function test_lif_bptt_fabric_schedule_matches_fixed_point_recurrence, which handles test lif bptt fabric schedule matches fixed point recurrence.

Line 564: `surrogate_address_shift=address_shift,` This is continuation line 8 of the 9-line logical statement that begins at source line 557. Its exact fragment is 'surrogate_address_shift=address_shift,'. The important operands are surrogate_address_shift: the value named 'surrogate address shift' in this block; address_shift: the value named 'address shift' in this block. Read together, the complete operation is: This assigns 'lif_bptt_fixed(membrane, spikes, grad_spikes, threshold=threshold, membrane_gradients=grad_membrane, surrogate_table_q15=table, surrogate_address_shift=address_shift,)' to 'expected_input, expected_h ' in host memory. Here expected_input means the value named 'expected input' in this block. The important operands are lif_bptt_fixed: the value named 'lif bptt fixed' in this block; membrane: the persistent LIF neuron state carrying charge between timesteps; spikes: a binary event produced when a neuron crosses its threshold. Context: the function test_lif_bptt_fabric_schedule_matches_fixed_point_recurrence, which handles test lif bptt fabric schedule matches fixed point recurrence.

Line 565: `)` This is continuation line 9 of the 9-line logical statement that begins at source line 557. Its exact fragment is ')'. The expression is a literal or structural operator and has no hidden software state. Read together, the complete operation is: This assigns 'lif_bptt_fixed(membrane, spikes, grad_spikes, threshold=threshold, membrane_gradients=grad_membrane, surrogate_table_q15=table, surrogate_address_shift=address_shift,)' to 'expected_input, expected_h ' in host memory. Here expected_input means the value named 'expected input' in this block. The important operands are lif_bptt_fixed: the value named 'lif bptt fixed' in this block; membrane: the persistent LIF neuron state carrying charge between timesteps; spikes: a binary event produced when a neuron crosses its threshold. Context: the function test_lif_bptt_fabric_schedule_matches_fixed_point_recurrence, which handles test lif bptt fabric schedule matches fixed point recurrence.

Line 566: `emulator = FabricOperatorEmulator()` This assigns 'FabricOperatorEmulator()' to 'emulator ' in host memory. Here emulator means the value named 'emulator' in this block. The important operands are FabricOperatorEmulator: the value named 'fabric operator emulator' in this block. Context: the function test_lif_bptt_fabric_schedule_matches_fixe which handles test lif bptt fabric schedule matches fixed point recurrence.

Line 567: `got_input, got_h = execute_lif_bptt(` This statement continues through source line 576; the explanation uses the complete expression rather than only the first visual fragment. This assigns 'execute_lif_bptt(emulator, membrane, spikes, grad_spikes, threshold=threshold, membrane_gradients=grad_membrane, surrogate_table_q15=table, surrogate_address_shift=address_shift,)' to 'got_input, got_h ' in host memory. Here got_input means the value named 'got input' in this block. The important operands are execute_lif_bptt: the value named 'execute lif bptt' in this block; emulator: the value named 'emulator' in this block; membrane: the persistent LIF neuron state carrying charge between timesteps. Context: the function test_lif_bptt_fabric_schedule_matches_fixed_point_recurrence, which handles test lif bptt fabric schedule matches fixed point recurrence.

Line 568: `emulator,` This is continuation line 2 of the 10-line logical statement that begins at source line 567. Its exact fragment is 'emulator,'. The important operands are emulator: the value named 'emulator' in this block. Read together, the complete operation is: This assigns 'execute_lif_bptt(emulator, membrane, spikes, grad_spikes, threshold=threshold, membrane_gradients=grad_membrane, surrogate_table_q15=table, surrogate_address_shift=address_shift,)' to 'got_input, got_h ' in host memory. Here got_input means the value named 'got input' in this block. The important operands are execute_lif_bptt: the value named 'execute lif bptt' in this block; emulator: the value named 'emulator' in this block; membrane: the persistent LIF neuron state carrying charge between timesteps. Context: the function test_lif_bptt_fabric_schedule_matches_fixed_point_recurrence, which handles test lif bptt fabric schedule matches fixed point recurrence.

Line 569: `membrane,` This is continuation line 3 of the 10-line logical statement that begins at source line 567. Its exact fragment is 'membrane,'. The important operands are membrane: the persistent LIF neuron state carrying charge between timesteps. Read together, the complete operation is: This assigns 'execute_lif_bptt(emulator, membrane, spikes, grad_spikes, threshold=threshold, membrane_gradients=grad_membrane, surrogate_table_q15=table, surrogate_address_shift=address_shift,)' to 'got_input, got_h ' in host memory. Here got_input means the value named 'got input' in this block. The important operands are execute_lif_bptt: the value named 'execute lif bptt' in this block; emulator: the value named 'emulator' in this block; membrane: the persistent LIF neuron state carrying charge between timesteps. Context: the function test_lif_bptt_fabric_schedule_matches_fixed_point_recurrence, which handles test lif bptt fabric schedule matches fixed point recurrence.

Line 570: `spikes,` This is continuation line 4 of the 10-line logical statement that begins at source line 567. Its exact fragment is 'spikes,'. The important operands are spikes: a binary event produced when a neuron crosses its threshold. Read together, the complete operation is: This assigns 'execute_lif_bptt(emulator, membrane, spikes, grad_spikes, threshold=threshold, membrane_gradients=grad_membrane, surrogate_table_q15=table, surrogate_address_shift=address_shif)' to 'got_input, got_h ' in host memory. Here got_input means the value named 'got input' in this block. The important operands are execute_lif_bptt: the value named 'execute lif bptt' in this block; emulator: the value named 'emulator' in this block; membrane: the persistent LIF neuron state carrying charge between timesteps. Context: the function test_lif_bptt_fabric_schedule_matches_fixed_point_recurrence, which handles test lif bptt fabric schedule matches fixed point recurrence.

Line 571: `grad_spikes,` This is continuation line 5 of the 10-line logical statement that begins at source line 567. Its exact fragment is 'grad_spikes,'. The important operands are grad_spikes: a binary event produced when a neuron crosses its threshold. Read together, the complete operation is: This assigns 'execute_lif_bptt(emulator, membrane, spikes, grad_spikes, threshold=threshold, membrane_gradients=grad_membrane, surrogate_table_q15=table, surrogate_address_shift=address_shift,)' to 'got_input, got_h ' in host memory. Here got_input means the value named 'got input' in this block. The important operands are execute_lif_bptt: the value named 'execute lif bptt' in this block; emulator: the value named 'emulator' in this block; membrane: the persistent LIF neuron state carrying charge between timesteps. Context: the function test_lif_bptt_fabric_schedule_matches_fixed_point_recurrence, which handles test lif bptt fabric schedule matches fixed point recurrence.

Line 572: `threshold=threshold,` This is continuation line 6 of the 10-line logical statement that begins at source line 567. Its exact fragment is 'threshold=threshold,'. The important operands are threshold: the membrane level at which a neuron emits a spike. Read together, the complete operation is: This assigns 'execute_lif_bptt(emulator, membrane, spikes, grad_spikes, threshold=threshold, membrane_gradients=grad_membrane, surrogate_table_q15=table, surrogate_address_shift=address_shift,)' to 'got_input, got_h ' in host memory. Here got_input means the value named 'got input' in this block. The important operands are execute_lif_bptt: the value named 'execute lif bptt' in this block; emulator: the value named 'emulator' in this block; membrane: the persistent LIF neuron state carrying charge between timesteps. Context: the function test_lif_bptt_fabric_schedule_matches_fixed_point_recurrence, which handles test lif bptt fabric schedule matches fixed point recurrence.

Line 573: `membrane_gradients=grad_membrane,` This is continuation line 7 of the 10-line logical statement that begins at source line 567. Its exact fragment is 'membrane_gradients=grad_membrane,'. The important operands are membrane_gradients: the persistent LIF neuron state carrying charge between timesteps; grad_membrane: the persistent LIF neuron state carrying charge between timesteps. Read together, the complete operation is: This assigns 'execute_lif_bptt(emulator, membrane, spikes, grad_spikes, threshold=threshold, membrane_gradients=grad_membrane, surrogate_table_q15=table, surrogate_address_shift=address_shift,)' to 'got_input, got_h ' in host memory. Here got_input means the value named 'got input' in this block. The important operands are execute_lif_bptt: the value named 'execute lif bptt' in this block; emulator: the value named 'emulator' in this block; membrane: the persistent LIF neuron state carrying charge between timesteps. Context: the function test_lif_bptt_fabric_schedule_matches_fixed_point_recur which handles test lif bptt fabric schedule matches fixed point recurrence.

Line 574: `surrogate_table_q15=table,` This is continuation line 8 of the 10-line logical statement that begins at source line 567. Its exact fragment is 'surrogate_table_q15=table,'. The important operands are surrogate_table_q15: the value named 'surrogate table q15' in this block; table: the value named 'table' in this block. Read together, the complete operation is: This assigns 'execute_lif_bptt(emulator, membrane, spikes, grad_spikes, threshold=threshold, membrane_gradients=grad_membrane, surrogate_table_q15=table, surrogate_address_shift=address_shift,)' to 'got_input, got_h ' in host memory. Here got_input means the value named 'got input' in this block. The important operands

are execute_lif_bptt: the value named 'execute lif bptt' in this block; emulator: the value named 'emulator' in this block; membrane: the persistent LIF neuron state carrying charge between timesteps. Context: the function test_lif_bptt_fabric_schedule_matches_fixed_point_recurrence, which handles test lif bptt fabric schedule matches fixed point recurrence.

Line 575: `surrogate_address_shift=address_shift,` This is continuation line 9 of the 10-line logical statement that begins at source line 567. Its exact fragment is 'surrogate_address_shift=address_shift,'. The important operands are surrogate_address_shift: the value named 'surrogate address shift' in this block; address_shift: the value named 'address shift' in this block. Read together, the complete operation is: This assigns 'execute_lif_bptt(emulator, membrane, spikes, grad_spikes, threshold=threshold, membrane_gradients=grad_membrane, surrogate_table_q15=table, surrogate_address_shift=address_shift,)' to 'got_input, got_h ' in host memory. Here got_input means the value named 'got input' in this block. The important operands are execute_lif_bptt: the value named 'execute lif bptt' in this block; emulator: the value named 'emulator' in this block; membrane: the persistent LIF neuron state carrying charge between timesteps. Context: the function test_lif_bptt_fabric_schedule_matches_fixed_point_recurrence, which handles test lif bptt fabric schedule matches fixed point recurrence.

Line 576: `)` This is continuation line 10 of the 10-line logical statement that begins at source line 567. Its exact fragment is ')'. The expression is a literal or structural operator and has no hidden software state. Read together, the complete operation is: This assigns 'execute_lif_bptt(emulator, membrane, spikes, grad_spikes, threshold=threshold, membrane_gradients=grad_membrane, surrogate_table_q15=table, surrogate_address_shift=address_shift,)' to 'got_input, got_h ' in host memory. Here got_input means the value named 'got input' in this block. The important operands are execute_lif_bptt: the value named 'execute lif bptt' in this block; emulator: the value named 'emulator' in this block; membrane: the persistent LIF neuron state carrying charge between timesteps. Context: the function test_lif_bptt_fabric_schedule_matches_fixed_point_recurrence, which handles test lif bptt fabric schedule matches fixed point recurrence.

Line 577: `np.testing.assert_array_equal(got_input, expected_input)` This calls 'np.testing.assert_array_equal' with 'got_input, expected_input' inside the function test_lif_bptt_fabric_schedule_matches_fixed_point_recurrence, which handles test lif bptt fabric schedule matches fixed point recurrence. The call advances the host-side job that checks neuraedge training behavior independently with Python assertions.

Line 578: `np.testing.assert_array_equal(got_h, expected_h)` This calls 'np.testing.assert_array_equal' with 'got_h, expected_h' inside the function test_lif_bptt_fabric_schedule_matches_fixed_point_recurrence, which handles test lif bptt fabric schedule matches fixed point recurrence. The call advances the host-side job that checks neuraedge training behavior independently with Python assertions.

Line 579: `self.assertEqual(emulator.command_count, 1 + time_steps * 3 * 7)` This calls 'self.assertEqual' with 'emulator.command_count, 1 + time_steps * 3 * 7' inside the function test_lif_bptt_fabric_schedule_matches_fixed_point_ which handles test lif bptt fabric schedule matches fixed point recurrence. The call advances the host-side job that checks neuraedge training behavior independently with Python assertions.

Line 581: `def test_maxpool_backward_matches_first_winner_and_overlap_accumulation(self) -> None:` This starts function test_maxpool_backward_matches_first_winner_and_overlap_accumulation. Its indented body performs test maxpool backward matches first winner and overlap accumulation as part of the file that checks neuraedge training behavior independently with Python assertions; it runs only when called.

Line 582: `values = self.rng.integers(-20, 21, size=(1, 2, 5, 6), dtype=np.int64)` This assigns 'self.rng.integers(-20, 21, size=(1, 2, 5, 6), dtype=np.int64)' to 'values ' in host memory. Here values means the value named 'values' in this block. The important operands are rng: the value named 'rng' in this block; integers: the value named 'integers' in this block; size: the value named 'size' in this block. Context: the function test_maxpool_backward_matches_first_winner_and_overla which handles test maxpool backward matches first winner and overlap accumulation.

Line 583: `values[:, :, 1:4, 1:5] = 7` This assigns '7' to 'values[' in host memory. Here values means the value named 'values' in this block. The expression is a literal or structural operator and has no hidden software state. Context: the function test_maxpool_backward_matches_first_winner_and_overlap_accumulation, which handles test maxpool backward matches first winner and overlap accumulation.

Line 584: `values[0, 0, 0, 0] = -(1 << 31)` This assigns '-(1 << 31)' to 'values[0, 0, 0, 0] ' in host memory. Here values means the value named 'values' in this block. The expression is a literal or structural operator and has no hidden software state. Context: the function test_maxpool_backward_matches_first_winner_and_overlap_accumulation, which handles test maxpool backward matches first winner and overlap accumulation.

Line 585: `gradients = self.rng.integers(-1000, 1001, size=(1, 2, 3, 3), dtype=np.int64)` This assigns 'self.rng.integers(-1000, 1001, size=(1, 2, 3, 3), dtype=np.int64)' to 'gradients ' in host memory. Here gradients means the signed loss derivative used to update a learned parameter. The important operands are rng: the value named 'rng' in this block; integers: the value named 'integers' in this block; size: the value named 'size' in this block. Context: the function test_maxpool_backward_matches_first_winner_and_overlap_accumulation, which handles test maxpool backward matches first winner and overlap accumulation.

Line 586: `expected_gradient, expected_winners = maxpool2d_backward_fixed(` This statement continues through source line 592; the explanation uses the complete expression rather than only the first visual fragment. This assigns 'maxpool2d_backward_fixed(values, gradients, kernel_size=3, stride=2, padding=1,)' to 'expected_gradient, expected_winners ' in host memory. Here expected_gradient means the signed loss derivative used to update a learned parameter. The important operands are maxpool2d_backward_fixed: the value named 'maxpool2d backward fixed' in this block; values: the value named 'values' in this block; gradients: the signed loss derivative used to update a learned parameter. Context: the function test_maxpool_backward_matches_first_winner_and_overlap_accumulation, which handles test maxpool backward matches first winner and overlap accumulation.

Line 587: `values,` This is continuation line 2 of the 7-line logical statement that begins at source line 586. Its exact fragment is 'values,'. The important operands are values: the value named 'values' in this block. Read together, the complete operation is: This assigns 'maxpool2d_backward_fixed(values, gradients, kernel_size=3, stride=2, padding=1,)' to 'expected_gradient, expected_winners ' in host memory. Here expected_gradient means the signed loss derivative used to update a learned parameter. The important operands are maxpool2d_backward_fixed: the value named 'maxpool2d backward fixed' in this block; values: the value named 'values' in this block; gradients: the signed loss derivative used to update a learned parameter. Context: the function test_maxpool_backward_matches_first_winner_and_overlap_accumulation, which handles test maxpool backward matches first winner and overlap accumulation.

Line 588: `gradients,` This is continuation line 3 of the 7-line logical statement that begins at source line 586. Its exact fragment is 'gradients,'. The important operands are gradients: the signed loss derivative used to update a learned parameter. Read together, the complete operation is: This assigns 'maxpool2d_backward_fixed(values, gradients, kernel_size=3, stride=2, padding=1,)' to 'expected_gradient, expected_winners ' in host memory. Here expected_gradient means the signed loss derivative used to update a learned parameter. The important operands are maxpool2d_backward_fixed: the value named 'maxpool2d backward fixed' in this block; values: the value named 'values' in this block; gradients: the signed loss derivative used to update a learned parameter. Context: the function test_maxpool_backward_matches_first_winner_and_overlap_accumulation, which handles test maxpool backward matches first winner and overlap accumulation.

Line 589: `kernel_size=3,` This is continuation line 4 of the 7-line logical statement that begins at source line 586. Its exact fragment is 'kernel_size=3,'. The important operands are kernel_size: the value named 'kernel size' in this block. Read together, the complete operation is: This assigns 'maxpool2d_backward_fixed(values, gradients, kernel_size=3, stride=2, padding=1,)' to 'expected_gradient, expected_winners ' in host memory. Here expected_gradient means the signed loss derivative used to update a learned parameter. The important operands are maxpool2d_backward_fixed: the value named 'maxpool2d backward fixed' in this block; values: the value named 'values' in this block; gradients: the signed loss derivative used to update a learned parameter. Context: the function test_maxpool_backward_matches_first_winner_and_overlap_accumulation, which handles test maxpool backward matches first winner and overlap accumulation.

Line 590: `stride=2,` This is continuation line 5 of the 7-line logical statement that begins at source line 586. Its exact fragment is 'stride=2,'. The important operands are stride: the value named 'stride' in this block. Read together, the complete operation is: This assigns 'maxpool2d_backward_fixed(values, gradients, kernel_size=3, stride=2, padding=1,)' to 'expected_gradient, expected_winners ' in host memory. Here expected_gradient means the signed loss derivative used to update a learned parameter. The important operands are maxpool2d_backward_fixed: the value named 'maxpool2d backward fixed' in this block; values: the value named 'values' in this block; gradients: the signed loss derivative used to

update a learned parameter. Context: the function test_maxpool_backward_matches_first_winner_and_overlap_accumulation, which handles test maxpool backward matches first winner and overlap accumulation.

Line 591: `padding=1,` This is continuation line 6 of the 7-line logical statement that begins at source line 586. Its exact fragment is 'padding=1,'. The important operands are padding: the value named 'padding' in this block. Read together, the complete operation is: This assigns 'maxpool2d_backward_fixed(values, gradients, kernel_size=3, stride=2, padding=1,)' to 'expected_gradient, expected_winners ' in host memory. Here expected_gradient means the signed loss derivative used to update a learned parameter. The important operands are maxpool2d_backward_fixed: the value named 'maxpool2d backward fixed' in this block; values: the value named 'values' in this block; gradients: the signed loss derivative used to update a learned parameter. Context: the function test_maxpool_backward_matches_first_winner_and_overla which handles test maxpool backward matches first winner and overlap accumulation.

Line 592: `)` This is continuation line 7 of the 7-line logical statement that begins at source line 586. Its exact fragment is ')'. The expression is a literal or structural operator and has no hidden software state. Read together, the complete operation is: This assigns 'maxpool2d_backward_fixed(values, gradients, kernel_size=3, stride=2, padding=1,)' to 'expected_gradient, expected_winners ' in host memory. Here expected_gradient means the signed loss derivative used to update a learned parameter. The important operands are maxpool2d_backward_fixed: the value named 'maxpool2d backward fixed' in this block; values: the value named 'values' in this block; gradients: the signed loss derivative used to update a learned parameter. Context: the function test_maxpool_backward_matches_first_winner_and_overlap_accumulation, which handles test maxpool backward matches first winner and overlap accumulation.

Line 593: `emulator = FabricOperatorEmulator()` This assigns 'FabricOperatorEmulator()' to 'emulator ' in host memory. Here emulator means the value named 'emulator' in this block. The important operands are FabricOperatorEmulator: the value named 'fabric operator emulator' in this block. Context: the function test_maxpool_backward_matches_first_wi which handles test maxpool backward matches first winner and overlap accumulation.

Line 594: `got_gradient, got_winners = execute_maxpool2d_backward(` This statement continues through source line 601; the explanation uses the complete expression rather than only the first visual fragment. This assigns 'execute_maxpool2d_backward(emulator, values, gradients, kernel_size=3, stride=2, padding=1,)' to 'got_gradient, got_winners ' in host memory. Here got_gradient means the signed loss derivative used to update a learned parameter. The important operands are execute_maxpool2d_backward: the value named 'execute maxpool2d backward' in this block; emulator: the value named 'emulator' in this block; values: the value named 'values' in this block. Context: the function test_maxpool_backward_matches_first_winner_and_overlap_accumulation, which handles test maxpool backward matches first winner and overlap accumulation.

Line 595: `emulator,` This is continuation line 2 of the 8-line logical statement that begins at source line 594. Its exact fragment is 'emulator,'. The important operands are emulator: the value named 'emulator' in this block. Read together, the complete operation is: This assigns 'execute_maxpool2d_backward(emulator, values, gradients, kernel_size=3, stride=2, padding=1,)' to 'got_gradient, got_winners ' in host memory. Here got_gradient means the signed loss derivative used to update a learned parameter. The important operands are execute_maxpool2d_backward: the value named 'execute maxpool2d backward' in this block; emulator: the value named 'emulator' in this block; values: the value named 'values' in this block. Context: the function test_maxpool_backward_matches_first_winner_and_overlap_accumulation, which handles test maxpool backward matches first winner and overlap accumulation.

Line 596: `values,` This is continuation line 3 of the 8-line logical statement that begins at source line 594. Its exact fragment is 'values,'. The important operands are values: the value named 'values' in this block. Read together, the complete operation is: This assigns 'execute_maxpool2d_backward(emulator, values, gradients, kernel_size=3, stride=2, padding=1,)' to 'got_gradient, got_winners ' in host memory. Here got_gradient means the signed loss derivative used to update a learned parameter. The important operands are execute_maxpool2d_backward: the value named 'execute maxpool2d backward' in this block; emulator: the value named 'emulator' in this block; values: the value named 'values' in this block. Context: the function test_maxpool_backward_matches_first_winner_and_overlap_accumulation, which handles test maxpool backward matches first winner and overlap accumulation.

Line 597: `gradients,` This is continuation line 4 of the 8-line logical statement that begins at source line 594. Its exact fragment is 'gradients,'. The important operands are gradients: the signed loss derivative used to update a learned parameter. Read together, the complete operation is: This assigns 'execute_maxpool2d_backward(emulator, values, gradients,

kernel_size=3, stride=2, padding=1,)‘ to ‘got_gradient, got_winners ‘ in host memory. Here got_gradient means the signed loss derivative used to update a learned parameter. The important operands are execute_maxpool2d_backward: the value named 'execute maxpool2d backward' in this block; emulator: the value named 'emulator' in this block; values: the value named 'values' in this block. Context: the function test_maxpool_backward_matches_first_winner_and_overlap_accum which handles test maxpool backward matches first winner and overlap accumulation.

Line 598: `kernel_size=3,` This is continuation line 5 of the 8-line logical statement that begins at source line 594. Its exact fragment is ‘kernel_size=3,‘. The important operands are kernel_size: the value named 'kernel size' in this block. Read together, the complete operation is: This assigns ‘execute_maxpool2d_backward(emulator, values, gradients, kernel_size=3, stride=2, padding=1,)‘ to ‘got_gradient, got_winners ‘ in host memory. Here got_gradient means the signed loss derivative used to update a learned parameter. The important operands are execute_maxpool2d_backward: the value named 'execute maxpool2d backward' in this block; emulator: the value named 'emulator' in this block; values: the value named 'values' in this block. Context: the function test_maxpool_backward_matches_first_winner_and_overlap_accumula which handles test maxpool backward matches first winner and overlap accumulation.

Line 599: `stride=2,` This is continuation line 6 of the 8-line logical statement that begins at source line 594. Its exact fragment is ‘stride=2,‘. The important operands are stride: the value named 'stride' in this block. Read together, the complete operation is: This assigns ‘execute_maxpool2d_backward(emulator, values, gradients, kernel_size=3, stride=2, padding=1,)‘ to ‘got_gradient, got_winners ‘ in host memory. Here got_gradient means the signed loss derivative used to update a learned parameter. The important operands are execute_maxpool2d_backward: the value named 'execute maxpool2d backward' in this block; emulator: the value named 'emulator' in this block; values: the value named 'values' in this block. Context: the function test_maxpool_backward_matches_first_winner_and_overlap_accumulation, which handles test maxpool backward matches first winner and overlap accumulation.

Line 600: `padding=1,` This is continuation line 7 of the 8-line logical statement that begins at source line 594. Its exact fragment is ‘padding=1,‘. The important operands are padding: the value named 'padding' in this block. Read together, the complete operation is: This assigns ‘execute_maxpool2d_backward(emulator, values, gradients, kernel_size=3, stride=2, padding=1,)‘ to ‘got_gradient, got_winners ‘ in host memory. Here got_gradient means the signed loss derivative used to update a learned parameter. The important operands are execute_maxpool2d_backward: the value named 'execute maxpool2d backward' in this block; emulator: the value named 'emulator' in this block; values: the value named 'values' in this block. Context: the function test_maxpool_backward_matches_first_winner_and_overlap_accumulation, which handles test maxpool backward matches first winner and overlap accumulation.

Line 601: `)` This is continuation line 8 of the 8-line logical statement that begins at source line 594. Its exact fragment is ‘)‘. The expression is a literal or structural operator and has no hidden software state. Read together, the complete operation is: This assigns ‘execute_maxpool2d_backward(emulator, values, gradients, kernel_size=3, stride=2, padding=1,)‘ to ‘got_gradient, got_winners ‘ in host memory. Here got_gradient means the signed loss derivative used to update a learned parameter. The important operands are execute_maxpool2d_backward: the value named 'execute maxpool2d backward' in this block; emulator: the value named 'emulator' in this block; values: the value named 'values' in this block. Context: the function test_maxpool_backward_matches_first_winner_and_overlap_accumulation, which handles test maxpool backward matches first winner and overlap accumulation.

Line 602: `np.testing.assert_array_equal(got_winners, expected_winners)` This calls ‘np.testing.assert_array_equal‘ with ‘got_winners, expected_winners‘ inside the function test_maxpool_backward_matches_first_winner_and_overlap_accumul which handles test maxpool backward matches first winner and overlap accumulation. The call advances the host-side job that checks neuraedge training behavior independently with Python assertions.

Line 603: `np.testing.assert_array_equal(got_gradient, expected_gradient)` This calls ‘np.testing.assert_array_equal‘ with ‘got_gradient, expected_gradient‘ inside the function test_maxpool_backward_matches_first_winner_and_overlap_accumu which handles test maxpool backward matches first winner and overlap accumulation. The call advances the host-side job that checks neuraedge training behavior independently with Python assertions.

Line 604: `self.assertGreater(emulator.command_count, 100)` This calls ‘self.assertGreater‘ with ‘emulator.command_count 100‘ inside the function test_maxpool_backward_matches_first_winner_and_overlap_accumulation, which handles test maxpool backward matches first winner and overlap accumulation. The call advances the host-side job that checks neuraedge training behavior independently with Python assertions.

Line 606: `def test_real_spikingformer_manifest_has_no_training_coverage_holes(self) -> None:` This starts function test_real_spikingformer_manifest_has_no_training_coverage_holes. Its indented body performs test real spikingformer manifest has no training coverage holes as part of the file that checks neuraedge training behavior independently with Python assertions; it runs only when called.

Line 607: `root = Path(__file__).resolve().parents[1]` This assigns 'Path(___file___).resolve().parents[1]' to 'root ' in host memory. Here root means the value named 'root' in this block. The important operands are Path: the value named 'path' in this block; ___file___: the value named 'file' in this block; resolve: the value named 'resolve' in this block. Context: the function test_real_spikingformer_manifest_has_no_training_coverage_holes, which handles test real spikingformer manifest has no training coverage holes.

Line 608: `result = build_spikingformer_training_coverage(` This statement continues through source line 611; the explanation uses the complete expression rather than only the first visual fragment. This assigns 'build_spikingformer_training_
root / "outputs" / "spikingformer_reference" / "spikingformer_execution_manifest.json", root / "outputs" / "spikingformer_hardware_parameters" / "spikingformer_neuraedge_weights.json",)' to 'result ' in host memory. Here result means the value named 'result' in this block. The important operands are build_spikingformer_training_coverage: the value named 'build spikingformer training coverage' in this block; root: the value named 'root' in this block; outputs: the value named 'outputs' in this block. Context: the function test_real_spikingformer_manifest_has_no_training_coverage_holes, which handles test real spikingformer manifest has no training coverage holes.

Line 609: `root / "outputs" / "spikingformer_reference" / "spikingformer_execution_manifest.json",` This is continuation line 2 of the 4-line logical statement that begins at source line 608. Its exact fragment is 'root / "outputs" / "spikingformer_reference" / "spikingformer_execution_manifest.json",'. The important operands are root: the value named 'root' in this block; outputs: the value named 'outputs' in this block; spikingformer_reference: the value named 'spikingformer reference' in this block. Read together, the complete operation is: This assigns 'build_spikingformer_training_covera
root / "outputs" / "spikingformer_reference" / "spikingformer_execution_manifest.json", root / "outputs" / "spikingformer_hardware_parameters" / "spikingformer_neuraedge_weights.json",)' to 'result ' in host memory. Here result means the value named 'result' in this block. The important operands are build_spikingformer_training_coverage: the value named 'build spikingformer training coverage' in this block; root: the value named 'root' in this block; outputs: the value named 'outputs' in this block. Context: the function test_real_spikingformer_manifest_has_no_training_coverage_holes, which handles test real spikingformer manifest has no training coverage holes.

Line 610: `root / "outputs" / "spikingformer_hardware_parameters" / "spikingformer_neuraedge_weights.json",` This is continuation line 3 of the 4-line logical statement that begins at source line 608. Its exact fragment is 'root / "outputs" / "spikingformer_hardware_parameters" / "spikingformer_neuraedge_weights.json",'. The important operands are root: the value named 'root' in this block; outputs: the value named 'outputs' in this block; spikingformer_hardware_parameters: the value named 'spikingformer hardware parameters' in this block. Read together, the complete operation is: This assigns 'build_spikingformer_training_coverage(root / "outputs" / "spikingformer_reference" / "spikingformer_execution_manifest.json", root / "outputs" / "spikingformer_hardware_parameters" / "spikingformer_neuraedge_weights.json",)' to 'result ' in host memory. Here result means the value named 'result' in this block. The important operands are build_spikingformer_training_c
the value named 'build spikingformer training coverage' in this block; root: the value named 'root' in this block; outputs: the value named 'outputs' in this block. Context: the function test_real_spikingformer_manifest_has_no_training_coverage_hole
which handles test real spikingformer manifest has no training coverage holes.

Line 611: `)` This is continuation line 4 of the 4-line logical statement that begins at source line 608. Its exact fragment is ')'. The expression is a literal or structural operator and has no hidden software state. Read together, the complete operation is: This assigns 'build_spikingformer_training_coverage(root / "outputs" / "spikingformer_reference" / "spikingformer_execution_manifest.json", root / "outputs" / "spikingformer_hardware_parameters" / "spikingformer_neuraedge_weights.json",)' to 'result ' in host memory. Here result means the value named 'result' in this block. The important operands are build_spikingformer_training_coverage: the value named 'build spikingformer training coverage' in this block; root: the value named 'root' in this block; outputs: the value named 'outputs' in this block. Context: the function test_real_spikingformer_manifest_has_no_training_coverage_holes, which handles test real spikingformer manifest has no training coverage holes.

Line 612: `summary = result["summary"]` This assigns 'result["summary"]' to 'summary ' in host memory. Here summary means the value named 'summary' in this block. The important operands are result: the value named 'result' in this

block; summary: the value named 'summary' in this block. Context: the function test_real_spikingformer_manifest_has_no_train which handles test real spikingformer manifest has no training coverage holes.

Line 613: `self.assertEqual(summary["execution_operator_count"], 43)` This calls 'self.assertEqual' with 'summary["execution_operator_count"], 43' inside the function test_real_spikingformer_manifest_has_no_training_coverage_holes, which handles test real spikingformer manifest has no training coverage holes. The call advances the host-side job that checks neuraedge training behavior independently with Python assertions.

Line 614: `self.assertEqual(summary["covered_execution_operator_count"], 43)` This calls 'self.assertEqual' with 'summary["covered_execution_operator_count"], 43' inside the function test_real_spikingformer_manifest_has_no_training which handles test real spikingformer manifest has no training coverage holes. The call advances the host-side job that checks neuraedge training behavior independently with Python assertions.

Line 615: `self.assertEqual(summary["learned_affine_group_count"], 30)` This calls 'self.assertEqual' with 'summary["learned_affine_group_count"], 30' inside the function test_real_spikingformer_manifest_has_no_training_coverage_ which handles test real spikingformer manifest has no training coverage holes. The call advances the host-side job that checks neuraedge training behavior independently with Python assertions.

Line 616: `self.assertEqual(summary["backbone_projection_count"], 29)` This calls 'self.assertEqual' with 'summary["backbone_projection_count"], 29' inside the function test_real_spikingformer_manifest_has_no_training_coverage_holes, which handles test real spikingformer manifest has no training coverage holes. The call advances the host-side job that checks neuraedge training behavior independently with Python assertions.

Line 617: `self.assertEqual(summary["dynamic_attention_matmul_count"], 8)` This calls 'self.assertEqual' with 'summary["dynamic_attention_matmul_count"], 8' inside the function test_real_spikingformer_manifest_has_no_training_cove which handles test real spikingformer manifest has no training coverage holes. The call advances the host-side job that checks neuraedge training behavior independently with Python assertions.

Line 618: `self.assertEqual(summary["lif_node_count"], 32)` This calls 'self.assertEqual' with 'summary["lif_node_count"] 32' inside the function test_real_spikingformer_manifest_has_no_training_coverage_holes, which handles test real spikingformer manifest has no training coverage holes. The call advances the host-side job that checks neuraedge training behavior independently with Python assertions.

Line 619: `self.assertEqual(summary["trainable_deployed_parameter_elements"], 9_295_978)` This calls 'self.assertEqu with 'summary["trainable_deployed_parameter_elements"], 9_295_978' inside the function test_real_spikingformer_manifest_ha which handles test real spikingformer manifest has no training coverage holes. The call advances the host-side job that checks neuraedge training behavior independently with Python assertions.

Line 620: `self.assertEqual(summary["uncovered_operator_count"], 0)` This calls 'self.assertEqual' with 'summary["uncovered_operator_count"], 0' inside the function test_real_spikingformer_manifest_has_no_training_coverage_holes, which handles test real spikingformer manifest has no training coverage holes. The call advances the host-side job that checks neuraedge training behavior independently with Python assertions.

Line 621: `self.assertTrue(summary["full_deployed_backbone_covered"])` This calls 'self.assertTrue' with 'summary["full_deployed_backbone_covered"]' inside the function test_real_spikingformer_manifest_has_no_training_coverage_hol which handles test real spikingformer manifest has no training coverage holes. The call advances the host-side job that checks neuraedge training behavior independently with Python assertions.

Line 622: `self.assertEqual(` This statement continues through source line 628; the explanation uses the complete expression rather than only the first visual fragment. This calls 'self.assertEqual' with ' {item["name"] for item in result["operator_coverage"]}, {item["name"] for item in result["learned_affine_coverage"]} | {item["name"] for item in result["dynamic_attention_coverage"]} | {f"block.{index}.residuals" for index in range(4)} | {"global_average_pool"}, ' inside the function test_real_spikingformer_manifest_has_no_training_coverage_holes, which handles test real spikingformer manifest has no training coverage holes. The call advances the host-side job that checks neuraedge training behavior independently with Python assertions.

Line 623: `{item["name"] for item in result["operator_coverage"]},` This is continuation line 2 of the 7-line logical statement that begins at source line 622. Its exact fragment is '{item["name"] for item in result["operator_coverage"]},'. The important operands are item: the value named 'item' in this block; name: the value named 'name' in this block; for: the value named 'for' in this block. Read together, the complete operation is: This calls 'self.assertEqual' with ' {item["name"] for item in result["operator_coverage"]}, {item["name"] for item in result["learned_affine_coverage"]} | {item["name"] for item in result["dynamic_attention_coverage"]} | {f"block.{index}.residuals" for index in range(4)} | {"global_average_pool"}, ' inside the function test_real_spikingformer_manifest_has_no_training_coverage_holes, which handles test real spikingformer manifest has no training coverage holes. The call advances the host-side job that checks neuraedge training behavior independently with Python assertions.

Line 624: `{item["name"] for item in result["learned_affine_coverage"]}` This is continuation line 3 of the 7-line logical statement that begins at source line 622. Its exact fragment is '{item["name"] for item in result["learned_affine_coverage"]' The important operands are item: the value named 'item' in this block; name: the value named 'name' in this block; for: the value named 'for' in this block. Read together, the complete operation is: This calls 'self.assertEqual' with ' {item["name"] for item in result["operator_coverage"]}, {item["name"] for item in result["learned_affine_coverage"]} | {item["name"] for item in result["dynamic_attention_coverage"]} | {f"block.{index}.residuals" for index in range(4)} | {"global_average_pool"}, ' inside the function test_real_spikingformer_manifest_has_no_training_coverage_holes, which handles test real spikingformer manifest has no training coverage holes. The call advances the host-side job that checks neuraedge training behavior independently with Python assertions.

Line 625: `| {item["name"] for item in result["dynamic_attention_coverage"]}` This is continuation line 4 of the 7-line logical statement that begins at source line 622. Its exact fragment is '| {item["name"] for item in result["dynamic_attention_coverage"]}'. The important operands are item: the value named 'item' in this block; name: the value named 'name' in this block; for: the value named 'for' in this block. Read together, the complete operation is: This calls 'self.assertEqual' with ' {item["name"] for item in result["operator_coverage"]}, {item["name"] for item in result["learned_affine_coverage"]} | {item["name"] for item in result["dynamic_attention_coverage"]} | {f"block.{index}.residuals" for index in range(4)} | {"global_average_pool"}, ' inside the function test_real_spikingformer_manifest_has_no_training_covera which handles test real spikingformer manifest has no training coverage holes. The call advances the host-side job that checks neuraedge training behavior independently with Python assertions.

Line 626: `| {f"block.{index}.residuals" for index in range(4)}` This is continuation line 5 of the 7-line logical statement that begins at source line 622. Its exact fragment is '| {f"block.{index}.residuals" for index in range(4)}'. The important operands are f: the value named 'f' in this block; block: the value named 'block' in this block; index: an integer selecting one tensor element, lane, bank, or state entry. Read together, the complete operation is: This calls 'self.assertEqual' with ' {item["name"] for item in result["operator_coverage"]}, {item["name"] for item in result["learned_affine_coverage"]} | {item["name"] for item in result["dynamic_attention_coverage"]} | {f"block.{index}.residuals" for index in range(4)} | {"global_average_pool"}, ' inside the function test_real_spikingformer_manifest_has_no_training_covera which handles test real spikingformer manifest has no training coverage holes. The call advances the host-side job that checks neuraedge training behavior independently with Python assertions.

Line 627: `| {"global_average_pool"},` This is continuation line 6 of the 7-line logical statement that begins at source line 622. Its exact fragment is '| {"global_average_pool"},'. The important operands are global_average_pool: the value named 'global average pool' in this block. Read together, the complete operation is: This calls 'self.assertEqual' with ' {item["name"] for item in result["operator_coverage"]}, {item["name"] for item in result["learned_affine_coverage"]} | {item["name"] for item in result["dynamic_attention_coverage"]} | {f"block.{index}.residuals" for index in range(4)} | {"global_average_pool"}, ' inside the function test_real_spikingformer_manifest_has_no_training_coverage_holes, which handles test real spikingformer manifest has no training coverage holes. The call advances the host-side job that checks neuraedge training behavior independently with Python assertions.

Line 628: `)` This is continuation line 7 of the 7-line logical statement that begins at source line 622. Its exact fragment is ')'. The expression is a literal or structural operator and has no hidden software state. Read together, the complete operation is: This calls 'self.assertEqual' with ' {item["name"] for item in result["operator_coverage"]}, {item["name"] for item in result["learned_affine_coverage"]} | {item["name"] for item in result["dynamic_attention_coverage"]} | {f"block.{index}.residuals" for index in range(4)} | {"global_average_pool"}, ' inside the function test_real_spikingformer_manifest_has_no_training_covera which handles test real spikingformer manifest has no training coverage holes. The call advances the host-side job that checks neuraedge training behavior independently with Python assertions.

Line 631: `if __name__ == "__main__":` This executes the following indented host-code branch only when ‘___name___ == "___main___"‘ is true. The important operands are ___name___: the value named ’name’ in this block; ___main___: the value named ’main’ in this block. Context: the file whose role is to checks neuraedge training behavior independently with Python assertions.

Line 632: `unittest.main()` This calls ‘unittest.main‘ with “ inside the file whose role is to checks neuraedge training behavior independently with Python assertions. The call advances the host-side job that checks neuraedge training behavior independently with Python assertions.

69 tests/test_run_spikingformer_pynq.py

Role in the complete system: checks run spikingformer pynq behavior independently with Python assertions.

69.1 Beginner architecture map

Dataflow responsibility This file's end-to-end responsibility is to checks run spikingformer pynq behavior independently with Python assertions.

Where it runs This is sequential host software. Python objects live in CPU memory; they become FPGA work only when the compiler packs a command or payload and the PYNQ driver transfers those bytes through AXI DMA or AXI-Lite.

Public structure Classes: PynqInferenceInputTests. Functions: test_raw_nhwc_and_nchw_normalization, test_rejects_wrong Each function annotation below names its enclosing function so an array operation is tied to the model, compiler, driver, test, or report phase that uses it.

Numeric and failure boundary Shapes, signedness, byte order, scaling, and saturation are part of the hardware contract. Validation exceptions are functional safety checks: rejecting malformed input before DMA is different from silently clipping, reshaping, or continuing with an incompatible artifact.

69.2 Complete source

```
from __future__ import annotations

import unittest

import numpy as np

from run_spikingformer_pynq import CIFAR10_MEAN, CIFAR10_STD, prepare_input

class PynqInferenceInputTests(unittest.TestCase):
    def test_raw_nhwc_and_nchw_normalization(self) -> None:
        raw_nhwc = np.zeros((32, 32, 3), dtype=np.uint8)
        raw_nhwc[..., 1] = 255
        result = prepare_input(raw_nhwc, "raw-u8")
        self.assertEqual(result.shape, (1, 3, 32, 32))
        self.assertAlmostEqual(float(result[0, 0, 0, 0]), -float(CIFAR10_MEAN[0] / CIFAR10_STD[0]), places=6)
        self.assertAlmostEqual(float(result[0, 1, 0, 0]), float((1 - CIFAR10_MEAN[1]) / CIFAR10_STD[1]), places=6)
        np.testing.assert_array_equal(
            prepare_input(result, "normalized"), result.astype(np.float32))

    def test_rejects_wrong_shape_and_out_of_range_raw_values(self) -> None:
        with self.assertRaises(ValueError):
            prepare_input(np.zeros((28, 28), dtype=np.uint8), "raw-u8")
        with self.assertRaises(ValueError):
            prepare_input(np.full((3, 32, 32), 256), "raw-u8")

if __name__ == "__main__":
    unittest.main()
```

69.3 Line annotations

Line 1: `from __future__ import annotations` This imports the named Python API so the file whose role is to checks run spikingformer pynq behavior independently with Python assertions can use it explicitly. Imports execute on the host processor and create no FPGA hardware.

Line 3: `import unittest` This imports the named Python API so the file whose role is to checks run spikingformer pynq behavior independently with Python assertions can use it explicitly. Imports execute on the host processor and create no FPGA hardware.

Line 5: `import numpy as np` This imports the named Python API so the file whose role is to checks run spikingformer pynq behavior independently with Python assertions can use it explicitly. Imports execute on the host processor and create no FPGA hardware.

Line 7: `from run_spikingformer_pynq import CIFAR10_MEAN, CIFAR10_STD, prepare_input` This imports the named Python API so the file whose role is to checks run spikingformer pynq behavior independently with Python assertions can use it explicitly. Imports execute on the host processor and create no FPGA hardware.

Line 10: `class PynqInferenceInputTests(unittest.TestCase):` This defines class PynqInferenceInputTests, which groups data and methods for pynq inference input tests. Instances exist in host memory and organize the flow that checks run spikingformer pynq behavior independently with Python assertions.

Line 11: `def test_raw_nhwc_and_nchw_normalization(self) -> None:` This starts function test_raw_nhwc_and_nchw_no Its indented body performs test raw nhwc and nchw normalization as part of the file that checks run spikingformer pynq behavior independently with Python assertions; it runs only when called.

Line 12: `raw_nhwc = np.zeros((32, 32, 3), dtype=np.uint8)` This assigns 'np.zeros((32, 32, 3), dtype=np.uint8)' to 'raw_nhwc ' in host memory. Here raw_nhwc means the value named 'raw nhwc' in this block. The important operands are zeros: the value named 'zeros' in this block; dtype: the value named 'dtype' in this block; uint8: the value named 'uint8' in this block. Context: the function test_raw_nhwc_and_nchw_normalization, which handles test raw nhwc and nchw normalization.

Line 13: `raw_nhwc[..., 1] = 255` This assigns '255' to 'raw_nhwc[..., 1] ' in host memory. Here raw_nhwc means the value named 'raw nhwc' in this block. The expression is a literal or structural operator and has no hidden software state. Context: the function test_raw_nhwc_and_nchw_normalization, which handles test raw nhwc and nchw normalization.

Line 14: `result = prepare_input(raw_nhwc, "raw-u8")` This assigns 'prepare_input(raw_nhwc, "raw-u8")' to 'result ' in host memory. Here result means the value named 'result' in this block. The important operands are prepare_input: the value named 'prepare input' in this block; raw_nhwc: the value named 'raw nhwc' in this block; raw: the value named 'raw' in this block. Context: the function test_raw_nhwc_and_nchw_normalization, which handles test raw nhwc and nchw normalization.

Line 15: `self.assertEqual(result.shape, (1, 3, 32, 32))` This calls 'self.assertEqual' with 'result.shape, (1, 3, 32, 32)' inside the function test_raw_nhwc_and_nchw_normalization, which handles test raw nhwc and nchw normalization. The call advances the host-side job that checks run spikingformer pynq behavior independently with Python assertions.

Line 16: `self.assertAlmostEqual(float(result[0, 0, 0, 0]), -float(CIFAR10_MEAN[0] / CIFAR10_STD[0]), places=6)` This calls 'self.assertAlmostEqual' with 'float(result[0, 0, 0, 0]), -float(CIFAR10_MEAN[0] / CIFAR10_STD[0]), places=6' inside the function test_raw_nhwc_and_nchw_normalization, which handles test raw nhwc and nchw normalization. The call advances the host-side job that checks run spikingformer pynq behavior independently with Python assertions.

Line 17: `self.assertAlmostEqual(float(result[0, 1, 0, 0]), float((1 - CIFAR10_MEAN[1]) / CIFAR10_STD[1]), places=6)` This calls 'self.assertAlmostEqual' with 'float(result[0, 1, 0, 0]), float((1 - CIFAR10_MEAN[1]) / CIFAR10_STD[1]), places=6' inside the function test_raw_nhwc_and_nchw_normalization, which handles test raw nhwc and nchw normalization. The call advances the host-side job that checks run spikingformer pynq behavior independently with Python assertions.

Line 18: `np.testing.assert_array_equal(` This statement continues through source line 19; the explanation uses the complete expression rather than only the first visual fragment. This calls 'np.testing.assert_array_equal' with ' prepare_input(result, "normalized"), result.astype(np.float32)' inside the function test_raw_nhwc_and_nchw_normalization, which handles test raw nhwc and nchw normalization. The call advances the host-side job that checks run spikingformer pynq behavior independently with Python assertions.

Line 19: `prepare_input(result, "normalized"), result.astype(np.float32))` This is continuation line 2 of the 2-line logical statement that begins at source line 18. Its exact fragment is 'prepare_input(result, "normalized"), result.astype(np.float32))'. The important operands are prepare_input: the value named 'prepare input' in this block;

result: the value named 'result' in this block; normalized: the value named 'normalized' in this block. Read together, the complete operation is: This calls ‘np.testing.assert_array_equal‘ with ‘ prepare_input(result, "normalized"), result.astype(np.float32)‘ inside the function test_raw_nhwc_and_nchw_normalization, which handles test raw nhwc and nchw normalization. The call advances the host-side job that checks run spikingformer pynq behavior independently with Python assertions.

Line 21: `def test_rejects_wrong_shape_and_out_of_range_raw_values(self) -> None:` This starts function test_rejects_wrong_shape_and_out_of_range_raw_values. Its indented body performs test rejects wrong shape and out of range raw values as part of the file that checks run spikingformer pynq behavior independently with Python assertions; it runs only when called.

Line 22: `with self.assertRaises(ValueError):` This opens a managed resource scope for ‘self.assertRaises(ValueError)‘ so files, tracing, or temporary state are finalized even if the function test_rejects_wrong_shape_and_out_of_range_raw_values, which handles test rejects wrong shape and out of range raw values raises an error.

Line 23: `prepare_input(np.zeros((28, 28), dtype=np.uint8), "raw-u8")` This calls ‘prepare_input‘ with ‘np.zeros((28, 28), dtype=np.uint8), "raw-u8"‘ inside the function test_rejects_wrong_shape_and_out_of_range_raw_values, which handles test rejects wrong shape and out of range raw values. The call advances the host-side job that checks run spikingformer pynq behavior independently with Python assertions.

Line 24: `with self.assertRaises(ValueError):` This opens a managed resource scope for ‘self.assertRaises(ValueError)‘ so files, tracing, or temporary state are finalized even if the function test_rejects_wrong_shape_and_out_of_range_raw_values, which handles test rejects wrong shape and out of range raw values raises an error.

Line 25: `prepare_input(np.full((3, 32, 32), 256), "raw-u8")` This calls ‘prepare_input‘ with ‘np.full((3, 32, 32), 256), "raw-u8"‘ inside the function test_rejects_wrong_shape_and_out_of_range_raw_values, which handles test rejects wrong shape and out of range raw values. The call advances the host-side job that checks run spikingformer pynq behavior independently with Python assertions.

Line 28: `if __name__ == "__main__":` This executes the following indented host-code branch only when ‘___name___ == "___main___"‘ is true. The important operands are ___name___: the value named 'name' in this block; ___main___: the value named 'main' in this block. Context: the file whose role is to checks run spikingformer pynq behavior independently with Python assertions.

Line 29: `unittest.main()` This calls ‘unittest.main‘ with “ inside the file whose role is to checks run spikingformer pynq behavior independently with Python assertions. The call advances the host-side job that checks run spikingformer pynq behavior independently with Python assertions.

70 tests/test_spikingformer_accelerator.py

Role in the complete system: checks spikingformer accelerator behavior independently with Python assertions.

70.1 Beginner architecture map

Dataflow responsibility This file's end-to-end responsibility is to checks spikingformer accelerator behavior independently with Python assertions.

Where it runs This is sequential host software. Python objects live in CPU memory; they become FPGA work only when the compiler packs a command or payload and the PYNQ driver transfers those bytes through AXI DMA or AXI-Lite.

Public structure Classes: VectorProgramEmulator, CombinedProgramEmulator, OneProjectionArchive, LifProgramEmulator, SpikingformerAcceleratorTests. Functions: _signed, execute_program, assert_vector_record, ___init___, execute_program, ___init___, projection, ___init___, execute_program, parameters, test_fabric_projection_requantizer_ma test_binary_projection_executes_tensor_and_vector_programs, test_asymmetric_dense_projection_executes_exact_zer test_chunked_lif_scheduler_preserves_every_logical_membrane, test_traced_lif_scheduler_returns_exact_pre_reset_m test_real_block0_archive_executes_exact_exported_integer_equation, test_vector_residual_and_binary_max_pool_cov test_global_pooling_and_head_division_execute_in_vector_fabric. Each function annotation below names its enclosing function so an array operation is tied to the model, compiler, driver, test, or report phase that uses it.

Numeric and failure boundary Shapes, signedness, byte order, scaling, and saturation are part of the hardware contract. Validation exceptions are functional safety checks: rejecting malformed input before DMA is different from silently clipping, reshaping, or continuing with an incompatible artifact.

Line 4: `from pathlib import Path` This imports the named Python API so the file whose role is to checks spikingformer accelerator behavior independently with Python assertions can use it explicitly. Imports execute on the host processor and create no FPGA hardware.

Line 6: `import numpy as np` This imports the named Python API so the file whose role is to checks spikingformer accelerator behavior independently with Python assertions can use it explicitly. Imports execute on the host processor and create no FPGA hardware.

Line 8: `from neuraedge_golden import VectorOperation, round_shift_signed, vector_alu` This imports the named Python API so the file whose role is to checks spikingformer accelerator behavior independently with Python assertions can use it explicitly. Imports execute on the host processor and create no FPGA hardware.

Line 9: `from neuraedge_protocol import Opcode, ProgramRecord, unpack_vector_result` This imports the named Python API so the file whose role is to checks spikingformer accelerator behavior independently with Python assertions can use it explicitly. Imports execute on the host processor and create no FPGA hardware.

Line 10: `from spikingformer_accelerator import (` This statement continues through source line 22; the explanation uses the complete expression rather than only the first visual fragment. This imports the named Python API so the file whose role is to checks spikingformer accelerator behavior independently with Python assertions can use it explicitly. Imports execute on the host processor and create no FPGA hardware.

Line 11: `SpikingformerProjectionExecutor,` This is continuation line 2 of the 13-line logical statement that begins at source line 10. Its exact fragment is 'SpikingformerProjectionExecutor,'. The important operands are SpikingformerProjectionExecutor: the value named 'spikingformer projection executor' in this block. Read together, the complete operation is: This imports the named Python API so the file whose role is to checks spikingformer accelerator behavior independently with Python assertions can use it explicitly. Imports execute on the host processor and create no FPGA hardware.

Line 12: `binary_max_pool2d_on_accelerator,` This is continuation line 3 of the 13-line logical statement that begins at source line 10. Its exact fragment is 'binary_max_pool2d_on_accelerator,'. The important operands are binary_max_pool2d_on_accelerator: the value named 'binary max pool2d on accelerator' in this block. Read together, the complete operation is: This imports the named Python API so the file whose role is to checks spikingformer accelerator behavior independently with Python assertions can use it explicitly. Imports execute on the host processor and create no FPGA hardware.

Line 13: `global_spatiotemporal_sum_on_accelerator,` This is continuation line 4 of the 13-line logical statement that begins at source line 10. Its exact fragment is 'global_spatiotemporal_sum_on_accelerator,'. The important operands are global_spatiotemporal_sum_on_accelerator: the value named 'global spatiotemporal sum on accelerator' in this block. Read together, the complete operation is: This imports the named Python API so the file whose role is to checks spikingformer accelerator behavior independently with Python assertions can use it explicitly. Imports execute on the host processor and create no FPGA hardware.

Line 14: `lif_sequence_on_accelerator,` This is continuation line 5 of the 13-line logical statement that begins at source line 10. Its exact fragment is 'lif_sequence_on_accelerator,'. The important operands are lif_sequence_on_accelerator: the value named 'lif sequence on accelerator' in this block. Read together, the complete operation is: This imports the named Python API so the file whose role is to checks spikingformer accelerator behavior independently with Python assertions can use it explicitly. Imports execute on the host processor and create no FPGA hardware.

Line 15: `lif_sequence_reference,` This is continuation line 6 of the 13-line logical statement that begins at source line 10. Its exact fragment is 'lif_sequence_reference,'. The important operands are lif_sequence_reference: the value named 'lif sequence reference' in this block. Read together, the complete operation is: This imports the named Python API so the file whose role is to checks spikingformer accelerator behavior independently with Python assertions can use it explicitly. Imports execute on the host processor and create no FPGA hardware.

Line 16: `lif_sequence_with_trace_on_accelerator,` This is continuation line 7 of the 13-line logical statement that begins at source line 10. Its exact fragment is 'lif_sequence_with_trace_on_accelerator,'. The important operands are lif_sequence_with_trace_on_accelerator: the value named 'lif sequence with trace on accelerator' in this block. Read together, the complete operation is: This imports the named Python API so the file whose role is to checks spikingformer accelerator behavior independently with Python assertions can use it explicitly. Imports execute on the host processor and create no FPGA hardware.

Line 17: `lif_sequence_with_trace_reference,` This is continuation line 8 of the 13-line logical statement that begins at source line 10. Its exact fragment is 'lif_sequence_with_trace_reference,'. The important operands are lif_sequence_with_trace_reference: the value named 'lif sequence with trace reference' in this block. Read together, the complete operation is: This imports the named Python API so the file whose role is to checks spikingformer accelerator behavior independently with Python assertions can use it explicitly. Imports execute on the host processor and create no FPGA hardware.

Line 18: `power_of_two_requantize_on_accelerator,` This is continuation line 9 of the 13-line logical statement that begins at source line 10. Its exact fragment is 'power_of_two_requantize_on_accelerator,'. The important operands are power_of_two_requantize_on_accelerator: the conversion of a wide accumulated result back into a bounded activation code. Read together, the complete operation is: This imports the named Python API so the file whose role is to checks spikingformer accelerator behavior independently with Python assertions can use it explicitly. Imports execute on the host processor and create no FPGA hardware.

Line 19: `requantize_projection_on_accelerator,` This is continuation line 10 of the 13-line logical statement that begins at source line 10. Its exact fragment is 'requantize_projection_on_accelerator,'. The important operands are requantize_projection_on_accelerator: the conversion of a wide accumulated result back into a bounded activation code. Read together, the complete operation is: This imports the named Python API so the file whose role is to checks spikingformer accelerator behavior independently with Python assertions can use it explicitly. Line 20: `requantize_projection_reference,` This is continuation line 11 of the 13-line logical statement that begins at source line 10. Its exact fragment is 'requantize_projection_reference,'. The important operands are requantize_projection_reference: the conversion of a wide accumulated result back into a bounded activation code. Read together, the complete operation is: This imports the named Python API so the file whose role is to checks spikingformer accelerator behavior independently with Python assertions can use it explicitly. Imports execute on the host processor and create no FPGA hardware.

Line 21: `vector_binary_on_accelerator,` This is continuation line 12 of the 13-line logical statement that begins at source line 10. Its exact fragment is 'vector_binary_on_accelerator,'. The important operands are vector_binary_on_accelerator: the value named 'vector binary on accelerator' in this block. Read together, the complete operation is: This imports the named Python API so the file whose role is to checks spikingformer accelerator behavior independently with Python assertions can use it explicitly. Imports execute on the host processor and create no FPGA hardware.

Line 22: `)` This is continuation line 13 of the 13-line logical statement that begins at source line 10. Its exact fragment is ')'. The expression is a literal or structural operator and has no hidden software state. Read together, the complete operation is: This imports the named Python API so the file whose role is to checks spikingformer accelerator behavior independently with Python assertions can use it explicitly. Imports execute on the host processor and create no FPGA hardware.

Line 23: `from spikingformer_parameters import ProjectionParameters, SpikingformerParameterArchive` This imports the named Python API so the file whose role is to checks spikingformer accelerator behavior independently with Python assertions can use it explicitly. Imports execute on the host processor and create no FPGA hardware.

Line 24: `from tests.test_neuraedge_compiler import TensorTransactionEmulator` This imports the named Python API so the file whose role is to checks spikingformer accelerator behavior independently with Python assertions can use it explicitly. Imports execute on the host processor and create no FPGA hardware.

Line 27: `def _signed(value: int, bits: int) -> int:` This starts function _signed. Its indented body performs signed as part of the file that checks spikingformer accelerator behavior independently with Python assertions; it runs only when called.

Line 28: `value &= (1 << bits) - 1` Inside the function _signed, which handles signed, this statement advances the host implementation that checks spikingformer accelerator behavior independently with Python assertions. The important operands are value: the value named 'value' in this block; bits: the value named 'bits' in this block.

Line 29: `return value - (1 << bits) if value & (1 << (bits - 1)) else value` This returns ‘value - (1 << bits) if value & (1 << (bits - 1)) else value‘ to the caller of the function _signed, which handles signed, ending this invocation. The important operands are value: the value named ’value’ in this block; bits: the value named ’bits’ in this block.

Line 32: `class VectorProgramEmulator:` This defines class VectorProgramEmulator, which groups data and methods for vector program emulator. Instances exist in host memory and organize the flow that checks spikingformer accelerator behavior independently with Python assertions.

Line 33: `def execute_program(self, records, *, timeout_seconds: float = 30.0):` This starts function execute_program. Its indented body performs execute program as part of the file that checks spikingformer accelerator behavior independently with Python assertions; it runs only when called.

Line 34: `del timeout_seconds` Inside the function execute_program, which handles execute program, this statement advances the host implementation that checks spikingformer accelerator behavior independently with Python assertions. The important operands are del: the value named ’del’ in this block; timeout_seconds: the value named ’timeout seconds’ in this block.

Line 35: `output: list[int] = []` This assigns ‘[]‘ to ‘output‘ in host memory. Here output means the value named ’output’ in this block. The expression is a literal or structural operator and has no hidden software state. Context: the function execute_program, which handles execute program.

Line 36: `for record in records:` This iterates record over ‘records‘. Each iteration repeats the indented host operation, commonly once per layer, tile, timestep, or test case in the function execute_program, which handles execute program.

Line 37: `self.assert_vector_record(record)` This calls ‘self.assert_vector_record‘ with ‘record‘ inside the function execute_program, which handles execute program. The call advances the host-side job that checks spikingformer accelerator behavior independently with Python assertions.

Line 38: `command = record.command.value` This assigns ‘record.command.value‘ to ‘command ‘ in host memory. Here command means the 128-bit instruction selecting an engine, shape, mode, and numeric parameters. The important operands are record: the value named ’record’ in this block; command: the 128-bit instruction selecting an engine, shape, mode, and numeric parameters; value: the value named ’value’ in this block. Context: the function execute_program, which handles execute program.

Line 39: `operation = (command >> 4) & 0xF` This assigns ‘(command >> 4) & 0xF‘ to ‘operation ‘ in host memory. Here operation means the value named ’operation’ in this block. The important operands are command: the 128-bit instruction selecting an engine, shape, mode, and numeric parameters. Context: the function execute_program, which handles execute program.

Line 40: `multiplier = _signed(command >> 8, 16)` This assigns ‘_signed(command >> 8, 16)‘ to ‘multiplier ‘ in host memory. Here multiplier means the value named ’multiplier’ in this block. The important operands are _signed: the value named ’signed’ in this block; command: the 128-bit instruction selecting an engine, shape, mode, and numeric parameters. Context: the function execute_program, which handles execute program.

Line 41: `shift = _signed(command >> 24, 5) if operation == 9 else (command >> 24) & 0x1F` Inside the function execute_program, which handles execute program, this statement advances the host implementation that checks spikingformer accelerator behavior independently with Python assertions. The important operands are shift: the value named ’shift’ in this block; _signed: the value named ’signed’ in this block; command: the 128-bit instruction selecting an engine, shape, mode, and numeric parameters.

Line 42: `offset = _signed(command >> 29, 16)` This assigns '_signed(command >> 29, 16)' to 'offset ' in host memory. Here offset means the value named 'offset' in this block. The important operands are _signed: the value named 'signed' in this block; command: the 128-bit instruction selecting an engine, shape, mode, and numeric parameters. Context: the function execute_program, which handles execute program.

Line 43: `clamp_word = record.input_beats[0].data` This assigns 'record.input_beats[0].data' to 'clamp_word ' in host memory. Here clamp_word means the value named 'clamp word' in this block. The important operands are record: the value named 'record' in this block; input_beats: the value named 'input beats' in this block; data: the value named 'data' in this block. Context: the function execute_program, which handles execute program.

Line 44: `clamp_minimum = _signed(clamp_word, 32)` This assigns '_signed(clamp_word, 32)' to 'clamp_minimum ' in host memory. Here clamp_minimum means the value named 'clamp minimum' in this block. The important operands are _signed: the value named 'signed' in this block; clamp_word: the value named 'clamp word' in this block. Context: the function execute_program, which handles execute program.

Line 45: `clamp_maximum = _signed(clamp_word >> 32, 32)` This assigns '_signed(clamp_word >> 32, 32)' to 'clamp_maximum ' in host memory. Here clamp_maximum means the value named 'clamp maximum' in this block. The important operands are _signed: the value named 'signed' in this block; clamp_word: the value named 'clamp word' in this block. Context: the function execute_program, which handles execute program.

Line 46: `a = unpack_vector_result([beat.data for beat in record.input_beats[1:5]])` This assigns 'unpack_vector_r for beat in record.input_beats[1:5]])' to 'a ' in host memory. Here a means the value named 'a' in this block. The important operands are unpack_vector_result: the value named 'unpack vector result' in this block; beat: the value named 'beat' in this block; data: the value named 'data' in this block. Context: the function execute_program, which handles execute program.

Line 47: `b = unpack_vector_result([beat.data for beat in record.input_beats[5:9]])` This assigns 'unpack_vector_r for beat in record.input_beats[5:9]])' to 'b ' in host memory. Here b means the value named 'b' in this block. The important operands are unpack_vector_result: the value named 'unpack vector result' in this block; beat: the value named 'beat' in this block; data: the value named 'data' in this block. Context: the function execute_program, which handles execute program.

Line 48: `lanes = vector_alu(` This statement continues through source line 52; the explanation uses the complete expression rather than only the first visual fragment. This assigns 'vector_alu(VectorOperation(operation), np.asarray(a), np.asarray(b), multiplier_q15=multiplier, right_shift=shift, output_zero_point=offset, clamp_minimum=clamp_minimum, clamp_maximum=clamp_maximum)' to 'lanes ' in host memory. Here lanes means one parallel arithmetic element within a vector or tensor datapath. The important operands are vector_alu: the value named 'vector alu' in this block; VectorOperation: the value named 'vector operation' in this block; operation: the value named 'operation' in this block. Context: the function execute_program, which handles execute program.

Line 49: `VectorOperation(operation), np.asarray(a), np.asarray(b),` This is continuation line 2 of the 5-line logical statement that begins at source line 48. Its exact fragment is 'VectorOperation(operation), np.asarray(a), np.asarray(b),'. The important operands are VectorOperation: the value named 'vector operation' in this block; operation: the value named 'operation' in this block; asarray: the value named 'asarray' in this block. Read together, the complete operation is: This assigns 'vector_alu(VectorOperation(operation), np.asarray(a), np.asarray(b), multiplier_q15=multiplier, right_shift=shift, output_zero_point=offset, clamp_minimum=clamp_minimum, clamp_maximum=clamp to 'lanes ' in host memory. Here lanes means one parallel arithmetic element within a vector or tensor datapath. The important operands are vector_alu: the value named 'vector alu' in this block; VectorOperation: the value named 'vector operation' in this block; operation: the value named 'operation' in this block. Context: the function execute_program, which handles execute program.

Line 50: `multiplier_q15=multiplier, right_shift=shift,` This is continuation line 3 of the 5-line logical statement that begins at source line 48. Its exact fragment is 'multiplier_q15=multiplier, right_shift=shift,'. The important operands are multiplier_q15: the value named 'multiplier q15' in this block; multiplier: the value named 'multiplier' in this

block; right_shift: the value named 'right shift' in this block. Read together, the complete operation is: This assigns ‘vector_alu(VectorOperation(operation), np.asarray(a), np.asarray(b), multiplier_q15=multiplier, right_shift=shift, output_zero_point=offset, clamp_minimum=clamp_minimum, clamp_maximum=clamp_maximum)‘ to ‘lanes ‘ in host memory. Here lanes means one parallel arithmetic element within a vector or tensor datapath. The important operands are vector_alu: the value named 'vector alu' in this block; VectorOperation: the value named 'vector operation' in this block; operation: the value named 'operation' in this block. Context: the function execute_program, which handles execute program.

Line 51: `output_zero_point=offset, clamp_minimum=clamp_minimum,` This is continuation line 4 of the 5-line logical statement that begins at source line 48. Its exact fragment is ‘output_zero_point=offset, clamp_minimum=clamp_minimum,‘. The important operands are output_zero_point: the integer code representing real numeric zero in affine quantization; offset: the value named 'offset' in this block; clamp_minimum: the value named 'clamp minimum' in this block. Read together, the complete operation is: This assigns ‘vector_alu(VectorOperation(operation), np.asarray(a), np.asarray(b), multiplier_q15=multiplier, right_shift=shift, output_zero_point=offset, clamp_minimum=clamp_minimum, clamp_maximum=
to ‘lanes ‘ in host memory. Here lanes means one parallel arithmetic element within a vector or tensor datapath. The important operands are vector_alu: the value named 'vector alu' in this block; VectorOperation: the value named 'vector operation' in this block; operation: the value named 'operation' in this block. Context: the function execute_program, which handles execute program.

Line 52: `clamp_maximum=clamp_maximum)` This is continuation line 5 of the 5-line logical statement that begins at source line 48. Its exact fragment is ‘clamp_maximum=clamp_maximum)‘. The important operands are clamp_maximum: the value named 'clamp maximum' in this block. Read together, the complete operation is: This assigns ‘vector_alu(VectorOperation(operation), np.asarray(a), np.asarray(b), multiplier_q15=multiplier, right_shift=shift, output_zero_point=offset, clamp_minimum=clamp_minimum, clamp_maximum=clamp_maximum)‘ to ‘lanes ‘ in host memory. Here lanes means one parallel arithmetic element within a vector or tensor datapath. The important operands are vector_alu: the value named 'vector alu' in this block; VectorOperation: the value named 'vector operation' in this block; operation: the value named 'operation' in this block. Context: the function execute_program, which handles execute program.

Line 53: `for lane in range(0, 8, 2):` This iterates lane over ‘range(0, 8, 2)‘. Each iteration repeats the indented host operation, commonly once per layer, tile, timestep, or test case in the function execute_program, which handles execute program.

Line 54: `output.append(` This statement continues through source line 56; the explanation uses the complete expression rather than only the first visual fragment. This calls ‘output.append‘ with ‘ (int(lanes[lane]) & 0xFFFFFFFF) | ((int(lanes[lane + 1]) & 0xFFFFFFFF) << 32)‘ inside the function execute_program, which handles execute program. The call advances the host-side job that checks spikingformer accelerator behavior independently with Python assertions.

Line 55: `(int(lanes[lane]) & 0xFFFFFFFF)` This is continuation line 2 of the 3-line logical statement that begins at source line 54. Its exact fragment is ‘(int(lanes[lane]) & 0xFFFFFFFF)‘. The important operands are lanes: one parallel arithmetic element within a vector or tensor datapath; lane: one parallel arithmetic element within a vector or tensor datapath. Read together, the complete operation is: This calls ‘output.append‘ with ‘ (int(lanes[lane]) & 0xFFFFFFFF) | ((int(lanes[lane + 1]) & 0xFFFFFFFF) << 32)‘ inside the function execute_program, which handles execute program. The call advances the host-side job that checks spikingformer accelerator behavior independently with Python assertions.

Line 56: `| ((int(lanes[lane + 1]) & 0xFFFFFFFF) << 32))` This is continuation line 3 of the 3-line logical statement that begins at source line 54. Its exact fragment is ‘| ((int(lanes[lane + 1]) & 0xFFFFFFFF) << 32))‘. The important operands are lanes: one parallel arithmetic element within a vector or tensor datapath; lane: one parallel arithmetic element within a vector or tensor datapath. Read together, the complete operation is: This calls ‘output.append‘ with ‘ (int(lanes[lane]) & 0xFFFFFFFF) | ((int(lanes[lane + 1]) & 0xFFFFFFFF) << 32)‘ inside the function execute_program, which handles execute program. The call advances the host-side job that checks spikingformer accelerator behavior independently with Python assertions.

Line 57: `return tuple(output)` This returns ‘tuple(output)‘ to the caller of the function execute_program, which handles execute program, ending this invocation. The important operands are tuple: the value named 'tuple' in this block; output: the value named 'output' in this block.

Line 59: `@staticmethod` This decorator changes how the following class or function is constructed. ‘@staticmethod‘ is applied at import time on the host and is part of the class VectorProgramEmulator, which handles vector program emulator; it creates no FPGA circuit by itself.

Line 60: `def assert_vector_record(record: ProgramRecord) -> None:` This starts function assert_vector_record. Its indented body performs assert vector record as part of the file that checks spikingformer accelerator behavior independently with Python assertions; it runs only when called.

Line 61: `if len(record.input_beats) != 9 or record.output_beats != 4:` This executes the following indented host-code branch only when ‘len(record.input_beats) != 9 or record.output_beats != 4‘ is true. The important operands are len: the value named ’len’ in this block; record: the value named ’record’ in this block; input_beats: the value named ’input beats’ in this block. Context: the function assert_vector_record, which handles assert vector record.

Line 62: `raise AssertionError("invalid vector record")` This rejects an invalid state by raising ‘AssertionError("invalid vector record")‘. Failing before DMA prevents malformed shapes or artifacts from silently becoming hardware results.

Line 65: `class CombinedProgramEmulator:` This defines class CombinedProgramEmulator, which groups data and methods for combined program emulator. Instances exist in host memory and organize the flow that checks spikingformer accelerator behavior independently with Python assertions.

Line 66: `def __init__(self) -> None:` This starts function ___init___. Its indented body performs init as part of the file that checks spikingformer accelerator behavior independently with Python assertions; it runs only when called.

Line 67: `self.tensor = TensorTransactionEmulator()` This assigns ‘TensorTransactionEmulator()‘ to ‘self.tensor ‘ in host memory. Here tensor means the value named ’tensor’ in this block. The important operands are TensorTransactionEmulator: the value named ’tensor transaction emulator’ in this block. Context: the function ___init___, which handles init.

Line 68: `self.vector = VectorProgramEmulator()` This assigns ‘VectorProgramEmulator()‘ to ‘self.vector ‘ in host memory. Here vector means the value named ’vector’ in this block. The important operands are VectorProgramEmulator: the value named ’vector program emulator’ in this block. Context: the function ___init___, which handles init.

Line 70: `def execute_program(self, records, *, timeout_seconds: float = 30.0):` This starts function execute_program. Its indented body performs execute program as part of the file that checks spikingformer accelerator behavior independently with Python assertions; it runs only when called.

Line 71: `if records and all(record.command.opcode == Opcode.VECTOR_ALU for record in records):` This executes the following indented host-code branch only when ‘records and all(record.command.opcode == Opcode.VECTOR_ALU for record in records)‘ is true. The important operands are records: the number of descriptor records accepted since program start; and: the value named ’and’ in this block; all: the value named ’all’ in this block. Context: the function execute_program, which handles execute program.

Line 72: `return self.vector.execute_program(records, timeout_seconds=timeout_seconds)` This returns ‘self.vector.exe timeout_seconds=timeout_seconds)‘ to the caller of the function execute_program, which handles execute program, ending this invocation. The important operands are vector: the value named ’vector’ in this block; execute_program: the value named ’execute program’ in this block; records: the number of descriptor records accepted since program start.

Line 73: `return self.tensor.execute_program(records, timeout_seconds=timeout_seconds)` This returns ‘self.tensor.exe timeout_seconds=timeout_seconds)‘ to the caller of the function execute_program, which handles execute program, ending this invocation. The important operands are tensor: the value named ’tensor’ in this block; execute_program: the value named ’execute program’ in this block; records: the number of descriptor records accepted since program start.

Line 76: `class OneProjectionArchive:` This defines class OneProjectionArchive, which groups data and methods for one projection archive. Instances exist in host memory and organize the flow that checks spikingformer accelerator behavior independently with Python assertions.

Line 77: `def __init__(self, parameters: ProjectionParameters) -> None:` This starts function ___init___. Its indented body performs init as part of the file that checks spikingformer accelerator behavior independently with Python assertions; it runs only when called.

Line 78: `self.parameters = parameters` This assigns ‘parameters‘ to ‘self.parameters ‘ in host memory. Here parameters means the value named ’parameters’ in this block. The important operands are parameters: the value named ’parameters’ in this block. Context: the function ___init___, which handles init.

Line 80: `def projection(self, name: str) -> ProjectionParameters:` This starts function projection. Its indented body performs projection as part of the file that checks spikingformer accelerator behavior independently with Python assertions; it runs only when called.

Line 81: `if name != self.parameters.name:` This executes the following indented host-code branch only when ‘name != self.parameters.name‘ is true. The important operands are name: the value named ’name’ in this block; parameters: the value named ’parameters’ in this block. Context: the function projection, which handles projection.

Line 82: `raise KeyError(name)` This rejects an invalid state by raising ‘KeyError(name)‘. Failing before DMA prevents malformed shapes or artifacts from silently becoming hardware results.

Line 83: `return self.parameters` This returns ‘self.parameters‘ to the caller of the function projection, which handles projection, ending this invocation. The important operands are parameters: the value named ’parameters’ in this block.

Line 86: `class LifProgramEmulator:` This defines class LifProgramEmulator, which groups data and methods for lif program emulator. Instances exist in host memory and organize the flow that checks spikingformer accelerator behavior independently with Python assertions.

Line 87: `def __init__(self) -> None:` This starts function ___init___. Its indented body performs init as part of the file that checks spikingformer accelerator behavior independently with Python assertions; it runs only when called.

Line 88: `self.membrane = np.zeros(32, dtype=np.int64)` This assigns ‘np.zeros(32, dtype=np.int64)‘ to ‘self.membrane ‘ in host memory. Here membrane means the persistent LIF neuron state carrying charge between timesteps. The important operands are zeros: the value named ’zeros’ in this block; dtype: the value named ’dtype’ in this block; int64: the value named ’int64’ in this block. Context: the function ___init___, which handles init.

Line 89: `self.timesteps = 0` This assigns ‘0‘ to ‘self.timesteps ‘ in host memory. Here timesteps means one discrete SNN update instant. The expression is a literal or structural operator and has no hidden software state. Context: the function ___init___, which handles init.

Line 91: `def execute_program(self, records, *, timeout_seconds: float = 30.0):` This starts function execute_program. Its indented body performs execute program as part of the file that checks spikingformer accelerator behavior independently with Python assertions; it runs only when called.

Line 92: `del timeout_seconds` Inside the function execute_program, which handles execute program, this statement advances the host implementation that checks spikingformer accelerator behavior independently with Python assertions. The important operands are del: the value named ’del’ in this block; timeout_seconds: the value named ’timeout seconds’ in this block.

Line 93: `output: list[int] = []` This assigns ‘[]‘ to ‘output‘ in host memory. Here output means the value named ’output’ in this block. The expression is a literal or structural operator and has no hidden software state. Context: the function execute_program, which handles execute program.

Line 94: `for record in records:` This iterates record over ‘records‘. Each iteration repeats the indented host operation, commonly once per layer, tile, timestep, or test case in the function execute_program, which handles execute program.

Line 95: `command = record.command.value` This assigns ‘record.command.value‘ to ‘command ‘ in host memory. Here command means the 128-bit instruction selecting an engine, shape, mode, and numeric parameters. The important operands are record: the value named ’record’ in this block; command: the 128-bit instruction selecting an engine, shape, mode, and numeric parameters; value: the value named ’value’ in this block. Context: the function execute_program, which handles execute program.

Line 96: `if record.command.opcode != Opcode.LIF_STEP:` This executes the following indented host-code branch only when ‘record.command.opcode != Opcode.LIF_STEP‘ is true. The important operands are record: the value named ’record’ in this block; command: the 128-bit instruction selecting an engine, shape, mode, and numeric parameters; opcode: the value named ’opcode’ in this block. Context: the function execute_program, which handles execute program.

Line 97: `raise AssertionError("expected an LIF record")` This rejects an invalid state by raising ‘AssertionError("expected an LIF record")‘. Failing before DMA prevents malformed shapes or artifacts from silently becoming hardware results.

Line 98: `leak_shift = (command >> 4) & 0x1F` This assigns ‘(command >> 4) & 0x1F‘ to ‘leak_shift ‘ in host memory. Here leak_shift means the retained fraction of prior membrane state. The important operands are command: the 128-bit instruction selecting an engine, shape, mode, and numeric parameters. Context: the function execute_program, which handles execute program.

Line 99: `threshold = _signed(command >> 9, 24)` This assigns ‘_signed(command >> 9, 24)‘ to ‘threshold ‘ in host memory. Here threshold means the membrane level at which a neuron emits a spike. The important operands are _signed: the value named ’signed’ in this block; command: the 128-bit instruction selecting an engine, shape, mode, and numeric parameters. Context: the function execute_program, which handles execute program.

Line 100: `reset = _signed(command >> 33, 24)` This assigns ‘_signed(command >> 33, 24)‘ to ‘reset ‘ in host memory. Here reset means the value named ’reset’ in this block. The important operands are _signed: the value named ’signed’ in this block; command: the 128-bit instruction selecting an engine, shape, mode, and numeric parameters. Context: the function execute_program, which handles execute program.

Line 101: `if (command >> 57) & 1:` This executes the following indented host-code branch only when ‘(command >> 57) & 1‘ is true. The important operands are command: the 128-bit instruction selecting an engine, shape, mode, and numeric parameters. Context: the function execute_program, which handles execute program.

Line 102: `self.membrane.fill(reset)` This calls ‘self.membrane.fill‘ with ‘reset‘ inside the function execute_program, which handles execute program. The call advances the host-side job that checks spikingformer accelerator behavior independently with Python assertions.

Line 103: `self.timesteps = 0` This assigns ‘0‘ to ‘self.timesteps ‘ in host memory. Here timesteps means one discrete SNN update instant. The expression is a literal or structural operator and has no hidden software state. Context: the function execute_program, which handles execute program.

Line 104: `currents: list[int] = []` This assigns ‘[]‘ to ‘currents‘ in host memory. Here currents means the value named ’currents’ in this block. The expression is a literal or structural operator and has no hidden software state. Context: the function execute_program, which handles execute program.

Line 105: `for beat in record.input_beats:` This iterates beat over ‘record.input_beats‘. Each iteration repeats the indented host operation, commonly once per layer, tile, timestep, or test case in the function execute_program, which handles execute program.

Line 106: `currents.extend(_signed(beat.data >> (16 * lane), 16) for lane in range(4))` This calls ‘currents.extend‘ with ‘_signed(beat.data >> (16 * lane), 16) for lane in range(4)‘ inside the function execute_program, which handles execute program. The call advances the host-side job that checks spikingformer accelerator behavior independently with Python assertions.

Line 107: `self.membrane = np.clip(` This statement continues through source line 111; the explanation uses the complete expression rather than only the first visual fragment. This assigns ‘np.clip(self.membrane - (self.membrane >> leak_shift) + np.asarray(currents), -(1 << 23), (1 << 23) - 1,)‘ to ‘self.membrane ‘ in host memory. Here membrane means the persistent LIF neuron state carrying charge between timesteps. The important operands are clip: the value named ’clip’ in this block; membrane: the persistent LIF neuron state carrying charge between timesteps; leak_shift: the retained fraction of prior membrane state. Context: the function execute_program, which handles execute program.

Line 108: `self.membrane - (self.membrane >> leak_shift) + np.asarray(currents),` This is continuation line 2 of the 5-line logical statement that begins at source line 107. Its exact fragment is ‘self.membrane - (self.membrane >> leak_shift) + np.asarray(currents),‘. The important operands are membrane: the persistent LIF neuron state carrying charge between timesteps; leak_shift: the retained fraction of prior membrane state; asarray: the value named ’asarray’ in this block. Read together, the complete operation is: This assigns ‘np.clip(self.membrane - (self.membrane >> leak_shift) + np.asarray(currents), -(1 << 23), (1 << 23) - 1,)‘ to ‘self.membrane ‘ in host memory. Here membrane means the persistent LIF neuron state carrying charge between timesteps. The important operands are clip: the value named ’clip’ in this block; membrane: the persistent LIF neuron state carrying charge between timesteps; leak_shift: the retained fraction of prior membrane state. Context: the function execute_program, which handles execute program.

Line 109: `-(1 << 23),` This is continuation line 3 of the 5-line logical statement that begins at source line 107. Its exact fragment is ‘-(1 << 23),‘. The expression is a literal or structural operator and has no hidden software state. Read together, the complete operation is: This assigns ‘np.clip(self.membrane - (self.membrane >> leak_shift) + np.asarray(currents), -(1 << 23), (1 << 23) - 1,)‘ to ‘self.membrane ‘ in host memory. Here membrane means the persistent LIF neuron state carrying charge between timesteps. The important operands are clip: the value named ’clip’ in this block; membrane: the persistent LIF neuron state carrying charge between timesteps; leak_shift: the retained fraction of prior membrane state. Context: the function execute_program, which handles execute program.

Line 110: `(1 << 23) - 1,` This is continuation line 4 of the 5-line logical statement that begins at source line 107. Its exact fragment is ‘(1 << 23) - 1,‘. The expression is a literal or structural operator and has no hidden software state. Read together, the complete operation is: This assigns ‘np.clip(self.membrane - (self.membrane >> leak_shift) + np.asarray(currents), -(1 << 23), (1 << 23) - 1,)‘ to ‘self.membrane ‘ in host memory. Here membrane means the persistent LIF neuron state carrying charge between timesteps. The important operands are clip: the value named ’clip’ in this block; membrane: the persistent LIF neuron state carrying charge between timesteps; leak_shift: the retained fraction of prior membrane state. Context: the function execute_program, which handles execute program.

Line 111: `)` This is continuation line 5 of the 5-line logical statement that begins at source line 107. Its exact fragment is ‘)‘. The expression is a literal or structural operator and has no hidden software state. Read together, the complete operation is: This assigns ‘np.clip(self.membrane - (self.membrane >> leak_shift) + np.asarray(currents), -(1 << 23), (1 << 23) - 1,)‘ to ‘self.membrane ‘ in host memory. Here membrane means the persistent LIF neuron state carrying charge between timesteps. The important operands are clip: the value named ’clip’ in this block; membrane: the persistent LIF neuron state carrying charge between timesteps; leak_shift: the retained fraction of prior membrane state. Context: the function execute_program, which handles execute program.

Line 112: `pre_reset_membrane = self.membrane.copy()` This assigns ‘self.membrane.copy()‘ to ‘pre_reset_membrane ‘ in host memory. Here pre_reset_membrane means the persistent LIF neuron state carrying charge between timesteps. The important operands are membrane: the persistent LIF neuron state carrying charge between timesteps; copy: the value named ’copy’ in this block. Context: the function execute_program, which handles execute program.

Line 113: `fired = self.membrane >= threshold` Inside the function execute_program, which handles execute program, this statement advances the host implementation that checks spikingformer accelerator behavior independently with Python assertions. The important operands are fired: the value named ’fired’ in this block; membrane: the persistent LIF neuron state carrying charge between timesteps; threshold: the membrane level at which a neuron emits a spike.

Line 114: `self.membrane = np.where(fired, reset, self.membrane)` This assigns ‘np.where(fired, reset, self.membrane)‘ to ‘self.membrane ‘ in host memory. Here membrane means the persistent LIF neuron state carrying charge between timesteps. The important operands are where: the value named ’where’ in this block; fired: the value named ’fired’ in this block; reset: the value named ’reset’ in this block. Context: the function execute_program, which handles execute program.

Line 115: `self.timesteps += 1` Inside the function execute_program, which handles execute program, this statement advances the host implementation that checks spikingformer accelerator behavior independently with Python assertions. The important operands are timesteps: one discrete SNN update instant.

Line 116: `spike_word = sum(int(fired[lane]) << lane for lane in range(32))` This assigns ‘sum(int(fired[lane]) << lane for lane in range(32))‘ to ‘spike_word ‘ in host memory. Here spike_word means a binary event produced when a neuron crosses its threshold. The important operands are sum: the value named ’sum’ in this block; fired: the value named ’fired’ in this block; lane: one parallel arithmetic element within a vector or tensor datapath. Context: the function execute_program, which handles execute program.

Line 117: `output.append(spike_word | (self.timesteps << 32))` This calls ‘output.append‘ with ‘spike_word | (self.timesteps << 32)‘ inside the function execute_program, which handles execute program. The call advances the host-side job that checks spikingformer accelerator behavior independently with Python assertions.

Line 118: `if (command >> 58) & 1:` This executes the following indented host-code branch only when ‘(command >> 58) & 1‘ is true. The important operands are command: the 128-bit instruction selecting an engine, shape, mode, and numeric parameters. Context: the function execute_program, which handles execute program.

Line 119: `packed = sum(` This statement continues through source line 122; the explanation uses the complete expression rather than only the first visual fragment. This assigns ‘sum((int(pre_reset_membrane[lane]) & 0xFFFFFF) << (24 * lane) for lane in range(32))‘ to ‘packed ‘ in host memory. Here packed means the value named ’packed’ in this block. The important operands are sum: the value named ’sum’ in this block; pre_reset_membrane: the persistent LIF neuron state carrying charge between timesteps; lane: one parallel arithmetic element within a vector or tensor datapath. Context: the function execute_program, which handles execute program.

Line 120: `(int(pre_reset_membrane[lane]) & 0xFFFFFF) << (24 * lane)` This is continuation line 2 of the 4-line logical statement that begins at source line 119. Its exact fragment is ‘(int(pre_reset_membrane[lane]) & 0xFFFFFF) << (24 * lane)‘. The important operands are pre_reset_membrane: the persistent LIF neuron state carrying charge between timesteps; lane: one parallel arithmetic element within a vector or tensor datapath. Read together, the complete operation is: This assigns ‘sum((int(pre_reset_membrane[lane]) & 0xFFFFFF) << (24 * lane) for lane in range(32))‘ to ‘packed ‘ in host memory. Here packed means the value named ’packed’ in this block. The important operands are sum: the value named ’sum’ in this block; pre_reset_membrane: the persistent LIF neuron state carrying charge between timesteps; lane: one parallel arithmetic element within a vector or tensor datapath. Context: the function execute_program, which handles execute program.

Line 121: `for lane in range(32)` This is continuation line 3 of the 4-line logical statement that begins at source line 119. Its exact fragment is ‘for lane in range(32)‘. The important operands are for: the value named ’for’ in this block; lane: one parallel arithmetic element within a vector or tensor datapath; in: the value named ’in’ in this block. Read together, the complete operation is: This assigns ‘sum((int(pre_reset_membrane[lane]) & 0xFFFFFF) << (24 * lane) for lane in range(32))‘ to ‘packed ‘ in host memory. Here packed means the value named ’packed’ in this block. The important operands are sum: the value named ’sum’ in this block; pre_reset_membrane: the persistent LIF neuron state carrying charge between timesteps; lane: one parallel arithmetic element within a vector or tensor datapath. Context: the function execute_program, which handles execute program.

Line 122: `)` This is continuation line 4 of the 4-line logical statement that begins at source line 119. Its exact fragment is ‘)‘. The expression is a literal or structural operator and has no hidden software state. Read together, the complete operation is: This assigns ‘sum((int(pre_reset_membrane[lane]) & 0xFFFFFF) << (24 * lane) for lane in range(32))‘ to ‘packed ‘ in host memory. Here packed means the value named ’packed’ in this block. The important operands are sum: the value named ’sum’ in this block; pre_reset_membrane: the persistent LIF neuron state carrying charge

between timesteps; lane: one parallel arithmetic element within a vector or tensor datapath. Context: the function execute_program, which handles execute program.

Line 123: `output.extend(` This statement continues through source line 126; the explanation uses the complete expression rather than only the first visual fragment. This calls ‘output.extend‘ with ‘ (packed >> (64 * word)) & 0xFFFFFFFFFFFFFFFF for word in range(12) ‘ inside the function execute_program, which handles execute program. The call advances the host-side job that checks spikingformer accelerator behavior independently with Python assertions.

Line 124: `(packed >> (64 * word)) & 0xFFFFFFFFFFFFFFFF` This is continuation line 2 of the 4-line logical statement that begins at source line 123. Its exact fragment is ‘(packed >> (64 * word)) & 0xFFFFFFFFFFFFFFFF‘. The important operands are packed: the value named ’packed’ in this block; word: the value named ’word’ in this block. Read together, the complete operation is: This calls ‘output.extend‘ with ‘ (packed >> (64 * word)) & 0xFFFFFFFFFFFFFFFF for word in range(12) ‘ inside the function execute_program, which handles execute program. The call advances the host-side job that checks spikingformer accelerator behavior independently with Python assertions.

Line 125: `for word in range(12)` This is continuation line 3 of the 4-line logical statement that begins at source line 123. Its exact fragment is ‘for word in range(12)‘. The important operands are for: the value named ’for’ in this block; word: the value named ’word’ in this block; in: the value named ’in’ in this block. Read together, the complete operation is: This calls ‘output.extend‘ with ‘ (packed >> (64 * word)) & 0xFFFFFFFFFFFFFFFF for word in range(12) ‘ inside the function execute_program, which handles execute program. The call advances the host-side job that checks spikingformer accelerator behavior independently with Python assertions.

Line 126: `)` This is continuation line 4 of the 4-line logical statement that begins at source line 123. Its exact fragment is ‘)‘. The expression is a literal or structural operator and has no hidden software state. Read together, the complete operation is: This calls ‘output.extend‘ with ‘ (packed >> (64 * word)) & 0xFFFFFFFFFFFFFFFF for word in range(12) ‘ inside the function execute_program, which handles execute program. The call advances the host-side job that checks spikingformer accelerator behavior independently with Python assertions.

Line 127: `if record.output_beats != 13:` This executes the following indented host-code branch only when ‘record.output_be
!= 13‘ is true. The important operands are record: the value named ’record’ in this block; output_beats: the value named ’output beats’ in this block. Context: the function execute_program, which handles execute program.

Line 128: `raise AssertionError("traced LIF record must request thirteen beats")` This rejects an invalid state by raising ‘AssertionError("traced LIF record must request thirteen beats")‘. Failing before DMA prevents malformed shapes or artifacts from silently becoming hardware results.

Line 129: `elif record.output_beats != 1:` This executes the following indented host-code branch only when ‘record.output_beats != 1‘ is true. The important operands are record: the value named ’record’ in this block; output_beats: the value named ’output beats’ in this block. Context: the function execute_program, which handles execute program.

Line 130: `raise AssertionError("untraced LIF record must request one beat")` This rejects an invalid state by raising ‘AssertionError("untraced LIF record must request one beat")‘. Failing before DMA prevents malformed shapes or artifacts from silently becoming hardware results.

Line 131: `return tuple(output)` This returns ‘tuple(output)‘ to the caller of the function execute_program, which handles execute program, ending this invocation. The important operands are tuple: the value named ’tuple’ in this block; output: the value named ’output’ in this block.

Line 134: `class SpikingformerAcceleratorTests(unittest.TestCase):` This defines class SpikingformerAcceleratorTests, which groups data and methods for spikingformer accelerator tests. Instances exist in host memory and organize the flow that checks spikingformer accelerator behavior independently with Python assertions.

Line 135: `@staticmethod` This decorator changes how the following class or function is constructed. '@staticmethod' is applied at import time on the host and is part of the class SpikingformerAcceleratorTests, which handles spikingformer accelerator tests; it creates no FPGA circuit by itself.

Line 136: `def parameters(name: str, weight: np.ndarray, opcode: str) -> ProjectionParameters:` This starts function parameters. Its indented body performs parameters as part of the file that checks spikingformer accelerator behavior independently with Python assertions; it runs only when called.

Line 137: `channels = weight.shape[1]` This assigns 'weight.shape[1]' to 'channels ' in host memory. Here channels means the value named 'channels' in this block. The important operands are weight: a learned coefficient multiplied by an activation; shape: the value named 'shape' in this block. Context: the function parameters, which handles parameters.

Line 138: `return ProjectionParameters(` This statement continues through source line 147; the explanation uses the complete expression rather than only the first visual fragment. This returns 'ProjectionParameters(name, weight.astype(np.int8), np.arange(channels, dtype=np.int32) * 17 - 31, np.asarray([16384 + 733 * channel for channel in range(channels)], dtype=np.int16), np.asarray([(channel % 3) - 1 for channel in range(channels)], dtype=np.int8), opcode, (channels, weight.shape[0], 1), 10,)' to the caller of the function parameters, which handles parameters, ending this invocation. The important operands are ProjectionParameters: the value named 'projection parameters' in this block; name: the value named 'name' in this block; weight: a learned coefficient multiplied by an activation.

Line 139: `name,` This is continuation line 2 of the 10-line logical statement that begins at source line 138. Its exact fragment is 'name,'. The important operands are name: the value named 'name' in this block. Read together, the complete operation is: This returns 'ProjectionParameters(name, weight.astype(np.int8), np.arange(channels, dtype=np.int32) * 17 - 31, np.asarray([16384 + 733 * channel for channel in range(channels)], dtype=np.int16), np.asarray([(channel % 3) - 1 for channel in range(channels)], dtype=np.int8), opcode, (channels, weight.shape[0], 1), 10,)' to the caller of the function parameters, which handles parameters, ending this invocation. The important operands are ProjectionParameters: the value named 'projection parameters' in this block; name: the value named 'name' in this block; weight: a learned coefficient multiplied by an activation.

Line 140: `weight.astype(np.int8),` This is continuation line 3 of the 10-line logical statement that begins at source line 138. Its exact fragment is 'weight.astype(np.int8),'. The important operands are weight: a learned coefficient multiplied by an activation; astype: the value named 'astype' in this block; int8: the value named 'int8' in this block. Read together, the complete operation is: This returns 'ProjectionParameters(name, weight.astype(np.int8), np.arange(channels, dtype=np.int32) * 17 - 31, np.asarray([16384 + 733 * channel for channel in range(channels)], dtype=np.int16), np.asarray([(channel % 3) - 1 for channel in range(channels)], dtype=np.int8), opcode, (channels, weight.shape[0], 1), 10,)' to the caller of the function parameters, which handles parameters, ending this invocation. The important operands are ProjectionParameters: the value named 'projection parameters' in this block; name: the value named 'name' in this block; weight: a learned coefficient multiplied by an activation.

Line 141: `np.arange(channels, dtype=np.int32) * 17 - 31,` This is continuation line 4 of the 10-line logical statement that begins at source line 138. Its exact fragment is 'np.arange(channels, dtype=np.int32) * 17 - 31,'. The important operands are arange: the value named 'arange' in this block; channels: the value named 'channels' in this block; dtype: the value named 'dtype' in this block. Read together, the complete operation is: This returns 'ProjectionParameters(name, weight.astype(np.int8), np.arange(channels, dtype=np.int32) * 17 - 31, np.asarray([16384 + 733 * channel for channel in range(channels)], dtype=np.int16), np.asarray([(channel % 3) - 1 for channel in range(channels)], dtype=np.int8), opcode, (channels, weight.shape[0], 1), 10,)' to the caller of the function parameters, which handles parameters, ending this invocation. The important operands are ProjectionParameters: the value named 'projection parameters' in this block; name: the value named 'name' in this block; weight: a learned coefficient multiplied by an activation.

Line 142: `np.asarray([16384 + 733 * channel for channel in range(channels)], dtype=np.int16),` This is continuation line 5 of the 10-line logical statement that begins at source line 138. Its exact fragment is 'np.asarray([16384 + 733 * channel for channel in range(channels)], dtype=np.int16),'. The important operands are asarray: the value named 'asarray' in this block; channel: the value named 'channel' in this block; for: the value named 'for' in this block. Read together, the complete operation is: This returns 'ProjectionParameters(name, weight.astype(np.int8), np.arange(channels, dtype=np.int32) * 17 - 31, np.asarray([16384 + 733 * channel for channel in range(channels)],

dtype=np.int16), np.asarray([(channel % 3) - 1 for channel in range(channels)], dtype=np.int8), opcode, (channels, weight.shape[0], 1), 10,)‘ to the caller of the function parameters, which handles parameters, ending this invocation. The important operands are ProjectionParameters: the value named 'projection parameters' in this block; name: the value named 'name' in this block; weight: a learned coefficient multiplied by an activation.

Line 143: `np.asarray([(channel % 3) - 1 for channel in range(channels)], dtype=np.int8),` This is continuation line 6 of the 10-line logical statement that begins at source line 138. Its exact fragment is ‘np.asarray([(channel % 3) - 1 for channel in range(channels)], dtype=np.int8),‘. The important operands are asarray: the value named 'asarray' in this block; channel: the value named 'channel' in this block; for: the value named 'for' in this block. Read together, the complete operation is: This returns ‘ProjectionParameters(name, weight.astype(np.int8), np.arange(channels, dtype=np.int32) * 17 - 31, np.asarray([16384 + 733 * channel for channel in range(channels)], dtype=np.int16), np.asarray([(channel % 3) - 1 for channel in range(channels)], dtype=np.int8), opcode, (channels, weight.shape[0], 1), 10,)‘ to the caller of the function parameters, which handles parameters, ending this invocation. The important operands are ProjectionParameters: the value named 'projection parameters' in this block; name: the value named 'name' in this block; weight: a learned coefficient multiplied by an activation.

Line 144: `opcode,` This is continuation line 7 of the 10-line logical statement that begins at source line 138. Its exact fragment is ‘opcode,‘. The important operands are opcode: the value named 'opcode' in this block. Read together, the complete operation is: This returns ‘ProjectionParameters(name, weight.astype(np.int8), np.arange(channels, dtype=np.int32) * 17 - 31, np.asarray([16384 + 733 * channel for channel in range(channels)], dtype=np.int16), np.asarray([(channel % 3) - 1 for channel in range(channels)], dtype=np.int8), opcode, (channels, weight.shape[0], 1), 10,)‘ to the caller of the function parameters, which handles parameters, ending this invocation. The important operands are ProjectionParameters: the value named 'projection parameters' in this block; name: the value named 'name' in this block; weight: a learned coefficient multiplied by an activation.

Line 145: `(channels, weight.shape[0], 1),` This is continuation line 8 of the 10-line logical statement that begins at source line 138. Its exact fragment is ‘(channels, weight.shape[0], 1),‘. The important operands are channels: the value named 'channels' in this block; weight: a learned coefficient multiplied by an activation; shape: the value named 'shape' in this block. Read together, the complete operation is: This returns ‘ProjectionParameters(name, weight.astype(np.int8), np.arange(channels, dtype=np.int32) * 17 - 31, np.asarray([16384 + 733 * channel for channel in range(channels)], dtype=np.int16), np.asarray([(channel % 3) - 1 for channel in range(channels)], dtype=np.int8), opcode, (channels, weight.shape[0], 1), 10,)‘ to the caller of the function parameters, which handles parameters, ending this invocation. The important operands are ProjectionParameters: the value named 'projection parameters' in this block; name: the value named 'name' in this block; weight: a learned coefficient multiplied by an activation.

Line 146: `10,` This is continuation line 9 of the 10-line logical statement that begins at source line 138. Its exact fragment is ‘10,‘. The expression is a literal or structural operator and has no hidden software state. Read together, the complete operation is: This returns ‘ProjectionParameters(name, weight.astype(np.int8), np.arange(channels, dtype=np.int32) * 17 - 31, np.asarray([16384 + 733 * channel for channel in range(channels)], dtype=np.int16), np.asarray([(channel % 3) - 1 for channel in range(channels)], dtype=np.int8), opcode, (channels, weight.shape[0], 1), 10,)‘ to the caller of the function parameters, which handles parameters, ending this invocation. The important operands are ProjectionParameters: the value named 'projection parameters' in this block; name: the value named 'name' in this block; weight: a learned coefficient multiplied by an activation.

Line 147: `)` This is continuation line 10 of the 10-line logical statement that begins at source line 138. Its exact fragment is ‘)‘. The expression is a literal or structural operator and has no hidden software state. Read together, the complete operation is: This returns ‘ProjectionParameters(name, weight.astype(np.int8), np.arange(channels, dtype=np.int32) * 17 - 31, np.asarray([16384 + 733 * channel for channel in range(channels)], dtype=np.int16), np.asarray([(channel % 3) - 1 for channel in range(channels)], dtype=np.int8), opcode, (channels, weight.shape[0], 1), 10,)‘ to the caller of the function parameters, which handles parameters, ending this invocation. The important operands are ProjectionParameters: the value named 'projection parameters' in this block; name: the value named 'name' in this block; weight: a learned coefficient multiplied by an activation.

Line 149: `def test_fabric_projection_requantizer_matches_independent_reference(self) -> None:` This starts function test_fabric_projection_requantizer_matches_independent_reference. Its indented body performs test fabric

projection requantizer matches independent reference as part of the file that checks spikingformer accelerator behavior independently with Python assertions; it runs only when called.

Line 150: `rng = np.random.default_rng(20260713)` This assigns ‘np.random.default_rng(20260713)‘ to ‘rng ‘ in host memory. Here rng means the value named ’rng’ in this block. The important operands are random: the value named ’random’ in this block; default_rng: the value named ’default rng’ in this block. Context: the function test_fabric_projection_requantizer_matches_independent_reference, which handles test fabric projection requantizer matches independent reference.

Line 151: `rows = 19` This assigns ‘19‘ to ‘rows ‘ in host memory. Here rows means one output-row position processed by the tensor tile. The expression is a literal or structural operator and has no hidden software state. Context: the function test_fabric_projection_requantizer_matches_independent_reference, which handles test fabric projection requantizer matches independent reference.

Line 152: `channels = 13` This assigns ‘13‘ to ‘channels ‘ in host memory. Here channels means the value named ’channels’ in this block. The expression is a literal or structural operator and has no hidden software state. Context: the function test_fabric_projection_requantizer_matches_independent_reference, which handles test fabric projection requantizer matches independent reference.

Line 153: `parameters = ProjectionParameters(` This statement continues through source line 162; the explanation uses the complete expression rather than only the first visual fragment. This assigns ‘ProjectionParameters("test", np.zeros((17, channels), dtype=np.int8), rng.integers(-3000, 3001, size=channels, dtype=np.int32), rng.integers(-32768, 32768, size=channels, dtype=np.int16), rng.integers(-10, 11, size=channels, dtype=np.int8), "COMPUTE_BINARY", (channels, 17, 1, 1), 10,)‘ to ‘parameters ‘ in host memory. Here parameters means the value named ’parameters’ in this block. The important operands are ProjectionParameters: the value named ’projection parameters’ in this block; test: the value named ’test’ in this block; zeros: the value named ’zeros’ in this block. Context: the function test_fabric_projection_requantizer_matches_independent_reference, which handles test fabric projection requantizer matches independent reference.

Line 154: `"test",` This is continuation line 2 of the 10-line logical statement that begins at source line 153. Its exact fragment is ‘"test",‘. The important operands are test: the value named ’test’ in this block. Read together, the complete operation is: This assigns ‘ProjectionParameters("test", np.zeros((17, channels), dtype=np.int8), rng.integers(-3000, 3001, size=channels, dtype=np.int32), rng.integers(-32768, 32768, size=channels, dtype=np.int16), rng.integers(-10, 11, size=channels, dtype=np.int8), "COMPUTE_BINARY", (channels, 17, 1, 1), 10,)‘ to ‘parameters ‘ in host memory. Here parameters means the value named ’parameters’ in this block. The important operands are ProjectionParameters: the value named ’projection parameters’ in this block; test: the value named ’test’ in this block; zeros: the value named ’zeros’ in this block. Context: the function test_fabric_projection_requantizer_matches_independent_reference, which handles test fabric projection requantizer matches independent reference.

Line 155: `np.zeros((17, channels), dtype=np.int8),` This is continuation line 3 of the 10-line logical statement that begins at source line 153. Its exact fragment is ‘np.zeros((17, channels), dtype=np.int8),‘. The important operands are zeros: the value named ’zeros’ in this block; channels: the value named ’channels’ in this block; dtype: the value named ’dtype’ in this block. Read together, the complete operation is: This assigns ‘ProjectionParameters("test", np.zeros((17, channels), dtype=np.int8), rng.integers(-3000, 3001, size=channels, dtype=np.int32), rng.integers(-32768, 32768, size=channels, dtype=np.int16), rng.integers(-10, 11, size=channels, dtype=np.int8), "COMPUTE_BINARY", (channels, 17, 1, 1), 10,)‘ to ‘parameters ‘ in host memory. Here parameters means the value named ’parameters’ in this block. The important operands are ProjectionParameters: the value named ’projection parameters’ in this block; test: the value named ’test’ in this block; zeros: the value named ’zeros’ in this block. Context: the function test_fabric_projection_requantizer_matches_independent_reference, which handles test fabric projection requantizer matches independent reference.

Line 156: `rng.integers(-3000, 3001, size=channels, dtype=np.int32),` This is continuation line 4 of the 10-line logical statement that begins at source line 153. Its exact fragment is ‘rng.integers(-3000, 3001, size=channels, dtype=np.int32),‘. The important operands are rng: the value named ’rng’ in this block; integers: the value named ’integers’ in this block; size: the value named ’size’ in this block. Read together, the complete operation is: This assigns ‘ProjectionParameters("test", np.zeros((17, channels), dtype=np.int8), rng.integers(-3000, 3001, size=channels,

dtype=np.int32), rng.integers(-32768, 32768, size=channels, dtype=np.int16), rng.integers(-10, 11, size=channels, dtype=np.int8), "COMPUTE_BINARY", (channels, 17, 1, 1), 10,)‘ to ‘parameters ‘ in host memory. Here parameters means the value named ’parameters’ in this block. The important operands are ProjectionParameters: the value named ’projection parameters’ in this block; test: the value named ’test’ in this block; zeros: the value named ’zeros’ in this block. Context: the function test_fabric_projection_requantizer_matches_independent_reference, which handles test fabric projection requantizer matches independent reference.

Line 157: `rng.integers(-32768, 32768, size=channels, dtype=np.int16),` This is continuation line 5 of the 10-line logical statement that begins at source line 153. Its exact fragment is ‘rng.integers(-32768, 32768, size=channels, dtype=np.int16),‘. The important operands are rng: the value named ’rng’ in this block; integers: the value named ’integers’ in this block; size: the value named ’size’ in this block. Read together, the complete operation is: This assigns ‘ProjectionParameters("test", np.zeros((17, channels), dtype=np.int8), rng.integers(-3000, 3001, size=channels, dtype=np.int32), rng.integers(-32768, 32768, size=channels, dtype=np.int16), rng.integers(-10, 11, size=channels, dtype=np.int8), "COMPUTE_BINARY", (channels, 17, 1, 1), 10,)‘ to ‘parameters ‘ in host memory. Here parameters means the value named ’parameters’ in this block. The important operands are ProjectionParameters: the value named ’projection parameters’ in this block; test: the value named ’test’ in this block; zeros: the value named ’zeros’ in this block. Context: the function test_fabric_projection_requantizer_matches_independent_reference, which handles test fabric projection requantizer matches independent reference.

Line 158: `rng.integers(-10, 11, size=channels, dtype=np.int8),` This is continuation line 6 of the 10-line logical statement that begins at source line 153. Its exact fragment is ‘rng.integers(-10, 11, size=channels, dtype=np.int8),‘. The important operands are rng: the value named ’rng’ in this block; integers: the value named ’integers’ in this block; size: the value named ’size’ in this block. Read together, the complete operation is: This assigns ‘ProjectionParameters("test", np.zeros((17, channels), dtype=np.int8), rng.integers(-3000, 3001, size=channels, dtype=np.int32), rng.integers(-32768, 32768, size=channels, dtype=np.int16), rng.integers(-10, 11, size=channels, dtype=np.int8), "COMPUTE_BINARY", (channels, 17, 1, 1), 10,)‘ to ‘parameters ‘ in host memory. Here parameters means the value named ’parameters’ in this block. The important operands are ProjectionParameters: the value named ’projection parameters’ in this block; test: the value named ’test’ in this block; zeros: the value named ’zeros’ in this block. Context: the function test_fabric_projection_requantizer_matches_independent_reference, which handles test fabric projection requantizer matches independent reference.

Line 159: `"COMPUTE_BINARY",` This is continuation line 7 of the 10-line logical statement that begins at source line 153. Its exact fragment is ‘"COMPUTE_BINARY",‘. The important operands are COMPUTE_BINARY: the value named ’compute binary’ in this block. Read together, the complete operation is: This assigns ‘ProjectionParameters("test", np.zeros((17, channels), dtype=np.int8), rng.integers(-3000, 3001, size=channels, dtype=np.int32), rng.integers(-32768, 32768, size=channels, dtype=np.int16), rng.integers(-10, 11, size=channels, dtype=np.int8), "COMPUTE_BINARY", (channels, 17, 1, 1), 10,)‘ to ‘parameters ‘ in host memory. Here parameters means the value named ’parameters’ in this block. The important operands are ProjectionParameters: the value named ’projection parameters’ in this block; test: the value named ’test’ in this block; zeros: the value named ’zeros’ in this block. Context: the function test_fabric_projection_requantizer_matches_independent_reference, which handles test fabric projection requantizer matches independent reference.

Line 160: `(channels, 17, 1, 1),` This is continuation line 8 of the 10-line logical statement that begins at source line 153. Its exact fragment is ‘(channels, 17, 1, 1),‘. The important operands are channels: the value named ’channels’ in this block. Read together, the complete operation is: This assigns ‘ProjectionParameters("test", np.zeros((17, channels), dtype=np.int8), rng.integers(-3000, 3001, size=channels, dtype=np.int32), rng.integers(-32768, 32768, size=channels, dtype=np.int16), rng.integers(-10, 11, size=channels, dtype=np.int8), "COMPUTE_BINARY", (channels, 17, 1, 1), 10,)‘ to ‘parameters ‘ in host memory. Here parameters means the value named ’parameters’ in this block. The important operands are ProjectionParameters: the value named ’projection parameters’ in this block; test: the value named ’test’ in this block; zeros: the value named ’zeros’ in this block. Context: the function test_fabric_projection_requantizer_matches_indepen which handles test fabric projection requantizer matches independent reference.

Line 161: `10,` This is continuation line 9 of the 10-line logical statement that begins at source line 153. Its exact fragment is ‘10,‘. The expression is a literal or structural operator and has no hidden software state. Read together, the complete operation is: This assigns ‘ProjectionParameters("test", np.zeros((17, channels), dtype=np.int8), rng.integers(-3000, 3001, size=channels, dtype=np.int32), rng.integers(-32768, 32768, size=channels, dtype=np.int16), rng.integers(-10, 11, size=channels, dtype=np.int8), "COMPUTE_BINARY", (channels, 17, 1, 1), 10,)‘ to ‘parameters ‘ in host

memory. Here parameters means the value named 'parameters' in this block. The important operands are ProjectionParameters: the value named 'projection parameters' in this block; test: the value named 'test' in this block; zeros: the value named 'zeros' in this block. Context: the function test_fabric_projection_requantizer_matches_independent_reference, which handles test fabric projection requantizer matches independent reference.

Line 162: `)` This is continuation line 10 of the 10-line logical statement that begins at source line 153. Its exact fragment is ')'. The expression is a literal or structural operator and has no hidden software state. Read together, the complete operation is: This assigns 'ProjectionParameters("test", np.zeros((17, channels), dtype=np.int8), rng.integers(-3000, 3001, size=channels, dtype=np.int32), rng.integers(-32768, 32768, size=channels, dtype=np.int16), rng.integers(-10, 11, size=channels, dtype=np.int8), "COMPUTE_BINARY", (channels, 17, 1, 1), 10,)' to 'parameters ' in host memory. Here parameters means the value named 'parameters' in this block. The important operands are ProjectionParameters: the value named 'projection parameters' in this block; test: the value named 'test' in this block; zeros: the value named 'zeros' in this block. Context: the function test_fabric_projection_requantizer_matches_independent_reference, which handles test fabric projection requantizer matches independent reference.

Line 163: `accumulators = rng.integers(-500_000, 500_001, size=(rows, channels), dtype=np.int64)` This assigns 'rng.integers(-500_000, 500_001, size=(rows, channels), dtype=np.int64)' to 'accumulators ' in host memory. Here accumulators means a widened running sum that prevents intermediate overflow. The important operands are rng: the value named 'rng' in this block; integers: the value named 'integers' in this block; size: the value named 'size' in this block. Context: the function test_fabric_projection_requantizer_matches_independent_reference, which handles test fabric projection requantizer matches independent reference.

Line 164: `expected = requantize_projection_reference(accumulators, parameters)` This assigns 'requantize_projection parameters)' to 'expected ' in host memory. Here expected means the value named 'expected' in this block. The important operands are requantize_projection_reference: the conversion of a wide accumulated result back into a bounded activation code; accumulators: a widened running sum that prevents intermediate overflow; parameters: the value named 'parameters' in this block. Context: the function test_fabric_projection_requantizer_matches_independent_reference, which handles test fabric projection requantizer matches independent reference.

Line 165: `actual = requantize_projection_on_accelerator(` This statement continues through source line 166; the explanation uses the complete expression rather than only the first visual fragment. This assigns 'requantize_projection_on_acce VectorProgramEmulator(), accumulators, parameters)' to 'actual ' in host memory. Here actual means the value named 'actual' in this block. The important operands are requantize_projection_on_accelerator: the conversion of a wide accumulated result back into a bounded activation code; VectorProgramEmulator: the value named 'vector program emulator' in this block; accumulators: a widened running sum that prevents intermediate overflow. Context: the function test_fabric_projection_requantizer_matches_independent_reference, which handles test fabric projection requantizer matches independent reference.

Line 166: `VectorProgramEmulator(), accumulators, parameters)` This is continuation line 2 of the 2-line logical statement that begins at source line 165. Its exact fragment is 'VectorProgramEmulator(), accumulators, parameters)'. The important operands are VectorProgramEmulator: the value named 'vector program emulator' in this block; accumulators: a widened running sum that prevents intermediate overflow; parameters: the value named 'parameters' in this block. Read together, the complete operation is: This assigns 'requantize_projection_on_accelerator(VectorProgramEmulator(), accumulators, parameters)' to 'actual ' in host memory. Here actual means the value named 'actual' in this block. The important operands are requantize_projection_on_accelerator: the conversion of a wide accumulated result back into a bounded activation code; VectorProgramEmulator: the value named 'vector program emulator' in this block; accumulators: a widened running sum that prevents intermediate overflow. Context: the function test_fabric_projection_requantizer_matches_independent_reference, which handles test fabric projection requantizer matches independent reference.

Line 167: `np.testing.assert_array_equal(actual, expected)` This calls 'np.testing.assert_array_equal' with 'actual, expected' inside the function test_fabric_projection_requantizer_matches_independent_reference, which handles test fabric projection requantizer matches independent reference. The call advances the host-side job that checks spikingformer accelerator behavior independently with Python assertions.

Line 169: `def test_binary_projection_executes_tensor_and_vector_programs(self) -> None:` This starts function test_binary_projection_executes_tensor_and_vector_programs. Its indented body performs test binary projection executes tensor and vector programs as part of the file that checks spikingformer accelerator behavior independently with Python assertions; it runs only when called.

Line 170: `rng = np.random.default_rng(11)` This assigns ‘np.random.default_rng(11)‘ to ‘rng ‘ in host memory. Here rng means the value named ’rng’ in this block. The important operands are random: the value named ’random’ in this block; default_rng: the value named ’default rng’ in this block. Context: the function test_binary_projection_executes_tensor_and which handles test binary projection executes tensor and vector programs.

Line 171: `spikes = rng.integers(0, 2, size=(11, 7), dtype=np.uint8)` This assigns ‘rng.integers(0, 2, size=(11, 7), dtype=np.uint8)‘ to ‘spikes ‘ in host memory. Here spikes means a binary event produced when a neuron crosses its threshold. The important operands are rng: the value named ’rng’ in this block; integers: the value named ’integers’ in this block; size: the value named ’size’ in this block. Context: the function test_binary_projection_executes_tensor_and_vector_progr which handles test binary projection executes tensor and vector programs.

Line 172: `weight = rng.integers(-127, 128, size=(7, 5), dtype=np.int16).astype(np.int8)` This assigns ‘rng.integers(-127, 128, size=(7, 5), dtype=np.int16).astype(np.int8)‘ to ‘weight ‘ in host memory. Here weight means a learned coefficient multiplied by an activation. The important operands are rng: the value named ’rng’ in this block; integers: the value named ’integers’ in this block; size: the value named ’size’ in this block. Context: the function test_binary_projection_executes_tensor_and_vector_programs, which handles test binary projection executes tensor and vector programs.

Line 173: `parameters = self.parameters("binary", weight, "COMPUTE_BINARY")` This assigns ‘self.parameters("binary", weight, "COMPUTE_BINARY")‘ to ‘parameters ‘ in host memory. Here parameters means the value named ’parameters’ in this block. The important operands are parameters: the value named ’parameters’ in this block; binary: the value named ’binary’ in this block; weight: a learned coefficient multiplied by an activation. Context: the function test_binary_projection_executes_tensor_and_vector_programs, which handles test binary projection executes tensor and vector programs.

Line 174: `executor = SpikingformerProjectionExecutor(` This statement continues through source line 175; the explanation uses the complete expression rather than only the first visual fragment. This assigns ‘SpikingformerProjectionExecutor(OneProjectionArchive(parameters), CombinedProgramEmulator())‘ to ‘executor ‘ in host memory. Here executor means the value named ’executor’ in this block. The important operands are SpikingformerProjectionExecutor: the value named ’spikingformer projection executor’ in this block; OneProjectionArchive: the value named ’one projection archive’ in this block; parameters: the value named ’parameters’ in this block. Context: the function test_binary_projection_executes_tensor_and_vector_programs, which handles test binary projection executes tensor and vector programs.

Line 175: `OneProjectionArchive(parameters), CombinedProgramEmulator())` This is continuation line 2 of the 2-line logical statement that begins at source line 174. Its exact fragment is ‘OneProjectionArchive(parameters), CombinedProgramEmulator())‘. The important operands are OneProjectionArchive: the value named ’one projection archive’ in this block; parameters: the value named ’parameters’ in this block; CombinedProgramEmulator: the value named ’combined program emulator’ in this block. Read together, the complete operation is: This assigns ‘SpikingformerProjectionExecutor(OneProjectionArchive(parameters), CombinedProgramEmulator())‘ to ‘executor ‘ in host memory. Here executor means the value named ’executor’ in this block. The important operands are SpikingformerProjectionExecutor: the value named ’spikingformer projection executor’ in this block; OneProjectionArchive: the value named ’one projection archive’ in this block; parameters: the value named ’parameters’ in this block. Context: the function test_binary_projection_executes_tensor_and_vector_programs, which handles test binary projection executes tensor and vector programs.

Line 176: `actual = executor.matrix("binary", spikes)` This assigns ‘executor.matrix("binary", spikes)‘ to ‘actual ‘ in host memory. Here actual means the value named ’actual’ in this block. The important operands are executor: the value named ’executor’ in this block; matrix: the value named ’matrix’ in this block; binary: the value named ’binary’ in this block. Context: the function test_binary_projection_executes_tensor_and_vector_programs, which handles test binary projection executes tensor and vector programs.

Line 177: `expected_accumulator = spikes.astype(np.int64) @ weight.astype(np.int64)` This assigns ‘spikes.astype(np.i @ weight.astype(np.int64)‘ to ‘expected_accumulator ‘ in host memory. Here expected_accumulator means a widened running sum that prevents intermediate overflow. The important operands are spikes: a binary event produced when a neuron crosses its threshold; astype: the value named ’astype’ in this block; int64: the value named ’int64’ in this block. Context: the function test_binary_projection_executes_tensor_and_vector_programs, which handles test binary projection executes tensor and vector programs.

Line 178: `expected = requantize_projection_reference(expected_accumulator, parameters)` This assigns ‘requantize_projection_reference(expected_accumulator, parameters)‘ to ‘expected ‘ in host memory. Here expected means the value named ’expected’ in this block. The important operands are requantize_projection_reference: the conversion of a wide accumulated result back into a bounded activation code; expected_accumulator: a widened running sum that prevents intermediate overflow; parameters: the value named ’parameters’ in this block. Context: the function test_binary_projection_executes_tensor_and_vector_programs, which handles test binary projection executes tensor and vector programs.

Line 179: `np.testing.assert_array_equal(actual, expected)` This calls ‘np.testing.assert_array_equal‘ with ‘actual, expected‘ inside the function test_binary_projection_executes_tensor_and_vector_programs, which handles test binary projection executes tensor and vector programs. The call advances the host-side job that checks spikingformer accelerator behavior independently with Python assertions.

Line 181: `def test_asymmetric_dense_projection_executes_exact_zero_point_math(self) -> None:` This starts function test_asymmetric_dense_projection_executes_exact_zero_point_math. Its indented body performs test asymmetric dense projection executes exact zero point math as part of the file that checks spikingformer accelerator behavior independently with Python assertions; it runs only when called.

Line 182: `rng = np.random.default_rng(12)` This assigns ‘np.random.default_rng(12)‘ to ‘rng ‘ in host memory. Here rng means the value named ’rng’ in this block. The important operands are random: the value named ’random’ in this block; default_rng: the value named ’default rng’ in this block. Context: the function test_asymmetric_dense_projection_executes which handles test asymmetric dense projection executes exact zero point math.

Line 183: `activations = rng.integers(0, 256, size=(9, 13), dtype=np.uint8)` This assigns ‘rng.integers(0, 256, size=(9, 13), dtype=np.uint8)‘ to ‘activations ‘ in host memory. Here activations means an input feature value consumed by a neuron or multiply-accumulate operation. The important operands are rng: the value named ’rng’ in this block; integers: the value named ’integers’ in this block; size: the value named ’size’ in this block. Context: the function test_asymmetric_dense_projection_executes_exact_zero_point_math, which handles test asymmetric dense projection executes exact zero point math.

Line 184: `weight = rng.integers(-127, 128, size=(13, 6), dtype=np.int16).astype(np.int8)` This assigns ‘rng.integers(-127, 128, size=(13, 6), dtype=np.int16).astype(np.int8)‘ to ‘weight ‘ in host memory. Here weight means a learned coefficient multiplied by an activation. The important operands are rng: the value named ’rng’ in this block; integers: the value named ’integers’ in this block; size: the value named ’size’ in this block. Context: the function test_asymmetric_dense_projection_executes_exact_zero_point_math, which handles test asymmetric dense projection executes exact zero point math.

Line 185: `parameters = self.parameters("dense", weight, "COMPUTE_DENSE_OUTER")` This assigns ‘self.parameters("dense weight, "COMPUTE_DENSE_OUTER")‘ to ‘parameters ‘ in host memory. Here parameters means the value named ’parameters’ in this block. The important operands are parameters: the value named ’parameters’ in this block; dense: the value named ’dense’ in this block; weight: a learned coefficient multiplied by an activation. Context: the function test_asymmetric_dense_projection_executes_exact_zero_point_math, which handles test asymmetric dense projection executes exact zero point math.

Line 186: `executor = SpikingformerProjectionExecutor(` This statement continues through source line 187; the explanation uses the complete expression rather than only the first visual fragment. This assigns ‘SpikingformerProjectionExecutor(OneProjectionArchive(parameters), CombinedProgramEmulator())‘ to ‘executor ‘ in host memory. Here

executor means the value named 'executor' in this block. The important operands are SpikingformerProjectionExecutor: the value named 'spikingformer projection executor' in this block; OneProjectionArchive: the value named 'one projection archive' in this block; parameters: the value named 'parameters' in this block. Context: the function test_asymmetric_dense_projection_executes_exact_zero_point_math, which handles test asymmetric dense projection executes exact zero point math.

Line 187: `OneProjectionArchive(parameters), CombinedProgramEmulator())` This is continuation line 2 of the 2-line logical statement that begins at source line 186. Its exact fragment is 'OneProjectionArchive(parameters), CombinedProgramEmulator())'. The important operands are OneProjectionArchive: the value named 'one projection archive' in this block; parameters: the value named 'parameters' in this block; CombinedProgramEmulator: the value named 'combined program emulator' in this block. Read together, the complete operation is: This assigns 'SpikingformerProjectionExecutor(OneProjectionArchive(parameters), CombinedProgramEmulator())' to 'executor ' in host memory. Here executor means the value named 'executor' in this block. Context: the function test_traced_lif_scheduler_returns_exact_pre_reset_membr which handles test traced lif scheduler returns exact pre reset membrane.

Line 207: `expected_spikes, expected_membrane = lif_sequence_with_trace_reference(` This statement continues through source line 208; the explanation uses the complete expression rather than only the first visual fragment. This assigns 'lif_sequence_with_trace_reference(values, threshold_q10=700, leak_shift=1, reset_q10=-17)' to 'expected_spikes, expected_membrane ' in host memory. Here expected_spikes means a binary event produced when a neuron crosses its threshold. The important operands are lif_sequence_with_trace_reference: the value named 'lif sequence with trace reference' in this block; values: the value named 'values' in this block; threshold_q10: the membrane level at which a neuron emits a spike. Context: the function test_traced_lif_scheduler_returns_exact_pre_reset_membrane, which handles test traced lif scheduler returns exact pre reset membrane.

Line 208: `values, threshold_q10=700, leak_shift=1, reset_q10=-17)` This is continuation line 2 of the 2-line logical statement that begins at source line 207. Its exact fragment is 'values, threshold_q10=700, leak_shift=1, reset_q10=-17)'. The important operands are values: the value named 'values' in this block; threshold_q10: the membrane level at which a neuron emits a spike; leak_shift: the retained fraction of prior membrane state. Read together, the complete operation is: This assigns 'lif_sequence_with_trace_reference(values, threshold_q10=700, leak_shift=1, reset_q10=-17)' to 'expected_spikes, expected_membrane ' in host memory. Here expected_spikes means a binary event produced when a neuron crosses its threshold. The important operands are lif_sequence_with_trace_reference: the value named 'lif sequence with trace reference' in this block; values: the value named 'values' in this block; threshold_q10: the membrane level at which a neuron emits a spike. Context: the function test_traced_lif_scheduler_returns_exact_pre_reset_memb which handles test traced lif scheduler returns exact pre reset membrane.

Line 209: `actual_spikes, actual_membrane = lif_sequence_with_trace_on_accelerator(` This statement continues through source line 211; the explanation uses the complete expression rather than only the first visual fragment. This assigns 'lif_sequence_with_trace_on_accelerator(LifProgramEmulator(), values, threshold_q10=700, leak_shift=1, reset_q10=-17)' to 'actual_spikes, actual_membrane ' in host memory. Here actual_spikes means a binary event produced when a neuron crosses its threshold. The important operands are lif_sequence_with_trace_on_accelerator: the

value named 'lif sequence with trace on accelerator' in this block; LifProgramEmulator: the value named 'lif program emulator' in this block; values: the value named 'values' in this block. Context: the function test_traced_lif_scheduler_returns_exact_p which handles test traced lif scheduler returns exact pre reset membrane.

Line 210: `LifProgramEmulator(), values,` This is continuation line 2 of the 3-line logical statement that begins at source line 209. Its exact fragment is 'LifProgramEmulator(), values,'. The important operands are LifProgramEmulator: the value named 'lif program emulator' in this block; values: the value named 'values' in this block. Read together, the complete operation is: This assigns 'lif_sequence_with_trace_on_accelerator(LifProgramEmulator(), values, threshold_q10=700, leak_shift=1, reset_q10=-17)' to 'actual_spikes, actual_membrane ' in host memory. Here actual_spikes means a binary event produced when a neuron crosses its threshold. The important operands are lif_sequence_with_trace_on_accelerator: the value named 'lif sequence with trace on accelerator' in this block; LifProgramEmulator: the value named 'lif program emulator' in this block; values: the value named 'values' in this block. Context: the function test_traced_lif_scheduler_returns_exact_pre_reset_membrane, which handles test traced lif scheduler returns exact pre reset membrane.

Line 211: `threshold_q10=700, leak_shift=1, reset_q10=-17)` This is continuation line 3 of the 3-line logical statement that begins at source line 209. Its exact fragment is 'threshold_q10=700, leak_shift=1, reset_q10=-17)'. The important operands are threshold_q10: the membrane level at which a neuron emits a spike; leak_shift: the retained fraction of prior membrane state; reset_q10: the value named 'reset q10' in this block. Read together, the complete operation is: This assigns 'lif_sequence_with_trace_on_accelerator(LifProgramEmulator(), values, threshold_q10=700, leak_shift=1, reset_q10=-17)' to 'actual_spikes, actual_membrane ' in host memory. Here actual_spikes means a binary event produced when a neuron crosses its threshold. The important operands are lif_sequence_with_trace_on_accelerator: the value named 'lif sequence with trace on accelerator' in this block; LifProgramEmulator: the value named 'lif program emulator' in this block; values: the value named 'values' in this block. Context: the function test_traced_lif_scheduler_returns_exa which handles test traced lif scheduler returns exact pre reset membrane.

Line 212: `np.testing.assert_array_equal(actual_spikes, expected_spikes)` This calls 'np.testing.assert_array_equal' with 'actual_spikes, expected_spikes' inside the function test_traced_lif_scheduler_returns_exact_pre_reset_membrane, which handles test traced lif scheduler returns exact pre reset membrane. The call advances the host-side job that checks spikingformer accelerator behavior independently with Python assertions.

Line 213: `np.testing.assert_array_equal(actual_membrane, expected_membrane)` This calls 'np.testing.assert_array_equ with 'actual_membrane, expected_membrane' inside the function test_traced_lif_scheduler_returns_exact_pre_reset_membrane which handles test traced lif scheduler returns exact pre reset membrane. The call advances the host-side job that checks spikingformer accelerator behavior independently with Python assertions.

Line 214: `self.assertTrue(np.any(actual_spikes))` This calls 'self.assertTrue' with 'np.any(actual_spikes)' inside the function test_traced_lif_scheduler_returns_exact_pre_reset_membrane, which handles test traced lif scheduler returns exact pre reset membrane. The call advances the host-side job that checks spikingformer accelerator behavior independently with Python assertions.

Line 215: `self.assertTrue(np.any(actual_membrane[actual_spikes.astype(bool)] >= 700))` This calls 'self.assertTrue' with 'np.any(actual_membrane[actual_spikes.astype(bool)] >= 700)' inside the function test_traced_lif_scheduler_returns_exact which handles test traced lif scheduler returns exact pre reset membrane. The call advances the host-side job that checks spikingformer accelerator behavior independently with Python assertions.

Line 217: `def test_real_block0_archive_executes_exact_exported_integer_equation(self) -> None:` This starts function test_real_block0_archive_executes_exact_exported_integer_equation. Its indented body performs test real block0 archive executes exact exported integer equation as part of the file that checks spikingformer accelerator behavior independently with Python assertions; it runs only when called.

Line 218: `manifest = Path(__file__).resolve().parents[1] / (` This statement continues through source line 220; the explanation uses the complete expression rather than only the first visual fragment. This assigns 'Path(___file___).resolve().p / ("outputs/spikingformer_hardware_parameters/" "spikingformer_neuraedge_weights.json")' to 'manifest ' in host memory. Here manifest means the value named 'manifest' in this block. The important operands are Path: the value

named 'path' in this block; ___file___: the value named 'file' in this block; resolve: the value named 'resolve' in this block. Context: the function test_real_block0_archive_executes_exact_exported_integer_equation, which handles test real block0 archive executes exact exported integer equation.

Line 219: `"outputs/spikingformer_hardware_parameters/"` This is continuation line 2 of the 3-line logical statement that begins at source line 218. Its exact fragment is '"outputs/spikingformer_hardware_parameters/"'. The important operands are outputs: the value named 'outputs' in this block; spikingformer_hardware_parameters: the value named 'spikingformer hardware parameters' in this block. Read together, the complete operation is: This assigns 'Path(___file___).resolve().parents[1] / ("outputs/spikingformer_hardware_parameters/" "spikingformer_neuraedge_weights.json" to 'manifest ' in host memory. Here manifest means the value named 'manifest' in this block. The important operands are Path: the value named 'path' in this block; ___file___: the value named 'file' in this block; resolve: the value named 'resolve' in this block. Context: the function test_real_block0_archive_executes_exact_exported_integer_equation, which handles test real block0 archive executes exact exported integer equation.

Line 220: `"spikingformer_neuraedge_weights.json")` This is continuation line 3 of the 3-line logical statement that begins at source line 218. Its exact fragment is '"spikingformer_neuraedge_weights.json")'. The important operands are spikingformer_neuraedge_weights: a learned coefficient multiplied by an activation; json: the value named 'json' in this block. Read together, the complete operation is: This assigns 'Path(___file___).resolve().parents[1] / ("outputs/spikingformer_hardware_parameters/" "spikingformer_neuraedge_weights.json")' to 'manifest ' in host memory. Here manifest means the value named 'manifest' in this block. The important operands are Path: the value named 'path' in this block; ___file___: the value named 'file' in this block; resolve: the value named 'resolve' in this block. Context: the function test_real_block0_archive_executes_exact_exported_integer_equation, which handles test real block0 archive executes exact exported integer equation.

Line 221: `if not manifest.exists():` This executes the following indented host-code branch only when 'not manifest.exists()' is true. The important operands are not: the value named 'not' in this block; manifest: the value named 'manifest' in this block; exists: the value named 'exists' in this block. Context: the function test_real_block0_archive_executes_exact_e which handles test real block0 archive executes exact exported integer equation.

Line 222: `self.skipTest("full trained parameter archive is not present")` This calls 'self.skipTest' with '"full trained parameter archive is not present"' inside the function test_real_block0_archive_executes_exact_exported_integer_eq which handles test real block0 archive executes exact exported integer equation. The call advances the host-side job that checks spikingformer accelerator behavior independently with Python assertions.

Line 223: `archive = SpikingformerParameterArchive(manifest)` This assigns 'SpikingformerParameterArchive(manifest)' to 'archive ' in host memory. Here archive means the value named 'archive' in this block. The important operands are SpikingformerParameterArchive: the value named 'spikingformer parameter archive' in this block; manifest: the value named 'manifest' in this block. Context: the function test_real_block0_archive_executes_exact_exported_integer_equation, which handles test real block0 archive executes exact exported integer equation.

Line 224: `parameters = archive.projection("patch_embed.block0")` This assigns 'archive.projection("patch_embed.block0 to 'parameters ' in host memory. Here parameters means the value named 'parameters' in this block. The important operands are archive: the value named 'archive' in this block; projection: the value named 'projection' in this block; patch_embed: the value named 'patch embed' in this block. Context: the function test_real_block0_archive_executes_exact_expo which handles test real block0 archive executes exact exported integer equation.

Line 225: `rng = np.random.default_rng(14)` This assigns 'np.random.default_rng(14)' to 'rng ' in host memory. Here rng means the value named 'rng' in this block. The important operands are random: the value named 'random' in this block; default_rng: the value named 'default rng' in this block. Context: the function test_real_block0_archive_executes_exact_e which handles test real block0 archive executes exact exported integer equation.

Line 226: `activations = rng.integers(` This statement continues through source line 227; the explanation uses the complete expression rather than only the first visual fragment. This assigns 'rng.integers(0, 256, size=(3, parameters.weight_k_by_n.shape[0]), dtype=np.uint8)' to 'activations ' in host memory. Here activations means an input feature value consumed by a neuron or multiply-accumulate operation. The important operands are rng: the value

named 'rng' in this block; integers: the value named 'integers' in this block; size: the value named 'size' in this block. Context: the function test_real_block0_archive_executes_exact_exported_integer_equation, which handles test real block0 archive executes exact exported integer equation.

Line 227: `0, 256, size=(3, parameters.weight_k_by_n.shape[0]), dtype=np.uint8)` This is continuation line 2 of the 2-line logical statement that begins at source line 226. Its exact fragment is '0, 256, size=(3, parameters.weight_k_by_n.shape[0]), dtype=np.uint8)'. The important operands are size: the value named 'size' in this block; parameters: the value named 'parameters' in this block; weight_k_by_n: a learned coefficient multiplied by an activation. Read together, the complete operation is: This assigns 'rng.integers(0, 256, size=(3, parameters.weight_k_by_n.shape[0]), dtype=np.uint8)' to 'activations ' in host memory. Here activations means an input feature value consumed by a neuron or multiply-accumulate operation. The important operands are rng: the value named 'rng' in this block; integers: the value named 'integers' in this block; size: the value named 'size' in this block. Context: the function test_real_block0_archive_executes_exact_exported_integer_equation, which handles test real block0 archive executes exact exported integer equation.

Line 228: `executor = SpikingformerProjectionExecutor(archive, CombinedProgramEmulator())` This assigns 'SpikingformerProjectionExecutor(archive, CombinedProgramEmulator())' to 'executor ' in host memory. Here executor means the value named 'executor' in this block. The important operands are SpikingformerProjectionExecutor: the value named 'spikingformer projection executor' in this block; archive: the value named 'archive' in this block; CombinedProgramEmulator: the value named 'combined program emulator' in this block. Context: the function test_real_block0_archive_executes_exact_exported_integer_equation, which handles test real block0 archive executes exact exported integer equation.

Line 229: `actual = executor.matrix(` This statement continues through source line 230; the explanation uses the complete expression rather than only the first visual fragment. This assigns 'executor.matrix("patch_embed.block0", activations, activation_zero_point=123)' to 'actual ' in host memory. Here actual means the value named 'actual' in this block. The important operands are executor: the value named 'executor' in this block; matrix: the value named 'matrix' in this block; patch_embed: the value named 'patch embed' in this block. Context: the function test_real_block0_archive_executes_exact_exported_integer_equation, which handles test real block0 archive executes exact exported integer equation.

Line 230: `"patch_embed.block0", activations, activation_zero_point=123)` This is continuation line 2 of the 2-line logical statement that begins at source line 229. Its exact fragment is '"patch_embed.block0", activations, activation_zero_point=123)'. The important operands are patch_embed: the value named 'patch embed' in this block; block0: the value named 'block0' in this block; activations: an input feature value consumed by a neuron or multiply-accumulate operation. Read together, the complete operation is: This assigns 'executor.matrix("patch_embed.block0", activations, activation_zero_point=123)' to 'actual ' in host memory. Here actual means the value named 'actual' in this block. The important operands are executor: the value named 'executor' in this block; matrix: the value named 'matrix' in this block; patch_embed: the value named 'patch embed' in this block. Context: the function test_real_block0_archive_executes_exact_exported_integer_equation, which handles test real block0 archive executes exact exported integer equation.

Line 231: `accumulators = (` This statement continues through source line 233; the explanation uses the complete expression rather than only the first visual fragment. This assigns '(activations.astype(np.int64) - 123) @ parameters.weight_k_by_n.astype(np.int64)' to 'accumulators ' in host memory. Here accumulators means a widened running sum that prevents intermediate overflow. The important operands are activations: an input feature value consumed by a neuron or multiply-accumulate operation; astype: the value named 'astype' in this block; int64: the value named 'int64' in this block. Context: the function test_real_block0_archive_executes_exact_exported_integer_equation, which handles test real block0 archive executes exact exported integer equation.

Line 232: `activations.astype(np.int64) - 123` This is continuation line 2 of the 3-line logical statement that begins at source line 231. Its exact fragment is 'activations.astype(np.int64) - 123'. The important operands are activations: an input feature value consumed by a neuron or multiply-accumulate operation; astype: the value named 'astype' in this block; int64: the value named 'int64' in this block. Read together, the complete operation is: This assigns '(activations.astype(np.int64) - 123) @ parameters.weight_k_by_n.astype(np.int64)' to 'accumulators ' in host memory. Here accumulators means a widened running sum that prevents intermediate overflow. The important operands are activations:

an input feature value consumed by a neuron or multiply-accumulate operation; astype: the value named 'astype' in this block; int64: the value named 'int64' in this block. Context: the function test_real_block0_archive_executes_exact_exported_inte which handles test real block0 archive executes exact exported integer equation.

Line 233: `) @ parameters.weight_k_by_n.astype(np.int64)` This is continuation line 3 of the 3-line logical statement that begins at source line 231. Its exact fragment is ‘) @ parameters.weight_k_by_n.astype(np.int64)‘. The important operands are parameters: the value named 'parameters' in this block; weight_k_by_n: a learned coefficient multiplied by an activation; astype: the value named 'astype' in this block. Read together, the complete operation is: This assigns ‘(activations.astype(np.int64) - 123) @ parameters.weight_k_by_n.astype(np.int64)‘ to ‘accumulators ‘ in host memory. Here accumulators means a widened running sum that prevents intermediate overflow. The important operands are activations: an input feature value consumed by a neuron or multiply-accumulate operation; astype: the value named 'astype' in this block; int64: the value named 'int64' in this block. Context: the function test_real_block0_archive_executes_exact_exported_integer_equation, which handles test real block0 archive executes exact exported integer equation.

Line 234: `expected = requantize_projection_reference(accumulators, parameters)` This assigns ‘requantize_projection parameters)‘ to ‘expected ‘ in host memory. Here expected means the value named 'expected' in this block. The important operands are requantize_projection_reference: the conversion of a wide accumulated result back into a bounded activation code; accumulators: a widened running sum that prevents intermediate overflow; parameters: the value named 'parameters' in this block. Context: the function test_real_block0_archive_executes_exact_exported_integer_equation, which handles test real block0 archive executes exact exported integer equation.

Line 235: `np.testing.assert_array_equal(actual, expected)` This calls ‘np.testing.assert_array_equal‘ with ‘actual, expected‘ inside the function test_real_block0_archive_executes_exact_exported_integer_equation, which handles test real block0 archive executes exact exported integer equation. The call advances the host-side job that checks spikingformer accelerator behavior independently with Python assertions.

Line 237: `def test_vector_residual_and_binary_max_pool_cover_edge_lanes(self) -> None:` This starts function test_vector_residual_and_binary_max_pool_cover_edge_lanes. Its indented body performs test vector residual and binary max pool cover edge lanes as part of the file that checks spikingformer accelerator behavior independently with Python assertions; it runs only when called.

Line 238: `left = np.asarray([-(1 << 31), -3, 0, 7, (1 << 31) - 1, 4, 5, 6, 7])` This assigns ‘np.asarray([-(1 << 31), -3, 0, 7, (1 << 31) - 1, 4, 5, 6, 7])‘ to ‘left ‘ in host memory. Here left means the value named 'left' in this block. The important operands are asarray: the value named 'asarray' in this block. Context: the function test_vector_residual_and_binary_max_pool_cover_edge_lanes, which handles test vector residual and binary max pool cover edge lanes.

Line 239: `right = np.asarray([-1, 8, 0, -2, 1, 3, 2, 1, 0])` This assigns ‘np.asarray([-1, 8, 0, -2, 1, 3, 2, 1, 0])‘ to ‘right ‘ in host memory. Here right means the value named 'right' in this block. The important operands are asarray: the value named 'asarray' in this block. Context: the function test_vector_residual_and_binary_max_pool_cover_edge_lanes, which handles test vector residual and binary max pool cover edge lanes.

Line 240: `added = vector_binary_on_accelerator(` This statement continues through source line 241; the explanation uses the complete expression rather than only the first visual fragment. This assigns ‘vector_binary_on_accelerator(VectorProgramEmulator(), VectorOperation.ADD_SAT, left, right)‘ to ‘added ‘ in host memory. Here added means the value named 'added' in this block. The important operands are vector_binary_on_accelerator: the value named 'vector binary on accelerator' in this block; VectorProgramEmulator: the value named 'vector program emulator' in this block; VectorOperation: the value named 'vector operation' in this block. Context: the function test_vector_residual_and_binary_max_ which handles test vector residual and binary max pool cover edge lanes.

Line 241: `VectorProgramEmulator(), VectorOperation.ADD_SAT, left, right)` This is continuation line 2 of the 2-line logical statement that begins at source line 240. Its exact fragment is ‘VectorProgramEmulator(), VectorOperation.ADD_SAT, left, right)‘. The important operands are VectorProgramEmulator: the value named 'vector program emulator' in this block; VectorOperation: the value named 'vector operation' in this block; ADD_SAT: the value named

'add sat' in this block. Read together, the complete operation is: This assigns ‘vector_binary_on_accelerator(VectorProgramEmulator(), VectorOperation.ADD_SAT, left, right)‘ to ‘added ‘ in host memory. Here added means the value named 'added' in this block. The important operands are vector_binary_on_accelerator: the value named 'vector binary on accelerator' in this block; VectorProgramEmulator: the value named 'vector program emulator' in this block; VectorOperation: the value named 'vector operation' in this block. Context: the function test_vector_residual_and_binary_max_pool_c which handles test vector residual and binary max pool cover edge lanes.

Line 242: `np.testing.assert_array_equal(` This statement continues through source line 243; the explanation uses the complete expression rather than only the first visual fragment. This calls ‘np.testing.assert_array_equal‘ with ‘ added, np.clip(left.astype(np.int64) + right, -(1 << 31), (1 << 31) - 1)‘ inside the function test_vector_residual_and_binary_max_pool_c which handles test vector residual and binary max pool cover edge lanes. The call advances the host-side job that checks spikingformer accelerator behavior independently with Python assertions.

Line 243: `added, np.clip(left.astype(np.int64) + right, -(1 << 31), (1 << 31) - 1))` This is continuation line 2 of the 2-line logical statement that begins at source line 242. Its exact fragment is ‘added, np.clip(left.astype(np.int64) + right, -(1 << 31), (1 << 31) - 1))‘. The important operands are added: the value named 'added' in this block; clip: the value named 'clip' in this block; left: the value named 'left' in this block. Read together, the complete operation is: This calls ‘np.testing.assert_array_equal‘ with ‘ added, np.clip(left.astype(np.int64) + right, -(1 << 31), (1 << 31) - 1)‘ inside the function test_vector_residual_and_binary_max_pool_cover_edge_lanes, which handles test vector residual and binary max pool cover edge lanes. The call advances the host-side job that checks spikingformer accelerator behavior independently with Python assertions.

Line 245: `rng = np.random.default_rng(15)` This assigns ‘np.random.default_rng(15)‘ to ‘rng ‘ in host memory. Here rng means the value named 'rng' in this block. The important operands are random: the value named 'random' in this block; default_rng: the value named 'default rng' in this block. Context: the function test_vector_residual_and_binary_max_pool which handles test vector residual and binary max pool cover edge lanes.

Line 246: `spikes = rng.integers(0, 2, size=(2, 3, 5, 7), dtype=np.uint8)` This assigns ‘rng.integers(0, 2, size=(2, 3, 5, 7), dtype=np.uint8)‘ to ‘spikes ‘ in host memory. Here spikes means a binary event produced when a neuron crosses its threshold. The important operands are rng: the value named 'rng' in this block; integers: the value named 'integers' in this block; size: the value named 'size' in this block. Context: the function test_vector_residual_and_binary_max_pool_co which handles test vector residual and binary max pool cover edge lanes.

Line 247: `actual = binary_max_pool2d_on_accelerator(VectorProgramEmulator(), spikes)` This assigns ‘binary_max_pool2d_on_accelerator(VectorProgramEmulator(), spikes)‘ to ‘actual ‘ in host memory. Here actual means the value named 'actual' in this block. The important operands are binary_max_pool2d_on_accelerator: the value named 'binary max pool2d on accelerator' in this block; VectorProgramEmulator: the value named 'vector program emulator' in this block; spikes: a binary event produced when a neuron crosses its threshold. Context: the function test_vector_residual_and_binary_max_pool_cover_edge_lanes, which handles test vector residual and binary max pool cover edge lanes.

Line 248: `padded = np.pad(spikes, ((0, 0), (0, 0), (1, 1), (1, 1)))` This assigns ‘np.pad(spikes, ((0, 0), (0, 0), (1, 1), (1, 1)))‘ to ‘padded ‘ in host memory. Here padded means the value named 'padded' in this block. The important operands are pad: the value named 'pad' in this block; spikes: a binary event produced when a neuron crosses its threshold. Context: the function test_vector_residual_and_binary_max_pool_cover_edge_lanes, which handles test vector residual and binary max pool cover edge lanes.

Line 249: `candidates = [` This statement continues through source line 252; the explanation uses the complete expression rather than only the first visual fragment. This assigns ‘[padded[:, :, y:y + 5:2, x:x + 7:2] for y in range(3) for x in range(3)]‘ to ‘candidates ‘ in host memory. Here candidates means the value named 'candidates' in this block. The important operands are padded: the value named 'padded' in this block; y: the value named 'y' in this block; x: the value named 'x' in this block. Context: the function test_vector_residual_and_binary_max_pool_cover_edge_lanes, which handles test vector residual and binary max pool cover edge lanes.

Line 250: `padded[:, :, y:y + 5:2, x:x + 7:2]` This is continuation line 2 of the 4-line logical statement that begins at source line 249. Its exact fragment is 'padded[:, :, y:y + 5:2, x:x + 7:2]'. The important operands are padded: the value named 'padded' in this block; y: the value named 'y' in this block; x: the value named 'x' in this block. Read together, the complete operation is: This assigns '[padded[:, :, y:y + 5:2, x:x + 7:2] for y in range(3) for x in range(3)]' to 'candidates ' in host memory. Here candidates means the value named 'candidates' in this block. The important operands are padded: the value named 'padded' in this block; y: the value named 'y' in this block; x: the value named 'x' in this block. Context: the function test_vector_residual_and_binary_max_pool_cover_edge_lanes, which handles test vector residual and binary max pool cover edge lanes.

Line 251: `for y in range(3) for x in range(3)` This is continuation line 3 of the 4-line logical statement that begins at source line 249. Its exact fragment is 'for y in range(3) for x in range(3)'. The important operands are for: the value named 'for' in this block; y: the value named 'y' in this block; in: the value named 'in' in this block. Read together, the complete operation is: This assigns '[padded[:, :, y:y + 5:2, x:x + 7:2] for y in range(3) for x in range(3)]' to 'candidates ' in host memory. Here candidates means the value named 'candidates' in this block. The important operands are padded: the value named 'padded' in this block; y: the value named 'y' in this block; x: the value named 'x' in this block. Context: the function test_vector_residual_and_binary_max_pool_cover_edge_lanes, which handles test vector residual and binary max pool cover edge lanes.

Line 252: `]` This is continuation line 4 of the 4-line logical statement that begins at source line 249. Its exact fragment is ']'. The expression is a literal or structural operator and has no hidden software state. Read together, the complete operation is: This assigns '[padded[:, :, y:y + 5:2, x:x + 7:2] for y in range(3) for x in range(3)]' to 'candidates ' in host memory. Here candidates means the value named 'candidates' in this block. The important operands are padded: the value named 'padded' in this block; y: the value named 'y' in this block; x: the value named 'x' in this block. Context: the function test_vector_residual_and_binary_max_pool_cover_edge_lanes, which handles test vector residual and binary max pool cover edge lanes.

Line 253: `expected = np.maximum.reduce(candidates)` This assigns 'np.maximum.reduce(candidates)' to 'expected ' in host memory. Here expected means the value named 'expected' in this block. The important operands are maximum: the value named 'maximum' in this block; reduce: the value named 'reduce' in this block; candidates: the value named 'candidates' in this block. Context: the function test_vector_residual_and_binary_max_pool_cover_edge_lanes, which handles test vector residual and binary max pool cover edge lanes.

Line 254: `np.testing.assert_array_equal(actual, expected)` This calls 'np.testing.assert_array_equal' with 'actual, expected' inside the function test_vector_residual_and_binary_max_pool_cover_edge_lanes, which handles test vector residual and binary max pool cover edge lanes. The call advances the host-side job that checks spikingformer accelerator behavior independently with Python assertions.

Line 256: `def test_global_pooling_and_head_division_execute_in_vector_fabric(self) -> None:` This starts function test_global_pooling_and_head_division_execute_in_vector_fabric. Its indented body performs test global pooling and head division execute in vector fabric as part of the file that checks spikingformer accelerator behavior independently with Python assertions; it runs only when called.

Line 257: `values = np.arange(-120, 120, dtype=np.int64).reshape(3, 2, 5, 4, 2)` This assigns 'np.arange(-120, 120, dtype=np.int64).reshape(3, 2, 5, 4, 2)' to 'values ' in host memory. Here values means the value named 'values' in this block. The important operands are arange: the value named 'arange' in this block; dtype: the value named 'dtype' in this block; int64: the value named 'int64' in this block. Context: the function test_global_pooling_and_head_division_execute_in which handles test global pooling and head division execute in vector fabric.

Line 258: `pooled = global_spatiotemporal_sum_on_accelerator(` This statement continues through source line 259; the explanation uses the complete expression rather than only the first visual fragment. This assigns 'global_spatiotemporal_su VectorProgramEmulator(), values)' to 'pooled ' in host memory. Here pooled means the value named 'pooled' in this block. The important operands are global_spatiotemporal_sum_on_accelerator: the value named 'global spatiotemporal sum on accelerator' in this block; VectorProgramEmulator: the value named 'vector program emulator' in this block; values: the value named 'values' in this block. Context: the function test_global_pooling_and_head_division_execute_in_vector_ which handles test global pooling and head division execute in vector fabric.

Line 259: `VectorProgramEmulator(), values)` This is continuation line 2 of the 2-line logical statement that begins at source line 258. Its exact fragment is 'VectorProgramEmulator(), values)'. The important operands are VectorProgramEmulator: the value named 'vector program emulator' in this block; values: the value named 'values' in this block. Read together, the complete operation is: This assigns 'global_spatiotemporal_sum_on_accelerator(VectorProgramEmulator(), values)' to 'pooled ' in host memory. Here pooled means the value named 'pooled' in this block. The important operands are global_spatiotemporal_sum_on_accelerator: the value named 'global spatiotemporal sum on accelerator' in this block; VectorProgramEmulator: the value named 'vector program emulator' in this block; values: the value named 'values' in this block. Context: the function test_global_pooling_and_head_division_execute_in_vector_fabric, which handles test global pooling and head division execute in vector fabric.

Line 260: `np.testing.assert_array_equal(pooled, values.sum(axis=(0, 3, 4)))` This calls 'np.testing.assert_array_equ with 'pooled, values.sum(axis=(0, 3, 4))' inside the function test_global_pooling_and_head_division_execute_in_vector_fabric, which handles test global pooling and head division execute in vector fabric. The call advances the host-side job that checks spikingformer accelerator behavior independently with Python assertions.

Line 261: `divided = power_of_two_requantize_on_accelerator(` This statement continues through source line 267; the explanation uses the complete expression rather than only the first visual fragment. This assigns 'power_of_two_requantize_ VectorProgramEmulator(), pooled, division_shift=5, clamp_minimum=-17, clamp_maximum=19,)' to 'divided ' in host memory. Here divided means the value named 'divided' in this block. The important operands are power_of_two_requantize_o the conversion of a wide accumulated result back into a bounded activation code; VectorProgramEmulator: the value named 'vector program emulator' in this block; pooled: the value named 'pooled' in this block. Context: the function test_global_pooling_and_head_division_execute_in_vector_fabric, which handles test global pooling and head division execute in vector fabric.

Line 262: `VectorProgramEmulator(),` This is continuation line 2 of the 7-line logical statement that begins at source line 261. Its exact fragment is 'VectorProgramEmulator(),'. The important operands are VectorProgramEmulator: the value named 'vector program emulator' in this block. Read together, the complete operation is: This assigns 'power_of_two_requantize_on_accelerator(VectorProgramEmulator(), pooled, division_shift=5, clamp_minimum=-17, clamp_maximum=19,)' to 'divided ' in host memory. Here divided means the value named 'divided' in this block. The important operands are power_of_two_requantize_on_accelerator: the conversion of a wide accumulated result back into a bounded activation code; VectorProgramEmulator: the value named 'vector program emulator' in this block; pooled: the value named 'pooled' in this block. Context: the function test_global_pooling_and_head_division_execute_in_vector which handles test global pooling and head division execute in vector fabric.

Line 263: `pooled,` This is continuation line 3 of the 7-line logical statement that begins at source line 261. Its exact fragment is 'pooled,'. The important operands are pooled: the value named 'pooled' in this block. Read together, the complete operation is: This assigns 'power_of_two_requantize_on_accelerator(VectorProgramEmulator(), pooled, division_shift=5, clamp_minimum=-17, clamp_maximum=19,)' to 'divided ' in host memory. Here divided means the value named 'divided' in this block. The important operands are power_of_two_requantize_on_accelerator: the conversion of a wide accumulated result back into a bounded activation code; VectorProgramEmulator: the value named 'vector program emulator' in this block; pooled: the value named 'pooled' in this block. Context: the function test_global_pooling_and_head_division_execute_in_vector_fabric, which handles test global pooling and head division execute in vector fabric.

Line 264: `division_shift=5,` This is continuation line 4 of the 7-line logical statement that begins at source line 261. Its exact fragment is 'division_shift=5,'. The important operands are division_shift: the value named 'division shift' in this block. Read together, the complete operation is: This assigns 'power_of_two_requantize_on_accelerator(VectorProgramEmulator(), pooled, division_shift=5, clamp_minimum=-17, clamp_maximum=19,)' to 'divided ' in host memory. Here divided means the value named 'divided' in this block. The important operands are power_of_two_requantize_on_accelerator: the conversion of a wide accumulated result back into a bounded activation code; VectorProgramEmulator: the value named 'vector program emulator' in this block; pooled: the value named 'pooled' in this block. Context: the function test_global_pooling_and_head_division_execute_in_vector_fabric, which handles test global pooling and head division execute in vector fabric.

Line 265: `clamp_minimum=-17,` This is continuation line 5 of the 7-line logical statement that begins at source line 261. Its exact fragment is 'clamp_minimum=-17,'. The important operands are clamp_minimum: the value named 'clamp

minimum' in this block. Read together, the complete operation is: This assigns 'power_of_two_requantize_on_accelerator(VectorProgramEmulator(), pooled, division_shift=5, clamp_minimum=-17, clamp_maximum=19,)' to 'divided ' in host memory. Here divided means the value named 'divided' in this block. The important operands are power_of_two_requantize_o the conversion of a wide accumulated result back into a bounded activation code; VectorProgramEmulator: the value named 'vector program emulator' in this block; pooled: the value named 'pooled' in this block. Context: the function test_global_pooling_and_head_division_execute_in_vector_fabric, which handles test global pooling and head division execute in vector fabric.

Line 266: `clamp_maximum=19,` This is continuation line 6 of the 7-line logical statement that begins at source line 261. Its exact fragment is 'clamp_maximum=19,'. The important operands are clamp_maximum: the value named 'clamp maximum' in this block. Read together, the complete operation is: This assigns 'power_of_two_requantize_on_accelerator(VectorProgramEmulator(), pooled, division_shift=5, clamp_minimum=-17, clamp_maximum=19,)' to 'divided ' in host memory. Here divided means the value named 'divided' in this block. The important operands are power_of_two_requantize_o the conversion of a wide accumulated result back into a bounded activation code; VectorProgramEmulator: the value named 'vector program emulator' in this block; pooled: the value named 'pooled' in this block. Context: the function test_global_pooling_and_head_division_execute_in_vector_fabric, which handles test global pooling and head division execute in vector fabric.

Line 267: `)` This is continuation line 7 of the 7-line logical statement that begins at source line 261. Its exact fragment is ')'. The expression is a literal or structural operator and has no hidden software state. Read together, the complete operation is: This assigns 'power_of_two_requantize_on_accelerator(VectorProgramEmulator(), pooled, division_shift=5, clamp_minimum=-17, clamp_maximum=19,)' to 'divided ' in host memory. Here divided means the value named 'divided' in this block. The important operands are power_of_two_requantize_on_accelerator: the conversion of a wide accumulated result back into a bounded activation code; VectorProgramEmulator: the value named 'vector program emulator' in this block; pooled: the value named 'pooled' in this block. Context: the function test_global_pooling_and_head_division_execute_in_vector_fabric, which handles test global pooling and head division execute in vector fabric.

Line 268: `np.testing.assert_array_equal(` This statement continues through source line 271; the explanation uses the complete expression rather than only the first visual fragment. This calls 'np.testing.assert_array_equal' with ' divided, np.clip(round_shift_signed(pooled, 5), -17, 19), ' inside the function test_global_pooling_and_head_division_execute_in_ which handles test global pooling and head division execute in vector fabric. The call advances the host-side job that checks spikingformer accelerator behavior independently with Python assertions.

Line 269: `divided,` This is continuation line 2 of the 4-line logical statement that begins at source line 268. Its exact fragment is 'divided,'. The important operands are divided: the value named 'divided' in this block. Read together, the complete operation is: This calls 'np.testing.assert_array_equal' with ' divided, np.clip(round_shift_signed(pooled, 5), -17, 19), ' inside the function test_global_pooling_and_head_division_execute_in_vector_fabric, which handles test global pooling and head division execute in vector fabric. The call advances the host-side job that checks spikingformer accelerator behavior independently with Python assertions.

Line 270: `np.clip(round_shift_signed(pooled, 5), -17, 19),` This is continuation line 3 of the 4-line logical statement that begins at source line 268. Its exact fragment is 'np.clip(round_shift_signed(pooled, 5), -17, 19),'. The important operands are clip: the value named 'clip' in this block; round_shift_signed: the value named 'round shift signed' in this block; pooled: the value named 'pooled' in this block. Read together, the complete operation is: This calls 'np.testing.assert_array_equal' with ' divided, np.clip(round_shift_signed(pooled, 5), -17, 19), ' inside the function test_global_pooling_and_head_division_execute_in_vector_fabric, which handles test global pooling and head division execute in vector fabric. The call advances the host-side job that checks spikingformer accelerator behavior independently with Python assertions.

Line 271: `)` This is continuation line 4 of the 4-line logical statement that begins at source line 268. Its exact fragment is ')'. The expression is a literal or structural operator and has no hidden software state. Read together, the complete operation is: This calls 'np.testing.assert_array_equal' with ' divided, np.clip(round_shift_signed(pooled, 5), -17, 19), ' inside the function test_global_pooling_and_head_division_execute_in_vector_fabric, which handles test global pooling and head division execute in vector fabric. The call advances the host-side job that checks spikingformer accelerator behavior independently with Python assertions.

Line 274: `if __name__ == "__main__":` This executes the following indented host-code branch only when ‘___name___ == "___main___"‘ is true. The important operands are ___name___: the value named ’name’ in this block; ___main___: the value named ’main’ in this block. Context: the file whose role is to checks spikingformer accelerator behavior independently with Python assertions.

Line 275: `unittest.main()` This calls ‘unittest.main‘ with “ inside the file whose role is to checks spikingformer accelerator behavior independently with Python assertions. The call advances the host-side job that checks spikingformer accelerator behavior independently with Python assertions.

71 tests/test_spikingformer_export.py

Role in the complete system: checks spikingformer export behavior independently with Python assertions.

71.1 Beginner architecture map

Dataflow responsibility This file's end-to-end responsibility is to checks spikingformer export behavior independently with Python assertions.

Where it runs This is sequential host software. Python objects live in CPU memory; they become FPGA work only when the compiler packs a command or payload and the PYNQ driver transfers those bytes through AXI DMA or AXI-Lite.

Public structure Classes: HardwareExportTests. Functions: test_aligned_writer_records_exact_payload_hash, test_tensor_w test_projection_export_matches_folded_float_equation. Each function annotation below names its enclosing function so an array operation is tied to the model, compiler, driver, test, or report phase that uses it.

Numeric and failure boundary Shapes, signedness, byte order, scaling, and saturation are part of the hardware contract. Validation exceptions are functional safety checks: rejecting malformed input before DMA is different from silently clipping, reshaping, or continuing with an incompatible artifact.

71.3 Line annotations

Line 1: `from __future__ import annotations` This imports the named Python API so the file whose role is to checks spikingformer export behavior independently with Python assertions can use it explicitly. Imports execute on the host processor and create no FPGA hardware.

Line 3: `import hashlib` This imports the named Python API so the file whose role is to checks spikingformer export behavior independently with Python assertions can use it explicitly. Imports execute on the host processor and create no FPGA hardware.

Line 4: `import unittest` This imports the named Python API so the file whose role is to checks spikingformer export behavior independently with Python assertions can use it explicitly. Imports execute on the host processor and create no FPGA hardware.

Line 6: `import numpy as np` This imports the named Python API so the file whose role is to checks spikingformer export behavior independently with Python assertions can use it explicitly. Imports execute on the host processor and create no FPGA hardware.

Line 7: `import torch` This imports the named Python API so the file whose role is to checks spikingformer export behavior independently with Python assertions can use it explicitly. Imports execute on the host processor and create no FPGA hardware.

Line 8: `import torch.nn as nn` This imports the named Python API so the file whose role is to checks spikingformer export behavior independently with Python assertions can use it explicitly. Imports execute on the host processor and create no FPGA hardware.

Line 10: `from export_spikingformer_hardware import (` This statement continues through source line 15; the explanation uses the complete expression rather than only the first visual fragment. This imports the named Python API so the file whose role is to checks spikingformer export behavior independently with Python assertions can use it explicitly. Imports execute on the host processor and create no FPGA hardware.

Line 11: `ALIGNMENT,` This is continuation line 2 of the 6-line logical statement that begins at source line 10. Its exact fragment is 'ALIGNMENT,'. The important operands are ALIGNMENT: the value named 'alignment' in this block. Read together, the complete operation is: This imports the named Python API so the file whose role is to checks spikingformer export behavior independently with Python assertions can use it explicitly. Imports execute on the host processor and create no FPGA hardware.

Line 12: `AlignedBinaryWriter,` This is continuation line 3 of the 6-line logical statement that begins at source line 10. Its exact fragment is 'AlignedBinaryWriter,'. The important operands are AlignedBinaryWriter: the value named 'aligned binary writer' in this block. Read together, the complete operation is: This imports the named Python API so the file whose role is to checks spikingformer export behavior independently with Python assertions can use it explicitly. Imports execute on the host processor and create no FPGA hardware.

Line 13: `export_projection,` This is continuation line 4 of the 6-line logical statement that begins at source line 10. Its exact fragment is 'export_projection,'. The important operands are export_projection: the value named 'export projection' in this block. Read together, the complete operation is: This imports the named Python API so the file whose role is to checks spikingformer export behavior independently with Python assertions can use it explicitly. Imports execute on the host processor and create no FPGA hardware.

Line 14: `quantize_weight_tensor,` This is continuation line 5 of the 6-line logical statement that begins at source line 10. Its exact fragment is ‘quantize_weight_tensor,‘. The important operands are quantize_weight_tensor: a learned coefficient multiplied by an activation. Read together, the complete operation is: This imports the named Python API so the file whose role is to checks spikingformer export behavior independently with Python assertions can use it explicitly. Imports execute on the host processor and create no FPGA hardware.

Line 15: `)` This is continuation line 6 of the 6-line logical statement that begins at source line 10. Its exact fragment is ‘)‘. The expression is a literal or structural operator and has no hidden software state. Read together, the complete operation is: This imports the named Python API so the file whose role is to checks spikingformer export behavior independently with Python assertions can use it explicitly. Imports execute on the host processor and create no FPGA hardware.

Line 18: `class HardwareExportTests(unittest.TestCase):` This defines class HardwareExportTests, which groups data and methods for hardware export tests. Instances exist in host memory and organize the flow that checks spikingformer export behavior independently with Python assertions.

Line 19: `def test_aligned_writer_records_exact_payload_hash(self) -> None:` This starts function test_aligned_writer Its indented body performs test aligned writer records exact payload hash as part of the file that checks spikingformer export behavior independently with Python assertions; it runs only when called.

Line 20: `writer = AlignedBinaryWriter()` This assigns ‘AlignedBinaryWriter()‘ to ‘writer ‘ in host memory. Here writer means the value named 'writer' in this block. The important operands are AlignedBinaryWriter: the value named 'aligned binary writer' in this block. Context: the function test_aligned_writer_records_exact_payload_hash, which handles test aligned writer records exact payload hash.

Line 21: `first = writer.append("first", np.arange(7, dtype=np.int8))` This assigns ‘writer.append("first", np.arange(7, dtype=np.int8))‘ to ‘first ‘ in host memory. Here first means the value named 'first' in this block. The important operands are writer: the value named 'writer' in this block; append: the value named 'append' in this block; first: the value named 'first' in this block. Context: the function test_aligned_writer_records_exact_payload_hash, which handles test aligned writer records exact payload hash.

Line 22: `second_value = np.arange(5, dtype="<i4")` This assigns ‘np.arange(5, dtype="<i4")‘ to ‘second_value ‘ in host memory. Here second_value means the value named 'second value' in this block. The important operands are arange: the value named 'arange' in this block; dtype: the value named 'dtype' in this block; i4: the value named 'i4' in this block. Context: the function test_aligned_writer_records_exact_payload_hash, which handles test aligned writer records exact payload hash.

Line 23: `second = writer.append("second", second_value)` This assigns ‘writer.append("second", second_value)‘ to ‘second ‘ in host memory. Here second means the value named 'second' in this block. The important operands are writer: the value named 'writer' in this block; append: the value named 'append' in this block; second: the value named 'second' in this block. Context: the function test_aligned_writer_records_exact_payload_hash, which handles test aligned writer records exact payload hash.

Line 24: `self.assertEqual(first.offset, 0)` This calls ‘self.assertEqual‘ with ‘first.offset, 0‘ inside the function test_aligned_writer_records_exact_payload_hash, which handles test aligned writer records exact payload hash. The call advances the host-side job that checks spikingformer export behavior independently with Python assertions.

Line 25: `self.assertEqual(second.offset % ALIGNMENT, 0)` This calls ‘self.assertEqual‘ with ‘second.offset % ALIGNMENT, 0‘ inside the function test_aligned_writer_records_exact_payload_hash, which handles test aligned writer records exact payload hash. The call advances the host-side job that checks spikingformer export behavior independently with Python assertions.

Line 26: `payload = second_value.tobytes()` This assigns ‘second_value.tobytes()‘ to ‘payload ‘ in host memory. Here payload means stream data belonging to the current command. The important operands are second_value: the value named ’second value’ in this block; tobytes: the value named ’tobytes’ in this block. Context: the function test_aligned_writer_records_exact_payload_hash, which handles test aligned writer records exact payload hash.

Line 27: `self.assertEqual(second.sha256, hashlib.sha256(payload).hexdigest())` This calls ‘self.assertEqual‘ with ‘second.sha256, hashlib.sha256(payload).hexdigest()‘ inside the function test_aligned_writer_records_exact_payload_hash, which handles test aligned writer records exact payload hash. The call advances the host-side job that checks spikingformer export behavior independently with Python assertions.

Line 28: `self.assertEqual(bytes(writer.data[second.offset:second.offset + second.length]), payload)` This calls ‘self.assertEqual‘ with ‘bytes(writer.data[second.offset:second.offset + second.length]), payload‘ inside the function test_aligned_writer_records_exact_payload_hash, which handles test aligned writer records exact payload hash. The call advances the host-side job that checks spikingformer export behavior independently with Python assertions.

Line 30: `def test_tensor_weight_quantization_uses_complete_int8_range(self) -> None:` This starts function test_tensor_weight_quantization_uses_complete_int8_range. Its indented body performs test tensor weight quantization uses complete int8 range as part of the file that checks spikingformer export behavior independently with Python assertions; it runs only when called.

Line 31: `weight = torch.tensor([[-2.0, 0.0, 1.0, 2.0]])` This assigns ‘torch.tensor([[-2.0, 0.0, 1.0, 2.0]])‘ to ‘weight ‘ in host memory. Here weight means a learned coefficient multiplied by an activation. The important operands are torch: the value named ’torch’ in this block; tensor: the value named ’tensor’ in this block. Context: the function test_tensor_weight_quantization_uses_complete_int8_range, which handles test tensor weight quantization uses complete int8 range.

Line 32: `integer, scale = quantize_weight_tensor(weight)` This assigns ‘quantize_weight_tensor(weight)‘ to ‘integer, scale ‘ in host memory. Here integer means the value named ’integer’ in this block. The important operands are quantize_weight_tensor: a learned coefficient multiplied by an activation; weight: a learned coefficient multiplied by an activation. Context: the function test_tensor_weight_quantization_uses_complete_int8_range, which handles test tensor weight quantization uses complete int8 range.

Line 33: `self.assertEqual(scale, 2.0 / 127.0)` This calls ‘self.assertEqual‘ with ‘scale, 2.0 / 127.0‘ inside the function test_tensor_weight_quantization_uses_complete_int8_range, which handles test tensor weight quantization uses complete int8 range. The call advances the host-side job that checks spikingformer export behavior independently with Python assertions.

Line 34: `torch.testing.assert_close(integer, torch.tensor([[-127, 0, 64, 127]], dtype=torch.int8))` This calls ‘torch.testing.assert_close‘ with ‘integer, torch.tensor([[-127, 0, 64, 127]], dtype=torch.int8)‘ inside the function test_tensor_weight_quantization_uses_complete_int8_range, which handles test tensor weight quantization uses complete int8 range. The call advances the host-side job that checks spikingformer export behavior independently with Python assertions.

Line 36: `def test_projection_export_matches_folded_float_equation(self) -> None:` This starts function test_projection_export_matches_folded_float_equation. Its indented body performs test projection export matches folded float equation as part of the file that checks spikingformer export behavior independently with Python assertions; it runs only when called.

Line 37: `torch.manual_seed(19)` This calls ‘torch.manual_seed‘ with ‘19‘ inside the function test_projection_export_matches_ which handles test projection export matches folded float equation. The call advances the host-side job that checks spikingformer export behavior independently with Python assertions.

Line 38: `convolution = nn.Conv1d(4, 3, kernel_size=1, bias=True).eval()` This assigns ‘nn.Conv1d(4, 3, kernel_size=1, bias=True).eval()‘ to ‘convolution ‘ in host memory. Here convolution means the value named ’convolution’ in this block. The important operands are nn: the value named ’nn’ in this block; Conv1d: the value named ’conv1d’ in this block; kernel_size: the value named ’kernel size’ in this block. Context: the function test_projection_export_matches_folded_float which handles test projection export matches folded float equation.

Line 39: `batch_norm = nn.BatchNorm1d(3).eval()` This assigns ‘nn.BatchNorm1d(3).eval()‘ to ‘batch_norm ‘ in host memory. Here batch_norm means the value named ’batch norm’ in this block. The important operands are nn: the value named ’nn’ in this block; BatchNorm1d: the value named ’batch norm1d’ in this block; eval: the value named ’eval’ in this block. Context: the function test_projection_export_matches_folded_float_equation, which handles test projection export matches folded float equation.

Line 40: `batch_norm.running_mean.copy_(torch.randn(3))` This calls ‘batch_norm.running_mean.copy_‘ with ‘torch.randn(3)‘ inside the function test_projection_export_matches_folded_float_equation, which handles test projection export matches folded float equation. The call advances the host-side job that checks spikingformer export behavior independently with Python assertions.

Line 41: `batch_norm.running_var.copy_(torch.rand(3) + 0.5)` This calls ‘batch_norm.running_var.copy_‘ with ‘torch.rand(3) + 0.5‘ inside the function test_projection_export_matches_folded_float_equation, which handles test projection export matches folded float equation. The call advances the host-side job that checks spikingformer export behavior independently with Python assertions.

Line 42: `writer = AlignedBinaryWriter()` This assigns ‘AlignedBinaryWriter()‘ to ‘writer ‘ in host memory. Here writer means the value named ’writer’ in this block. The important operands are AlignedBinaryWriter: the value named ’aligned binary writer’ in this block. Context: the function test_projection_export_matches_folded_float_equation, which handles test projection export matches folded float equation.

Line 43: `exported = export_projection(` This statement continues through source line 52; the explanation uses the complete expression rather than only the first visual fragment. This assigns ‘export_projection(writer, name="probe", convolution=convolution, batch_norm=batch_norm, input_scale=1.0, fractional_bits=10, input_encoding="binary spike 0/1", compute_opcode="COMPUTE_BINARY",)‘ to ‘exported ‘ in host memory. Here exported means the value named ’exported’ in this block. The important operands are export_projection: the value named ’export projection’ in this block; writer: the value named ’writer’ in this block; name: the value named ’name’ in this block. Context: the function test_projection_export_matches_folded_float_equation, which handles test projection export matches folded float equation.

Line 44: `writer,` This is continuation line 2 of the 10-line logical statement that begins at source line 43. Its exact fragment is ‘writer,‘. The important operands are writer: the value named ’writer’ in this block. Read together, the complete operation is: This assigns ‘export_projection(writer, name="probe", convolution=convolution, batch_norm=batch_norm, input_scale=1.0, fractional_bits=10, input_encoding="binary spike 0/1", compute_opcode="COMPU)‘ to ‘exported ‘ in host memory. Here exported means the value named ’exported’ in this block. The important operands are export_projection: the value named ’export projection’ in this block; writer: the value named ’writer’ in this block; name: the value named ’name’ in this block. Context: the function test_projection_export_matches_folded_float_equation, which handles test projection export matches folded float equation.

Line 45: `name="probe",` This is continuation line 3 of the 10-line logical statement that begins at source line 43. Its exact fragment is ‘name="probe",‘. The important operands are name: the value named ’name’ in this block; probe: the value named ’probe’ in this block. Read together, the complete operation is: This assigns ‘export_projection(writer, name="probe", convolution=convolution, batch_norm=batch_norm, input_scale=1.0, fractional_bits=10, input_encoding="binary spike 0/1", compute_opcode="COMPUTE_BINARY",)‘ to ‘exported ‘ in host memory. Here exported means the value named ’exported’ in this block. The important operands are export_projection: the value named ’export projection’ in this block; writer: the value named ’writer’ in this block; name: the value named ’name’ in this block. Context: the function test_projection_export_matches_folded_float_equation, which handles test projection export matches folded float equation.

Line 46: `convolution=convolution,` This is continuation line 4 of the 10-line logical statement that begins at source line 43. Its exact fragment is 'convolution=convolution,'. The important operands are convolution: the value named 'convolution' in this block. Read together, the complete operation is: This assigns 'export_projection(writer, name="probe", convolution=convolution, batch_norm=batch_norm, input_scale=1.0, fractional_bits=10, input_encoding="binary spike 0/1", compute_opcode="COMPUTE_BINARY",)' to 'exported ' in host memory. Here exported means the value named 'exported' in this block. The important operands are export_projection: the value named 'export projection' in this block; writer: the value named 'writer' in this block; name: the value named 'name' in this block. Context: the function test_projection_export_matches_folded_float_equation, which handles test projection export matches folded float equation.

Line 47: `batch_norm=batch_norm,` This is continuation line 5 of the 10-line logical statement that begins at source line 43. Its exact fragment is 'batch_norm=batch_norm,'. The important operands are batch_norm: the value named 'batch norm' in this block. Read together, the complete operation is: This assigns 'export_projection(writer, name="probe", convolution=convolution, batch_norm=batch_norm, input_scale=1.0, fractional_bits=10, input_encoding="binary spike 0/1", compute_opcode="COMPUTE_BINARY",)' to 'exported ' in host memory. Here exported means the value named 'exported' in this block. The important operands are export_projection: the value named 'export projection' in this block; writer: the value named 'writer' in this block; name: the value named 'name' in this block. Context: the function test_projection_export_matches_folded_float_equation, which handles test projection export matches folded float equation.

Line 48: `input_scale=1.0,` This is continuation line 6 of the 10-line logical statement that begins at source line 43. Its exact fragment is 'input_scale=1.0,'. The important operands are input_scale: the real-value spacing represented by one quantized integer step. Read together, the complete operation is: This assigns 'export_projection(writer, name="probe", convolution=convolution, batch_norm=batch_norm, input_scale=1.0, fractional_bits=10, input_encoding="binary spike 0/1", compute_opcode="COMPUTE_BINARY",)' to 'exported ' in host memory. Here exported means the value named 'exported' in this block. The important operands are export_projection: the value named 'export projection' in this block; writer: the value named 'writer' in this block; name: the value named 'name' in this block. Context: the function test_projection_export_matches_folded_float_equation, which handles test projection export matches folded float equation.

Line 49: `fractional_bits=10,` This is continuation line 7 of the 10-line logical statement that begins at source line 43. Its exact fragment is 'fractional_bits=10,'. The important operands are fractional_bits: the value named 'fractional bits' in this block. Read together, the complete operation is: This assigns 'export_projection(writer, name="probe", convolution=convolution, batch_norm=batch_norm, input_scale=1.0, fractional_bits=10, input_encoding="binary spike 0/1", compute_opcode="COMPUTE_BINARY",)' to 'exported ' in host memory. Here exported means the value named 'exported' in this block. The important operands are export_projection: the value named 'export projection' in this block; writer: the value named 'writer' in this block; name: the value named 'name' in this block. Context: the function test_projection_export_matches_folded_float_equation, which handles test projection export matches folded float equation.

Line 50: `input_encoding="binary spike 0/1",` This is continuation line 8 of the 10-line logical statement that begins at source line 43. Its exact fragment is 'input_encoding="binary spike 0/1",'. The important operands are input_encoding: the value named 'input encoding' in this block; binary: the value named 'binary' in this block; spike: a binary event produced when a neuron crosses its threshold. Read together, the complete operation is: This assigns 'export_projection(writer, name="probe", convolution=convolution, batch_norm=batch_norm, input_scale=1.0, fractional_bits=10, input_encoding="binary spike 0/1", compute_opcode="COMPUTE_BINARY",)' to 'exported ' in host memory. Here exported means the value named 'exported' in this block. The important operands are export_projection: the value named 'export projection' in this block; writer: the value named 'writer' in this block; name: the value named 'name' in this block. Context: the function test_projection_export_matches_folded_float_equation, which handles test projection export matches folded float equation.

Line 51: `compute_opcode="COMPUTE_BINARY",` This is continuation line 9 of the 10-line logical statement that begins at source line 43. Its exact fragment is 'compute_opcode="COMPUTE_BINARY",'. The important operands are compute_opcode: the value named 'compute opcode' in this block; COMPUTE_BINARY: the value named 'compute binary' in this block. Read together, the complete operation is: This assigns 'export_projection(writer, name="probe", convolution=convolution, batch_norm=batch_norm, input_scale=1.0, fractional_bits=10, input_encoding="binary spike 0/1", compute_opcode="COMPUTE_BINARY",)' to 'exported ' in host memory. Here exported means the value

named 'exported' in this block. The important operands are export_projection: the value named 'export projection' in this block; writer: the value named 'writer' in this block; name: the value named 'name' in this block. Context: the function test_projection_export_matches_folded_float_equation, which handles test projection export matches folded float equation.

Line 52: `)` This is continuation line 10 of the 10-line logical statement that begins at source line 43. Its exact fragment is ')'. The expression is a literal or structural operator and has no hidden software state. Read together, the complete operation is: This assigns 'export_projection(writer, name="probe", convolution=convolution, batch_norm=batch_norm, input_scale=1.0, fractional_bits=10, input_encoding="binary spike 0/1", compute_opcode="COMPUTE_BINARY",)' to 'exported ' in host memory. Here exported means the value named 'exported' in this block. The important operands are export_projection: the value named 'export projection' in this block; writer: the value named 'writer' in this block; name: the value named 'name' in this block. Context: the function test_projection_export_matches_folded_float_equation, which handles test projection export matches folded float equation.

Line 53: `self.assertEqual(exported.hardware_matrix_shape, (4, 3))` This calls 'self.assertEqual' with 'exported.hardware_matrix_shape, (4, 3)' inside the function test_projection_export_matches_folded_float_equation, which handles test projection export matches folded float equation. The call advances the host-side job that checks spikingformer export behavior independently with Python assertions.

Line 54: `self.assertEqual(len(exported.sections), 4)` This calls 'self.assertEqual' with 'len(exported.sections), 4' inside the function test_projection_export_matches_folded_float_equation, which handles test projection export matches folded float equation. The call advances the host-side job that checks spikingformer export behavior independently with Python assertions.

Line 55: `self.assertLess(exported.represented_factor_maximum_error, 0.001)` This calls 'self.assertLess' with 'exported.represented_factor_maximum_error, 0.001' inside the function test_projection_export_matches_folded_float_equation which handles test projection export matches folded float equation. The call advances the host-side job that checks spikingformer export behavior independently with Python assertions.

Line 56: `for section in exported.sections:` This iterates section over 'exported.sections'. Each iteration repeats the indented host operation, commonly once per layer, tile, timestep, or test case in the function test_projection_export_matches_fo which handles test projection export matches folded float equation.

Line 57: `self.assertEqual(section.offset % ALIGNMENT, 0)` This calls 'self.assertEqual' with 'section.offset % ALIGNMENT, 0' inside the function test_projection_export_matches_folded_float_equation, which handles test projection export matches folded float equation. The call advances the host-side job that checks spikingformer export behavior independently with Python assertions.

Line 60: `if __name__ == "__main__":` This executes the following indented host-code branch only when '___name___ == "___main___"' is true. The important operands are ___name___: the value named 'name' in this block; ___main___: the value named 'main' in this block. Context: the file whose role is to checks spikingformer export behavior independently with Python assertions.

Line 61: `unittest.main()` This calls 'unittest.main' with " inside the file whose role is to checks spikingformer export behavior independently with Python assertions. The call advances the host-side job that checks spikingformer export behavior independently with Python assertions.

72 tests/test_spikingformer_manifest.py

Role in the complete system: checks spikingformer manifest behavior independently with Python assertions.

72.1 Beginner architecture map

Dataflow responsibility This file's end-to-end responsibility is to checks spikingformer manifest behavior independently with Python assertions.

Where it runs This is sequential host software. Python objects live in CPU memory; they become FPGA work only when the compiler packs a command or payload and the PYNQ driver transfers those bytes through AXI DMA or AXI-Lite.

Public structure Classes: MatrixScheduleTests, SpikingformerManifestTests. Functions: test_outer_product_schedule_counts_ test_dot8_schedule_pads_reduction_without_changing_mac_count, test_large_reduction_is_split_at_hardware_limit, test_manifest_covers_every_learned_projection, test_temporal_hoist_counts_block0_once. Each function annotation below names its enclosing function so an array operation is tied to the model, compiler, driver, test, or report phase that uses it.

Numeric and failure boundary Shapes, signedness, byte order, scaling, and saturation are part of the hardware contract. Validation exceptions are functional safety checks: rejecting malformed input before DMA is different from silently clipping, reshaping, or continuing with an incompatible artifact.

72.2 Complete source

```
from __future__ import annotations

import unittest

from generate_spikingformer_manifest import build_operator_manifest, matrix_schedule

class MatrixScheduleTests(unittest.TestCase):
    def test_outer_product_schedule_counts_tiles_and_commands(self) -> None:
        schedule = matrix_schedule(
            9, 17, 18, arithmetic="binary_spike_add")
        self.assertEqual(schedule.compute_tiles, 4)
        self.assertEqual(schedule.commands, 10)
        self.assertEqual(schedule.mac_equivalents, 9 * 17 * 18)
        self.assertEqual(schedule.reduction_chunks, 1)

    def test_dot8_schedule_pads_reduction_without_changing_mac_count(self) -> None:

72.3 Line annotations

Line 1: `from __future__ import annotations` This imports the named Python API so the file whose role is to checks spikingformer manifest behavior independently with Python assertions can use it explicitly. Imports execute on the host processor and create no FPGA hardware.

Line 3: `import unittest` This imports the named Python API so the file whose role is to checks spikingformer manifest behavior independently with Python assertions can use it explicitly. Imports execute on the host processor and create no FPGA hardware.

Line 5: `from generate_spikingformer_manifest import build_operator_manifest, matrix_schedule` This imports the named Python API so the file whose role is to checks spikingformer manifest behavior independently with Python assertions can use it explicitly. Imports execute on the host processor and create no FPGA hardware.

Line 8: `class MatrixScheduleTests(unittest.TestCase):` This defines class MatrixScheduleTests, which groups data and methods for matrix schedule tests. Instances exist in host memory and organize the flow that checks spikingformer manifest behavior independently with Python assertions.

Line 9: `def test_outer_product_schedule_counts_tiles_and_commands(self) -> None:` This starts function test_outer_product_schedule_counts_tiles_and_commands. Its indented body performs test outer product schedule counts tiles and commands as part of the file that checks spikingformer manifest behavior independently with Python assertions; it runs only when called.

Line 10: `schedule = matrix_schedule(` This statement continues through source line 11; the explanation uses the complete expression rather than only the first visual fragment. This assigns ‘matrix_schedule(9, 17, 18, arithmetic="binary_spike_add")‘ to ‘schedule ‘ in host memory. Here schedule means the value named ’schedule’ in this block. The important operands are matrix_schedule: the value named ’matrix schedule’ in this block; arithmetic: the value named ’arithmetic’ in this block; binary_spike_add: a binary event produced when a neuron crosses its threshold. Context: the function test_outer_product_schedule_counts_tiles_and_commands, which handles test outer product schedule counts tiles and commands.

Line 11: `9, 17, 18, arithmetic="binary_spike_add")` This is continuation line 2 of the 2-line logical statement that begins at source line 10. Its exact fragment is ‘9, 17, 18, arithmetic="binary_spike_add")‘. The important operands are arithmetic: the value named ’arithmetic’ in this block; binary_spike_add: a binary event produced when a neuron crosses its threshold. Read together, the complete operation is: This assigns ‘matrix_schedule(9, 17, 18, arithmetic="binary_spike_add")‘ to ‘schedule ‘ in host memory. Here schedule means the value named ’schedule’ in this block. The important operands are matrix_schedule: the value named ’matrix schedule’ in this block; arithmetic: the value named ’arithmetic’ in this block; binary_spike_add: a binary event produced when a neuron crosses its threshold. Context: the function test_outer_product_schedule_counts_tiles_and_commands, which handles test outer product schedule counts tiles and commands.

Line 12: `self.assertEqual(schedule.compute_tiles, 4)` This calls ‘self.assertEqual‘ with ‘schedule.compute_tiles, 4‘ inside the function test_outer_product_schedule_counts_tiles_and_commands, which handles test outer product schedule counts tiles and commands. The call advances the host-side job that checks spikingformer manifest behavior independently with Python assertions.

Line 13: `self.assertEqual(schedule.commands, 10)` This calls ‘self.assertEqual‘ with ‘schedule.commands, 10‘ inside the function test_outer_product_schedule_counts_tiles_and_commands, which handles test outer product schedule counts tiles and commands. The call advances the host-side job that checks spikingformer manifest behavior independently with Python assertions.

Line 14: `self.assertEqual(schedule.mac_equivalents, 9 * 17 * 18)` This calls ‘self.assertEqual‘ with ‘schedule.mac_equivalents, 9 * 17 * 18‘ inside the function test_outer_product_schedule_counts_tiles_and_commands, which handles test outer product schedule counts tiles and commands. The call advances the host-side job that checks spikingformer manifest behavior independently with Python assertions.

Line 15: `self.assertEqual(schedule.reduction_chunks, 1)` This calls ‘self.assertEqual‘ with ‘schedule.reduction_chunks, 1‘ inside the function test_outer_product_schedule_counts_tiles_and_commands, which handles test outer product schedule counts tiles and commands. The call advances the host-side job that checks spikingformer manifest behavior independently with Python assertions.

Line 17: `def test_dot8_schedule_pads_reduction_without_changing_mac_count(self) -> None:` This starts function test_dot8_schedule_pads_reduction_without_changing_mac_count. Its indented body performs test dot8 schedule pads reduction without changing mac count as part of the file that checks spikingformer manifest behavior independently with Python assertions; it runs only when called.

Line 18: `schedule = matrix_schedule(1, 17, 18, arithmetic="u8_mac")` This assigns ‘matrix_schedule(1, 17, 18, arithmetic="u8_mac")‘ to ‘schedule ‘ in host memory. Here schedule means the value named ’schedule’ in this block. The important operands are matrix_schedule: the value named ’matrix schedule’ in this block; arithmetic: the value named ’arithmetic’ in this block; u8_mac: the value named ’u8 mac’ in this block. Context: the function test_dot8_schedule_pads_reduction_without_changing_mac_count, which handles test dot8 schedule pads reduction without changing mac count.

Line 19: `self.assertEqual(schedule.compute_tiles, 2)` This calls ‘self.assertEqual‘ with ‘schedule.compute_tiles, 2‘ inside the function test_dot8_schedule_pads_reduction_without_changing_mac_count, which handles test dot8 schedule pads reduction without changing mac count. The call advances the host-side job that checks spikingformer manifest behavior independently with Python assertions.

Line 20: `self.assertEqual(schedule.commands, 5)` This calls ‘self.assertEqual‘ with ‘schedule.commands, 5‘ inside the function test_dot8_schedule_pads_reduction_without_changing_mac_count, which handles test dot8 schedule pads reduction without changing mac count. The call advances the host-side job that checks spikingformer manifest behavior independently with Python assertions.

Line 21: `self.assertEqual(schedule.mac_equivalents, 1 * 17 * 18)` This calls ‘self.assertEqual‘ with ‘schedule.mac_equivalents, 1 * 17 * 18‘ inside the function test_dot8_schedule_pads_reduction_without_changing_mac_count, which handles test dot8 schedule pads reduction without changing mac count. The call advances the host-side job that checks spikingformer manifest behavior independently with Python assertions.

Line 23: `def test_large_reduction_is_split_at_hardware_limit(self) -> None:` This starts function test_large_reducti Its indented body performs test large reduction is split at hardware limit as part of the file that checks spikingformer manifest behavior independently with Python assertions; it runs only when called.

Line 24: `schedule = matrix_schedule(8, 3456, 16, arithmetic="binary_spike_add")` This assigns ‘matrix_schedule(8, 3456, 16, arithmetic="binary_spike_add")‘ to ‘schedule ‘ in host memory. Here schedule means the value named ’schedule’ in this block. The important operands are matrix_schedule: the value named ’matrix schedule’ in this block; arithmetic: the value named ’arithmetic’ in this block; binary_spike_add: a binary event produced when a neuron crosses its threshold. Context: the function test_large_reduction_is_split_at_hardware_limit, which handles test large reduction is split at hardware limit.

Line 25: `self.assertEqual(schedule.reduction_chunks, 2)` This calls ‘self.assertEqual‘ with ‘schedule.reduction_chunks, 2‘ inside the function test_large_reduction_is_split_at_hardware_limit, which handles test large reduction is split at hardware limit. The call advances the host-side job that checks spikingformer manifest behavior independently with Python assertions.

Line 26: `self.assertEqual(schedule.compute_tiles, 2)` This calls ‘self.assertEqual‘ with ‘schedule.compute_tiles, 2‘ inside the function test_large_reduction_is_split_at_hardware_limit, which handles test large reduction is split at hardware limit. The call advances the host-side job that checks spikingformer manifest behavior independently with Python assertions.

Line 27: `self.assertEqual(schedule.commands, 6)` This calls ‘self.assertEqual‘ with ‘schedule.commands, 6‘ inside the function test_large_reduction_is_split_at_hardware_limit, which handles test large reduction is split at hardware limit. The call advances the host-side job that checks spikingformer manifest behavior independently with Python assertions.

Line 30: `class SpikingformerManifestTests(unittest.TestCase):` This defines class SpikingformerManifestTests, which groups data and methods for spikingformer manifest tests. Instances exist in host memory and organize the flow that checks spikingformer manifest behavior independently with Python assertions.

Line 31: `def test_manifest_covers_every_learned_projection(self) -> None:` This starts function test_manifest_covers Its indented body performs test manifest covers every learned projection as part of the file that checks spikingformer manifest behavior independently with Python assertions; it runs only when called.

Line 32: `operators = build_operator_manifest()` This assigns ‘build_operator_manifest()‘ to ‘operators ‘ in host memory. Here operators means the value named ’operators’ in this block. The important operands are build_operator_manifest: the value named ’build operator manifest’ in this block. Context: the function test_manifest_covers_every_learned_projection, which handles test manifest covers every learned projection.

Line 33: `matrix_operators = [item for item in operators if item.matrix is not None]` This assigns ‘[item for item in operators if item.matrix is not None]‘ to ‘matrix_operators ‘ in host memory. Here matrix_operators means the value named ’matrix operators’ in this block. The important operands are item: the value named ’item’ in this block; for: the value named ’for’ in this block; in: the value named ’in’ in this block. Context: the function test_manifest_covers_every_learned_projection, which handles test manifest covers every learned projection.

Line 34: `self.assertEqual(len(matrix_operators), 5 + 4 * 8 + 1)` This calls ‘self.assertEqual‘ with ‘len(matrix_operator 5 + 4 * 8 + 1‘ inside the function test_manifest_covers_every_learned_projection, which handles test manifest covers every learned projection. The call advances the host-side job that checks spikingformer manifest behavior independently with Python assertions.

Line 35: `names = {item.name for item in matrix_operators}` This assigns ‘{item.name for item in matrix_operators}‘ to ‘names ‘ in host memory. Here names means the value named ’names’ in this block. The important operands are item: the value named ’item’ in this block; name: the value named ’name’ in this block; for: the value named ’for’ in this block. Context: the function test_manifest_covers_every_learned_projection, which handles test manifest covers every learned projection.

Line 36: `self.assertIn("patch_embed.block0", names)` This calls ‘self.assertIn‘ with ‘"patch_embed.block0", names‘ inside the function test_manifest_covers_every_learned_projection, which handles test manifest covers every learned projection. The call advances the host-side job that checks spikingformer manifest behavior independently with Python assertions.

Line 37: `self.assertIn("block.3.attn.qk", names)` This calls ‘self.assertIn‘ with ‘"block.3.attn.qk", names‘ inside the function test_manifest_covers_every_learned_projection, which handles test manifest covers every learned projection. The call advances the host-side job that checks spikingformer manifest behavior independently with Python assertions.

Line 38: `self.assertIn("block.3.mlp.fc2", names)` This calls ‘self.assertIn‘ with ‘"block.3.mlp.fc2", names‘ inside the function test_manifest_covers_every_learned_projection, which handles test manifest covers every learned projection. The call advances the host-side job that checks spikingformer manifest behavior independently with Python assertions.

Line 39: `self.assertIn("head", names)` This calls ‘self.assertIn‘ with ‘"head", names‘ inside the function test_manifest_covers which handles test manifest covers every learned projection. The call advances the host-side job that checks spikingformer manifest behavior independently with Python assertions.

Line 41: `def test_temporal_hoist_counts_block0_once(self) -> None:` This starts function test_temporal_hoist_counts_ Its indented body performs test temporal hoist counts block0 once as part of the file that checks spikingformer manifest behavior independently with Python assertions; it runs only when called.

Line 42: `operators = {item.name: item for item in build_operator_manifest()}` This assigns '{item.name: item for item in build_operator_manifest()}' to 'operators ' in host memory. Here operators means the value named 'operators' in this block. The important operands are item: the value named 'item' in this block; name: the value named 'name' in this block; for: the value named 'for' in this block. Context: the function test_temporal_hoist_counts_block0_once, which handles test temporal hoist counts block0 once.

Line 43: `block0 = operators["patch_embed.block0"]` This assigns 'operators["patch_embed.block0"]' to 'block0 ' in host memory. Here block0 means the value named 'block0' in this block. The important operands are operators: the value named 'operators' in this block; patch_embed: the value named 'patch embed' in this block; block0: the value named 'block0' in this block. Context: the function test_temporal_hoist_counts_block0_once, which handles test temporal hoist counts block0 once.

Line 44: `self.assertEqual(block0.matrix.repetitions, 1)` This calls 'self.assertEqual' with 'block0.matrix.repetitions, 1' inside the function test_temporal_hoist_counts_block0_once, which handles test temporal hoist counts block0 once. The call advances the host-side job that checks spikingformer manifest behavior independently with Python assertions.

Line 45: `self.assertIsNotNone(block0.exact_optimization)` This calls 'self.assertIsNotNone' with 'block0.exact_optimizati inside the function test_temporal_hoist_counts_block0_once, which handles test temporal hoist counts block0 once. The call advances the host-side job that checks spikingformer manifest behavior independently with Python assertions.

Line 48: `if __name__ == "__main__":` This executes the following indented host-code branch only when '___name___ == "___main___"' is true. The important operands are ___name___: the value named 'name' in this block; ___main___: the value named 'main' in this block. Context: the file whose role is to checks spikingformer manifest behavior independently with Python assertions.

Line 49: `unittest.main()` This calls 'unittest.main' with " inside the file whose role is to checks spikingformer manifest behavior independently with Python assertions. The call advances the host-side job that checks spikingformer manifest behavior independently with Python assertions.

73 tests/test_spikingformer_parameters.py

Role in the complete system: checks spikingformer parameters behavior independently with Python assertions.

73.1 Beginner architecture map

Dataflow responsibility This file's end-to-end responsibility is to checks spikingformer parameters behavior independently with Python assertions.

Where it runs This is sequential host software. Python objects live in CPU memory; they become FPGA work only when the compiler packs a command or payload and the PYNQ driver transfers those bytes through AXI DMA or AXI-Lite.

Public structure Classes: ParameterArchiveTests. Functions: _write_archive, test_loads_typed_read_only_projection_and_h test_rejects_one_corrupted_parameter_byte, test_rejects_overlapping_section_metadata_without_hash_checks. Each function annotation below names its enclosing function so an array operation is tied to the model, compiler, driver, test, or report phase that uses it.

Numeric and failure boundary Shapes, signedness, byte order, scaling, and saturation are part of the hardware contract. Validation exceptions are functional safety checks: rejecting malformed input before DMA is different from silently clipping, reshaping, or continuing with an incompatible artifact.

73.3 Line annotations

Line 1: `from __future__ import annotations` This imports the named Python API so the file whose role is to checks spikingformer parameters behavior independently with Python assertions can use it explicitly. Imports execute on the host processor and create no FPGA hardware.

Line 3: `import hashlib` This imports the named Python API so the file whose role is to checks spikingformer parameters behavior independently with Python assertions can use it explicitly. Imports execute on the host processor and create no FPGA hardware.

Line 4: `import json` This imports the named Python API so the file whose role is to checks spikingformer parameters behavior independently with Python assertions can use it explicitly. Imports execute on the host processor and create no FPGA hardware.

Line 5: `import tempfile` This imports the named Python API so the file whose role is to checks spikingformer parameters behavior independently with Python assertions can use it explicitly. Imports execute on the host processor and create no FPGA hardware.

Line 6: `import unittest` This imports the named Python API so the file whose role is to checks spikingformer parameters behavior independently with Python assertions can use it explicitly. Imports execute on the host processor and create no FPGA hardware.

Line 7: `from pathlib import Path` This imports the named Python API so the file whose role is to checks spikingformer parameters behavior independently with Python assertions can use it explicitly. Imports execute on the host processor and create no FPGA hardware.

Line 9: `import numpy as np` This imports the named Python API so the file whose role is to checks spikingformer parameters behavior independently with Python assertions can use it explicitly. Imports execute on the host processor and create no FPGA hardware.

Line 11: `from export_spikingformer_hardware import AlignedBinaryWriter` This imports the named Python API so the file whose role is to checks spikingformer parameters behavior independently with Python assertions can use it explicitly. Imports execute on the host processor and create no FPGA hardware.

Line 12: `from spikingformer_parameters import FORMAT, SpikingformerParameterArchive` This imports the named Python API so the file whose role is to checks spikingformer parameters behavior independently with Python assertions can use it explicitly. Imports execute on the host processor and create no FPGA hardware.

Line 15: `class ParameterArchiveTests(unittest.TestCase):` This defines class ParameterArchiveTests, which groups data and methods for parameter archive tests. Instances exist in host memory and organize the flow that checks spikingformer parameters behavior independently with Python assertions.

Line 16: `def _write_archive(self, directory: Path) -> Path:` This starts function _write_archive. Its indented body performs write archive as part of the file that checks spikingformer parameters behavior independently with Python assertions; it runs only when called.

Line 17: `writer = AlignedBinaryWriter()` This assigns ‘AlignedBinaryWriter()‘ to ‘writer ‘ in host memory. Here writer means the value named ’writer’ in this block. The important operands are AlignedBinaryWriter: the value named ’aligned binary writer’ in this block. Context: the function _write_archive, which handles write archive.

Line 18: `sections = [` This statement continues through source line 25; the explanation uses the complete expression rather than only the first visual fragment. This assigns ‘[writer.append("unit.weight_k_by_n_int8", np.arange(12, dtype=np.int8).reshape(3, 4)), writer.append("unit.bias_q10", np.arange(4, dtype="<i4")), writer.append("unit.multiplier_q15", np.arange(4, dtype="<i2")), writer.append("unit.binary_point_shift", np.arange(4, dtype=np.int8)), writer.append("head.weight_
np.arange(8, dtype=np.int8).reshape(4, 2)), writer.append("head.bias_accumulator_units", np.arange(2, dtype="<i4")),]‘ to ‘sections ‘ in host memory. Here sections means the value named ’sections’ in this block. The important operands are writer: the value named ’writer’ in this block; append: the value named ’append’ in this block; unit: the value named ’unit’ in this block. Context: the function _write_archive, which handles write archive.

Line 19: `writer.append("unit.weight_k_by_n_int8", np.arange(12, dtype=np.int8).reshape(3, 4)),` This is continuation line 2 of the 8-line logical statement that begins at source line 18. Its exact fragment is ‘writer.append("unit.weight_k_
np.arange(12, dtype=np.int8).reshape(3, 4)),‘. The important operands are writer: the value named ’writer’ in this block; append: the value named ’append’ in this block; unit: the value named ’unit’ in this block. Read together, the complete operation is: This assigns ‘[writer.append("unit.weight_k_by_n_int8", np.arange(12, dtype=np.int8).reshape(3, 4)), writer.append("unit.bias_q10", np.arange(4, dtype="<i4")), writer.append("unit.multiplier_q15", np.arange(4, dtype="<i2")), writer.append("unit.binary_point_shift", np.arange(4, dtype=np.int8)), writer.append("head.weight_k_by_n_int8", np.arange(8, dtype=np.int8).reshape(4, 2)), writer.append("head.bias_accumulator_units", np.arange(2, dtype="<i4")),]‘ to ‘sections ‘ in host memory. Here sections means the value named ’sections’ in this block. The important operands are writer: the value named ’writer’ in this block; append: the value named ’append’ in this block; unit: the value named ’unit’ in this block. Context: the function _write_archive, which handles write archive.

Line 20: `writer.append("unit.bias_q10", np.arange(4, dtype="<i4")),` This is continuation line 3 of the 8-line logical statement that begins at source line 18. Its exact fragment is ‘writer.append("unit.bias_q10", np.arange(4, dtype="<i4")),‘. The important operands are writer: the value named ’writer’ in this block; append: the value named ’append’ in this block; unit: the value named ’unit’ in this block. Read together, the complete operation is: This assigns ‘[writer.append("unit.weight_k_by_n_int8", np.arange(12, dtype=np.int8).reshape(3, 4)), writer.append("unit.bias_q10", np.arange(4, dtype="<i4")), writer.append("unit.multiplier_q15", np.arange(4, dtype="<i2")), writer.append("unit.binary_point_s
np.arange(4, dtype=np.int8)), writer.append("head.weight_k_by_n_int8", np.arange(8, dtype=np.int8).reshape(4, 2)), writer.append("head.bias_accumulator_units", np.arange(2, dtype="<i4")),]‘ to ‘sections ‘ in host memory. Here sections means the value named ’sections’ in this block. The important operands are writer: the value named ’writer’ in this block; append: the value named ’append’ in this block; unit: the value named ’unit’ in this block. Context: the function _write_archive, which handles write archive.

Line 21: `writer.append("unit.multiplier_q15", np.arange(4, dtype="<i2")),` This is continuation line 4 of the 8-line logical statement that begins at source line 18. Its exact fragment is ‘writer.append("unit.multiplier_q15", np.arange(4, dtype="<i2")),‘. The important operands are writer: the value named ’writer’ in this block; append: the value named ’append’ in this block; unit: the value named ’unit’ in this block. Read together, the complete operation is: This assigns ‘[writer.append("unit.weight_k_by_n_int8", np.arange(12, dtype=np.int8).reshape(3, 4)), writer.append("unit.bias_q10", np.arange(4, dtype="<i4")), writer.append("unit.multiplier_q15", np.arange(4, dtype="<i2")), writer.append("unit.binary_point_shift", np.arange(4, dtype=np.int8)), writer.append("head.weight_k_by_n_int8", np.arange(8,

dtype=np.int8).reshape(4, 2)), writer.append("head.bias_accumulator_units", np.arange(2, dtype="<i4")),]‘ to ‘sections ‘ in host memory. Here sections means the value named ’sections’ in this block. The important operands are writer: the value named ’writer’ in this block; append: the value named ’append’ in this block; unit: the value named ’unit’ in this block. Context: the function _write_archive, which handles write archive.

Line 22: `writer.append("unit.binary_point_shift", np.arange(4, dtype=np.int8)),` This is continuation line 5 of the 8-line logical statement that begins at source line 18. Its exact fragment is ‘writer.append("unit.binary_point_shift", np.arange(4, dtype=np.int8)),‘. The important operands are writer: the value named ’writer’ in this block; append: the value named ’append’ in this block; unit: the value named ’unit’ in this block. Read together, the complete operation is: This assigns ‘[writer.append("unit.weight_k_by_n_int8", np.arange(12, dtype=np.int8).reshape(3, 4)), writer.append("unit.bias_q10", np.arange(4, dtype="<i4")), writer.append("unit.multiplier_q15", np.arange(4, dtype="<i2")), writer.append("unit.binary_point_shift", np.arange(4, dtype=np.int8)), writer.append("head.weight_k_by_n_int8", np.arange(8, dtype=np.int8).reshape(4, 2)), writer.append("head.bias_accumulator_units", np.arange(2, dtype="<i4")),]‘ to ‘sections ‘ in host memory. Here sections means the value named ’sections’ in this block. The important operands are writer: the value named ’writer’ in this block; append: the value named ’append’ in this block; unit: the value named ’unit’ in this block. Context: the function _write_archive, which handles write archive.

Line 23: `writer.append("head.weight_k_by_n_int8", np.arange(8, dtype=np.int8).reshape(4, 2)),` This is continuation line 6 of the 8-line logical statement that begins at source line 18. Its exact fragment is ‘writer.append("head.weight_k_b np.arange(8, dtype=np.int8).reshape(4, 2)),‘. The important operands are writer: the value named ’writer’ in this block; append: the value named ’append’ in this block; head: the value named ’head’ in this block. Read together, the complete operation is: This assigns ‘[writer.append("unit.weight_k_by_n_int8", np.arange(12, dtype=np.int8).reshape(3, 4)), writer.append("unit.bias_q10", np.arange(4, dtype="<i4")), writer.append("unit.multiplier_q15", np.arange(4, dtype="<i2")), writer.append("unit.binary_point_shift", np.arange(4, dtype=np.int8)), writer.append("head.weight_k_by_n_int8", np.arange(8, dtype=np.int8).reshape(4, 2)), writer.append("head.bias_accumulator_units", np.arange(2, dtype="<i4")),]‘ to ‘sections ‘ in host memory. Line 42: `"sections": [section.__dict__ for section in sections],` This is continuation line 15 of the 16-line logical statement that begins at source line 28. Its exact fragment is ‘"sections": [section.___dict___ for section in sections],‘. The important operands are sections: the value named ’sections’ in this block; section: the value named

'section' in this block; ___dict___: the value named 'dict' in this block. Read together, the complete operation is: This assigns '{ "format": FORMAT, "binary_file": binary.name, "binary_bytes": len(writer.data), "binary_sha256": hashlib.sha256(writer.data).hexdigest(), "alignment_bytes": 64, "projections": [{ "name": "unit", "compute_opcode": "COMPUTE_BINARY", "source_weight_shape": [4, 3, 1, 1], "output_fractional_bits": 10, "sections": [section.___dict___ for section in sections[:4]], }], "head": {"sections": [section.___dict___ for section in sections[4:]]}, "sections": [section.___dict___ for section in sections], }' to 'manifest ' in host memory. Here manifest means the value named 'manifest' in this block. The important operands are format: the value named 'format' in this block; FORMAT: the value named 'format' in this block; binary_file: the value named 'binary file' in this block. Context: the function _write_archive, which handles write archive.

Line 43: `}` This is continuation line 16 of the 16-line logical statement that begins at source line 28. Its exact fragment is '}'. The expression is a literal or structural operator and has no hidden software state. Read together, the complete operation is: This assigns '{ "format": FORMAT, "binary_file": binary.name, "binary_bytes": len(writer.data), "binary_sha256": hashlib.sha256(writer.data).hexdigest(), "alignment_bytes": 64, "projections": [{ "name": "unit", "compute_opcode": "COMPUTE_BINARY", "source_weight_shape": [4, 3, 1, 1], "output_fractional_bits": 10, "sections": [section.___dict___ for section in sections[:4]], }], "head": {"sections": [section.___dict___ for section in sections[4:]]}, "sections": [section.___dict___ for section in sections], }' to 'manifest ' in host memory. Here manifest means the value named 'manifest' in this block. The important operands are format: the value named 'format' in this block; FORMAT: the value named 'format' in this block; binary_file: the value named 'binary file' in this block. Context: the function _write_archive, which handles write archive.

Line 44: `path = directory / "parameters.json"` This assigns 'directory / "parameters.json"' to 'path ' in host memory. Here path means the value named 'path' in this block. The important operands are directory: the value named 'directory' in this block; parameters: the value named 'parameters' in this block; json: the value named 'json' in this block. Context: the function _write_archive, which handles write archive.

Line 45: `path.write_text(json.dumps(manifest), encoding="ascii")` This calls 'path.write_text' with 'json.dumps(manife encoding="ascii"' inside the function _write_archive, which handles write archive. The call advances the host-side job that checks spikingformer parameters behavior independently with Python assertions.

Line 46: `return path` This returns 'path' to the caller of the function _write_archive, which handles write archive, ending this invocation. The important operands are path: the value named 'path' in this block.

Line 48: `def test_loads_typed_read_only_projection_and_head(self) -> None:` This starts function test_loads_typed_r Its indented body performs test loads typed read only projection and head as part of the file that checks spikingformer parameters behavior independently with Python assertions; it runs only when called.

Line 49: `with tempfile.TemporaryDirectory() as temporary:` This opens a managed resource scope for 'tempfile.TemporaryDirectory() as temporary' so files, tracing, or temporary state are finalized even if the function test_loads_typed_read which handles test loads typed read only projection and head raises an error.

Line 50: `archive = SpikingformerParameterArchive(self._write_archive(Path(temporary)))` This assigns 'SpikingformerParameterArchive(self._write_archive(Path(temporary)))' to 'archive ' in host memory. Here archive means the value named 'archive' in this block. The important operands are SpikingformerParameterArchive: the value named 'spikingformer parameter archive' in this block; _write_archive: the value named 'write archive' in this block; Path: the value named 'path' in this block. Context: the function test_loads_typed_read_only_projection_and_head, which handles test loads typed read only projection and head.

Line 51: `projection = archive.projection("unit")` This assigns 'archive.projection("unit")' to 'projection ' in host memory. Here projection means the value named 'projection' in this block. The important operands are archive: the value named 'archive' in this block; projection: the value named 'projection' in this block; unit: the value named 'unit' in this block. Context: the function test_loads_typed_read_only_projection_and_head, which handles test loads typed read only projection and head.

Line 52: `self.assertEqual(projection.weight_k_by_n.shape, (3, 4))` This calls ‘self.assertEqual‘ with ‘projection.weight_k_by_n.shape, (3, 4)‘ inside the function test_loads_typed_read_only_projection_and_head, which handles test loads typed read only projection and head. The call advances the host-side job that checks spikingformer parameters behavior independently with Python assertions.

Line 53: `self.assertEqual(projection.weight_k_by_n.dtype, np.dtype("int8"))` This calls ‘self.assertEqual‘ with ‘projection.weight_k_by_n.dtype, np.dtype("int8")‘ inside the function test_loads_typed_read_only_projection_and_head, which handles test loads typed read only projection and head. The call advances the host-side job that checks spikingformer parameters behavior independently with Python assertions.

Line 54: `self.assertFalse(projection.weight_k_by_n.flags.writeable)` This calls ‘self.assertFalse‘ with ‘projection.weight_k_by_n.flags.writeable‘ inside the function test_loads_typed_read_only_projection_and_head, which handles test loads typed read only projection and head. The call advances the host-side job that checks spikingformer parameters behavior independently with Python assertions.

Line 55: `self.assertEqual(archive.head.weight_k_by_n.shape, (4, 2))` This calls ‘self.assertEqual‘ with ‘archive.head.we (4, 2)‘ inside the function test_loads_typed_read_only_projection_and_head, which handles test loads typed read only projection and head. The call advances the host-side job that checks spikingformer parameters behavior independently with Python assertions.

Line 56: `self.assertEqual(archive.projection_names, ("unit",))` This calls ‘self.assertEqual‘ with ‘archive.projection_na ("unit",)‘ inside the function test_loads_typed_read_only_projection_and_head, which handles test loads typed read only projection and head. The call advances the host-side job that checks spikingformer parameters behavior independently with Python assertions.

Line 58: `def test_rejects_one_corrupted_parameter_byte(self) -> None:` This starts function test_rejects_one_corrupt Its indented body performs test rejects one corrupted parameter byte as part of the file that checks spikingformer parameters behavior independently with Python assertions; it runs only when called.

Line 59: `with tempfile.TemporaryDirectory() as temporary:` This opens a managed resource scope for ‘tempfile.TemporaryDirectory() as temporary‘ so files, tracing, or temporary state are finalized even if the function test_rejects_one_corru which handles test rejects one corrupted parameter byte raises an error.

Line 60: `directory = Path(temporary)` This assigns ‘Path(temporary)‘ to ‘directory ‘ in host memory. Here directory means the value named ’directory’ in this block. The important operands are Path: the value named ’path’ in this block; temporary: the value named ’temporary’ in this block. Context: the function test_rejects_one_corrupted_parameter_byte, which handles test rejects one corrupted parameter byte.

Line 61: `manifest = self._write_archive(directory)` This assigns ‘self._write_archive(directory)‘ to ‘manifest ‘ in host memory. Here manifest means the value named ’manifest’ in this block. The important operands are _write_archive: the value named ’write archive’ in this block; directory: the value named ’directory’ in this block. Context: the function test_rejects_one_corrupted_parameter_byte, which handles test rejects one corrupted parameter byte.

Line 62: `binary = directory / "parameters.bin"` This assigns ‘directory / "parameters.bin"‘ to ‘binary ‘ in host memory. Here binary means the value named ’binary’ in this block. The important operands are directory: the value named ’directory’ in this block; parameters: the value named ’parameters’ in this block; bin: the value named ’bin’ in this block. Context: the function test_rejects_one_corrupted_parameter_byte, which handles test rejects one corrupted parameter byte.

Line 63: `payload = bytearray(binary.read_bytes())` This assigns ‘bytearray(binary.read_bytes())‘ to ‘payload ‘ in host memory. Here payload means stream data belonging to the current command. The important operands are bytearray: the value named ’bytearray’ in this block; binary: the value named ’binary’ in this block; read_bytes: the value named ’read bytes’ in this block. Context: the function test_rejects_one_corrupted_parameter_byte, which handles test rejects one corrupted parameter byte.

Line 64: `payload[0] ^= 0x80` Inside the function test_rejects_one_corrupted_parameter_byte, which handles test rejects one corrupted parameter byte, this statement advances the host implementation that checks spikingformer parameters behavior independently with Python assertions. The important operands are payload: stream data belonging to the current command.

Line 65: `binary.write_bytes(payload)` This calls 'binary.write_bytes' with 'payload' inside the function test_rejects_one_cor which handles test rejects one corrupted parameter byte. The call advances the host-side job that checks spikingformer parameters behavior independently with Python assertions.

Line 66: `with self.assertRaisesRegex(ValueError, "SHA-256 mismatch"):` This opens a managed resource scope for 'self.assertRaisesRegex(ValueError, "SHA-256 mismatch")' so files, tracing, or temporary state are finalized even if the function test_rejects_one_corrupted_parameter_byte, which handles test rejects one corrupted parameter byte raises an error.

Line 67: `SpikingformerParameterArchive(manifest)` This calls 'SpikingformerParameterArchive' with 'manifest' inside the function test_rejects_one_corrupted_parameter_byte, which handles test rejects one corrupted parameter byte. The call advances the host-side job that checks spikingformer parameters behavior independently with Python assertions.

Line 69: `def test_rejects_overlapping_section_metadata_without_hash_checks(self) -> None:` This starts function test_rejects_overlapping_section_metadata_without_hash_checks. Its indented body performs test rejects overlapping section metadata without hash checks as part of the file that checks spikingformer parameters behavior independently with Python assertions; it runs only when called.

Line 70: `with tempfile.TemporaryDirectory() as temporary:` This opens a managed resource scope for 'tempfile.TemporaryDirectory() as temporary' so files, tracing, or temporary state are finalized even if the function test_rejects_overlappin which handles test rejects overlapping section metadata without hash checks raises an error.

Line 71: `directory = Path(temporary)` This assigns 'Path(temporary)' to 'directory ' in host memory. Here directory means the value named 'directory' in this block. The important operands are Path: the value named 'path' in this block; temporary: the value named 'temporary' in this block. Context: the function test_rejects_overlapping_section_metadata_w which handles test rejects overlapping section metadata without hash checks.

Line 72: `manifest_path = self._write_archive(directory)` This assigns 'self._write_archive(directory)' to 'manifest_path ' in host memory. Here manifest_path means the value named 'manifest path' in this block. The important operands are _write_archive: the value named 'write archive' in this block; directory: the value named 'directory' in this block. Context: the function test_rejects_overlapping_section_metadata_without_hash_checks, which handles test rejects overlapping section metadata without hash checks.

Line 73: `manifest = json.loads(manifest_path.read_text(encoding="ascii"))` This assigns 'json.loads(manifest_path.rea to 'manifest ' in host memory. Here manifest means the value named 'manifest' in this block. The important operands are json: the value named 'json' in this block; loads: the value named 'loads' in this block; manifest_path: the value named 'manifest path' in this block. Context: the function test_rejects_overlapping_section_metadata_without_hash_checks, which handles test rejects overlapping section metadata without hash checks.

Line 74: `manifest["sections"][1]["offset"] = manifest["sections"][0]["offset"]` Inside the function test_rejects_ove which handles test rejects overlapping section metadata without hash checks, this statement advances the host implementation that checks spikingformer parameters behavior independently with Python assertions. The important operands are manifest: the value named 'manifest' in this block; sections: the value named 'sections' in this block; offset: the value named 'offset' in this block.

Line 75: `manifest_path.write_text(json.dumps(manifest), encoding="ascii")` This calls 'manifest_path.write_text' with 'json.dumps(manifest), encoding="ascii"' inside the function test_rejects_overlapping_section_metadata_without_hash_che which handles test rejects overlapping section metadata without hash checks. The call advances the host-side job that checks spikingformer parameters behavior independently with Python assertions.

Line 76: `with self.assertRaisesRegex(ValueError, "overlaps"):` This opens a managed resource scope for ‘self.assertRaisesRegex(ValueError, "overlaps")‘ so files, tracing, or temporary state are finalized even if the function test_rejects_overlapping_section_metadata_without_hash_checks, which handles test rejects overlapping section metadata without hash checks raises an error.

Line 77: `SpikingformerParameterArchive(manifest_path, verify_hashes=False)` This calls ‘SpikingformerParameterArchive‘ with ‘manifest_path, verify_hashes=False‘ inside the function test_rejects_overlapping_section_metadata_witho which handles test rejects overlapping section metadata without hash checks. The call advances the host-side job that checks spikingformer parameters behavior independently with Python assertions.

Line 80: `if __name__ == "__main__":` This executes the following indented host-code branch only when ‘___name___ == "___main___"‘ is true. The important operands are ___name___: the value named ’name’ in this block; ___main___: the value named ’main’ in this block. Context: the file whose role is to checks spikingformer parameters behavior independently with Python assertions.

Line 81: `unittest.main()` This calls ‘unittest.main‘ with “ inside the file whose role is to checks spikingformer parameters behavior independently with Python assertions. The call advances the host-side job that checks spikingformer parameters behavior independently with Python assertions.

74 tests/test_spikingformer_reference.py

Role in the complete system: checks spikingformer reference behavior independently with Python assertions.

74.1 Beginner architecture map

Dataflow responsibility This file's end-to-end responsibility is to checks spikingformer reference behavior independently with Python assertions.

Where it runs This is sequential host software. Python objects live in CPU memory; they become FPGA work only when the compiler packs a command or payload and the PYNQ driver transfers those bytes through AXI DMA or AXI-Lite.

Public structure Classes: MultiStepLIFTests, BatchNormFoldingTests, ReferenceGraphTests. Functions: test_hard_reset_sequ test_fixed_point_lif_matches_rtl_step_order, test_attention_threshold_is_inclusive, test_conv2d_fold_matches_eval_g test_conv1d_fold_matches_eval_graph, test_small_graph_shape_and_binary_observations, test_calibration_observer_a test_hardware_emulation_quantizes_all_learned_operators, observer. Each function annotation below names its enclosing function so an array operation is tied to the model, compiler, driver, test, or report phase that uses it.

Numeric and failure boundary Shapes, signedness, byte order, scaling, and saturation are part of the hardware contract. Validation exceptions are functional safety checks: rejecting malformed input before DMA is different from silently clipping, reshaping, or continuing with an incompatible artifact.

The important operands are quantize_cifar_input_u8: the value named 'quantize cifar input u8' in this block. Read together, the complete operation is: This imports the named Python API so the file whose role is to checks spikingformer reference behavior independently with Python assertions can use it explicitly. Imports execute on the host processor and create no FPGA hardware.

Line 19: `)` This is continuation line 6 of the 6-line logical statement that begins at source line 14. Its exact fragment is ')'. The expression is a literal or structural operator and has no hidden software state. Read together, the complete operation is: This imports the named Python API so the file whose role is to checks spikingformer reference behavior independently with Python assertions can use it explicitly. Imports execute on the host processor and create no FPGA hardware.

Line 22: `class MultiStepLIFTests(unittest.TestCase):` This defines class MultiStepLIFTests, which groups data and methods for multi step liftests. Instances exist in host memory and organize the flow that checks spikingformer reference behavior independently with Python assertions.

Line 23: `def test_hard_reset_sequence(self) -> None:` This starts function test_hard_reset_sequence. Its indented body performs test hard reset sequence as part of the file that checks spikingformer reference behavior independently with Python assertions; it runs only when called.

Line 24: `neuron = MultiStepHardResetLIF(tau=2.0, threshold=1.0)` This assigns ‘MultiStepHardResetLIF(tau=2.0, threshold=1.0)‘ to ‘neuron ‘ in host memory. Here neuron means the value named ’neuron’ in this block. The important operands are MultiStepHardResetLIF: the value named ’multi step hard reset lif’ in this block; tau: the value named ’tau’ in this block; threshold: the membrane level at which a neuron emits a spike. Context: the function test_hard_reset_sequence, which handles test hard reset sequence.

Line 25: `sequence = torch.tensor([[1.0], [1.0], [1.0], [2.0], [1.0]])` This assigns ‘torch.tensor([[1.0], [1.0], [1.0], [2.0], [1.0]])‘ to ‘sequence ‘ in host memory. Here sequence means the value named ’sequence’ in this block. The important operands are torch: the value named ’torch’ in this block; tensor: the value named ’tensor’ in this block. Context: the function test_hard_reset_sequence, which handles test hard reset sequence.

Line 26: `expected = torch.tensor([[0.0], [0.0], [0.0], [1.0], [0.0]])` This assigns ‘torch.tensor([[0.0], [0.0], [0.0], [1.0], [0.0]])‘ to ‘expected ‘ in host memory. Here expected means the value named ’expected’ in this block. The important operands are torch: the value named ’torch’ in this block; tensor: the value named ’tensor’ in this block. Context: the function test_hard_reset_sequence, which handles test hard reset sequence.

Line 27: `torch.testing.assert_close(neuron(sequence), expected)` This calls ‘torch.testing.assert_close‘ with ‘neuron(sequence), expected‘ inside the function test_hard_reset_sequence, which handles test hard reset sequence. The call advances the host-side job that checks spikingformer reference behavior independently with Python assertions.

Line 29: `def test_fixed_point_lif_matches_rtl_step_order(self) -> None:` This starts function test_fixed_point_lif_m
Its indented body performs test fixed point lif matches rtl step order as part of the file that checks spikingformer reference behavior independently with Python assertions; it runs only when called.

Line 30: `neuron = FixedPointHardResetLIF(threshold=1.0, fractional_bits=4)` This assigns ‘FixedPointHardResetLIF(t
fractional_bits=4)‘ to ‘neuron ‘ in host memory. Here neuron means the value named ’neuron’ in this block. The important operands are FixedPointHardResetLIF: the value named ’fixed point hard reset lif’ in this block; threshold: the membrane level at which a neuron emits a spike; fractional_bits: the value named ’fractional bits’ in this block. Context: the function test_fixed_point_lif_matches_rtl_step_order, which handles test fixed point lif matches rtl step order.

Line 31: `sequence = torch.tensor([[1.0], [1.0], [1.0], [2.0], [1.0]])` This assigns ‘torch.tensor([[1.0], [1.0], [1.0], [2.0], [1.0]])‘ to ‘sequence ‘ in host memory. Here sequence means the value named ’sequence’ in this block. The important operands are torch: the value named ’torch’ in this block; tensor: the value named ’tensor’ in this block. Context: the function test_fixed_point_lif_matches_rtl_step_order, which handles test fixed point lif matches rtl step order.

Line 32: `expected = torch.tensor([[0.0], [0.0], [0.0], [1.0], [0.0]])` This assigns ‘torch.tensor([[0.0], [0.0], [0.0], [1.0], [0.0]])‘ to ‘expected ‘ in host memory. Here expected means the value named ’expected’ in this block. The important operands are torch: the value named ’torch’ in this block; tensor: the value named ’tensor’ in this block. Context: the function test_fixed_point_lif_matches_rtl_step_order, which handles test fixed point lif matches rtl step order.

Line 33: `torch.testing.assert_close(neuron(sequence), expected)` This calls ‘torch.testing.assert_close‘ with ‘neuron(sequence), expected‘ inside the function test_fixed_point_lif_matches_rtl_step_order, which handles test fixed point lif matches rtl step order. The call advances the host-side job that checks spikingformer reference behavior independently with Python assertions.

Line 35: `def test_attention_threshold_is_inclusive(self) -> None:` This starts function test_attention_threshold_is_i
Its indented body performs test attention threshold is inclusive as part of the file that checks spikingformer reference behavior independently with Python assertions; it runs only when called.

Line 36: `neuron = MultiStepHardResetLIF(tau=2.0, threshold=0.5)` This assigns ‘MultiStepHardResetLIF(tau=2.0, threshold=0.5)‘ to ‘neuron ‘ in host memory. Here neuron means the value named ’neuron’ in this block. The important operands are MultiStepHardResetLIF: the value named ’multi step hard reset lif’ in this block; tau: the value

named 'tau' in this block; threshold: the membrane level at which a neuron emits a spike. Context: the function test_attention_threshold_is_inclusive, which handles test attention threshold is inclusive.

Line 37: `sequence = torch.tensor([[1.0], [0.0]])` This assigns 'torch.tensor([[1.0], [0.0]])' to 'sequence ' in host memory. Here sequence means the value named 'sequence' in this block. The important operands are torch: the value named 'torch' in this block; tensor: the value named 'tensor' in this block. Context: the function test_attention_threshold_is_inclus which handles test attention threshold is inclusive.

Line 38: `expected = torch.tensor([[1.0], [0.0]])` This assigns 'torch.tensor([[1.0], [0.0]])' to 'expected ' in host memory. Here expected means the value named 'expected' in this block. The important operands are torch: the value named 'torch' in this block; tensor: the value named 'tensor' in this block. Context: the function test_attention_threshold_is_inclus which handles test attention threshold is inclusive.

Line 39: `torch.testing.assert_close(neuron(sequence), expected)` This calls 'torch.testing.assert_close' with 'neuron(sequence), expected' inside the function test_attention_threshold_is_inclusive, which handles test attention threshold is inclusive. The call advances the host-side job that checks spikingformer reference behavior independently with Python assertions.

Line 42: `class BatchNormFoldingTests(unittest.TestCase):` This defines class BatchNormFoldingTests, which groups data and methods for batch norm folding tests. Instances exist in host memory and organize the flow that checks spikingformer reference behavior independently with Python assertions.

Line 43: `def test_conv2d_fold_matches_eval_graph(self) -> None:` This starts function test_conv2d_fold_matches_eval Its indented body performs test conv2d fold matches eval graph as part of the file that checks spikingformer reference behavior independently with Python assertions; it runs only when called.

Line 44: `torch.manual_seed(7)` This calls 'torch.manual_seed' with '7' inside the function test_conv2d_fold_matches_eval_gr which handles test conv2d fold matches eval graph. The call advances the host-side job that checks spikingformer reference behavior independently with Python assertions.

Line 45: `convolution = nn.Conv2d(3, 5, kernel_size=3, padding=1, bias=False)` This assigns 'nn.Conv2d(3, 5, kernel_size=3, padding=1, bias=False)' to 'convolution ' in host memory. Here convolution means the value named 'convolution' in this block. The important operands are nn: the value named 'nn' in this block; Conv2d: the value named 'conv2d' in this block; kernel_size: the value named 'kernel size' in this block. Context: the function test_conv2d_fold_matches_eva which handles test conv2d fold matches eval graph.

Line 46: `batch_norm = nn.BatchNorm2d(5)` This assigns 'nn.BatchNorm2d(5)' to 'batch_norm ' in host memory. Here batch_norm means the value named 'batch norm' in this block. The important operands are nn: the value named 'nn' in this block; BatchNorm2d: the value named 'batch norm2d' in this block. Context: the function test_conv2d_fold_matches_eval_graph, which handles test conv2d fold matches eval graph.

Line 47: `batch_norm.running_mean.copy_(torch.randn(5))` This calls 'batch_norm.running_mean.copy_' with 'torch.randn(5)' inside the function test_conv2d_fold_matches_eval_graph, which handles test conv2d fold matches eval graph. The call advances the host-side job that checks spikingformer reference behavior independently with Python assertions.

Line 48: `batch_norm.running_var.copy_(torch.rand(5) + 0.2)` This calls 'batch_norm.running_var.copy_' with 'torch.rand(5) + 0.2' inside the function test_conv2d_fold_matches_eval_graph, which handles test conv2d fold matches eval graph. The call advances the host-side job that checks spikingformer reference behavior independently with Python assertions.

Line 49: `batch_norm.weight.data.copy_(torch.randn(5))` This calls 'batch_norm.weight.data.copy_' with 'torch.randn(5)' inside the function test_conv2d_fold_matches_eval_graph, which handles test conv2d fold matches eval graph. The call advances the host-side job that checks spikingformer reference behavior independently with Python assertions.

Line 50: `batch_norm.bias.data.copy_(torch.randn(5))` This calls ‘batch_norm.bias.data.copy_‘ with ‘torch.randn(5)‘ inside the function test_conv2d_fold_matches_eval_graph, which handles test conv2d fold matches eval graph. The call advances the host-side job that checks spikingformer reference behavior independently with Python assertions.

Line 51: `convolution.eval()` This calls ‘convolution.eval‘ with “ inside the function test_conv2d_fold_matches_eval_graph, which handles test conv2d fold matches eval graph. The call advances the host-side job that checks spikingformer reference behavior independently with Python assertions.

Line 52: `batch_norm.eval()` This calls ‘batch_norm.eval‘ with “ inside the function test_conv2d_fold_matches_eval_graph, which handles test conv2d fold matches eval graph. The call advances the host-side job that checks spikingformer reference behavior independently with Python assertions.

Line 53: `image = torch.randn(2, 3, 7, 7)` This assigns ‘torch.randn(2, 3, 7, 7)‘ to ‘image ‘ in host memory. Here image means the value named ’image’ in this block. The important operands are torch: the value named ’torch’ in this block; randn: the value named ’randn’ in this block. Context: the function test_conv2d_fold_matches_eval_graph, which handles test conv2d fold matches eval graph.

Line 55: `folded_weight, folded_bias = fold_batch_norm(convolution, batch_norm)` This assigns ‘fold_batch_norm(con batch_norm)‘ to ‘folded_weight, folded_bias ‘ in host memory. Here folded_weight means a learned coefficient multiplied by an activation. The important operands are fold_batch_norm: the value named ’fold batch norm’ in this block; convolution: the value named ’convolution’ in this block; batch_norm: the value named ’batch norm’ in this block. Context: the function test_conv2d_fold_matches_eval_graph, which handles test conv2d fold matches eval graph.

Line 56: `folded = nn.Conv2d(3, 5, kernel_size=3, padding=1, bias=True)` This assigns ‘nn.Conv2d(3, 5, kernel_size=3, padding=1, bias=True)‘ to ‘folded ‘ in host memory. Here folded means the value named ’folded’ in this block. The important operands are nn: the value named ’nn’ in this block; Conv2d: the value named ’conv2d’ in this block; kernel_size: the value named ’kernel size’ in this block. Context: the function test_conv2d_fold_matches_eval_graph, which handles test conv2d fold matches eval graph.

Line 57: `folded.weight.data.copy_(folded_weight)` This calls ‘folded.weight.data.copy_‘ with ‘folded_weight‘ inside the function test_conv2d_fold_matches_eval_graph, which handles test conv2d fold matches eval graph. The call advances the host-side job that checks spikingformer reference behavior independently with Python assertions.

Line 58: `folded.bias.data.copy_(folded_bias)` This calls ‘folded.bias.data.copy_‘ with ‘folded_bias‘ inside the function test_conv2d_fold_matches_eval_graph, which handles test conv2d fold matches eval graph. The call advances the host-side job that checks spikingformer reference behavior independently with Python assertions.

Line 59: `folded.eval()` This calls ‘folded.eval‘ with “ inside the function test_conv2d_fold_matches_eval_graph, which handles test conv2d fold matches eval graph. The call advances the host-side job that checks spikingformer reference behavior independently with Python assertions.

Line 61: `torch.testing.assert_close(` This statement continues through source line 62; the explanation uses the complete expression rather than only the first visual fragment. Line 69: `batch_norm.running_var.copy_(torch.rand(6) + 0.2)` This calls ‘batch_norm.running_var.copy_‘ with ‘torch.rand(6) + 0.2‘ inside the function test_conv1d_fold_matches_eval_graph, which handles test conv1d fold matches eval graph. The call advances the host-side job that checks spikingformer reference behavior independently with Python assertions.

Line 70: `convolution.eval()` This calls ‘convolution.eval‘ with “ inside the function test_conv1d_fold_matches_eval_graph, which handles test conv1d fold matches eval graph. The call advances the host-side job that checks spikingformer reference behavior independently with Python assertions.

Line 71: `batch_norm.eval()` This calls ‘batch_norm.eval‘ with “ inside the function test_conv1d_fold_matches_eval_graph, which handles test conv1d fold matches eval graph. The call advances the host-side job that checks spikingformer reference behavior independently with Python assertions.

Line 72: `values = torch.randn(3, 4, 9)` This assigns ‘torch.randn(3, 4, 9)‘ to ‘values ‘ in host memory. Here values means the value named ’values’ in this block. The important operands are torch: the value named ’torch’ in this block; randn: the value named ’randn’ in this block. Context: the function test_conv1d_fold_matches_eval_graph, which handles test conv1d fold matches eval graph.

Line 74: `folded_weight, folded_bias = fold_batch_norm(convolution, batch_norm)` This assigns ‘fold_batch_norm(con
batch_norm)‘ to ‘folded_weight, folded_bias ‘ in host memory. Here folded_weight means a learned coefficient multiplied by an activation. The important operands are fold_batch_norm: the value named ’fold batch norm’ in this block; convolution: the value named ’convolution’ in this block; batch_norm: the value named ’batch norm’ in this block. Context: the function test_conv1d_fold_matches_eval_graph, which handles test conv1d fold matches eval graph.

Line 75: `folded = nn.Conv1d(4, 6, kernel_size=1, bias=True)` This assigns ‘nn.Conv1d(4, 6, kernel_size=1, bias=True)‘ to ‘folded ‘ in host memory. Here folded means the value named ’folded’ in this block. The important operands are nn: the value named ’nn’ in this block; Conv1d: the value named ’conv1d’ in this block; kernel_size: the value named ’kernel size’ in this block. Context: the function test_conv1d_fold_matches_eval_graph, which handles test conv1d fold matches eval graph.

Line 76: `folded.weight.data.copy_(folded_weight)` This calls ‘folded.weight.data.copy_‘ with ‘folded_weight‘ inside the function test_conv1d_fold_matches_eval_graph, which handles test conv1d fold matches eval graph. The call advances the host-side job that checks spikingformer reference behavior independently with Python assertions.

Line 77: `folded.bias.data.copy_(folded_bias)` This calls ‘folded.bias.data.copy_‘ with ‘folded_bias‘ inside the function test_conv1d_fold_matches_eval_graph, which handles test conv1d fold matches eval graph. The call advances the host-side job that checks spikingformer reference behavior independently with Python assertions.

Line 78: `folded.eval()` This calls ‘folded.eval‘ with “ inside the function test_conv1d_fold_matches_eval_graph, which handles test conv1d fold matches eval graph. The call advances the host-side job that checks spikingformer reference behavior independently with Python assertions.

Line 80: `torch.testing.assert_close(` This statement continues through source line 81; the explanation uses the complete expression rather than only the first visual fragment. This calls ‘torch.testing.assert_close‘ with ‘ folded(values), batch_norm(convolution(values)), rtol=2e-5, atol=2e-6‘ inside the function test_conv1d_fold_matches_eval_graph, which handles test conv1d fold matches eval graph. The call advances the host-side job that checks spikingformer reference behavior independently with Python assertions.

Line 81: `folded(values), batch_norm(convolution(values)), rtol=2e-5, atol=2e-6)` This is continuation line 2 of the 2-line logical statement that begins at source line 80. Its exact fragment is ‘folded(values), batch_norm(convolution(values)), rtol=2e-5, atol=2e-6)‘. The important operands are folded: the value named ’folded’ in this block; values: the value named ’values’ in this block; batch_norm: the value named ’batch norm’ in this block. Read together, the complete operation is: This calls ‘torch.testing.assert_close‘ with ‘ folded(values), batch_norm(convolution(values)), rtol=2e-5, atol=2e-6‘ inside the function test_conv1d_fold_matches_eval_graph, which handles test conv1d fold matches eval graph. The call advances the host-side job that checks spikingformer reference behavior independently with Python assertions.

Line 84: `class ReferenceGraphTests(unittest.TestCase):` This defines class ReferenceGraphTests, which groups data and methods for reference graph tests. Instances exist in host memory and organize the flow that checks spikingformer reference behavior independently with Python assertions.

Line 85: `def test_small_graph_shape_and_binary_observations(self) -> None:` This starts function test_small_graph_s Its indented body performs test small graph shape and binary observations as part of the file that checks spikingformer reference behavior independently with Python assertions; it runs only when called.

Line 86: `torch.manual_seed(13)` This calls ‘torch.manual_seed‘ with ‘13‘ inside the function test_small_graph_shape_and_bi which handles test small graph shape and binary observations. The call advances the host-side job that checks spikingformer reference behavior independently with Python assertions.

Line 87: `model = Spikingformer(` This statement continues through source line 95; the explanation uses the complete expression rather than only the first visual fragment. This assigns ‘Spikingformer(time_steps=2, input_channels=3, classes=10, embed_dim=24, heads=3, depth=1, mlp_ratio=2,).eval()‘ to ‘model ‘ in host memory. Here model means the value named ’model’ in this block. The important operands are Spikingformer: the value named ’spikingformer’ in this block; time_steps: the value named ’time steps’ in this block; input_channels: the value named ’input channels’ in this block. Context: the function test_small_graph_shape_and_binary_observations, which handles test small graph shape and binary observations.

Line 88: `time_steps=2,` This is continuation line 2 of the 9-line logical statement that begins at source line 87. Its exact fragment is ‘time_steps=2,‘. The important operands are time_steps: the value named ’time steps’ in this block. Read together, the complete operation is: This assigns ‘Spikingformer(time_steps=2, input_channels=3, classes=10, embed_dim=24, heads=3, depth=1, mlp_ratio=2,).eval()‘ to ‘model ‘ in host memory. Here model means the value named ’model’ in this block. The important operands are Spikingformer: the value named ’spikingformer’ in this block; time_steps: the value named ’time steps’ in this block; input_channels: the value named ’input channels’ in this block. Context: the function test_small_graph_shape_and_binary_observations, which handles test small graph shape and binary observations.

Line 89: `input_channels=3,` This is continuation line 3 of the 9-line logical statement that begins at source line 87. Its exact fragment is 'input_channels=3,'. The important operands are input_channels: the value named 'input channels' in this block. Read together, the complete operation is: This assigns 'Spikingformer(time_steps=2, input_channels=3, classes=10, embed_dim=24, heads=3, depth=1, mlp_ratio=2,).eval()' to 'model ' in host memory. Here model means the value named 'model' in this block. The important operands are Spikingformer: the value named 'spikingformer' in this block; time_steps: the value named 'time steps' in this block; input_channels: the value named 'input channels' in this block. Context: the function test_small_graph_shape_and_binary_observations, which handles test small graph shape and binary observations.

Line 90: `classes=10,` This is continuation line 4 of the 9-line logical statement that begins at source line 87. Its exact fragment is 'classes=10,'. The important operands are classes: the value named 'classes' in this block. Read together, the complete operation is: This assigns 'Spikingformer(time_steps=2, input_channels=3, classes=10, embed_dim=24, heads=3, depth=1, mlp_ratio=2,).eval()' to 'model ' in host memory. Here model means the value named 'model' in this block. The important operands are Spikingformer: the value named 'spikingformer' in this block; time_steps: the value named 'time steps' in this block; input_channels: the value named 'input channels' in this block. Context: the function test_small_graph_shape_and_binary_observations, which handles test small graph shape and binary observations.

Line 91: `embed_dim=24,` This is continuation line 5 of the 9-line logical statement that begins at source line 87. Its exact fragment is 'embed_dim=24,'. The important operands are embed_dim: the value named 'embed dim' in this block. Read together, the complete operation is: This assigns 'Spikingformer(time_steps=2, input_channels=3, classes=10, embed_dim=24, heads=3, depth=1, mlp_ratio=2,).eval()' to 'model ' in host memory. Here model means the value named 'model' in this block. The important operands are Spikingformer: the value named 'spikingformer' in this block; time_steps: the value named 'time steps' in this block; input_channels: the value named 'input channels' in this block. Context: the function test_small_graph_shape_and_binary_observations, which handles test small graph shape and binary observations.

Line 92: `heads=3,` This is continuation line 6 of the 9-line logical statement that begins at source line 87. Its exact fragment is 'heads=3,'. The important operands are heads: the value named 'heads' in this block. Read together, the complete operation is: This assigns 'Spikingformer(time_steps=2, input_channels=3, classes=10, embed_dim=24, heads=3, depth=1, mlp_ratio=2,).eval()' to 'model ' in host memory. Here model means the value named 'model' in this block. The important operands are Spikingformer: the value named 'spikingformer' in this block; time_steps: the value named 'time steps' in this block; input_channels: the value named 'input channels' in this block. Context: the function test_small_graph_shape_and_binary_observations, which handles test small graph shape and binary observations.

Line 93: `depth=1,` This is continuation line 7 of the 9-line logical statement that begins at source line 87. Its exact fragment is 'depth=1,'. The important operands are depth: the value named 'depth' in this block. Read together, the complete operation is: This assigns 'Spikingformer(time_steps=2, input_channels=3, classes=10, embed_dim=24, heads=3, depth=1, mlp_ratio=2,).eval()' to 'model ' in host memory. Here model means the value named 'model' in this block. The important operands are Spikingformer: the value named 'spikingformer' in this block; time_steps: the value named 'time steps' in this block; input_channels: the value named 'input channels' in this block. Context: the function test_small_graph_shape_and_binary_observations, which handles test small graph shape and binary observations.

Line 94: `mlp_ratio=2,` This is continuation line 8 of the 9-line logical statement that begins at source line 87. Its exact fragment is 'mlp_ratio=2,'. The important operands are mlp_ratio: the value named 'mlp ratio' in this block. Read together, the complete operation is: This assigns 'Spikingformer(time_steps=2, input_channels=3, classes=10, embed_dim=24, heads=3, depth=1, mlp_ratio=2,).eval()' to 'model ' in host memory. Here model means the value named 'model' in this block. The important operands are Spikingformer: the value named 'spikingformer' in this block; time_steps: the value named 'time steps' in this block; input_channels: the value named 'input channels' in this block. Context: the function test_small_graph_shape_and_binary_observations, which handles test small graph shape and binary observations.

Line 95: `).eval()` This is continuation line 9 of the 9-line logical statement that begins at source line 87. Its exact fragment is ').eval()'. The important operands are eval: the value named 'eval' in this block. Read together, the complete operation is: This assigns 'Spikingformer(time_steps=2, input_channels=3, classes=10, embed_dim=24, heads=3, depth=1, mlp_ratio=2,).eval()' to 'model ' in host memory. Here model means the value named 'model' in this block. The important operands are Spikingformer: the value named 'spikingformer' in this block; time_steps: the value

named 'time steps' in this block; input_channels: the value named 'input channels' in this block. Context: the function test_small_graph_shape_and_binary_observations, which handles test small graph shape and binary observations.

Line 96: `observed_spikes: list[torch.Tensor] = []` This assigns '[]' to 'observed_spikes' in host memory. Here observed_spikes means a binary event produced when a neuron crosses its threshold. The expression is a literal or structural operator and has no hidden software state. Context: the function test_small_graph_shape_and_binary_observations, which handles test small graph shape and binary observations.

Line 98: `def observer(_name: str, value: torch.Tensor, is_spike: bool) -> None:` This starts function observer. Its indented body performs observer as part of the file that checks spikingformer reference behavior independently with Python assertions; it runs only when called.

Line 99: `if is_spike:` This executes the following indented host-code branch only when 'is_spike' is true. The important operands are is_spike: a binary event produced when a neuron crosses its threshold. Context: the function observer, which handles observer.

Line 100: `observed_spikes.append(value.detach())` This calls 'observed_spikes.append' with 'value.detach()' inside the function observer, which handles observer. The call advances the host-side job that checks spikingformer reference behavior independently with Python assertions.

Line 102: `with torch.no_grad():` This opens a managed resource scope for 'torch.no_grad()' so files, tracing, or temporary state are finalized even if the function test_small_graph_shape_and_binary_observations, which handles test small graph shape and binary observations raises an error.

Line 103: `result = model(torch.randn(2, 3, 8, 8), observer=observer)` This assigns 'model(torch.randn(2, 3, 8, 8), observer=observer)' to 'result ' in host memory. Here result means the value named 'result' in this block. The important operands are model: the value named 'model' in this block; torch: the value named 'torch' in this block; randn: the value named 'randn' in this block. Context: the function test_small_graph_shape_and_binary_observations, which handles test small graph shape and binary observations.

Line 104: `self.assertEqual(tuple(result.shape), (2, 10))` This calls 'self.assertEqual' with 'tuple(result.shape), (2, 10)' inside the function test_small_graph_shape_and_binary_observations, which handles test small graph shape and binary observations. The call advances the host-side job that checks spikingformer reference behavior independently with Python assertions.

Line 105: `self.assertGreater(len(observed_spikes), 0)` This calls 'self.assertGreater' with 'len(observed_spikes), 0' inside the function test_small_graph_shape_and_binary_observations, which handles test small graph shape and binary observations. The call advances the host-side job that checks spikingformer reference behavior independently with Python assertions.

Line 106: `for spike in observed_spikes:` This iterates spike over 'observed_spikes'. Each iteration repeats the indented host operation, commonly once per layer, tile, timestep, or test case in the function test_small_graph_shape_and_binary_ob which handles test small graph shape and binary observations.

Line 107: `self.assertTrue(torch.all((spike == 0) | (spike == 1)).item())` This calls 'self.assertTrue' with 'torch.all((spike == 0) | (spike == 1)).item()' inside the function test_small_graph_shape_and_binary_observations, which handles test small graph shape and binary observations. The call advances the host-side job that checks spikingformer reference behavior independently with Python assertions.

Line 109: `def test_calibration_observer_aggregates_without_feature_storage(self) -> None:` This starts function test_calibration_observer_aggregates_without_feature_storage. Its indented body performs test calibration observer aggregates without feature storage as part of the file that checks spikingformer reference behavior independently with Python assertions; it runs only when called.

Line 110: `observer = CalibrationObserver()` This assigns ‘CalibrationObserver()‘ to ‘observer ‘ in host memory. Here observer means the value named ’observer’ in this block. The important operands are CalibrationObserver: the value named ’calibration observer’ in this block. Context: the function test_calibration_observer_aggregates_without_feature_storage, which handles test calibration observer aggregates without feature storage.

Line 111: `observer("analog", torch.tensor([[-1.0, 1.0], [2.0, 0.0]]), False)` This calls ‘observer‘ with ‘"analog", torch.tensor([[-1.0, 1.0], [2.0, 0.0]]), False‘ inside the function test_calibration_observer_aggregates_without_feature_sto which handles test calibration observer aggregates without feature storage. The call advances the host-side job that checks spikingformer reference behavior independently with Python assertions.

Line 112: `observer("analog", torch.tensor([[3.0, 1.0]]), False)` This calls ‘observer‘ with ‘"analog", torch.tensor([[3.0, 1.0]]), False‘ inside the function test_calibration_observer_aggregates_without_feature_storage, which handles test calibration observer aggregates without feature storage. The call advances the host-side job that checks spikingformer reference behavior independently with Python assertions.

Line 113: `report = observer.as_dict()["analog"]` This assigns ‘observer.as_dict()["analog"]‘ to ‘report ‘ in host memory. Here report means the value named ’report’ in this block. The important operands are observer: the value named ’observer’ in this block; as_dict: the value named ’as dict’ in this block; analog: the value named ’analog’ in this block. Context: the function test_calibration_observer_aggregates_without_feature_storage, which handles test calibration observer aggregates without feature storage.

Line 114: `self.assertEqual(report["elements"], 6)` This calls ‘self.assertEqual‘ with ‘report["elements"], 6‘ inside the function test_calibration_observer_aggregates_without_feature_storage, which handles test calibration observer aggregates without feature storage. The call advances the host-side job that checks spikingformer reference behavior independently with Python assertions.

Line 115: `self.assertEqual(report["batches"], 2)` This calls ‘self.assertEqual‘ with ‘report["batches"], 2‘ inside the function test_calibration_observer_aggregates_without_feature_storage, which handles test calibration observer aggregates without feature storage. The call advances the host-side job that checks spikingformer reference behavior independently with Python assertions.

Line 116: `self.assertEqual(report["minimum"], -1.0)` This calls ‘self.assertEqual‘ with ‘report["minimum"], -1.0‘ inside the function test_calibration_observer_aggregates_without_feature_storage, which handles test calibration observer aggregates without feature storage. The call advances the host-side job that checks spikingformer reference behavior independently with Python assertions.

Line 117: `self.assertEqual(report["maximum"], 3.0)` This calls ‘self.assertEqual‘ with ‘report["maximum"], 3.0‘ inside the function test_calibration_observer_aggregates_without_feature_storage, which handles test calibration observer aggregates without feature storage. The call advances the host-side job that checks spikingformer reference behavior independently with Python assertions.

Line 118: `self.assertAlmostEqual(report["mean"], 1.0)` This calls ‘self.assertAlmostEqual‘ with ‘report["mean"], 1.0‘ inside the function test_calibration_observer_aggregates_without_feature_storage, which handles test calibration observer aggregates without feature storage. The call advances the host-side job that checks spikingformer reference behavior independently with Python assertions.

Line 119: `self.assertAlmostEqual(report["nonzero_fraction"], 5.0 / 6.0)` This calls ‘self.assertAlmostEqual‘ with ‘report["nonzero_fraction"], 5.0 / 6.0‘ inside the function test_calibration_observer_aggregates_without_feature_storage, which handles test calibration observer aggregates without feature storage. The call advances the host-side job that checks spikingformer reference behavior independently with Python assertions.

Line 121: `def test_hardware_emulation_quantizes_all_learned_operators(self) -> None:` This starts function test_hardware_emulation_quantizes_all_learned_operators. Its indented body performs test hardware emulation quantizes all learned operators as part of the file that checks spikingformer reference behavior independently with Python assertions; it runs only when called.

Line 122: `torch.manual_seed(17)` This calls ‘torch.manual_seed‘ with ‘17‘ inside the function test_hardware_emulation_quant which handles test hardware emulation quantizes all learned operators. The call advances the host-side job that checks spikingformer reference behavior independently with Python assertions.

Line 123: `model = Spikingformer(` This statement continues through source line 131; the explanation uses the complete expression rather than only the first visual fragment. This assigns ‘Spikingformer(time_steps=2, input_channels=3, classes=10, embed_dim=24, heads=3, depth=1, mlp_ratio=2,).eval()‘ to ‘model ‘ in host memory. Here model means the value named ’model’ in this block. The important operands are Spikingformer: the value named ’spikingformer’ in this block; time_steps: the value named ’time steps’ in this block; input_channels: the value named ’input channels’ in this block. Context: the function test_hardware_emulation_quantizes_all_learned_operators, which handles test hardware emulation quantizes all learned operators.

Line 124: `time_steps=2,` This is continuation line 2 of the 9-line logical statement that begins at source line 123. Its exact fragment is ‘time_steps=2,‘. The important operands are time_steps: the value named ’time steps’ in this block. Read together, the complete operation is: This assigns ‘Spikingformer(time_steps=2, input_channels=3, classes=10, embed_dim=24, heads=3, depth=1, mlp_ratio=2,).eval()‘ to ‘model ‘ in host memory. Here model means the value named ’model’ in this block. The important operands are Spikingformer: the value named ’spikingformer’ in this block; time_steps: the value named ’time steps’ in this block; input_channels: the value named ’input channels’ in this block. Context: the function test_hardware_emulation_quantizes_all_learned_operators, which handles test hardware emulation quantizes all learned operators.

Line 125: `input_channels=3,` This is continuation line 3 of the 9-line logical statement that begins at source line 123. Its exact fragment is ‘input_channels=3,‘. The important operands are input_channels: the value named ’input channels’ in this block. Read together, the complete operation is: This assigns ‘Spikingformer(time_steps=2, input_channels=3, classes=10, embed_dim=24, heads=3, depth=1, mlp_ratio=2,).eval()‘ to ‘model ‘ in host memory. Here model means the value named ’model’ in this block. The important operands are Spikingformer: the value named ’spikingformer’ in this block; time_steps: the value named ’time steps’ in this block; input_channels: the value named ’input channels’ in this block. Context: the function test_hardware_emulation_quantizes_all_learned_operators, which handles test hardware emulation quantizes all learned operators.

Line 126: `classes=10,` This is continuation line 4 of the 9-line logical statement that begins at source line 123. Its exact fragment is ‘classes=10,‘. The important operands are classes: the value named ’classes’ in this block. Read together, the complete operation is: This assigns ‘Spikingformer(time_steps=2, input_channels=3, classes=10, embed_dim=24, heads=3, depth=1, mlp_ratio=2,).eval()‘ to ‘model ‘ in host memory. Here model means the value named ’model’ in this block. The important operands are Spikingformer: the value named ’spikingformer’ in this block; time_steps: the value named ’time steps’ in this block; input_channels: the value named ’input channels’ in this block. Context: the function test_hardware_emulation_quantizes_all_learned_operators, which handles test hardware emulation quantizes all learned operators.

Line 127: `embed_dim=24,` This is continuation line 5 of the 9-line logical statement that begins at source line 123. Its exact fragment is ‘embed_dim=24,‘. The important operands are embed_dim: the value named ’embed dim’ in this block. Read together, the complete operation is: This assigns ‘Spikingformer(time_steps=2, input_channels=3, classes=10, embed_dim=24, heads=3, depth=1, mlp_ratio=2,).eval()‘ to ‘model ‘ in host memory. Here model means the value named ’model’ in this block. The important operands are Spikingformer: the value named ’spikingformer’ in this block; time_steps: the value named ’time steps’ in this block; input_channels: the value named ’input channels’ in this block. Context: the function test_hardware_emulation_quantizes_all_learned_operators, which handles test hardware emulation quantizes all learned operators.

Line 128: `heads=3,` This is continuation line 6 of the 9-line logical statement that begins at source line 123. Its exact fragment is ‘heads=3,‘. The important operands are heads: the value named ’heads’ in this block. Read together, the complete operation is: This assigns ‘Spikingformer(time_steps=2, input_channels=3, classes=10, embed_dim=24, heads=3, depth=1, mlp_ratio=2,).eval()‘ to ‘model ‘ in host memory. Here model means the value named ’model’ in this block. The important operands are Spikingformer: the value named ’spikingformer’ in this block; time_steps: the value named ’time steps’ in this block; input_channels: the value named ’input channels’ in this block. Context: the function test_hardware_emulation_quantizes_all_learned_operators, which handles test hardware emulation quantizes all learned operators.

Line 129: `depth=1,` This is continuation line 7 of the 9-line logical statement that begins at source line 123. Its exact fragment is 'depth=1,'. The important operands are depth: the value named 'depth' in this block. Read together, the complete operation is: This assigns 'Spikingformer(time_steps=2, input_channels=3, classes=10, embed_dim=24, heads=3, depth=1, mlp_ratio=2,).eval()' to 'model ' in host memory. Here model means the value named 'model' in this block. The important operands are Spikingformer: the value named 'spikingformer' in this block; time_steps: the value named 'time steps' in this block; input_channels: the value named 'input channels' in this block. Context: the function test_hardware_emulation_quantizes_all_learned_operators, which handles test hardware emulation quantizes all learned operators.

Line 130: `mlp_ratio=2,` This is continuation line 8 of the 9-line logical statement that begins at source line 123. Its exact fragment is 'mlp_ratio=2,'. The important operands are mlp_ratio: the value named 'mlp ratio' in this block. Read together, the complete operation is: This assigns 'Spikingformer(time_steps=2, input_channels=3, classes=10, embed_dim=24, heads=3, depth=1, mlp_ratio=2,).eval()' to 'model ' in host memory. Here model means the value named 'model' in this block. The important operands are Spikingformer: the value named 'spikingformer' in this block; time_steps: the value named 'time steps' in this block; input_channels: the value named 'input channels' in this block. Context: the function test_hardware_emulation_quantizes_all_learned_operators, which handles test hardware emulation quantizes all learned operators.

Line 131: `).eval()` This is continuation line 9 of the 9-line logical statement that begins at source line 123. Its exact fragment is ').eval()'. The important operands are eval: the value named 'eval' in this block. Read together, the complete operation is: This assigns 'Spikingformer(time_steps=2, input_channels=3, classes=10, embed_dim=24, heads=3, depth=1, mlp_ratio=2,).eval()' to 'model ' in host memory. Here model means the value named 'model' in this block. The important operands are Spikingformer: the value named 'spikingformer' in this block; time_steps: the value named 'time steps' in this block; input_channels: the value named 'input channels' in this block. Context: the function test_hardware_emulation_quantizes_all_learned_operators, which handles test hardware emulation quantizes all learned operators.

Line 132: `quantized, report = prepare_hardware_emulation(` This statement continues through source line 133; the explanation uses the complete expression rather than only the first visual fragment. This assigns 'prepare_hardware_emulation(model, fractional_bits=8, weight_granularity="tensor")' to 'quantized, report ' in host memory. Here quantized means the value named 'quantized' in this block. The important operands are prepare_hardware_emulation: the value named 'prepare hardware emulation' in this block; model: the value named 'model' in this block; fractional_bits: the value named 'fractional bits' in this block. Context: the function test_hardware_emulation_quantizes_all_learned_operators, which handles test hardware emulation quantizes all learned operators.

Line 133: `model, fractional_bits=8, weight_granularity="tensor")` This is continuation line 2 of the 2-line logical statement that begins at source line 132. Its exact fragment is 'model, fractional_bits=8, weight_granularity="tensor")'. The important operands are model: the value named 'model' in this block; fractional_bits: the value named 'fractional bits' in this block; weight_granularity: a learned coefficient multiplied by an activation. Read together, the complete operation is: This assigns 'prepare_hardware_emulation(model, fractional_bits=8, weight_granularity="tensor")' to 'quantized, report ' in host memory. Here quantized means the value named 'quantized' in this block. The important operands are prepare_hardware_emulation: the value named 'prepare hardware emulation' in this block; model: the value named 'model' in this block; fractional_bits: the value named 'fractional bits' in this block. Context: the function test_hardware_emulation_quantizes_all_learned_operators, which handles test hardware emulation quantizes all learned operators.

Line 134: `self.assertEqual(len(report.quantized_weights), 12)` This calls 'self.assertEqual' with 'len(report.quantized_w 12' inside the function test_hardware_emulation_quantizes_all_learned_operators, which handles test hardware emulation quantizes all learned operators. The call advances the host-side job that checks spikingformer reference behavior independently with Python assertions.

Line 135: `self.assertTrue(all(item.integer_minimum >= -127 for item in report.quantized_weights))` This calls 'self.assertTrue' with 'all(item.integer_minimum >= -127 for item in report.quantized_weights)' inside the function test_hardware_emulation_quantizes_all_learned_operators, which handles test hardware emulation quantizes all learned operators. The call advances the host-side job that checks spikingformer reference behavior independently with Python assertions.

Line 136: `self.assertTrue(all(item.integer_maximum <= 127 for item in report.quantized_weights))` This calls ‘self.assertTrue‘ with ‘all(item.integer_maximum <= 127 for item in report.quantized_weights)‘ inside the function test_hardware_emulation_quantizes_all_learned_operators, which handles test hardware emulation quantizes all learned operators. The call advances the host-side job that checks spikingformer reference behavior independently with Python assertions.

Line 137: `image = torch.randn(2, 3, 8, 8)` This assigns ‘torch.randn(2, 3, 8, 8)‘ to ‘image ‘ in host memory. Here image means the value named ’image’ in this block. The important operands are torch: the value named ’torch’ in this block; randn: the value named ’randn’ in this block. Context: the function test_hardware_emulation_quantizes_all_learned_opera which handles test hardware emulation quantizes all learned operators.

Line 138: `image_quantized, scale, zero_point = quantize_cifar_input_u8(image)` This assigns ‘quantize_cifar_input_ to ‘image_quantized, scale, zero_point ‘ in host memory. Here image_quantized means the value named ’image quantized’ in this block. The important operands are quantize_cifar_input_u8: the value named ’quantize cifar input u8’ in this block; image: the value named ’image’ in this block. Context: the function test_hardware_emulation_quantizes_all_learned_ which handles test hardware emulation quantizes all learned operators.

Line 139: `self.assertGreater(scale, 0.0)` This calls ‘self.assertGreater‘ with ‘scale, 0.0‘ inside the function test_hardware_emulation_quantizes_all_learned_operators, which handles test hardware emulation quantizes all learned operators. The call advances the host-side job that checks spikingformer reference behavior independently with Python assertions.

Line 140: `self.assertTrue(0 <= zero_point <= 255)` This calls ‘self.assertTrue‘ with ‘0 <= zero_point <= 255‘ inside the function test_hardware_emulation_quantizes_all_learned_operators, which handles test hardware emulation quantizes all learned operators. The call advances the host-side job that checks spikingformer reference behavior independently with Python assertions.

Line 141: `self.assertEqual(report.head_activation_scale, 0.125)` This calls ‘self.assertEqual‘ with ‘report.head_activati 0.125‘ inside the function test_hardware_emulation_quantizes_all_learned_operators, which handles test hardware emulation quantizes all learned operators. The call advances the host-side job that checks spikingformer reference behavior independently with Python assertions.

Line 142: `self.assertGreater(report.head_accumulator_scale, 0.0)` This calls ‘self.assertGreater‘ with ‘report.head_accumulator_scale, 0.0‘ inside the function test_hardware_emulation_quantizes_all_learned_operators, which handles test hardware emulation quantizes all learned operators. The call advances the host-side job that checks spikingformer reference behavior independently with Python assertions.

Line 143: `with torch.no_grad():` This opens a managed resource scope for ‘torch.no_grad()‘ so files, tracing, or temporary state are finalized even if the function test_hardware_emulation_quantizes_all_learned_operators, which handles test hardware emulation quantizes all learned operators raises an error.

Line 144: `result = quantized(image_quantized)` This assigns ‘quantized(image_quantized)‘ to ‘result ‘ in host memory. Here result means the value named ’result’ in this block. The important operands are quantized: the value named ’quantized’ in this block; image_quantized: the value named ’image quantized’ in this block. Context: the function test_hardware_emulation_quantizes_all_learned_operators, which handles test hardware emulation quantizes all learned operators.

Line 145: `self.assertEqual(tuple(result.shape), (2, 10))` This calls ‘self.assertEqual‘ with ‘tuple(result.shape), (2, 10)‘ inside the function test_hardware_emulation_quantizes_all_learned_operators, which handles test hardware emulation quantizes all learned operators. The call advances the host-side job that checks spikingformer reference behavior independently with Python assertions.

Line 146: `fixed = fake_fixed_point(torch.tensor([-1.1, 0.1, 1.1]), 4)` This assigns ‘fake_fixed_point(torch.tensor([-1.1, 0.1, 1.1]), 4)‘ to ‘fixed ‘ in host memory. Here fixed means the value named ’fixed’ in this block. The important operands are fake_fixed_point: the value named ’fake fixed point’ in this block; torch: the value named ’torch’ in this block; tensor: the value named ’tensor’ in this block. Context: the function test_hardware_emulation_quantizes_all_learned_oper which handles test hardware emulation quantizes all learned operators.

Line 147: `torch.testing.assert_close(fixed * 16, torch.round(fixed * 16))` This calls ‘torch.testing.assert_close‘ with ‘fixed * 16, torch.round(fixed * 16)‘ inside the function test_hardware_emulation_quantizes_all_learned_operators, which handles test hardware emulation quantizes all learned operators. The call advances the host-side job that checks spikingformer reference behavior independently with Python assertions.

Line 150: `if __name__ == "__main__":` This executes the following indented host-code branch only when ‘___name___ == "___main___"‘ is true. The important operands are ___name___: the value named ’name’ in this block; ___main___: the value named ’main’ in this block. Context: the file whose role is to checks spikingformer reference behavior independently with Python assertions.

Line 151: `unittest.main()` This calls ‘unittest.main‘ with “ inside the file whose role is to checks spikingformer reference behavior independently with Python assertions. The call advances the host-side job that checks spikingformer reference behavior independently with Python assertions.

75 tests/test_spikingformer_training_runtime.py

Role in the complete system: checks spikingformer training runtime behavior independently with Python assertions.

75.1 Beginner architecture map

Dataflow responsibility This file's end-to-end responsibility is to checks spikingformer training runtime behavior independently with Python assertions.

Where it runs This is sequential host software. Python objects live in CPU memory; they become FPGA work only when the compiler packs a command or payload and the PYNQ driver transfers those bytes through AXI DMA or AXI-Lite.

Public structure Classes: TinyParameterArchive, TinyFullGraphArchive, SpikingformerTrainingRuntimeTests. Functions: ___init___, projection_names, projection, head, ___init___, projection_names, projection, head, setUp, test_block_floating_shift_normalize_and_add_are_exact, test_projection_derivative_uses_exported_channel_scales, test_affine_backward_returns_exact_dx_dw_and_bias, test_hardware_softmax_and_batch_mean_cross_entropy_grad test_low_rate_bias_update_retains_q16_learning_rate_resolution, test_full_parameter_update_and_atomic_checkpoin test_complete_spikingformer_topology_forward_backward_and_update, add_conv, add_matrix. Each function annotation below names its enclosing function so an array operation is tied to the model, compiler, driver, test, or report phase that uses it.

Numeric and failure boundary Shapes, signedness, byte order, scaling, and saturation are part of the hardware contract. Validation exceptions are functional safety checks: rejecting malformed input before DMA is different from silently clipping, reshaping, or continuing with an incompatible artifact.

75.3 Line annotations

Line 1: `from __future__ import annotations` This imports the named Python API so the file whose role is to checks spikingformer training runtime behavior independently with Python assertions can use it explicitly. Imports execute on the host processor and create no FPGA hardware.

Line 3: `import tempfile` This imports the named Python API so the file whose role is to checks spikingformer training runtime behavior independently with Python assertions can use it explicitly. Imports execute on the host processor and create no FPGA hardware.

Line 4: `import unittest` This imports the named Python API so the file whose role is to checks spikingformer training runtime behavior independently with Python assertions can use it explicitly. Imports execute on the host processor and create no FPGA hardware.

Line 5: `from pathlib import Path` This imports the named Python API so the file whose role is to checks spikingformer training runtime behavior independently with Python assertions can use it explicitly. Imports execute on the host processor and create no FPGA hardware.

Line 7: `import numpy as np` This imports the named Python API so the file whose role is to checks spikingformer training runtime behavior independently with Python assertions can use it explicitly. Imports execute on the host processor and create no FPGA hardware.

Line 9: `from neuraedge_golden import round_shift_signed` This imports the named Python API so the file whose role is to checks spikingformer training runtime behavior independently with Python assertions can use it explicitly. Imports execute on the host processor and create no FPGA hardware.

Line 10: `from spikingformer_parameters import HeadParameters, ProjectionParameters` This imports the named Python API so the file whose role is to checks spikingformer training runtime behavior independently with Python assertions can use it explicitly. Imports execute on the host processor and create no FPGA hardware.

Line 11: `from spikingformer_training_runtime import (` This statement continues through source line 24; the explanation uses the complete expression rather than only the first visual fragment. This imports the named Python API so the file whose role is to checks spikingformer training runtime behavior independently with Python assertions can use it explicitly. Imports execute on the host processor and create no FPGA hardware.

Line 12: `BlockGradient,` This is continuation line 2 of the 14-line logical statement that begins at source line 11. Its exact fragment is 'BlockGradient,'. The important operands are BlockGradient: the signed loss derivative used to update a learned parameter. Read together, the complete operation is: This imports the named Python API so the file whose role is to checks spikingformer training runtime behavior independently with Python assertions can use it explicitly. Imports execute on the host processor and create no FPGA hardware.

Line 13: `MasterTensor,` This is continuation line 3 of the 14-line logical statement that begins at source line 11. Its exact fragment is 'MasterTensor,'. The important operands are MasterTensor: the value named 'master tensor' in this block. Read together, the complete operation is: This imports the named Python API so the file whose role is to checks spikingformer training runtime behavior independently with Python assertions can use it explicitly. Imports execute on the host processor and create no FPGA hardware.

Line 14: `ParameterGradient,` This is continuation line 4 of the 14-line logical statement that begins at source line 11. Its exact fragment is 'ParameterGradient,'. The important operands are ParameterGradient: the signed loss derivative used to update a learned parameter. Read together, the complete operation is: This imports the named Python API so the file whose role is to checks spikingformer training runtime behavior independently with Python assertions can use it explicitly. Imports execute on the host processor and create no FPGA hardware.

Line 15: `TrainableSpikingformerState,` This is continuation line 5 of the 14-line logical statement that begins at source line 11. Its exact fragment is 'TrainableSpikingformerState,'. The important operands are TrainableSpikingformerState: the finite-state-machine phase retained in flip-flops. Read together, the complete operation is: This imports the named Python API so the file whose role is to checks spikingformer training runtime behavior independently with Python assertions can use it explicitly. Imports execute on the host processor and create no FPGA hardware.

Line 16: `SpikingformerOnDeviceTrainer,` This is continuation line 6 of the 14-line logical statement that begins at source line 11. Its exact fragment is 'SpikingformerOnDeviceTrainer,'. The important operands are SpikingformerOnDeviceTrainer: the value named 'spikingformer on device trainer' in this block. Read together, the complete operation is: This imports the named Python API so the file whose role is to checks spikingformer training runtime behavior independently with Python assertions can use it explicitly. Imports execute on the host processor and create no FPGA hardware.

Line 17: `add_block_gradients,` This is continuation line 7 of the 14-line logical statement that begins at source line 11. Its exact fragment is 'add_block_gradients,'. The important operands are add_block_gradients: the signed loss derivative used to update a learned parameter. Read together, the complete operation is: This imports the named Python API so the file whose role is to checks spikingformer training runtime behavior independently with Python assertions can use it explicitly. Imports execute on the host processor and create no FPGA hardware.

Line 18: `backward_requantize_projection,` This is continuation line 8 of the 14-line logical statement that begins at source line 11. Its exact fragment is 'backward_requantize_projection,'. The important operands are backward_requantize_projection: the conversion of a wide accumulated result back into a bounded activation code. Read together, the complete operation is: This imports the named Python API so the file whose role is to checks spikingformer training runtime behavior independently with Python assertions can use it explicitly. Imports execute on the host processor and create no FPGA hardware.

Line 19: `execute_affine_backward_block,` This is continuation line 9 of the 14-line logical statement that begins at source line 11. Its exact fragment is 'execute_affine_backward_block,'. The important operands are execute_affine_backward_block: the value named 'execute affine backward block' in this block. Read together, the complete operation is: This imports the named Python API so the file whose role is to checks spikingformer training runtime behavior independently with Python assertions can use it explicitly. Imports execute on the host processor and create no FPGA hardware.

Line 20: `execute_cross_entropy_gradient_q15,` This is continuation line 10 of the 14-line logical statement that begins at source line 11. Its exact fragment is 'execute_cross_entropy_gradient_q15,'. The important operands are execute_cross_entropy_gradient_q15: the signed loss derivative used to update a learned parameter. Read together, the complete operation is: This imports the named Python API so the file whose role is to checks spikingformer training runtime behavior independently with Python assertions can use it explicitly. Imports execute on the host processor and create no FPGA hardware.

Line 21: `execute_power_of_two_scale,` This is continuation line 11 of the 14-line logical statement that begins at source line 11. Its exact fragment is 'execute_power_of_two_scale,'. The important operands are execute_power_of_two_scale: the real-value spacing represented by one quantized integer step. Read together, the complete operation is: This imports the named Python API so the file whose role is to checks spikingformer training runtime behavior independently with Python assertions can use it explicitly. Imports execute on the host processor and create no FPGA hardware.

Line 22: `execute_softmax_q15,` This is continuation line 12 of the 14-line logical statement that begins at source line 11. Its exact fragment is 'execute_softmax_q15,'. The important operands are execute_softmax_q15: the value named 'execute softmax q15' in this block. Read together, the complete operation is: This imports the named Python API so

the file whose role is to checks spikingformer training runtime behavior independently with Python assertions can use it explicitly. Imports execute on the host processor and create no FPGA hardware.

Line 23: `normalize_gradient_s16,` This is continuation line 13 of the 14-line logical statement that begins at source line 11. Its exact fragment is ‘normalize_gradient_s16,‘. The important operands are normalize_gradient_s16: the signed loss derivative used to update a learned parameter. Read together, the complete operation is: This imports the named Python API so the file whose role is to checks spikingformer training runtime behavior independently with Python assertions can use it explicitly. Imports execute on the host processor and create no FPGA hardware.

Line 24: `)` This is continuation line 14 of the 14-line logical statement that begins at source line 11. Its exact fragment is ‘)‘. The expression is a literal or structural operator and has no hidden software state. Read together, the complete operation is: This imports the named Python API so the file whose role is to checks spikingformer training runtime behavior independently with Python assertions can use it explicitly. Imports execute on the host processor and create no FPGA hardware.

Line 25: `from tests.test_neuraedge_training import FullTrainingEmulator` This imports the named Python API so the file whose role is to checks spikingformer training runtime behavior independently with Python assertions can use it explicitly. Imports execute on the host processor and create no FPGA hardware.

Line 28: `class TinyParameterArchive:` This defines class TinyParameterArchive, which groups data and methods for tiny parameter archive. Instances exist in host memory and organize the flow that checks spikingformer training runtime behavior independently with Python assertions.

Line 29: `def __init__(self) -> None:` This starts function ___init___. Its indented body performs init as part of the file that checks spikingformer training runtime behavior independently with Python assertions; it runs only when called.

Line 30: `self.manifest = {` This statement continues through source line 38; the explanation uses the complete expression rather than only the first visual fragment. This assigns ‘{ "binary_sha256": "a" * 64, "fixed_point": { "activation_fractional_bits": 10, "image_input_scale": 0.02, "image_input_zero_point": 123, "head_activation_scale": 0.125, }, }‘ to ‘self.manifest ‘ in host memory. Here manifest means the value named ’manifest’ in this block. The important operands are binary_sha256: the value named ’binary sha256’ in this block; a: the value named ’a’ in this block; fixed_point: the value named ’fixed point’ in this block. Context: the function ___init___, which handles init.

Line 31: `"binary_sha256": "a" * 64,` This is continuation line 2 of the 9-line logical statement that begins at source line 30. Its exact fragment is ‘"binary_sha256": "a" * 64,‘. The important operands are binary_sha256: the value named ’binary sha256’ in this block; a: the value named ’a’ in this block. Read together, the complete operation is: This assigns ‘{ "binary_sha256": "a" * 64, "fixed_point": { "activation_fractional_bits": 10, "image_input_scale": 0.02, "image_input_zero_point": 123, "head_activation_scale": 0.125, }, }‘ to ‘self.manifest ‘ in host memory. Here manifest means the value named ’manifest’ in this block. The important operands are binary_sha256: the value named ’binary sha256’ in this block; a: the value named ’a’ in this block; fixed_point: the value named ’fixed point’ in this block. Context: the function ___init___, which handles init.

Line 32: `"fixed_point": {` This is continuation line 3 of the 9-line logical statement that begins at source line 30. Its exact fragment is ‘"fixed_point": {‘. The important operands are fixed_point: the value named ’fixed point’ in this block. Read together, the complete operation is: This assigns ‘{ "binary_sha256": "a" * 64, "fixed_point": { "activation_fractional_bits": 10, "image_input_scale": 0.02, "image_input_zero_point": 123, "head_activation_scale": 0.125, }, }‘ to ‘self.manifest ‘ in host memory. Here manifest means the value named ’manifest’ in this block. The important operands are binary_sha256: the value named ’binary sha256’ in this block; a: the value named ’a’ in this block; fixed_point: the value named ’fixed point’ in this block. Context: the function ___init___, which handles init.

Line 33: `"activation_fractional_bits": 10,` This is continuation line 4 of the 9-line logical statement that begins at source line 30. Its exact fragment is ‘"activation_fractional_bits": 10,‘. The important operands are activation_fractional_bits: an input feature value consumed by a neuron or multiply-accumulate operation. Read together, the complete operation is: This assigns ‘{ "binary_sha256": "a" * 64, "fixed_point": { "activation_fractional_bits": 10,

"image_input_scale": 0.02, "image_input_zero_point": 123, "head_activation_scale": 0.125, }, }‘ to ‘self.manifest ‘ in host memory. Here manifest means the value named ’manifest’ in this block. The important operands are binary_sha256: the value named ’binary sha256’ in this block; a: the value named ’a’ in this block; fixed_point: the value named ’fixed point’ in this block. Context: the function ___init___, which handles init.

Line 34: `"image_input_scale": 0.02,` This is continuation line 5 of the 9-line logical statement that begins at source line 30. Its exact fragment is ‘"image_input_scale": 0.02,‘. The important operands are image_input_scale: the real-value spacing represented by one quantized integer step. Read together, the complete operation is: This assigns ‘{ "binary_sha256": "a" * 64, "fixed_point": { "activation_fractional_bits": 10, "image_input_scale": 0.02, "image_input_zero_point": 123, "head_activation_scale": 0.125, }, }‘ to ‘self.manifest ‘ in host memory. Here manifest means the value named ’manifest’ in this block. The important operands are binary_sha256: the value named ’binary sha256’ in this block; a: the value named ’a’ in this block; fixed_point: the value named ’fixed point’ in this block. Context: the function ___init___, which handles init.

Line 35: `"image_input_zero_point": 123,` This is continuation line 6 of the 9-line logical statement that begins at source line 30. Its exact fragment is ‘"image_input_zero_point": 123,‘. The important operands are image_input_zero_point: the integer code representing real numeric zero in affine quantization. Read together, the complete operation is: This assigns ‘{ "binary_sha256": "a" * 64, "fixed_point": { "activation_fractional_bits": 10, "image_input_scale": 0.02, "image_input_zero_point": 123, "head_activation_scale": 0.125, }, }‘ to ‘self.manifest ‘ in host memory. Here manifest means the value named ’manifest’ in this block. The important operands are binary_sha256: the value named ’binary sha256’ in this block; a: the value named ’a’ in this block; fixed_point: the value named ’fixed point’ in this block. Context: the function ___init___, which handles init.

Line 36: `"head_activation_scale": 0.125,` This is continuation line 7 of the 9-line logical statement that begins at source line 30. Its exact fragment is ‘"head_activation_scale": 0.125,‘. The important operands are head_activation_scale: an input feature value consumed by a neuron or multiply-accumulate operation. Read together, the complete operation is: This assigns ‘{ "binary_sha256": "a" * 64, "fixed_point": { "activation_fractional_bits": 10, "image_input_scale": 0.02, "image_input_zero_point": 123, "head_activation_scale": 0.125, }, }‘ to ‘self.manifest ‘ in host memory. Here manifest means the value named ’manifest’ in this block. The important operands are binary_sha256: the value named ’binary sha256’ in this block; a: the value named ’a’ in this block; fixed_point: the value named ’fixed point’ in this block. Context: the function ___init___, which handles init.

Line 37: `},` This is continuation line 8 of the 9-line logical statement that begins at source line 30. Its exact fragment is ‘},‘. The expression is a literal or structural operator and has no hidden software state. Read together, the complete operation is: This assigns ‘{ "binary_sha256": "a" * 64, "fixed_point": { "activation_fractional_bits": 10, "image_input_scale": 0.02, "image_input_zero_point": 123, "head_activation_scale": 0.125, }, }‘ to ‘self.manifest ‘ in host memory. Here manifest means the value named ’manifest’ in this block. The important operands are binary_sha256: the value named ’binary sha256’ in this block; a: the value named ’a’ in this block; fixed_point: the value named ’fixed point’ in this block. Context: the function ___init___, which handles init.

Line 38: `}` This is continuation line 9 of the 9-line logical statement that begins at source line 30. Its exact fragment is ‘}‘. The expression is a literal or structural operator and has no hidden software state. Read together, the complete operation is: This assigns ‘{ "binary_sha256": "a" * 64, "fixed_point": { "activation_fractional_bits": 10, "image_input_scale": 0.02, "image_input_zero_point": 123, "head_activation_scale": 0.125, }, }‘ to ‘self.manifest ‘ in host memory. Here manifest means the value named ’manifest’ in this block. The important operands are binary_sha256: the value named ’binary sha256’ in this block; a: the value named ’a’ in this block; fixed_point: the value named ’fixed point’ in this block. Context: the function ___init___, which handles init.

Line 39: `self._projection = ProjectionParameters(` This statement continues through source line 48; the explanation uses the complete expression rather than only the first visual fragment. This assigns ‘ProjectionParameters("tiny", np.asarray([[3, -4], [-2, 5]], dtype=np.int8), np.asarray([7, -9], dtype=np.int32), np.asarray([16384, 24576], dtype=np.int16), np.asarray([-1, 1], dtype=np.int8), "COMPUTE_BINARY", (2, 2, 1), 10,)‘ to ‘self._projection ‘ in host memory. Here _projection means the value named ’projection’ in this block. The important operands are ProjectionParameters: the value named ’projection parameters’ in this block; tiny: the value named ’tiny’ in this block; asarray: the value named ’asarray’ in this block. Context: the function ___init___, which handles init.

Line 40: `"tiny",` This is continuation line 2 of the 10-line logical statement that begins at source line 39. Its exact fragment is '"tiny",'. The important operands are tiny: the value named 'tiny' in this block. Read together, the complete operation is: This assigns 'ProjectionParameters("tiny", np.asarray([[3, -4], [-2, 5]], dtype=np.int8), np.asarray([7, -9], dtype=np.int32), np.asarray([16384, 24576], dtype=np.int16), np.asarray([-1, 1], dtype=np.int8), "COMPUTE_BINARY", (2, 2, 1), 10,)' to 'self._projection ' in host memory. Here _projection means the value named 'projection' in this block. The important operands are ProjectionParameters: the value named 'projection parameters' in this block; tiny: the value named 'tiny' in this block; asarray: the value named 'asarray' in this block. Context: the function ___init___, which handles init.

Line 41: `np.asarray([[3, -4], [-2, 5]], dtype=np.int8),` This is continuation line 3 of the 10-line logical statement that begins at source line 39. Its exact fragment is 'np.asarray([[3, -4], [-2, 5]], dtype=np.int8),'. The important operands are asarray: the value named 'asarray' in this block; dtype: the value named 'dtype' in this block; int8: the value named 'int8' in this block. Read together, the complete operation is: This assigns 'ProjectionParameters("tiny", np.asarray([[3, -4], [-2, 5]], dtype=np.int8), np.asarray([7, -9], dtype=np.int32), np.asarray([16384, 24576], dtype=np.int16), np.asarray([-1, 1], dtype=np.int8), "COMPUTE_BINARY", (2, 2, 1), 10,)' to 'self._projection ' in host memory. Here _projection means the value named 'projection' in this block. The important operands are ProjectionParameters: the value named 'projection parameters' in this block; tiny: the value named 'tiny' in this block; asarray: the value named 'asarray' in this block. Context: the function ___init___, which handles init.

Line 42: `np.asarray([7, -9], dtype=np.int32),` This is continuation line 4 of the 10-line logical statement that begins at source line 39. Its exact fragment is 'np.asarray([7, -9], dtype=np.int32),'. The important operands are asarray: the value named 'asarray' in this block; dtype: the value named 'dtype' in this block; int32: the value named 'int32' in this block. Read together, the complete operation is: This assigns 'ProjectionParameters("tiny", np.asarray([[3, -4], [-2, 5]], dtype=np.int8), np.asarray([7, -9], dtype=np.int32), np.asarray([16384, 24576], dtype=np.int16), np.asarray([-1, 1], dtype=np.int8), "COMPUTE_BINARY", (2, 2, 1), 10,)' to 'self._projection ' in host memory. Line 48: `)` This is continuation line 10 of the 10-line logical statement that begins at source line 39. Its exact fragment is ')'. The expression is a literal or structural operator and has no hidden software state. Read together, the complete operation is: This assigns 'ProjectionParameters("tiny", np.asarray([[3, -4], [-2, 5]], dtype=np.int8), np.asarray([7, -9], dtype=np.int32), np.asarray([16384, 24576], dtype=np.int16), np.asarray([-1, 1], dtype=np.int8), "COMPUTE_BINARY", (2, 2, 1), 10,)' to 'self._projection ' in host memory. Here _projection means the value named 'projection' in this block. The important operands are ProjectionParameters: the value named 'projection parameters' in this block; tiny: the value named 'tiny' in this block; asarray: the value named 'asarray' in this block. Context: the function ___init___, which handles init.

Line 49: `self._head = HeadParameters(` This statement continues through source line 52; the explanation uses the complete expression rather than only the first visual fragment. This assigns 'HeadParameters(np.asarray([[6, -7], [8, 9]], dtype=np.int8), np.asarray([11, -13], dtype=np.int32),)' to 'self._head ' in host memory. Here _head means the value named 'head' in this block. The important operands are HeadParameters: the value named 'head parameters' in this block; asarray: the value named 'asarray' in this block; dtype: the value named 'dtype' in this block. Context: the function ___init___, which handles init.

Line 50: `np.asarray([[6, -7], [8, 9]], dtype=np.int8),` This is continuation line 2 of the 4-line logical statement that begins at source line 49. Its exact fragment is 'np.asarray([[6, -7], [8, 9]], dtype=np.int8),'. The important operands are asarray: the value named 'asarray' in this block; dtype: the value named 'dtype' in this block; int8: the value named 'int8' in this block. Read together, the complete operation is: This assigns 'HeadParameters(np.asarray([[6, -7], [8, 9]], dtype=np.int8), np.asarray([11, -13], dtype=np.int32),)' to 'self._head ' in host memory. Here _head means the value named 'head' in this block. The important operands are HeadParameters: the value named 'head parameters' in this block; asarray: the value named 'asarray' in this block; dtype: the value named 'dtype' in this block. Context: the function ___init___, which handles init.

Line 51: `np.asarray([11, -13], dtype=np.int32),` This is continuation line 3 of the 4-line logical statement that begins at source line 49. Its exact fragment is 'np.asarray([11, -13], dtype=np.int32),'. The important operands are asarray: the value named 'asarray' in this block; dtype: the value named 'dtype' in this block; int32: the value named 'int32' in this block. Read together, the complete operation is: This assigns 'HeadParameters(np.asarray([[6, -7], [8, 9]], dtype=np.int8), np.asarray([11, -13], dtype=np.int32),)' to 'self._head ' in host memory. Here _head means the value named 'head' in this block. The important operands are HeadParameters: the value named 'head parameters' in this block; asarray: the value named 'asarray' in this block; dtype: the value named 'dtype' in this block. Context: the function ___init___, which handles init.

Line 52: `)` This is continuation line 4 of the 4-line logical statement that begins at source line 49. Its exact fragment is ')'. The expression is a literal or structural operator and has no hidden software state. Read together, the complete operation is: This assigns 'HeadParameters(np.asarray([[6, -7], [8, 9]], dtype=np.int8), np.asarray([11, -13], dtype=np.int32),)' to 'self._head ' in host memory. Here _head means the value named 'head' in this block. The important operands are

HeadParameters: the value named 'head parameters' in this block; asarray: the value named 'asarray' in this block; dtype: the value named 'dtype' in this block. Context: the function ___init___, which handles init.

Line 54: `@property` This decorator changes how the following class or function is constructed. '@property' is applied at import time on the host and is part of the class TinyParameterArchive, which handles tiny parameter archive; it creates no FPGA circuit by itself.

Line 55: `def projection_names(self) -> tuple[str, ...]:` This starts function projection_names. Its indented body performs projection names as part of the file that checks spikingformer training runtime behavior independently with Python assertions; it runs only when called.

Line 56: `return ("tiny",)` This returns '("tiny",)' to the caller of the function projection_names, which handles projection names, ending this invocation. The important operands are tiny: the value named 'tiny' in this block.

Line 58: `def projection(self, name: str) -> ProjectionParameters:` This starts function projection. Its indented body performs projection as part of the file that checks spikingformer training runtime behavior independently with Python assertions; it runs only when called.

Line 59: `if name != "tiny":` This executes the following indented host-code branch only when 'name != "tiny"' is true. The important operands are name: the value named 'name' in this block; tiny: the value named 'tiny' in this block. Context: the function projection, which handles projection.

Line 60: `raise KeyError(name)` This rejects an invalid state by raising 'KeyError(name)'. Failing before DMA prevents malformed shapes or artifacts from silently becoming hardware results.

Line 61: `return self._projection` This returns 'self._projection' to the caller of the function projection, which handles projection, ending this invocation. The important operands are _projection: the value named 'projection' in this block.

Line 63: `@property` This decorator changes how the following class or function is constructed. '@property' is applied at import time on the host and is part of the class TinyParameterArchive, which handles tiny parameter archive; it creates no FPGA circuit by itself.

Line 64: `def head(self) -> HeadParameters:` This starts function head. Its indented body performs head as part of the file that checks spikingformer training runtime behavior independently with Python assertions; it runs only when called.

Line 65: `return self._head` This returns 'self._head' to the caller of the function head, which handles head, ending this invocation. The important operands are _head: the value named 'head' in this block.

Line 68: `class TinyFullGraphArchive:` This defines class TinyFullGraphArchive, which groups data and methods for tiny full graph archive. Instances exist in host memory and organize the flow that checks spikingformer training runtime behavior independently with Python assertions.

Line 69: `def __init__(self) -> None:` This starts function ___init___. Its indented body performs init as part of the file that checks spikingformer training runtime behavior independently with Python assertions; it runs only when called.

Line 70: `self.manifest = {` This statement continues through source line 79; the explanation uses the complete expression rather than only the first visual fragment. This assigns '{ "binary_sha256": "b" * 64, "fixed_point": { "activation_fractional_bits": 10, "image_input_scale": 0.02, "image_input_zero_point": 123, "head_activation_scale": 0.125, }, "head": {"accumulator_scale": 1.0 / 1024.0}, }' to 'self.manifest ' in host memory. Here manifest means the value named 'manifest' in this block. The important operands are binary_sha256: the value named 'binary sha256' in

this block; b: the value named 'b' in this block; fixed_point: the value named 'fixed point' in this block. Context: the function ___init___, which handles init.

Line 71: `"binary_sha256": "b" * 64,` This is continuation line 2 of the 10-line logical statement that begins at source line 70. Its exact fragment is '"binary_sha256": "b" * 64,'. The important operands are binary_sha256: the value named 'binary sha256' in this block; b: the value named 'b' in this block. Read together, the complete operation is: This assigns '{ "binary_sha256": "b" * 64, "fixed_point": { "activation_fractional_bits": 10, "image_input_scale": 0.02, "image_input_zero_point": 123, "head_activation_scale": 0.125, }, "head": {"accumulator_scale": 1.0 / 1024.0}, }' to 'self.manifest ' in host memory. Here manifest means the value named 'manifest' in this block. The important operands are binary_sha256: the value named 'binary sha256' in this block; b: the value named 'b' in this block; fixed_point: the value named 'fixed point' in this block. The important operands are ProjectionParameters: the value named 'projection parameters' in this block; name: the value named 'name' in this block; weight: a learned coefficient multiplied by an activation. Context: the function add_conv, which handles add conv.

Line 96: `(output_channels, input_channels, 3, 3),` This is continuation line 8 of the 10-line logical statement that begins at source line 89. Its exact fragment is '(output_channels, input_channels, 3, 3),'. The important operands are output_channels: the value named 'output channels' in this block; input_channels: the value named 'input channels' in this block. Read together, the complete operation is: This assigns 'ProjectionParameters(name, weight, np.full(output_channels, 2200, dtype=np.int32), np.full(output_channels, 16384, dtype=np.int16), np.full(output_channels, -1, dtype=np.int8), "COMPUTE_DENSE_OUTER" if dense else "COMPUTE_BINARY", (output_channels, input_channels, 3, 3), 10,)' to 'self._projections[name] ' in host memory. Here _projections means the value named 'projections' in this block. The important operands are ProjectionParameters: the value named 'pro-

jection parameters' in this block; name: the value named 'name' in this block; weight: a learned coefficient multiplied by an activation. Context: the function add_conv, which handles add conv.

Line 97: `10,` This is continuation line 9 of the 10-line logical statement that begins at source line 89. Its exact fragment is '10,'. The expression is a literal or structural operator and has no hidden software state. Read together, the complete operation is: This assigns 'ProjectionParameters(name, weight, np.full(output_channels, 2200, dtype=np.int32), np.full(output_channels, 16384, dtype=np.int16), np.full(output_channels, -1, dtype=np.int8), "COMPUTE_DENSE_OUTER" if dense else "COMPUTE_BINARY", (output_channels, input_channels, 3, 3), 10,)' to 'self._projections[name] ' in host memory. Here _projections means the value named 'projections' in this block. The important operands are ProjectionParameters: the value named 'projection parameters' in this block; name: the value named 'name' in this block; weight: a learned coefficient multiplied by an activation. Context: the function add_conv, which handles add conv.

Line 98: `)` This is continuation line 10 of the 10-line logical statement that begins at source line 89. Its exact fragment is ')'. The expression is a literal or structural operator and has no hidden software state. Read together, the complete operation is: This assigns 'ProjectionParameters(name, weight, np.full(output_channels, 2200, dtype=np.int32), np.full(output_channels, 16384, dtype=np.int16), np.full(output_channels, -1, dtype=np.int8), "COMPUTE_DENSE_OUTER" if dense else "COMPUTE_BINARY", (output_channels, input_channels, 3, 3), 10,)' to 'self._projections[name] ' in host memory. Here _projections means the value named 'projections' in this block. The important operands are ProjectionParameters: the value named 'projection parameters' in this block; name: the value named 'name' in this block; weight: a learned coefficient multiplied by an activation. Context: the function add_conv, which handles add conv.

Line 100: `add_conv("patch_embed.block0", 3, 2, dense=True)` This calls 'add_conv' with '"patch_embed.block0", 3, 2, dense=True' inside the function ___init___, which handles init. The call advances the host-side job that checks spikingformer training runtime behavior independently with Python assertions.

Line 101: `for index in range(1, 5):` This iterates index over 'range(1, 5)'. Each iteration repeats the indented host operation, commonly once per layer, tile, timestep, or test case in the function ___init___, which handles init.

Line 102: `add_conv(f"patch_embed.block{index}", 2, 2)` This calls 'add_conv' with 'f"patch_embed.block{index}", 2, 2' inside the function ___init___, which handles init. The call advances the host-side job that checks spikingformer training runtime behavior independently with Python assertions.

Line 104: `def add_matrix(name: str, inputs: int, outputs: int, bias: int = 2200) -> None:` This starts function add_matrix. Its indented body performs add matrix as part of the file that checks spikingformer training runtime behavior independently with Python assertions; it runs only when called.

Line 105: `weight = np.fromfunction(` This statement continues through source line 109; the explanation uses the complete expression rather than only the first visual fragment. This assigns 'np.fromfunction(lambda row, column: ((2 * row + column) % 3) - 1, (inputs, outputs), dtype=int,).astype(np.int8)' to 'weight ' in host memory. Here weight means a learned coefficient multiplied by an activation. The important operands are fromfunction: the value named 'fromfunction' in this block; lambda: the value named 'lambda' in this block; row: one output-row position processed by the tensor tile. Context: the function add_matrix, which handles add matrix.

Line 106: `lambda row, column: ((2 * row + column) % 3) - 1,` This is continuation line 2 of the 5-line logical statement that begins at source line 105. Its exact fragment is 'lambda row, column: ((2 * row + column) % 3) - 1,'. The important operands are lambda: the value named 'lambda' in this block; row: one output-row position processed by the tensor tile; column: one output-feature position processed in parallel. Read together, the complete operation is: This assigns 'np.fromfunction(lambda row, column: ((2 * row + column) % 3) - 1, (inputs, outputs), dtype=int,).astype(np.int8)' to 'weight ' in host memory. Here weight means a learned coefficient multiplied by an activation. The important operands are fromfunction: the value named 'fromfunction' in this block; lambda: the value named 'lambda' in this block; row: one output-row position processed by the tensor tile. Context: the function add_matrix, which handles add matrix.

Line 107: `(inputs, outputs),` This is continuation line 3 of the 5-line logical statement that begins at source line 105. Its exact fragment is '(inputs, outputs),'. The important operands are inputs: the value named 'inputs' in this block; outputs: the value named 'outputs' in this block. Read together, the complete operation is: This assigns 'np.fromfunction(lambda row, column: ((2 * row + column) % 3) - 1, (inputs, outputs), dtype=int,).astype(np.int8)' to 'weight ' in host memory. Here weight means a learned coefficient multiplied by an activation. The important operands are fromfunction: the value named 'fromfunction' in this block; lambda: the value named 'lambda' in this block; row: one output-row position processed by the tensor tile. Context: the function add_matrix, which handles add matrix.

Line 108: `dtype=int,` This is continuation line 4 of the 5-line logical statement that begins at source line 105. Its exact fragment is 'dtype=int,'. The important operands are dtype: the value named 'dtype' in this block. Read together, the complete operation is: This assigns 'np.fromfunction(lambda row, column: ((2 * row + column) % 3) - 1, (inputs, outputs), dtype=int,).astype(np.int8)' to 'weight ' in host memory. Here weight means a learned coefficient multiplied by an activation. The important operands are fromfunction: the value named 'fromfunction' in this block; lambda: the value named 'lambda' in this block; row: one output-row position processed by the tensor tile. Context: the function add_matrix, which handles add matrix.

Line 109: `).astype(np.int8)` This is continuation line 5 of the 5-line logical statement that begins at source line 105. Its exact fragment is ').astype(np.int8)'. The important operands are astype: the value named 'astype' in this block; int8: the value named 'int8' in this block. Read together, the complete operation is: This assigns 'np.fromfunction(lambda row, column: ((2 * row + column) % 3) - 1, (inputs, outputs), dtype=int,).astype(np.int8)' to 'weight ' in host memory. Here weight means a learned coefficient multiplied by an activation. The important operands are fromfunction: the value named 'fromfunction' in this block; lambda: the value named 'lambda' in this block; row: one output-row position processed by the tensor tile. Context: the function add_matrix, which handles add matrix.

Line 110: `self._projections[name] = ProjectionParameters(` This statement continues through source line 119; the explanation uses the complete expression rather than only the first visual fragment. This assigns 'ProjectionParameters(name, weight, np.full(outputs, bias, dtype=np.int32), np.full(outputs, 16384, dtype=np.int16), np.full(outputs, -1, dtype=np.int8), "COMPUTE_BINARY", (outputs, inputs, 1), 10,)' to 'self._projections[name] ' in host memory. Here _projections means the value named 'projections' in this block. The important operands are ProjectionParameters: the value named 'projection parameters' in this block; name: the value named 'name' in this block; weight: a learned coefficient multiplied by an activation. Context: the function add_matrix, which handles add matrix.

Line 111: `name,` This is continuation line 2 of the 10-line logical statement that begins at source line 110. Its exact fragment is 'name,'. The important operands are name: the value named 'name' in this block. Read together, the complete operation is: This assigns 'ProjectionParameters(name, weight, np.full(outputs, bias, dtype=np.int32), np.full(outputs, 16384, dtype=np.int16), np.full(outputs, -1, dtype=np.int8), "COMPUTE_BINARY", (outputs, inputs, 1), 10,)' to 'self._projections[name] ' in host memory. Here _projections means the value named 'projections' in this block. The important operands are ProjectionParameters: the value named 'projection parameters' in this block; name: the value named 'name' in this block; weight: a learned coefficient multiplied by an activation. Context: the function add_matrix, which handles add matrix.

Line 112: `weight,` This is continuation line 3 of the 10-line logical statement that begins at source line 110. Its exact fragment is 'weight,'. The important operands are weight: a learned coefficient multiplied by an activation. Read together, the complete operation is: This assigns 'ProjectionParameters(name, weight, np.full(outputs, bias, dtype=np.int32), np.full(outputs, 16384, dtype=np.int16), np.full(outputs, -1, dtype=np.int8), "COMPUTE_BINARY", (outputs, inputs, 1), 10,)' to 'self._projections[name] ' in host memory. Here _projections means the value named 'projections' in this block. The important operands are ProjectionParameters: the value named 'projection parameters' in this block; name: the value named 'name' in this block; weight: a learned coefficient multiplied by an activation. Context: the function add_matrix, which handles add matrix.

Line 113: `np.full(outputs, bias, dtype=np.int32),` This is continuation line 4 of the 10-line logical statement that begins at source line 110. Its exact fragment is 'np.full(outputs, bias, dtype=np.int32),'. The important operands are full: the value named 'full' in this block; outputs: the value named 'outputs' in this block; bias: an additive learned offset applied after accumulation. Read together, the complete operation is: This assigns 'ProjectionParameters(name, weight, np.full(outputs, bias, dtype=np.int32), np.full(outputs, 16384, dtype=np.int16), np.full(outputs, -1, dtype=np.int8), "COMPUTE_BINARY", (outputs, inputs, 1), 10,)' to 'self._projections[name] ' in host memory. Here _projections

means the value named 'projections' in this block. The important operands are ProjectionParameters: the value named 'projection parameters' in this block; name: the value named 'name' in this block; weight: a learned coefficient multiplied by an activation. Context: the function add_matrix, which handles add matrix.

Line 114: `np.full(outputs, 16384, dtype=np.int16),` This is continuation line 5 of the 10-line logical statement that begins at source line 110. Its exact fragment is 'np.full(outputs, 16384, dtype=np.int16),'. The important operands are full: the value named 'full' in this block; outputs: the value named 'outputs' in this block; dtype: the value named 'dtype' in this block. Read together, the complete operation is: This assigns 'ProjectionParameters(name, weight, np.full(outputs, bias, dtype=np.int32), np.full(outputs, 16384, dtype=np.int16), np.full(outputs, -1, dtype=np.int8), "COMPUTE_BINARY", (outputs, inputs, 1), 10,)' to 'self._projections[name] ' in host memory. Here _projections means the value named 'projections' in this block. The important operands are ProjectionParameters: the value named 'projection parameters' in this block; name: the value named 'name' in this block; weight: a learned coefficient multiplied by an activation. Context: the function add_matrix, which handles add matrix.

Line 115: `np.full(outputs, -1, dtype=np.int8),` This is continuation line 6 of the 10-line logical statement that begins at source line 110. Its exact fragment is 'np.full(outputs, -1, dtype=np.int8),'. The important operands are full: the value named 'full' in this block; outputs: the value named 'outputs' in this block; dtype: the value named 'dtype' in this block. Read together, the complete operation is: This assigns 'ProjectionParameters(name, weight, np.full(outputs, bias, dtype=np.int32), np.full(outputs, 16384, dtype=np.int16), np.full(outputs, -1, dtype=np.int8), "COMPUTE_BINARY", (outputs, inputs, 1), 10,)' to 'self._projections[name] ' in host memory. Here _projections means the value named 'projections' in this block. The important operands are ProjectionParameters: the value named 'projection parameters' in this block; name: the value named 'name' in this block; weight: a learned coefficient multiplied by an activation. Context: the function add_matrix, which handles add matrix.

Line 116: `"COMPUTE_BINARY",` This is continuation line 7 of the 10-line logical statement that begins at source line 110. Its exact fragment is '"COMPUTE_BINARY",'. The important operands are COMPUTE_BINARY: the value named 'compute binary' in this block. Read together, the complete operation is: This assigns 'ProjectionParameters(name, weight, np.full(outputs, bias, dtype=np.int32), np.full(outputs, 16384, dtype=np.int16), np.full(outputs, -1, dtype=np.int8), "COMPUTE_BINARY", (outputs, inputs, 1), 10,)' to 'self._projections[name] ' in host memory. Here _projections means the value named 'projections' in this block. The important operands are ProjectionParameters: the value named 'projection parameters' in this block; name: the value named 'name' in this block; weight: a learned coefficient multiplied by an activation. Context: the function add_matrix, which handles add matrix.

Line 117: `(outputs, inputs, 1),` This is continuation line 8 of the 10-line logical statement that begins at source line 110. Its exact fragment is '(outputs, inputs, 1),'. The important operands are outputs: the value named 'outputs' in this block; inputs: the value named 'inputs' in this block. Read together, the complete operation is: This assigns 'ProjectionParameters(name, weight, np.full(outputs, bias, dtype=np.int32), np.full(outputs, 16384, dtype=np.int16), np.full(outputs, -1, dtype=np.int8), "COMPUTE_BINARY", (outputs, inputs, 1), 10,)' to 'self._projections[name] ' in host memory. Here _projections means the value named 'projections' in this block. The important operands are ProjectionParameters: the value named 'projection parameters' in this block; name: the value named 'name' in this block; weight: a learned coefficient multiplied by an activation. Context: the function add_matrix, which handles add matrix.

Line 118: `10,` This is continuation line 9 of the 10-line logical statement that begins at source line 110. Its exact fragment is '10,'. The expression is a literal or structural operator and has no hidden software state. Read together, the complete operation is: This assigns 'ProjectionParameters(name, weight, np.full(outputs, bias, dtype=np.int32), np.full(outputs, 16384, dtype=np.int16), np.full(outputs, -1, dtype=np.int8), "COMPUTE_BINARY", (outputs, inputs, 1), 10,)' to 'self._projections[name] ' in host memory. Here _projections means the value named 'projections' in this block. The important operands are ProjectionParameters: the value named 'projection parameters' in this block; name: the value named 'name' in this block; weight: a learned coefficient multiplied by an activation. Context: the function add_matrix, which handles add matrix.

Line 119: `)` This is continuation line 10 of the 10-line logical statement that begins at source line 110. Its exact fragment is ')'. The expression is a literal or structural operator and has no hidden software state. Read together, the complete operation is: This assigns 'ProjectionParameters(name, weight, np.full(outputs, bias, dtype=np.int32), np.full(outputs, 16384, dtype=np.int16), np.full(outputs, -1, dtype=np.int8), "COMPUTE_BINARY", (outputs, inputs,

1), 10,)‘ to ‘self._projections[name] ‘ in host memory. Here _projections means the value named ’projections’ in this block. The important operands are ProjectionParameters: the value named ’projection parameters’ in this block; name: the value named ’name’ in this block; weight: a learned coefficient multiplied by an activation. Context: the function add_matrix, which handles add matrix.

Line 121: `for name in ("q", "k", "v"):` This iterates name over ‘("q", "k", "v")‘. Each iteration repeats the indented host operation, commonly once per layer, tile, timestep, or test case in the function ___init___, which handles init.

Line 122: `add_matrix(f"block.0.attn.{name}", 2, 2)` This calls ‘add_matrix‘ with ‘f"block.0.attn.{name}", 2, 2‘ inside the function ___init___, which handles init. The call advances the host-side job that checks spikingformer training runtime behavior independently with Python assertions.

Line 123: `add_matrix("block.0.attn.proj", 2, 2, bias=0)` This calls ‘add_matrix‘ with ‘"block.0.attn.proj", 2, 2, bias=0‘ inside the function ___init___, which handles init. The call advances the host-side job that checks spikingformer training runtime behavior independently with Python assertions.

Line 124: `add_matrix("block.0.mlp.fc1", 2, 3)` This calls ‘add_matrix‘ with ‘"block.0.mlp.fc1", 2, 3‘ inside the function ___init___, which handles init. The call advances the host-side job that checks spikingformer training runtime behavior independently with Python assertions.

Line 125: `add_matrix("block.0.mlp.fc2", 3, 2, bias=0)` This calls ‘add_matrix‘ with ‘"block.0.mlp.fc2", 3, 2, bias=0‘ inside the function ___init___, which handles init. The call advances the host-side job that checks spikingformer training runtime behavior independently with Python assertions.

Line 126: `self._head = HeadParameters(` This statement continues through source line 129; the explanation uses the complete expression rather than only the first visual fragment. This assigns ‘HeadParameters(np.asarray([[3, -2, 1], [-1, 2, 4]], dtype=np.int8), np.asarray([17, -11, 5], dtype=np.int32),)‘ to ‘self._head ‘ in host memory. Here _head means the value named ’head’ in this block. The important operands are HeadParameters: the value named ’head parameters’ in this block; asarray: the value named ’asarray’ in this block; dtype: the value named ’dtype’ in this block. Context: the function ___init___, which handles init.

Line 127: `np.asarray([[3, -2, 1], [-1, 2, 4]], dtype=np.int8),` This is continuation line 2 of the 4-line logical statement that begins at source line 126. Its exact fragment is ‘np.asarray([[3, -2, 1], [-1, 2, 4]], dtype=np.int8),‘. The important operands are asarray: the value named ’asarray’ in this block; dtype: the value named ’dtype’ in this block; int8: the value named ’int8’ in this block. Read together, the complete operation is: This assigns ‘HeadParameters(np.asarray([[3, -2, 1], [-1, 2, 4]], dtype=np.int8), np.asarray([17, -11, 5], dtype=np.int32),)‘ to ‘self._head ‘ in host memory. Here _head means the value named ’head’ in this block. The important operands are HeadParameters: the value named ’head parameters’ in this block; asarray: the value named ’asarray’ in this block; dtype: the value named ’dtype’ in this block. Context: the function ___init___, which handles init.

Line 128: `np.asarray([17, -11, 5], dtype=np.int32),` This is continuation line 3 of the 4-line logical statement that begins at source line 126. Its exact fragment is ‘np.asarray([17, -11, 5], dtype=np.int32),‘. The important operands are asarray: the value named ’asarray’ in this block; dtype: the value named ’dtype’ in this block; int32: the value named ’int32’ in this block. Read together, the complete operation is: This assigns ‘HeadParameters(np.asarray([[3, -2, 1], [-1, 2, 4]], dtype=np.int8), np.asarray([17, -11, 5], dtype=np.int32),)‘ to ‘self._head ‘ in host memory. Here _head means the value named ’head’ in this block. The important operands are HeadParameters: the value named ’head parameters’ in this block; asarray: the value named ’asarray’ in this block; dtype: the value named ’dtype’ in this block. Context: the function ___init___, which handles init.

Line 129: `)` This is continuation line 4 of the 4-line logical statement that begins at source line 126. Its exact fragment is ‘)‘. The expression is a literal or structural operator and has no hidden software state. Read together, the complete operation is: This assigns ‘HeadParameters(np.asarray([[3, -2, 1], [-1, 2, 4]], dtype=np.int8), np.asarray([17, -11, 5], dtype=np.int32),)‘ to ‘self._head ‘ in host memory. Here _head means the value named ’head’ in this block. The important operands are HeadParameters: the value named ’head parameters’ in this block; asarray: the value named

'asarray' in this block; dtype: the value named 'dtype' in this block. Context: the function ___init___, which handles init.

Line 131: `@property` This decorator changes how the following class or function is constructed. '@property' is applied at import time on the host and is part of the class TinyFullGraphArchive, which handles tiny full graph archive; it creates no FPGA circuit by itself.

Line 132: `def projection_names(self) -> tuple[str, ...]:` This starts function projection_names. Its indented body performs projection names as part of the file that checks spikingformer training runtime behavior independently with Python assertions; it runs only when called.

Line 133: `return tuple(self._projections)` This returns 'tuple(self._projections)' to the caller of the function projection_names, which handles projection names, ending this invocation. The important operands are tuple: the value named 'tuple' in this block; _projections: the value named 'projections' in this block.

Line 135: `def projection(self, name: str) -> ProjectionParameters:` This starts function projection. Its indented body performs projection as part of the file that checks spikingformer training runtime behavior independently with Python assertions; it runs only when called.

Line 136: `return self._projections[name]` This returns 'self._projections[name]' to the caller of the function projection, which handles projection, ending this invocation. The important operands are _projections: the value named 'projections' in this block; name: the value named 'name' in this block.

Line 138: `@property` This decorator changes how the following class or function is constructed. '@property' is applied at import time on the host and is part of the class TinyFullGraphArchive, which handles tiny full graph archive; it creates no FPGA circuit by itself.

Line 139: `def head(self) -> HeadParameters:` This starts function head. Its indented body performs head as part of the file that checks spikingformer training runtime behavior independently with Python assertions; it runs only when called.

Line 140: `return self._head` This returns 'self._head' to the caller of the function head, which handles head, ending this invocation. The important operands are _head: the value named 'head' in this block.

Line 143: `class SpikingformerTrainingRuntimeTests(unittest.TestCase):` This defines class SpikingformerTrainingRuntimeTests, which groups data and methods for spikingformer training runtime tests. Instances exist in host memory and organize the flow that checks spikingformer training runtime behavior independently with Python assertions.

Line 144: `def setUp(self) -> None:` This starts function setUp. Its indented body performs set up as part of the file that checks spikingformer training runtime behavior independently with Python assertions; it runs only when called.

Line 145: `self.driver = FullTrainingEmulator()` This assigns 'FullTrainingEmulator()' to 'self.driver ' in host memory. Here driver means the value named 'driver' in this block. The important operands are FullTrainingEmulator: the value named 'full training emulator' in this block. Context: the function setUp, which handles set up.

Line 147: `def test_block_floating_shift_normalize_and_add_are_exact(self) -> None:` This starts function test_block_floating_shift_normalize_and_add_are_exact. Its indented body performs test block floating shift normalize and add are exact as part of the file that checks spikingformer training runtime behavior independently with Python assertions; it runs only when called.

Line 148: `values = np.asarray([[-2_000_000, -65537, 0, 65537, 2_000_000]], dtype=np.int64)` This assigns 'np.asarray([[-2_000_000, -65537, 0, 65537, 2_000_000]], dtype=np.int64)' to 'values ' in host memory. Here values means the value named 'values' in this block. The important operands are asarray: the value named 'asarray' in this block; dtype: the value named 'dtype' in this block; int64: the value named 'int64' in this block. Context: the function test_block_floating_shift_normalize_and_add_are_exact, which handles test block floating shift normalize and add are exact.

Line 149: `shifted = execute_power_of_two_scale(self.driver, values, -4)` This assigns 'execute_power_of_two_scale values, -4)' to 'shifted ' in host memory. Here shifted means the value named 'shifted' in this block. The important operands are execute_power_of_two_scale: the real-value spacing represented by one quantized integer step; driver: the value named 'driver' in this block; values: the value named 'values' in this block. Context: the function test_block_floating_shift_normalize_and_add_are_exact, which handles test block floating shift normalize and add are exact.

Line 150: `np.testing.assert_array_equal(shifted, round_shift_signed(values, 4))` This calls 'np.testing.assert_array with 'shifted, round_shift_signed(values, 4)' inside the function test_block_floating_shift_normalize_and_add_are_exact, which handles test block floating shift normalize and add are exact. The call advances the host-side job that checks spikingformer training runtime behavior independently with Python assertions.

Line 151: `normalized = normalize_gradient_s16(self.driver, BlockGradient(values, -15))` This assigns 'normalize_gradient_s16(self.driver, BlockGradient(values, -15))' to 'normalized ' in host memory. Here normalized means the value named 'normalized' in this block. The important operands are normalize_gradient_s16: the signed loss derivative used to update a learned parameter; driver: the value named 'driver' in this block; BlockGradient: the signed loss derivative used to update a learned parameter. Context: the function test_block_floating_shift_normalize_and_add_are_exact, which handles test block floating shift normalize and add are exact.

Line 152: `self.assertGreater(normalized.exponent, -15)` This calls 'self.assertGreater' with 'normalized.exponent, -15' inside the function test_block_floating_shift_normalize_and_add_are_exact, which handles test block floating shift normalize and add are exact. The call advances the host-side job that checks spikingformer training runtime behavior independently with Python assertions.

Line 153: `self.assertLessEqual(int(np.abs(normalized.values).max()), 32767)` This calls 'self.assertLessEqual' with 'int(np.abs(normalized.values).max()), 32767' inside the function test_block_floating_shift_normalize_and_add_are_exact, which handles test block floating shift normalize and add are exact. The call advances the host-side job that checks spikingformer training runtime behavior independently with Python assertions.

Line 154: `left = BlockGradient(np.asarray([100, -200, 300]), -12)` This assigns 'BlockGradient(np.asarray([100, -200, 300]), -12)' to 'left ' in host memory. Here left means the value named 'left' in this block. The important operands are BlockGradient: the signed loss derivative used to update a learned parameter; asarray: the value named 'asarray' in this block. Context: the function test_block_floating_shift_normalize_and_add_are_exact, which handles test block floating shift normalize and add are exact.

Line 155: `right = BlockGradient(np.asarray([800, 400, -1200]), -15)` This assigns 'BlockGradient(np.asarray([800, 400, -1200]), -15)' to 'right ' in host memory. Here right means the value named 'right' in this block. The important operands are BlockGradient: the signed loss derivative used to update a learned parameter; asarray: the value named 'asarray' in this block. Context: the function test_block_floating_shift_normalize_and_add_are_exact, which handles test block floating shift normalize and add are exact.

Line 156: `added = add_block_gradients(self.driver, left, right)` This assigns 'add_block_gradients(self.driver, left, right)' to 'added ' in host memory. Here added means the value named 'added' in this block. The important operands are add_block_gradients: the signed loss derivative used to update a learned parameter; driver: the value named 'driver' in this block; left: the value named 'left' in this block. Context: the function test_block_floating_shift_normalize_and_add_are_e which handles test block floating shift normalize and add are exact.

Line 157: `self.assertEqual(added.exponent, -12)` This calls 'self.assertEqual' with 'added.exponent, -12' inside the function test_block_floating_shift_normalize_and_add_are_exact, which handles test block floating shift normalize and add are exact. The call advances the host-side job that checks spikingformer training runtime behavior independently with Python assertions.

Line 158: `np.testing.assert_array_equal(` This statement continues through source line 161; the explanation uses the complete expression rather than only the first visual fragment. This calls 'np.testing.assert_array_equal' with ' added.values, left.values + round_shift_signed(right.values, 3), ' inside the function test_block_floating_shift_normalize_and_ad which handles test block floating shift normalize and add are exact. The call advances the host-side job that checks spikingformer training runtime behavior independently with Python assertions.

Line 159: `added.values,` This is continuation line 2 of the 4-line logical statement that begins at source line 158. Its exact fragment is 'added.values,'. The important operands are added: the value named 'added' in this block; values: the value named 'values' in this block. Read together, the complete operation is: This calls 'np.testing.assert_array_equal' with ' added.values, left.values + round_shift_signed(right.values, 3), ' inside the function test_block_floating_shift_normalize_an which handles test block floating shift normalize and add are exact. The call advances the host-side job that checks spikingformer training runtime behavior independently with Python assertions.

Line 160: `left.values + round_shift_signed(right.values, 3),` This is continuation line 3 of the 4-line logical statement that begins at source line 158. Its exact fragment is 'left.values + round_shift_signed(right.values, 3),'. The important operands are left: the value named 'left' in this block; values: the value named 'values' in this block; round_shift_signed: the value named 'round shift signed' in this block. Read together, the complete operation is: This calls 'np.testing.assert_array_equal' with ' added.values, left.values + round_shift_signed(right.values, 3), ' inside the function test_block_floating_shift_normalize_and_add_are_exact, which handles test block floating shift normalize and add are exact. The call advances the host-side job that checks spikingformer training runtime behavior independently with Python assertions.

Line 161: `)` This is continuation line 4 of the 4-line logical statement that begins at source line 158. Its exact fragment is ')'. The expression is a literal or structural operator and has no hidden software state. Read together, the complete operation is: This calls 'np.testing.assert_array_equal' with ' added.values, left.values + round_shift_signed(right.values, 3), ' inside the function test_block_floating_shift_normalize_and_add_are_exact, which handles test block floating shift normalize and add are exact. The call advances the host-side job that checks spikingformer training runtime behavior independently with Python assertions.

Line 163: `def test_projection_derivative_uses_exported_channel_scales(self) -> None:` This starts function test_projection_derivative_uses_exported_channel_scales. Its indented body performs test projection derivative uses exported channel scales as part of the file that checks spikingformer training runtime behavior independently with Python assertions; it runs only when called.

Line 164: `parameters = TinyParameterArchive().projection("tiny")` This assigns 'TinyParameterArchive().projection("ti to 'parameters ' in host memory. Here parameters means the value named 'parameters' in this block. The important operands are TinyParameterArchive: the value named 'tiny parameter archive' in this block; projection: the value named 'projection' in this block; tiny: the value named 'tiny' in this block. Context: the function test_projection_derivative_uses_exported which handles test projection derivative uses exported channel scales.

Line 165: `gradient = BlockGradient(` This statement continues through source line 168; the explanation uses the complete expression rather than only the first visual fragment. This assigns 'BlockGradient(np.asarray([[31000, -27000], [-11000, 9000], [777, -333]], dtype=np.int64), -15,)' to 'gradient ' in host memory. Here gradient means the signed loss derivative used to update a learned parameter. The important operands are BlockGradient: the signed loss derivative used to update a learned parameter; asarray: the value named 'asarray' in this block; dtype: the value named 'dtype' in this block. Context: the function test_projection_derivative_uses_exported_channel_scales, which handles test projection derivative uses exported channel scales.

Line 166: `np.asarray([[31000, -27000], [-11000, 9000], [777, -333]], dtype=np.int64),` This is continuation line 2 of the 4-line logical statement that begins at source line 165. Its exact fragment is 'np.asarray([[31000,

-27000], [-11000, 9000], [777, -333]], dtype=np.int64),‘. The important operands are asarray: the value named ’asarray’ in this block; dtype: the value named ’dtype’ in this block; int64: the value named ’int64’ in this block. Read together, the complete operation is: This assigns ‘BlockGradient(np.asarray([[31000, -27000], [-11000, 9000], [777, -333]], dtype=np.int64), -15,)‘ to ‘gradient ‘ in host memory. Here gradient means the signed loss derivative used to update a learned parameter. The important operands are BlockGradient: the signed loss derivative used to update a learned parameter; asarray: the value named ’asarray’ in this block; dtype: the value named ’dtype’ in this block. Context: the function test_projection_derivative_uses_exported_channel_scales, which handles test projection derivative uses exported channel scales.

Line 167: `-15,` This is continuation line 3 of the 4-line logical statement that begins at source line 165. Its exact fragment is ‘-15,‘. The expression is a literal or structural operator and has no hidden software state. Read together, the complete operation is: This assigns ‘BlockGradient(np.asarray([[31000, -27000], [-11000, 9000], [777, -333]], dtype=np.int64), -15,)‘ to ‘gradient ‘ in host memory. Here gradient means the signed loss derivative used to update a learned parameter. The important operands are BlockGradient: the signed loss derivative used to update a learned parameter; asarray: the value named ’asarray’ in this block; dtype: the value named ’dtype’ in this block. Context: the function test_projection_derivative_uses_exported_channel_scales, which handles test projection derivative uses exported channel scales.

Line 168: `)` This is continuation line 4 of the 4-line logical statement that begins at source line 165. Its exact fragment is ‘)‘. The expression is a literal or structural operator and has no hidden software state. Read together, the complete operation is: This assigns ‘BlockGradient(np.asarray([[31000, -27000], [-11000, 9000], [777, -333]], dtype=np.int64), -15,)‘ to ‘gradient ‘ in host memory. Here gradient means the signed loss derivative used to update a learned parameter. The important operands are BlockGradient: the signed loss derivative used to update a learned parameter; asarray: the value named ’asarray’ in this block; dtype: the value named ’dtype’ in this block. Context: the function test_projection_derivative_uses_exported_channel_scales, which handles test projection derivative uses exported channel scales.

Line 169: `actual = backward_requantize_projection(self.driver, gradient, parameters)` This assigns ‘backward_requantize_projection(self.driver, gradient, parameters)‘ to ‘actual ‘ in host memory. Here actual means the value named ’actual’ in this block. The important operands are backward_requantize_projection: the conversion of a wide accumulated result back into a bounded activation code; driver: the value named ’driver’ in this block; gradient: the signed loss derivative used to update a learned parameter. Context: the function test_projection_derivative_uses_exported_channel_scal which handles test projection derivative uses exported channel scales.

Line 170: `boost = gradient.exponent - actual.exponent` This assigns ‘gradient.exponent - actual.exponent‘ to ‘boost ‘ in host memory. Here boost means the value named ’boost’ in this block. The important operands are gradient: the signed loss derivative used to update a learned parameter; exponent: the value named ’exponent’ in this block; actual: the value named ’actual’ in this block. Context: the function test_projection_derivative_uses_exported_channel_scales, which handles test projection derivative uses exported channel scales.

Line 171: `expected = np.empty_like(gradient.values)` This assigns ‘np.empty_like(gradient.values)‘ to ‘expected ‘ in host memory. Here expected means the value named ’expected’ in this block. The important operands are empty_like: the value named ’empty like’ in this block; gradient: the signed loss derivative used to update a learned parameter; values: the value named ’values’ in this block. Context: the function test_projection_derivative_uses_exported_channel_scales, which handles test projection derivative uses exported channel scales.

Line 172: `for channel in range(2):` This iterates channel over ‘range(2)‘. Each iteration repeats the indented host operation, commonly once per layer, tile, timestep, or test case in the function test_projection_derivative_uses_exported_channel_ which handles test projection derivative uses exported channel scales.

Line 173: `expected[:, channel] = round_shift_signed(` This statement continues through source line 176; the explanation uses the complete expression rather than only the first visual fragment. This assigns ‘round_shift_signed(gradient.values[:, channel] * int(parameters.multiplier_q15[channel]), 15 + int(parameters.binary_point_shift[channel]) - boost,)‘ to ‘expected[‘ in host memory. Here expected means the value named ’expected’ in this block. The important operands are round_shift_signed: the value named ’round shift signed’ in this block; gradient: the signed loss

derivative used to update a learned parameter; values: the value named 'values' in this block. Context: the function test_projection_derivative_uses_exported_channel_scales, which handles test projection derivative uses exported channel scales.

Line 174: `gradient.values[:, channel] * int(parameters.multiplier_q15[channel]),` This is continuation line 2 of the 4-line logical statement that begins at source line 173. Its exact fragment is 'gradient.values[:, channel] * int(parameters.multiplier_q15[channel]),'. The important operands are gradient: the signed loss derivative used to update a learned parameter; values: the value named 'values' in this block; channel: the value named 'channel' in this block. Read together, the complete operation is: This assigns 'round_shift_signed(gradient.values[:, channel] * int(parameters.multiplier_q15[channel]), 15 + int(parameters.binary_point_shift[channel]) - boost,)' to 'expected[' in host memory. Here expected means the value named 'expected' in this block. The important operands are round_shift_signed: the value named 'round shift signed' in this block; gradient: the signed loss derivative used to update a learned parameter; values: the value named 'values' in this block. Context: the function test_projection_derivative_uses_exported which handles test projection derivative uses exported channel scales.

Line 175: `15 + int(parameters.binary_point_shift[channel]) - boost,` This is continuation line 3 of the 4-line logical statement that begins at source line 173. Its exact fragment is '15 + int(parameters.binary_point_shift[channel]) - boost,'. The important operands are parameters: the value named 'parameters' in this block; binary_point_shift: the value named 'binary point shift' in this block; channel: the value named 'channel' in this block. Read together, the complete operation is: This assigns 'round_shift_signed(gradient.values[:, channel] * int(parameters.multiplier_q15[channel]), 15 + int(parameters.binary_point_shift[channel]) - boost,)' to 'expected[' in host memory. Here expected means the value named 'expected' in this block. The important operands are round_shift_signed: the value named 'round shift signed' in this block; gradient: the signed loss derivative used to update a learned parameter; values: the value named 'values' in this block. Context: the function test_projection_derivative_uses_exported_channel_scales, which handles test projection derivative uses exported channel scales.

Line 176: `)` This is continuation line 4 of the 4-line logical statement that begins at source line 173. Its exact fragment is ')'. The expression is a literal or structural operator and has no hidden software state. Read together, the complete operation is: This assigns 'round_shift_signed(gradient.values[:, channel] * int(parameters.multiplier_q15[channel]), 15 + int(parameters.binary_point_shift[channel]) - boost,)' to 'expected[' in host memory. Here expected means the value named 'expected' in this block. The important operands are round_shift_signed: the value named 'round shift signed' in this block; gradient: the signed loss derivative used to update a learned parameter; values: the value named 'values' in this block. Context: the function test_projection_derivative_uses_exported_channel_scales, which handles test projection derivative uses exported channel scales.

Line 177: `np.testing.assert_array_equal(actual.values, expected)` This calls 'np.testing.assert_array_equal' with 'actual.values, expected' inside the function test_projection_derivative_uses_exported_channel_scales, which handles test projection derivative uses exported channel scales. The call advances the host-side job that checks spikingformer training runtime behavior independently with Python assertions.

Line 178: `self.assertLessEqual(int(np.abs(actual.values).max()), 32767)` This calls 'self.assertLessEqual' with 'int(np.abs(actual.values).max()), 32767' inside the function test_projection_derivative_uses_exported_channel_scales, which handles test projection derivative uses exported channel scales. The call advances the host-side job that checks spikingformer training runtime behavior independently with Python assertions.

Line 180: `def test_affine_backward_returns_exact_dx_dw_and_bias(self) -> None:` This starts function test_affine_bac Its indented body performs test affine backward returns exact dx dw and bias as part of the file that checks spikingformer training runtime behavior independently with Python assertions; it runs only when called.

Line 181: `x = np.asarray([[3, -2, 1], [-4, 5, 2], [7, 1, -3]], dtype=np.int64)` This assigns 'np.asarray([[3, -2, 1], [-4, 5, 2], [7, 1, -3]], dtype=np.int64)' to 'x ' in host memory. Here x means the value named 'x' in this block. The important operands are asarray: the value named 'asarray' in this block; dtype: the value named 'dtype' in this block; int64: the value named 'int64' in this block. Context: the function test_affine_backward_returns_exact_dx_dw_and_bias, which handles test affine backward returns exact dx dw and bias.

Line 182: `w = np.asarray([[2, -1], [4, 3], [-5, 6]], dtype=np.int64)` This assigns ‘np.asarray([[2, -1], [4, 3], [-5, 6]], dtype=np.int64)‘ to ‘w ‘ in host memory. Here w means the value named ’w’ in this block. The important operands are asarray: the value named ’asarray’ in this block; dtype: the value named ’dtype’ in this block; int64: the value named ’int64’ in this block. Context: the function test_affine_backward_returns_exact_dx_dw_and_bias, which handles test affine backward returns exact dx dw and bias.

Line 183: `bias = np.asarray([9, -8], dtype=np.int64)` This assigns ‘np.asarray([9, -8], dtype=np.int64)‘ to ‘bias ‘ in host memory. Here bias means an additive learned offset applied after accumulation. The important operands are asarray: the value named ’asarray’ in this block; dtype: the value named ’dtype’ in this block; int64: the value named ’int64’ in this block. Context: the function test_affine_backward_returns_exact_dx_dw_and_bias, which handles test affine backward returns exact dx dw and bias.

Line 184: `dy = np.asarray([[11, -7], [5, 13], [-3, 2]], dtype=np.int64)` This assigns ‘np.asarray([[11, -7], [5, 13], [-3, 2]], dtype=np.int64)‘ to ‘dy ‘ in host memory. Here dy means the value named ’dy’ in this block. The important operands are asarray: the value named ’asarray’ in this block; dtype: the value named ’dtype’ in this block; int64: the value named ’int64’ in this block. Context: the function test_affine_backward_returns_exact_dx_dw_and_bias, which handles test affine backward returns exact dx dw and bias.

Line 185: `dx, parameter = execute_affine_backward_block(` This statement continues through source line 186; the explanation uses the complete expression rather than only the first visual fragment. This assigns ‘execute_affine_backward_bloc self.driver, x, w, bias, BlockGradient(dy, -15))‘ to ‘dx, parameter ‘ in host memory. Here dx means the value named ’dx’ in this block. The important operands are execute_affine_backward_block: the value named ’execute affine backward block’ in this block; driver: the value named ’driver’ in this block; x: the value named ’x’ in this block. Context: the function test_affine_backward_returns_exact_dx_dw_and_bias, which handles test affine backward returns exact dx dw and bias.

Line 186: `self.driver, x, w, bias, BlockGradient(dy, -15))` This is continuation line 2 of the 2-line logical statement that begins at source line 185. Its exact fragment is ‘self.driver, x, w, bias, BlockGradient(dy, -15))‘. The important operands are driver: the value named ’driver’ in this block; x: the value named ’x’ in this block; w: the value named ’w’ in this block. Read together, the complete operation is: This assigns ‘execute_affine_backward_block(self.driver, x, w, bias, BlockGradient(dy, -15))‘ to ‘dx, parameter ‘ in host memory. Here dx means the value named ’dx’ in this block. The important operands are execute_affine_backward_block: the value named ’execute affine backward block’ in this block; driver: the value named ’driver’ in this block; x: the value named ’x’ in this block. Context: the function test_affine_backward_returns_exact_dx_dw_and_bias, which handles test affine backward returns exact dx dw and bias.

Line 187: `self.assertEqual(dx.exponent, -15)` This calls ‘self.assertEqual‘ with ‘dx.exponent, -15‘ inside the function test_affine_backward_returns_exact_dx_dw_and_bias, which handles test affine backward returns exact dx dw and bias. The call advances the host-side job that checks spikingformer training runtime behavior independently with Python assertions.

Line 188: `self.assertEqual(parameter.weight.exponent, -15)` This calls ‘self.assertEqual‘ with ‘parameter.weight.exponent -15‘ inside the function test_affine_backward_returns_exact_dx_dw_and_bias, which handles test affine backward returns exact dx dw and bias. The call advances the host-side job that checks spikingformer training runtime behavior independently with Python assertions.

Line 189: `np.testing.assert_array_equal(dx.values, dy @ w.T)` This calls ‘np.testing.assert_array_equal‘ with ‘dx.values, dy @ w.T‘ inside the function test_affine_backward_returns_exact_dx_dw_and_bias, which handles test affine backward returns exact dx dw and bias. The call advances the host-side job that checks spikingformer training runtime behavior independently with Python assertions.

Line 190: `np.testing.assert_array_equal(parameter.weight.values, x.T @ dy)` This calls ‘np.testing.assert_array_equa with ‘parameter.weight.values, x.T @ dy‘ inside the function test_affine_backward_returns_exact_dx_dw_and_bias, which handles test affine backward returns exact dx dw and bias. The call advances the host-side job that checks spikingformer training runtime behavior independently with Python assertions.

Line 191: `np.testing.assert_array_equal(parameter.bias.values, dy.sum(axis=0))` This calls ‘np.testing.assert_array_ with ‘parameter.bias.values, dy.sum(axis=0)‘ inside the function test_affine_backward_returns_exact_dx_dw_and_bias, which handles test affine backward returns exact dx dw and bias. The call advances the host-side job that checks spikingformer training runtime behavior independently with Python assertions.

Line 193: `def test_hardware_softmax_and_batch_mean_cross_entropy_gradient(self) -> None:` This starts function test_hardware_softmax_and_batch_mean_cross_entropy_gradient. Its indented body performs test hardware softmax and batch mean cross entropy gradient as part of the file that checks spikingformer training runtime behavior independently with Python assertions; it runs only when called.

Line 194: `logits = np.asarray([[1200, -300, 77], [-80, 900, 100]], dtype=np.int64)` This assigns ‘np.asarray([[1200 -300, 77], [-80, 900, 100]], dtype=np.int64)‘ to ‘logits ‘ in host memory. Here logits means the ten unnormalized classifier scores used for argmax. The important operands are asarray: the value named ’asarray’ in this block; dtype: the value named ’dtype’ in this block; int64: the value named ’int64’ in this block. Context: the function test_hardware_softmax_and_batch_mean_cross_entropy_gradient, which handles test hardware softmax and batch mean cross entropy gradient.

Line 195: `probabilities = execute_softmax_q15(` This statement continues through source line 196; the explanation uses the complete expression rather than only the first visual fragment. This assigns ‘execute_softmax_q15(self.driver, logits, difference_shift=8)‘ to ‘probabilities ‘ in host memory. Here probabilities means the value named ’probabilities’ in this block. The important operands are execute_softmax_q15: the value named ’execute softmax q15’ in this block; driver: the value named ’driver’ in this block; logits: the ten unnormalized classifier scores used for argmax. Context: the function test_hardware_softmax_and_batch_mean_cross_entropy_gradient, which handles test hardware softmax and batch mean cross entropy gradient.

Line 196: `self.driver, logits, difference_shift=8)` This is continuation line 2 of the 2-line logical statement that begins at source line 195. Its exact fragment is ‘self.driver, logits, difference_shift=8)‘. The important operands are driver: the value named ’driver’ in this block; logits: the ten unnormalized classifier scores used for argmax; difference_shift: the value named ’difference shift’ in this block. Read together, the complete operation is: This assigns ‘execute_softmax_q15(self.driver, logits, difference_shift=8)‘ to ‘probabilities ‘ in host memory. Here probabilities means the value named ’probabilities’ in this block. The important operands are execute_softmax_q15: the value named ’execute softmax q15’ in this block; driver: the value named ’driver’ in this block; logits: the ten unnormalized classifier scores used for argmax. Context: the function test_hardware_softmax_and_batch_mean_cross_entropy_gradient, which handles test hardware softmax and batch mean cross entropy gradient.

Line 197: `gradient = execute_cross_entropy_gradient_q15(` This statement continues through source line 198; the explanation uses the complete expression rather than only the first visual fragment. This assigns ‘execute_cross_entropy_gradien self.driver, probabilities, np.asarray([0, 2]))‘ to ‘gradient ‘ in host memory. Here gradient means the signed loss derivative used to update a learned parameter. The important operands are execute_cross_entropy_gradient_q15: the signed loss derivative used to update a learned parameter; driver: the value named ’driver’ in this block; probabilities: the value named ’probabilities’ in this block. Context: the function test_hardware_softmax_and_batch_mean_cross_entropy_gradient, which handles test hardware softmax and batch mean cross entropy gradient.

Line 198: `self.driver, probabilities, np.asarray([0, 2]))` This is continuation line 2 of the 2-line logical statement that begins at source line 197. Its exact fragment is ‘self.driver, probabilities, np.asarray([0, 2]))‘. The important operands are driver: the value named ’driver’ in this block; probabilities: the value named ’probabilities’ in this block; asarray: the value named ’asarray’ in this block. Read together, the complete operation is: This assigns ‘execute_cross_entropy_gradient_q15(self.driver, probabilities, np.asarray([0, 2]))‘ to ‘gradient ‘ in host memory. Here gradient means the signed loss derivative used to update a learned parameter. The important operands are execute_cross_entropy_gradient_q15: the signed loss derivative used to update a learned parameter; driver: the value named ’driver’ in this block; probabilities: the value named ’probabilities’ in this block. Context: the function test_hardware_softmax_and_batch_mean_cross_entropy_gradient, which handles test hardware softmax and batch mean cross entropy gradient.

Line 199: `self.assertEqual(gradient.exponent, -15)` This calls ‘self.assertEqual‘ with ‘gradient.exponent, -15‘ inside the function test_hardware_softmax_and_batch_mean_cross_entropy_gradient, which handles test hardware

softmax and batch mean cross entropy gradient. The call advances the host-side job that checks spikingformer training runtime behavior independently with Python assertions.

Line 200: `expected = probabilities.copy()` This assigns ‘probabilities.copy()‘ to ‘expected ‘ in host memory. Here expected means the value named ’expected’ in this block. The important operands are probabilities: the value named ’probabilities’ in this block; copy: the value named ’copy’ in this block. Context: the function test_hardware_softmax_and_batch_
which handles test hardware softmax and batch mean cross entropy gradient.

Line 201: `expected[0, 0] -= 1 << 15` Inside the function test_hardware_softmax_and_batch_mean_cross_entropy_gradie
which handles test hardware softmax and batch mean cross entropy gradient, this statement advances the host implementation that checks spikingformer training runtime behavior independently with Python assertions. The important operands are expected: the value named ’expected’ in this block.

Line 202: `expected[1, 2] -= 1 << 15` Inside the function test_hardware_softmax_and_batch_mean_cross_entropy_gradie
which handles test hardware softmax and batch mean cross entropy gradient, this statement advances the host implementation that checks spikingformer training runtime behavior independently with Python assertions. The important operands are expected: the value named ’expected’ in this block.

Line 203: `expected = round_shift_signed(expected, 1)` This assigns ‘round_shift_signed(expected, 1)‘ to ‘expected ‘ in host memory. Here expected means the value named ’expected’ in this block. The important operands are round_shift_signed: the value named ’round shift signed’ in this block; expected: the value named ’expected’ in this block. Context: the function test_hardware_softmax_and_batch_mean_cross_entropy_gradient, which handles test hardware softmax and batch mean cross entropy gradient.

Line 204: `np.testing.assert_array_equal(gradient.values, expected)` This calls ‘np.testing.assert_array_equal‘ with ‘gradient.values, expected‘ inside the function test_hardware_softmax_and_batch_mean_cross_entropy_gradient, which handles test hardware softmax and batch mean cross entropy gradient. The call advances the host-side job that checks spikingformer training runtime behavior independently with Python assertions.

Line 206: `def test_low_rate_bias_update_retains_q16_learning_rate_resolution(self) -> None:` This starts function test_low_rate_bias_update_retains_q16_learning_rate_resolution. Its indented body performs test low rate bias update retains q16 learning rate resolution as part of the file that checks spikingformer training runtime behavior independently with Python assertions; it runs only when called.

Line 207: `tensor = MasterTensor(` This statement continues through source line 213; the explanation uses the complete expression rather than only the first visual fragment. This assigns ‘MasterTensor(np.asarray([0], dtype=np.int16), np.asarray([0], dtype=np.int32), 2, -(1 << 15), (1 << 15) - 1,)‘ to ‘tensor ‘ in host memory. Here tensor means the value named ’tensor’ in this block. The important operands are MasterTensor: the value named ’master tensor’ in this block; asarray: the value named ’asarray’ in this block; dtype: the value named ’dtype’ in this block. Context: the function test_low_rate_bias_update_retains_q16_learning_rate_resolution, which handles test low rate bias update retains q16 learning rate resolution.

Line 208: `np.asarray([0], dtype=np.int16),` This is continuation line 2 of the 7-line logical statement that begins at source line 207. Its exact fragment is ‘np.asarray([0], dtype=np.int16),‘. The important operands are asarray: the value named ’asarray’ in this block; dtype: the value named ’dtype’ in this block; int16: the value named ’int16’ in this block. Read together, the complete operation is: This assigns ‘MasterTensor(np.asarray([0], dtype=np.int16), np.asarray([0], dtype=np.int32), 2, -(1 << 15), (1 << 15) - 1,)‘ to ‘tensor ‘ in host memory. Here tensor means the value named ’tensor’ in this block. The important operands are MasterTensor: the value named ’master tensor’ in this block; asarray: the value named ’asarray’ in this block; dtype: the value named ’dtype’ in this block. Context: the function test_low_rate_bias_update_retains_q16_learning_rate_resolution, which handles test low rate bias update retains q16 learning rate resolution.

Line 209: `np.asarray([0], dtype=np.int32),` This is continuation line 3 of the 7-line logical statement that begins at source line 207. Its exact fragment is ‘np.asarray([0], dtype=np.int32),‘. The important operands are asarray: the value named ’asarray’ in this block; dtype: the value named ’dtype’ in this block; int32: the value named ’int32’ in

this block. Read together, the complete operation is: This assigns ‘MasterTensor(np.asarray([0], dtype=np.int16), np.asarray([0], dtype=np.int32), 2, -(1 << 15), (1 << 15) - 1,)‘ to ‘tensor ‘ in host memory. Here tensor means the value named ’tensor’ in this block. The important operands are MasterTensor: the value named ’master tensor’ in this block; asarray: the value named ’asarray’ in this block; dtype: the value named ’dtype’ in this block. Context: the function test_low_rate_bias_update_retains_q16_learning_rate_resolution, which handles test low rate bias update retains q16 learning rate resolution.

Line 210: `2,` This is continuation line 4 of the 7-line logical statement that begins at source line 207. Its exact fragment is ‘2,‘. The expression is a literal or structural operator and has no hidden software state. Read together, the complete operation is: This assigns ‘MasterTensor(np.asarray([0], dtype=np.int16), np.asarray([0], dtype=np.int32), 2, -(1 << 15), (1 << 15) - 1,)‘ to ‘tensor ‘ in host memory. Here tensor means the value named ’tensor’ in this block. The important operands are MasterTensor: the value named ’master tensor’ in this block; asarray: the value named ’asarray’ in this block; dtype: the value named ’dtype’ in this block. Context: the function test_low_rate_bias_update_retains_q16_learning_rate_resol which handles test low rate bias update retains q16 learning rate resolution.

Line 211: `-(1 << 15),` This is continuation line 5 of the 7-line logical statement that begins at source line 207. Its exact fragment is ‘-(1 << 15),‘. The expression is a literal or structural operator and has no hidden software state. Read together, the complete operation is: This assigns ‘MasterTensor(np.asarray([0], dtype=np.int16), np.asarray([0], dtype=np.int32), 2, -(1 << 15), (1 << 15) - 1,)‘ to ‘tensor ‘ in host memory. Here tensor means the value named ’tensor’ in this block. The important operands are MasterTensor: the value named ’master tensor’ in this block; asarray: the value named ’asarray’ in this block; dtype: the value named ’dtype’ in this block. Context: the function test_low_rate_bias_update_retains_q16_learning_rate_resolution, which handles test low rate bias update retains q16 learning rate resolution.

Line 212: `(1 << 15) - 1,` This is continuation line 6 of the 7-line logical statement that begins at source line 207. Its exact fragment is ‘(1 << 15) - 1,‘. The expression is a literal or structural operator and has no hidden software state. Read together, the complete operation is: This assigns ‘MasterTensor(np.asarray([0], dtype=np.int16), np.asarray([0], dtype=np.int32), 2, -(1 << 15), (1 << 15) - 1,)‘ to ‘tensor ‘ in host memory. Here tensor means the value named ’tensor’ in this block. The important operands are MasterTensor: the value named ’master tensor’ in this block; asarray: the value named ’asarray’ in this block; dtype: the value named ’dtype’ in this block. Context: the function test_low_rate_bias_update_retains_q16_learning_rate_resolution, which handles test low rate bias update retains q16 learning rate resolution.

Line 213: `)` This is continuation line 7 of the 7-line logical statement that begins at source line 207. Its exact fragment is ‘)‘. The expression is a literal or structural operator and has no hidden software state. Read together, the complete operation is: This assigns ‘MasterTensor(np.asarray([0], dtype=np.int16), np.asarray([0], dtype=np.int32), 2, -(1 << 15), (1 << 15) - 1,)‘ to ‘tensor ‘ in host memory. Here tensor means the value named ’tensor’ in this block. The important operands are MasterTensor: the value named ’master tensor’ in this block; asarray: the value named ’asarray’ in this block; dtype: the value named ’dtype’ in this block. Context: the function test_low_rate_bias_update_retains_q16_learning_rate_resol which handles test low rate bias update retains q16 learning rate resolution.

Line 214: `coefficients = TrainableSpikingformerState._optimizer_coefficients(` This statement continues through source line 215; the explanation uses the complete expression rather than only the first visual fragment. This assigns ‘TrainableSpikingformerState._optimizer_coefficients(tensor, 0.01, 0.9, 0.0)‘ to ‘coefficients ‘ in host memory. Here coefficients means the value named ’coefficients’ in this block. The important operands are TrainableSpikingformerState: the finite-state-machine phase retained in flip-flops; _optimizer_coefficients: the value named ’optimizer coefficients’ in this block; tensor: the value named ’tensor’ in this block. Context: the function test_low_rate_bias_update_retains_q16_learning which handles test low rate bias update retains q16 learning rate resolution.

Line 215: `tensor, 0.01, 0.9, 0.0)` This is continuation line 2 of the 2-line logical statement that begins at source line 214. Its exact fragment is ‘tensor, 0.01, 0.9, 0.0)‘. The important operands are tensor: the value named ’tensor’ in this block. Read together, the complete operation is: This assigns ‘TrainableSpikingformerState._optimizer_coefficients(tensor, 0.01, 0.9, 0.0)‘ to ‘coefficients ‘ in host memory. Here coefficients means the value named ’coefficients’ in this block. The important operands are TrainableSpikingformerState: the finite-state-machine phase retained in flip-flops; _optimizer_coefficients: the value named ’optimizer coefficients’ in this block; tensor: the value named ’tensor’ in this

block. Context: the function test_low_rate_bias_update_retains_q16_learning_rate_resolution, which handles test low rate bias update retains q16 learning rate resolution.

Line 216: `self.assertEqual(coefficients, (655, 58982, 0, 29))` This calls 'self.assertEqual' with 'coefficients, (655, 58982, 0, 29)' inside the function test_low_rate_bias_update_retains_q16_learning_rate_resolution, which handles test low rate bias update retains q16 learning rate resolution. The call advances the host-side job that checks spikingformer training runtime behavior independently with Python assertions.

Line 217: `with self.assertRaises(ValueError):` This opens a managed resource scope for 'self.assertRaises(ValueError)' so files, tracing, or temporary state are finalized even if the function test_low_rate_bias_update_retains_q16_learning_rate_resol which handles test low rate bias update retains q16 learning rate resolution raises an error.

Line 218: `TrainableSpikingformerState._optimizer_coefficients(` This statement continues through source line 219; the explanation uses the complete expression rather than only the first visual fragment. This calls 'TrainableSpikingformerState._optimizer_coefficients' with ' tensor, 1.0e-7, 0.9, 0.0' inside the function test_low_rate_bias_update_retains_q16_le which handles test low rate bias update retains q16 learning rate resolution. The call advances the host-side job that checks spikingformer training runtime behavior independently with Python assertions.

Line 219: `tensor, 1.0e-7, 0.9, 0.0)` This is continuation line 2 of the 2-line logical statement that begins at source line 218. Its exact fragment is 'tensor, 1.0e-7, 0.9, 0.0)'. The important operands are tensor: the value named 'tensor' in this block. Read together, the complete operation is: This calls 'TrainableSpikingformerState._optimizer_coefficients' with ' tensor, 1.0e-7, 0.9, 0.0' inside the function test_low_rate_bias_update_retains_q16_learning_rate_resolution, which handles test low rate bias update retains q16 learning rate resolution. The call advances the host-side job that checks spikingformer training runtime behavior independently with Python assertions.

Line 221: `def test_full_parameter_update_and_atomic_checkpoint_round_trip(self) -> None:` This starts function test_full_parameter_update_and_atomic_checkpoint_round_trip. Its indented body performs test full parameter update and atomic checkpoint round trip as part of the file that checks spikingformer training runtime behavior independently with Python assertions; it runs only when called.

Line 222: `state = TrainableSpikingformerState(TinyParameterArchive())` This assigns 'TrainableSpikingformerState(TinyParameterArchive())' to 'state ' in host memory. Here state means the finite-state-machine phase retained in flip-flops. The important operands are TrainableSpikingformerState: the finite-state-machine phase retained in flip-flops; TinyParameterArchive: the value named 'tiny parameter archive' in this block. Context: the function test_full_parameter_update_and_atomic_checkpoint_round_trip, which handles test full parameter update and atomic checkpoint round trip.

Line 223: `projection = state.projection("tiny")` This assigns 'state.projection("tiny")' to 'projection ' in host memory. Here projection means the value named 'projection' in this block. The important operands are state: the finite-state-machine phase retained in flip-flops; projection: the value named 'projection' in this block; tiny: the value named 'tiny' in this block. Context: the function test_full_parameter_update_and_atomic_checkpoint_round_trip, which handles test full parameter update and atomic checkpoint round trip.

Line 224: `head = state.head` This assigns 'state.head' to 'head ' in host memory. Here head means the value named 'head' in this block. The important operands are state: the finite-state-machine phase retained in flip-flops; head: the value named 'head' in this block. Context: the function test_full_parameter_update_and_atomic_checkpoint_round_trip, which handles test full parameter update and atomic checkpoint round trip.

Line 225: `gradients = {` This statement continues through source line 234; the explanation uses the complete expression rather than only the first visual fragment. This assigns '{ "tiny": ParameterGradient(BlockGradient(np.full(projection.weight_k 65536), -15), BlockGradient(np.full(projection.bias_q10.shape, -32768), -15),), "head": ParameterGradient(BlockGradient(np.full(head.weight_k_by_n.shape, -65536), -15), BlockGradient(np.full(head.bias_accumulator_units.shape, 32768), -15),), }' to 'gradients ' in host memory. Here gradients means the signed loss derivative used to update a learned parameter. The important operands are tiny: the value named 'tiny' in this block; ParameterGradient: the signed loss derivative used to update a learned parameter; BlockGradient: the signed loss derivative used to update a

learned parameter. Context: the function test_full_parameter_update_and_atomic_checkpoint_round_trip, which handles test full parameter update and atomic checkpoint round trip.

Line 226: `"tiny": ParameterGradient(` This is continuation line 2 of the 10-line logical statement that begins at source line 225. Its exact fragment is '"tiny": ParameterGradient('. The important operands are tiny: the value named 'tiny' in this block; ParameterGradient: the signed loss derivative used to update a learned parameter. Read together, the complete operation is: This assigns '{ "tiny": ParameterGradient(BlockGradient(np.full(projection.weight_k_by_n.shape, 65536), -15), BlockGradient(np.full(projection.bias_q10.shape, -32768), -15),), "head": ParameterGradient(BlockGradient(np.full(head.weight_k_by_n.shape, -65536), -15), BlockGradient(np.full(head.bias_accumulator_units.shape, 32768), -15),), }' to 'gradients ' in host memory. Here gradients means the signed loss derivative used to update a learned parameter. The important operands are tiny: the value named 'tiny' in this block; ParameterGradient: the signed loss derivative used to update a learned parameter; BlockGradient: the signed loss derivative used to update a learned parameter. Context: the function test_full_parameter_update_and_atomic_checkpoint_round_trip, which handles test full parameter update and atomic checkpoint round trip.

Line 227: `BlockGradient(np.full(projection.weight_k_by_n.shape, 65536), -15),` This is continuation line 3 of the 10-line logical statement that begins at source line 225. Its exact fragment is 'BlockGradient(np.full(projection.weight_k_by_n
65536), -15),'. The important operands are BlockGradient: the signed loss derivative used to update a learned parameter; full: the value named 'full' in this block; projection: the value named 'projection' in this block. Read together, the complete operation is: This assigns '{ "tiny": ParameterGradient(BlockGradient(np.full(projection.weight_k_by_n.shape, 65536), -15), BlockGradient(np.full(projection.bias_q10.shape, -32768), -15),), "head": ParameterGradient(BlockGradient(np.full(head.weight_k_by_n.shape, -65536), -15), BlockGradient(np.full(head.bias_accumulator_units.shape, 32768), -15),), }' to 'gradients ' in host memory. Here gradients means the signed loss derivative used to update a learned parameter. The important operands are tiny: the value named 'tiny' in this block; ParameterGradient: the signed loss derivative used to update a learned parameter; BlockGradient: the signed loss derivative used to update a learned parameter. Context: the function test_full_parameter_update_and_atomic_checkpoint_round_trip, which handles test full parameter update and atomic checkpoint round trip.

Line 228: `BlockGradient(np.full(projection.bias_q10.shape, -32768), -15),` This is continuation line 4 of the 10-line logical statement that begins at source line 225. Its exact fragment is 'BlockGradient(np.full(projection.bias_q10.shape, -32768), -15),'. The important operands are BlockGradient: the signed loss derivative used to update a learned parameter; full: the value named 'full' in this block; projection: the value named 'projection' in this block. Read together, the complete operation is: This assigns '{ "tiny": ParameterGradient(BlockGradient(np.full(projection.weight_k_by_n.shape, 65536), -15), BlockGradient(np.full(projection.bias_q10.shape, -32768), -15),), "head": ParameterGradient(BlockGradient(np.full(head.weight_k_by_n.shape, -65536), -15), BlockGradient(np.full(head.bias_accumulator_units.shape, 32768), -15),), }' to 'gradients ' in host memory. Context: the function test_full_parameter_update_and_atomic_checkpoint_round_trip, which handles test full parameter update and atomic checkpoint round trip.

Line 235: `state.apply_gradients(` This statement continues through source line 241; the explanation uses the complete expression rather than only the first visual fragment. This calls ‘state.apply_gradients‘ with ‘ self.driver, gradients, learning_rate=0.25, momentum=0.0, weight_decay=0.0, ‘ inside the function test_full_parameter_update_and_atomic_checkpoi which handles test full parameter update and atomic checkpoint round trip. The call advances the host-side job that checks spikingformer training runtime behavior independently with Python assertions.

Line 236: `self.driver,` This is continuation line 2 of the 7-line logical statement that begins at source line 235. Its exact fragment is ‘self.driver,‘. The important operands are driver: the value named ’driver’ in this block. Read together, the complete operation is: This calls ‘state.apply_gradients‘ with ‘ self.driver, gradients, learning_rate=0.25, momentum=0.0, weight_decay=0.0, ‘ inside the function test_full_parameter_update_and_atomic_checkpoint_round_trip, which handles test full parameter update and atomic checkpoint round trip. The call advances the host-side job that checks spikingformer training runtime behavior independently with Python assertions.

Line 237: `gradients,` This is continuation line 3 of the 7-line logical statement that begins at source line 235. Its exact fragment is ‘gradients,‘. The important operands are gradients: the signed loss derivative used to update a learned parameter. Read together, the complete operation is: This calls ‘state.apply_gradients‘ with ‘ self.driver, gradients, learning_rate=0.25, momentum=0.0, weight_decay=0.0, ‘ inside the function test_full_parameter_update_and_atomic_checkpoint_r which handles test full parameter update and atomic checkpoint round trip. The call advances the host-side job that checks spikingformer training runtime behavior independently with Python assertions.

Line 238: `learning_rate=0.25,` This is continuation line 4 of the 7-line logical statement that begins at source line 235. Its exact fragment is ‘learning_rate=0.25,‘. The important operands are learning_rate: the fixed-point multiplier controlling update magnitude. Read together, the complete operation is: This calls ‘state.apply_gradients‘ with ‘ self.driver, gradients, learning_rate=0.25, momentum=0.0, weight_decay=0.0, ‘ inside the function test_full_parameter_update_a which handles test full parameter update and atomic checkpoint round trip. The call advances the host-side job that checks spikingformer training runtime behavior independently with Python assertions.

Line 239: `momentum=0.0,` This is continuation line 5 of the 7-line logical statement that begins at source line 235. Its exact fragment is ‘momentum=0.0,‘. The important operands are momentum: the value named ’momentum’ in this block. Read together, the complete operation is: This calls ‘state.apply_gradients‘ with ‘ self.driver, gradients, learning_rate=0.25, momentum=0.0, weight_decay=0.0, ‘ inside the function test_full_parameter_update_and_atomic_checkpoint_r which handles test full parameter update and atomic checkpoint round trip. The call advances the host-side job that checks spikingformer training runtime behavior independently with Python assertions.

Line 240: `weight_decay=0.0,` This is continuation line 6 of the 7-line logical statement that begins at source line 235. Its exact fragment is ‘weight_decay=0.0,‘. The important operands are weight_decay: a learned coefficient multiplied by an activation. Read together, the complete operation is: This calls ‘state.apply_gradients‘ with ‘ self.driver, gradients, learning_rate=0.25, momentum=0.0, weight_decay=0.0, ‘ inside the function test_full_parameter_update_and_atomic_checkpoi which handles test full parameter update and atomic checkpoint round trip. The call advances the host-side job that checks spikingformer training runtime behavior independently with Python assertions.

Line 241: `)` This is continuation line 7 of the 7-line logical statement that begins at source line 235. Its exact fragment is ‘)‘. The expression is a literal or structural operator and has no hidden software state. Read together, the complete operation is: This calls ‘state.apply_gradients‘ with ‘ self.driver, gradients, learning_rate=0.25, momentum=0.0, weight_decay=0.0, ‘ inside the function test_full_parameter_update_and_atomic_checkpoint_round_trip, which handles test full parameter update and atomic checkpoint round trip. The call advances the host-side job that checks spikingformer training runtime behavior independently with Python assertions.

Line 242: `self.assertEqual(state.optimizer_step, 1)` This calls ‘self.assertEqual‘ with ‘state.optimizer_step, 1‘ inside the function test_full_parameter_update_and_atomic_checkpoint_round_trip, which handles test full parameter update and atomic checkpoint round trip. The call advances the host-side job that checks spikingformer training runtime behavior independently with Python assertions.

Line 243: `self.assertFalse(np.array_equal(state.projection("tiny").weight_k_by_n,` This statement continues through source line 244; the explanation uses the complete expression rather than only the first visual fragment.

This calls ‘self.assertFalse‘ with ‘np.array_equal(state.projection("tiny").weight_k_by_n, projection.weight_k_by_n)‘ inside the function test_full_parameter_update_and_atomic_checkpoint_round_trip, which handles test full parameter update and atomic checkpoint round trip. The call advances the host-side job that checks spikingformer training runtime behavior independently with Python assertions.

Line 244: `projection.weight_k_by_n))` This is continuation line 2 of the 2-line logical statement that begins at source line 243. Its exact fragment is ‘projection.weight_k_by_n))‘. The important operands are projection: the value named ’projection’ in this block; weight_k_by_n: a learned coefficient multiplied by an activation. Read together, the complete operation is: This calls ‘self.assertFalse‘ with ‘np.array_equal(state.projection("tiny").weight_k_by_n, projection.weight_k_by_n)‘ inside the function test_full_parameter_update_and_atomic_checkpoint_round_trip, which handles test full parameter update and atomic checkpoint round trip. The call advances the host-side job that checks spikingformer training runtime behavior independently with Python assertions.

Line 245: `self.assertFalse(np.array_equal(state.head.weight_k_by_n, head.weight_k_by_n))` This calls ‘self.assertFal with ‘np.array_equal(state.head.weight_k_by_n, head.weight_k_by_n)‘ inside the function test_full_parameter_update_and_a which handles test full parameter update and atomic checkpoint round trip. The call advances the host-side job that checks spikingformer training runtime behavior independently with Python assertions.

Line 247: `with tempfile.TemporaryDirectory() as temporary:` This opens a managed resource scope for ‘tempfile.TemporaryDirectory() as temporary‘ so files, tracing, or temporary state are finalized even if the function test_full_parameter_u which handles test full parameter update and atomic checkpoint round trip raises an error.

Line 248: `checkpoint = Path(temporary) / "latest_checkpoint.npz"` This assigns ‘Path(temporary) / "latest_checkpoint.n to ‘checkpoint ‘ in host memory. Here checkpoint means the value named ’checkpoint’ in this block. The important operands are Path: the value named ’path’ in this block; temporary: the value named ’temporary’ in this block; latest_checkpoint: the value named ’latest checkpoint’ in this block. Context: the function test_full_parameter_update_and_atomic which handles test full parameter update and atomic checkpoint round trip.

Line 249: `digest = state.save_checkpoint(` This statement continues through source line 255; the explanation uses the complete expression rather than only the first visual fragment. This assigns ‘state.save_checkpoint(checkpoint, epoch=3, batch_index=17, best_accuracy_percent=95.75, extra={"reason": "unit-test"},)‘ to ‘digest ‘ in host memory. Here digest means the value named ’digest’ in this block. The important operands are state: the finite-state-machine phase retained in flip-flops; save_checkpoint: the value named ’save checkpoint’ in this block; checkpoint: the value named ’checkpoint’ in this block. Context: the function test_full_parameter_update_and_atomic_checkpoint_round_trip, which handles test full parameter update and atomic checkpoint round trip.

Line 250: `checkpoint,` This is continuation line 2 of the 7-line logical statement that begins at source line 249. Its exact fragment is ‘checkpoint,‘. The important operands are checkpoint: the value named ’checkpoint’ in this block. Read together, the complete operation is: This assigns ‘state.save_checkpoint(checkpoint, epoch=3, batch_index=17, best_accuracy_percent=95.75, extra={"reason": "unit-test"},)‘ to ‘digest ‘ in host memory. Here digest means the value named ’digest’ in this block. The important operands are state: the finite-state-machine phase retained in flip-flops; save_checkpoint: the value named ’save checkpoint’ in this block; checkpoint: the value named ’checkpoint’ in this block. Context: the function test_full_parameter_update_and_atomic_checkpoint_round_trip, which handles test full parameter update and atomic checkpoint round trip.

Line 251: `epoch=3,` This is continuation line 3 of the 7-line logical statement that begins at source line 249. Its exact fragment is ‘epoch=3,‘. The important operands are epoch: the value named ’epoch’ in this block. Read together, the complete operation is: This assigns ‘state.save_checkpoint(checkpoint, epoch=3, batch_index=17, best_accuracy_percent=95.75, extra={"reason": "unit-test"},)‘ to ‘digest ‘ in host memory. Here digest means the value named ’digest’ in this block. The important operands are state: the finite-state-machine phase retained in flip-flops; save_checkpoint: the value named ’save checkpoint’ in this block; checkpoint: the value named ’checkpoint’ in this block. Context: the function test_full_parameter_update_and_atomic_checkpoint_round_trip, which handles test full parameter update and atomic checkpoint round trip.

Line 252: `batch_index=17,` This is continuation line 4 of the 7-line logical statement that begins at source line 249. Its exact fragment is 'batch_index=17,'. The important operands are batch_index: an integer selecting one tensor element, lane, bank, or state entry. Read together, the complete operation is: This assigns 'state.save_checkpoint(checkpoint, epoch=3, batch_index=17, best_accuracy_percent=95.75, extra={"reason": "unit-test"},)' to 'digest ' in host memory. Here digest means the value named 'digest' in this block. The important operands are state: the finite-state-machine phase retained in flip-flops; save_checkpoint: the value named 'save checkpoint' in this block; checkpoint: the value named 'checkpoint' in this block. Context: the function test_full_parameter_update_and_atomic_checkpoint_round_trip, which handles test full parameter update and atomic checkpoint round trip.

Line 253: `best_accuracy_percent=95.75,` This is continuation line 5 of the 7-line logical statement that begins at source line 249. Its exact fragment is 'best_accuracy_percent=95.75,'. The important operands are best_accuracy_percent: the value named 'best accuracy percent' in this block. Read together, the complete operation is: This assigns 'state.save_checkpoint(checkpoint, epoch=3, batch_index=17, best_accuracy_percent=95.75, extra={"reason": "unit-test"},)' to 'digest ' in host memory. Here digest means the value named 'digest' in this block. The important operands are state: the finite-state-machine phase retained in flip-flops; save_checkpoint: the value named 'save checkpoint' in this block; checkpoint: the value named 'checkpoint' in this block. Context: the function test_full_parameter_update_and_atomic_checkpoint_round_trip, which handles test full parameter update and atomic checkpoint round trip.

Line 254: `extra={"reason": "unit-test"},` This is continuation line 6 of the 7-line logical statement that begins at source line 249. Its exact fragment is 'extra={"reason": "unit-test"},'. The important operands are extra: the value named 'extra' in this block; reason: the value named 'reason' in this block; unit: the value named 'unit' in this block. Read together, the complete operation is: This assigns 'state.save_checkpoint(checkpoint, epoch=3, batch_index=17, best_accuracy_percent=95.75, extra={"reason": "unit-test"},)' to 'digest ' in host memory. Here digest means the value named 'digest' in this block. The important operands are state: the finite-state-machine phase retained in flip-flops; save_checkpoint: the value named 'save checkpoint' in this block; checkpoint: the value named 'checkpoint' in this block. Context: the function test_full_parameter_update_and_atomic_checkpoint_round_trip, which handles test full parameter update and atomic checkpoint round trip.

Line 255: `)` This is continuation line 7 of the 7-line logical statement that begins at source line 249. Its exact fragment is ')'. The expression is a literal or structural operator and has no hidden software state. Read together, the complete operation is: This assigns 'state.save_checkpoint(checkpoint, epoch=3, batch_index=17, best_accuracy_percent=95.75, extra={"reason": "unit-test"},)' to 'digest ' in host memory. Here digest means the value named 'digest' in this block. The important operands are state: the finite-state-machine phase retained in flip-flops; save_checkpoint: the value named 'save checkpoint' in this block; checkpoint: the value named 'checkpoint' in this block. Context: the function test_full_parameter_update_and_atomic_checkpoint_round_trip, which handles test full parameter update and atomic checkpoint round trip.

Line 256: `self.assertEqual(len(digest), 64)` This calls 'self.assertEqual' with 'len(digest), 64' inside the function test_full_parameter_update_and_atomic_checkpoint_round_trip, which handles test full parameter update and atomic checkpoint round trip. The call advances the host-side job that checks spikingformer training runtime behavior independently with Python assertions.

Line 257: `restored = TrainableSpikingformerState(TinyParameterArchive())` This assigns 'TrainableSpikingformerState(TinyParameterArchive())' to 'restored ' in host memory. Here restored means the value named 'restored' in this block. The important operands are TrainableSpikingformerState: the finite-state-machine phase retained in flip-flops; TinyParameterArchive: the value named 'tiny parameter archive' in this block. Context: the function test_full_parameter_update_and_atomic_checkpoint_round_trip, which handles test full parameter update and atomic checkpoint round trip.

Line 258: `metadata = restored.load_checkpoint(checkpoint)` This assigns 'restored.load_checkpoint(checkpoint)' to 'metadata ' in host memory. Here metadata means the value named 'metadata' in this block. The important operands are restored: the value named 'restored' in this block; load_checkpoint: the value named 'load checkpoint' in this block; checkpoint: the value named 'checkpoint' in this block. Context: the function test_full_parameter_update_and_atomic_checkpoin which handles test full parameter update and atomic checkpoint round trip.

Line 259: `self.assertEqual(metadata["epoch"], 3)` This calls ‘self.assertEqual‘ with ‘metadata["epoch"], 3‘ inside the function test_full_parameter_update_and_atomic_checkpoint_round_trip, which handles test full parameter update and atomic checkpoint round trip. The call advances the host-side job that checks spikingformer training runtime behavior independently with Python assertions.

Line 260: `self.assertEqual(metadata["batch_index"], 17)` This calls ‘self.assertEqual‘ with ‘metadata["batch_index"], 17‘ inside the function test_full_parameter_update_and_atomic_checkpoint_round_trip, which handles test full parameter update and atomic checkpoint round trip. The call advances the host-side job that checks spikingformer training runtime behavior independently with Python assertions.

Line 261: `self.assertEqual(restored.optimizer_step, 1)` This calls ‘self.assertEqual‘ with ‘restored.optimizer_step, 1‘ inside the function test_full_parameter_update_and_atomic_checkpoint_round_trip, which handles test full parameter update and atomic checkpoint round trip. The call advances the host-side job that checks spikingformer training runtime behavior independently with Python assertions.

Line 262: `np.testing.assert_array_equal(` This statement continues through source line 265; the explanation uses the complete expression rather than only the first visual fragment. This calls ‘np.testing.assert_array_equal‘ with ‘ restored.projection("tiny").weight_k_by_n, state.projection("tiny").weight_k_by_n, ‘ inside the function test_full_parameter_upda which handles test full parameter update and atomic checkpoint round trip. The call advances the host-side job that checks spikingformer training runtime behavior independently with Python assertions.

Line 263: `restored.projection("tiny").weight_k_by_n,` This is continuation line 2 of the 4-line logical statement that begins at source line 262. Its exact fragment is ‘restored.projection("tiny").weight_k_by_n,‘. The important operands are restored: the value named ’restored’ in this block; projection: the value named ’projection’ in this block; tiny: the value named ’tiny’ in this block. Read together, the complete operation is: This calls ‘np.testing.assert_array_equal‘ with ‘ restored.projection("tiny").weight_k_by_n, state.projection("tiny").weight_k_by_n, ‘ inside the function test_full_paramet which handles test full parameter update and atomic checkpoint round trip. The call advances the host-side job that checks spikingformer training runtime behavior independently with Python assertions.

Line 264: `state.projection("tiny").weight_k_by_n,` This is continuation line 3 of the 4-line logical statement that begins at source line 262. Its exact fragment is ‘state.projection("tiny").weight_k_by_n,‘. The important operands are state: the finite-state-machine phase retained in flip-flops; projection: the value named ’projection’ in this block; tiny: the value named ’tiny’ in this block. Read together, the complete operation is: This calls ‘np.testing.assert_array_equal‘ with ‘ restored.projection("tiny").weight_k_by_n, state.projection("tiny").weight_k_by_n, ‘ inside the function test_full_parameter_u which handles test full parameter update and atomic checkpoint round trip. The call advances the host-side job that checks spikingformer training runtime behavior independently with Python assertions.

Line 265: `)` This is continuation line 4 of the 4-line logical statement that begins at source line 262. Its exact fragment is ‘)‘. The expression is a literal or structural operator and has no hidden software state. Read together, the complete operation is: This calls ‘np.testing.assert_array_equal‘ with ‘ restored.projection("tiny").weight_k_by_n, state.projection("tiny").weight_k_by_n, ‘ inside the function test_full_parameter_update_and_atomic_checkpoint_round_trip, which handles test full parameter update and atomic checkpoint round trip. The call advances the host-side job that checks spikingformer training runtime behavior independently with Python assertions.

Line 266: `np.testing.assert_array_equal(restored.head.weight_k_by_n, state.head.weight_k_by_n)` This calls ‘np.testing.assert_array_equal‘ with ‘restored.head.weight_k_by_n, state.head.weight_k_by_n‘ inside the function test_full_parameter_update_and_atomic_checkpoint_round_trip, which handles test full parameter update and atomic checkpoint round trip. The call advances the host-side job that checks spikingformer training runtime behavior independently with Python assertions.

Line 268: `def test_complete_spikingformer_topology_forward_backward_and_update(self) -> None:` This starts function test_complete_spikingformer_topology_forward_backward_and_update. Its indented body performs test complete spikingformer topology forward backward and update as part of the file that checks spikingformer training runtime behavior independently with Python assertions; it runs only when called.

Line 269: `state = TrainableSpikingformerState(TinyFullGraphArchive())` This assigns 'TrainableSpikingformerState(TinyFullGraphArchive())' to 'state ' in host memory. Here state means the finite-state-machine phase retained in flip-flops. The important operands are TrainableSpikingformerState: the finite-state-machine phase retained in flip-flops; TinyFullGraphArchive: the value named 'tiny full graph archive' in this block. Context: the function test_complete_spikingformer_topology_forward_backward_and_update, which handles test complete spikingformer topology forward backward and update.

Line 270: `trainer = SpikingformerOnDeviceTrainer(` This statement continues through source line 277; the explanation uses the complete expression rather than only the first visual fragment. This assigns 'SpikingformerOnDeviceTrainer(state, self.driver, transformer_blocks=1, attention_heads=1, timesteps=2, input_shape=(3, 8, 8),)' to 'trainer ' in host memory. Here trainer means the value named 'trainer' in this block. The important operands are SpikingformerOnDeviceTrainer: the value named 'spikingformer on device trainer' in this block; state: the finite-state-machine phase retained in flip-flops; driver: the value named 'driver' in this block. Context: the function test_complete_spikingformer_topology_forward_backward_and_update, which handles test complete spikingformer topology forward backward and update.

Line 271: `state,` This is continuation line 2 of the 8-line logical statement that begins at source line 270. Its exact fragment is 'state,'. The important operands are state: the finite-state-machine phase retained in flip-flops. Read together, the complete operation is: This assigns 'SpikingformerOnDeviceTrainer(state, self.driver, transformer_blocks=1, attention_heads=1, timesteps=2, input_shape=(3, 8, 8),)' to 'trainer ' in host memory. Here trainer means the value named 'trainer' in this block. The important operands are SpikingformerOnDeviceTrainer: the value named 'spikingformer on device trainer' in this block; state: the finite-state-machine phase retained in flip-flops; driver: the value named 'driver' in this block. Context: the function test_complete_spikingformer_topology_forward_backward_and_update, which handles test complete spikingformer topology forward backward and update.

Line 272: `self.driver,` This is continuation line 3 of the 8-line logical statement that begins at source line 270. Its exact fragment is 'self.driver,'. The important operands are driver: the value named 'driver' in this block. Read together, the complete operation is: This assigns 'SpikingformerOnDeviceTrainer(state, self.driver, transformer_blocks=1, attention_heads=1, timesteps=2, input_shape=(3, 8, 8),)' to 'trainer ' in host memory. Here trainer means the value named 'trainer' in this block. The important operands are SpikingformerOnDeviceTrainer: the value named 'spikingformer on device trainer' in this block; state: the finite-state-machine phase retained in flip-flops; driver: the value named 'driver' in this block. Context: the function test_complete_spikingformer_topology_forward_backward_and_update, which handles test complete spikingformer topology forward backward and update.

Line 273: `transformer_blocks=1,` This is continuation line 4 of the 8-line logical statement that begins at source line 270. Its exact fragment is 'transformer_blocks=1,'. The important operands are transformer_blocks: the value named 'transformer blocks' in this block. Read together, the complete operation is: This assigns 'SpikingformerOnDeviceTrainer(state, self.driver, transformer_blocks=1, attention_heads=1, timesteps=2, input_shape=(3, 8, 8),)' to 'trainer ' in host memory. Here trainer means the value named 'trainer' in this block. The important operands are SpikingformerOnDeviceTrainer: the value named 'spikingformer on device trainer' in this block; state: the finite-state-machine phase retained in flip-flops; driver: the value named 'driver' in this block. Context: the function test_complete_spikingformer_topology_forward_backward_and_update, which handles test complete spikingformer topology forward backward and update.

Line 274: `attention_heads=1,` This is continuation line 5 of the 8-line logical statement that begins at source line 270. Its exact fragment is 'attention_heads=1,'. The important operands are attention_heads: the value named 'attention heads' in this block. Read together, the complete operation is: This assigns 'SpikingformerOnDeviceTrainer(state, self.driver, transformer_blocks=1, attention_heads=1, timesteps=2, input_shape=(3, 8, 8),)' to 'trainer ' in host memory. Here trainer means the value named 'trainer' in this block. The important operands are SpikingformerOnDeviceTrainer: the value named 'spikingformer on device trainer' in this block; state: the finite-state-machine phase retained in flip-flops; driver: the value named 'driver' in this block. Context: the function test_complete_spikingformer_topology_forward_ba
which handles test complete spikingformer topology forward backward and update.

Line 275: `timesteps=2,` This is continuation line 6 of the 8-line logical statement that begins at source line 270. Its exact fragment is 'timesteps=2,'. The important operands are timesteps: one discrete SNN update instant. Read together, the complete operation is: This assigns 'SpikingformerOnDeviceTrainer(state, self.driver, transformer_blocks=1,

attention_heads=1, timesteps=2, input_shape=(3, 8, 8),)‘ to ‘trainer ‘ in host memory. Here trainer means the value named ’trainer’ in this block. The important operands are SpikingformerOnDeviceTrainer: the value named ’spikingformer on device trainer’ in this block; state: the finite-state-machine phase retained in flip-flops; driver: the value named ’driver’ in this block. Context: the function test_complete_spikingformer_topology_forward_backward_and_update, which handles test complete spikingformer topology forward backward and update.

Line 276: `input_shape=(3, 8, 8),` This is continuation line 7 of the 8-line logical statement that begins at source line 270. Its exact fragment is ‘input_shape=(3, 8, 8),‘. The important operands are input_shape: the value named ’input shape’ in this block. Read together, the complete operation is: This assigns ‘SpikingformerOnDeviceTrainer(state, self.driver, transformer_blocks=1, attention_heads=1, timesteps=2, input_shape=(3, 8, 8),)‘ to ‘trainer ‘ in host memory. Here trainer means the value named ’trainer’ in this block. The important operands are SpikingformerOnDeviceTrainer: the value named ’spikingformer on device trainer’ in this block; state: the finite-state-machine phase retained in flip-flops; driver: the value named ’driver’ in this block. Context: the function test_complete_spikingformer_topology_forward_ba which handles test complete spikingformer topology forward backward and update.

Line 277: `)` This is continuation line 8 of the 8-line logical statement that begins at source line 270. Its exact fragment is ‘)‘. The expression is a literal or structural operator and has no hidden software state. Read together, the complete operation is: This assigns ‘SpikingformerOnDeviceTrainer(state, self.driver, transformer_blocks=1, attention_heads=1, timesteps=2, input_shape=(3, 8, 8),)‘ to ‘trainer ‘ in host memory. Here trainer means the value named ’trainer’ in this block. The important operands are SpikingformerOnDeviceTrainer: the value named ’spikingformer on device trainer’ in this block; state: the finite-state-machine phase retained in flip-flops; driver: the value named ’driver’ in this block. Context: the function test_complete_spikingformer_topology_forward_backward_and_update, which handles test complete spikingformer topology forward backward and update.

Line 278: `self.assertEqual(trainer.attention_scale_shift, 7)` This calls ‘self.assertEqual‘ with ‘trainer.attention_scale_ 7‘ inside the function test_complete_spikingformer_topology_forward_backward_and_update, which handles test complete spikingformer topology forward backward and update. The call advances the host-side job that checks spikingformer training runtime behavior independently with Python assertions.

Line 279: `image = np.zeros((1, 3, 8, 8), dtype=np.float32)` This assigns ‘np.zeros((1, 3, 8, 8), dtype=np.float32)‘ to ‘image ‘ in host memory. Here image means the value named ’image’ in this block. The important operands are zeros: the value named ’zeros’ in this block; dtype: the value named ’dtype’ in this block; float32: the value named ’float32’ in this block. Context: the function test_complete_spikingformer_topology_forward_backward_and_update, which handles test complete spikingformer topology forward backward and update.

Line 280: `cache = trainer.forward(image)` This assigns ‘trainer.forward(image)‘ to ‘cache ‘ in host memory. Here cache means the value named ’cache’ in this block. The important operands are trainer: the value named ’trainer’ in this block; forward: the value named ’forward’ in this block; image: the value named ’image’ in this block. Context: the function test_complete_spikingformer_topology_forward_backward_and_update, which handles test complete spikingformer topology forward backward and update.

Line 281: `self.assertEqual(cache.final_value.shape, (2, 1, 2, 2, 2))` This calls ‘self.assertEqual‘ with ‘cache.final_va (2, 1, 2, 2, 2)‘ inside the function test_complete_spikingformer_topology_forward_backward_and_update, which handles test complete spikingformer topology forward backward and update. The call advances the host-side job that checks spikingformer training runtime behavior independently with Python assertions.

Line 282: `self.assertEqual(len(cache.tokenizer), 5)` This calls ‘self.assertEqual‘ with ‘len(cache.tokenizer), 5‘ inside the function test_complete_spikingformer_topology_forward_backward_and_update, which handles test complete spikingformer topology forward backward and update. The call advances the host-side job that checks spikingformer training runtime behavior independently with Python assertions.

Line 283: `self.assertEqual(len(cache.blocks), 1)` This calls ‘self.assertEqual‘ with ‘len(cache.blocks), 1‘ inside the function test_complete_spikingformer_topology_forward_backward_and_update, which handles test complete spikingformer topology forward backward and update. The call advances the host-side job that checks spikingformer training runtime behavior independently with Python assertions.

Line 284: `self.assertEqual(cache.logits_accumulator.shape, (1, 3))` This calls 'self.assertEqual' with 'cache.logits_accu (1, 3)' inside the function test_complete_spikingformer_topology_forward_backward_and_update, which handles test complete spikingformer topology forward backward and update. The call advances the host-side job that checks spikingformer training runtime behavior independently with Python assertions.

Line 285: `backward = trainer.backward(cache, np.asarray([1]))` This assigns 'trainer.backward(cache, np.asarray([1]))' to 'backward ' in host memory. Here backward means the value named 'backward' in this block. The important operands are trainer: the value named 'trainer' in this block; backward: the value named 'backward' in this block; cache: the value named 'cache' in this block. Context: the function test_complete_spikingformer_topology_forward_backward_and_update, which handles test complete spikingformer topology forward backward and update.

Line 286: `self.assertTrue(np.isfinite(backward.loss))` This calls 'self.assertTrue' with 'np.isfinite(backward.loss)' inside the function test_complete_spikingformer_topology_forward_backward_and_update, which handles test complete spikingformer topology forward backward and update. The call advances the host-side job that checks spikingformer training runtime behavior independently with Python assertions.

Line 287: `self.assertEqual(backward.input_gradient.values.shape, image.shape)` This calls 'self.assertEqual' with 'backward.input_gradient.values.shape, image.shape' inside the function test_complete_spikingformer_topology_forward_ba which handles test complete spikingformer topology forward backward and update. The call advances the host-side job that checks spikingformer training runtime behavior independently with Python assertions.

Line 288: `self.assertEqual(` This statement continues through source line 291; the explanation uses the complete expression rather than only the first visual fragment. This calls 'self.assertEqual' with ' set(backward.parameter_gradients), set(state.projection_names) | {"head"}, ' inside the function test_complete_spikingformer_topology_forward_backward_and_upd which handles test complete spikingformer topology forward backward and update. The call advances the host-side job that checks spikingformer training runtime behavior independently with Python assertions.

Line 289: `set(backward.parameter_gradients),` This is continuation line 2 of the 4-line logical statement that begins at source line 288. Its exact fragment is 'set(backward.parameter_gradients),'. The important operands are set: the value named 'set' in this block; backward: the value named 'backward' in this block; parameter_gradients: the signed loss derivative used to update a learned parameter. Read together, the complete operation is: This calls 'self.assertEqual' with ' set(backward.parameter_gradients), set(state.projection_names) | {"head"}, ' inside the function test_complete_spikingformer_topology_forward_backward_and_update, which handles test complete spikingformer topology forward backward and update. The call advances the host-side job that checks spikingformer training runtime behavior independently with Python assertions.

Line 290: `set(state.projection_names) | {"head"},` This is continuation line 3 of the 4-line logical statement that begins at source line 288. Its exact fragment is 'set(state.projection_names) | {"head"},'. The important operands are set: the value named 'set' in this block; state: the finite-state-machine phase retained in flip-flops; projection_names: the value named 'projection names' in this block. Read together, the complete operation is: This calls 'self.assertEqual' with ' set(backward.parameter_gradients), set(state.projection_names) | {"head"}, ' inside the function test_complete_spikingformer_top which handles test complete spikingformer topology forward backward and update. The call advances the host-side job that checks spikingformer training runtime behavior independently with Python assertions.

Line 291: `)` This is continuation line 4 of the 4-line logical statement that begins at source line 288. Its exact fragment is ')'. The expression is a literal or structural operator and has no hidden software state. Read together, the complete operation is: This calls 'self.assertEqual' with ' set(backward.parameter_gradients), set(state.projection_names) | {"head"}, ' inside the function test_complete_spikingformer_topology_forward_backward_and_update, which handles test complete spikingformer topology forward backward and update. The call advances the host-side job that checks spikingformer training runtime behavior independently with Python assertions.

Line 292: `nonzero_gradients = 0` This assigns '0' to 'nonzero_gradients ' in host memory. Here nonzero_gradients means the signed loss derivative used to update a learned parameter. The expression is a literal or structural operator and has no hidden software state. Context: the function test_complete_spikingformer_topology_forward_backward_and_update, which handles test complete spikingformer topology forward backward and update.

Line 293: `for name, gradient in backward.parameter_gradients.items():` This iterates name, gradient over ‘backward.parameter_gradients.items()‘. Each iteration repeats the indented host operation, commonly once per layer, tile, timestep, or test case in the function test_complete_spikingformer_topology_forward_backward_and_update, which handles test complete spikingformer topology forward backward and update.

Line 294: `expected_weight = state.head.weight_k_by_n.shape if name == "head" else (` This statement continues through source line 295; the explanation uses the complete expression rather than only the first visual fragment. Inside the function test_complete_spikingformer_topology_forward_backward_and_update, which handles test complete spikingformer topology forward backward and update, this statement advances the host implementation that checks spikingformer training runtime behavior independently with Python assertions. The important operands are expected_weight: a learned coefficient multiplied by an activation; state: the finite-state-machine phase retained in flip-flops; head: the value named ’head’ in this block.

Line 295: `state.projection(name).weight_k_by_n.shape)` This is continuation line 2 of the 2-line logical statement that begins at source line 294. Its exact fragment is ‘state.projection(name).weight_k_by_n.shape)‘. The important operands are state: the finite-state-machine phase retained in flip-flops; projection: the value named ’projection’ in this block; name: the value named ’name’ in this block. Read together, the complete operation is: Inside the function test_complete_spikingformer_topology_forward_backward_and_update, which handles test complete spikingformer topology forward backward and update, this statement advances the host implementation that checks spikingformer training runtime behavior independently with Python assertions. The important operands are expected_weight: a learned coefficient multiplied by an activation; state: the finite-state-machine phase retained in flip-flops; head: the value named ’head’ in this block.

Line 296: `expected_bias = state.head.bias_accumulator_units.shape if name == "head" else (` This statement continues through source line 297; the explanation uses the complete expression rather than only the first visual fragment. Inside the function test_complete_spikingformer_topology_forward_backward_and_update, which handles test complete spikingformer topology forward backward and update, this statement advances the host implementation that checks spikingformer training runtime behavior independently with Python assertions. The important operands are expected_bias: an additive learned offset applied after accumulation; state: the finite-state-machine phase retained in flip-flops; head: the value named ’head’ in this block.

Line 297: `state.projection(name).bias_q10.shape)` This is continuation line 2 of the 2-line logical statement that begins at source line 296. Its exact fragment is ‘state.projection(name).bias_q10.shape)‘. The important operands are state: the finite-state-machine phase retained in flip-flops; projection: the value named ’projection’ in this block; name: the value named ’name’ in this block. Read together, the complete operation is: Inside the function test_complete_spikingformer_to which handles test complete spikingformer topology forward backward and update, this statement advances the host implementation that checks spikingformer training runtime behavior independently with Python assertions. The important operands are expected_bias: an additive learned offset applied after accumulation; state: the finite-state-machine phase retained in flip-flops; head: the value named ’head’ in this block.

Line 298: `self.assertEqual(gradient.weight.values.shape, expected_weight)` This calls ‘self.assertEqual‘ with ‘gradient.weight.values.shape, expected_weight‘ inside the function test_complete_spikingformer_topology_forward_backward_a which handles test complete spikingformer topology forward backward and update. The call advances the host-side job that checks spikingformer training runtime behavior independently with Python assertions.

Line 299: `self.assertEqual(gradient.bias.values.shape, expected_bias)` This calls ‘self.assertEqual‘ with ‘gradient.bias.values.shape, expected_bias‘ inside the function test_complete_spikingformer_topology_forward_backward_and_u which handles test complete spikingformer topology forward backward and update. The call advances the host-side job that checks spikingformer training runtime behavior independently with Python assertions.

Line 300: `nonzero_gradients += int(np.count_nonzero(gradient.weight.values))` Inside the function test_complete_spi which handles test complete spikingformer topology forward backward and update, this statement advances the host implementation that checks spikingformer training runtime behavior independently with Python assertions. The important operands are nonzero_gradients: the signed loss derivative used to update a learned parameter; count_nonzero: the value named ’count nonzero’ in this block; gradient: the signed loss derivative used to update a learned parameter.

Line 301: `nonzero_gradients += int(np.count_nonzero(gradient.bias.values))` Inside the function test_complete_spiki which handles test complete spikingformer topology forward backward and update, this statement advances the host implementation that checks spikingformer training runtime behavior independently with Python assertions. The important operands are nonzero_gradients: the signed loss derivative used to update a learned parameter; count_nonzero: the value named 'count nonzero' in this block; gradient: the signed loss derivative used to update a learned parameter.

Line 302: `self.assertGreater(nonzero_gradients, 0)` This calls 'self.assertGreater' with 'nonzero_gradients, 0' inside the function test_complete_spikingformer_topology_forward_backward_and_update, which handles test complete spikingformer topology forward backward and update. The call advances the host-side job that checks spikingformer training runtime behavior independently with Python assertions.

Line 303: `state.apply_gradients(` This statement continues through source line 309; the explanation uses the complete expression rather than only the first visual fragment. This calls 'state.apply_gradients' with ' self.driver, backward.parameter_gradients, learning_rate=0.25, momentum=0.0, weight_decay=0.0, ' inside the function test_complete_spikingfor which handles test complete spikingformer topology forward backward and update. The call advances the host-side job that checks spikingformer training runtime behavior independently with Python assertions.

Line 304: `self.driver,` This is continuation line 2 of the 7-line logical statement that begins at source line 303. Its exact fragment is 'self.driver,'. The important operands are driver: the value named 'driver' in this block. Read together, the complete operation is: This calls 'state.apply_gradients' with ' self.driver, backward.parameter_gradients, learning_rate=0.25, momentum=0.0, weight_decay=0.0, ' inside the function test_complete_spikingformer_topology_forward_backwa which handles test complete spikingformer topology forward backward and update. The call advances the host-side job that checks spikingformer training runtime behavior independently with Python assertions.

Line 305: `backward.parameter_gradients,` This is continuation line 3 of the 7-line logical statement that begins at source line 303. Its exact fragment is 'backward.parameter_gradients,'. The important operands are backward: the value named 'backward' in this block; parameter_gradients: the signed loss derivative used to update a learned parameter. Read together, the complete operation is: This calls 'state.apply_gradients' with ' self.driver, backward.parameter_gradients, learning_rate=0.25, momentum=0.0, weight_decay=0.0, ' inside the function test_complete_spikingformer_topology_forward_ba which handles test complete spikingformer topology forward backward and update. The call advances the host-side job that checks spikingformer training runtime behavior independently with Python assertions.

Line 306: `learning_rate=0.25,` This is continuation line 4 of the 7-line logical statement that begins at source line 303. Its exact fragment is 'learning_rate=0.25,'. The important operands are learning_rate: the fixed-point multiplier controlling update magnitude. Read together, the complete operation is: This calls 'state.apply_gradients' with ' self.driver, backward.parameter_gradients, learning_rate=0.25, momentum=0.0, weight_decay=0.0, ' inside the function test_complete_spikingformer_topology_forward_backward_and_update, which handles test complete spikingformer topology forward backward and update. The call advances the host-side job that checks spikingformer training runtime behavior independently with Python assertions.

Line 307: `momentum=0.0,` This is continuation line 5 of the 7-line logical statement that begins at source line 303. Its exact fragment is 'momentum=0.0,'. The important operands are momentum: the value named 'momentum' in this block. Read together, the complete operation is: This calls 'state.apply_gradients' with ' self.driver, backward.parameter_gradients, learning_rate=0.25, momentum=0.0, weight_decay=0.0, ' inside the function test_complete_spikingfor which handles test complete spikingformer topology forward backward and update. The call advances the host-side job that checks spikingformer training runtime behavior independently with Python assertions.

Line 308: `weight_decay=0.0,` This is continuation line 6 of the 7-line logical statement that begins at source line 303. Its exact fragment is 'weight_decay=0.0,'. The important operands are weight_decay: a learned coefficient multiplied by an activation. Read together, the complete operation is: This calls 'state.apply_gradients' with ' self.driver, backward.parameter_gradients, learning_rate=0.25, momentum=0.0, weight_decay=0.0, ' inside the function test_complete_spikingformer_topology_forward_backward_and_update, which handles test complete spikingformer topology forward backward and update. The call advances the host-side job that checks spikingformer training runtime behavior independently with Python assertions.

Line 309: `)` This is continuation line 7 of the 7-line logical statement that begins at source line 303. Its exact fragment is ')'. The expression is a literal or structural operator and has no hidden software state. Read together, the complete operation is: This calls 'state.apply_gradients' with ' self.driver, backward.parameter_gradients, learning_rate=0.25, momentum=0.0, weight_decay=0.0, ' inside the function test_complete_spikingformer_topology_forward_backward_and_update, which handles test complete spikingformer topology forward backward and update. The call advances the host-side job that checks spikingformer training runtime behavior independently with Python assertions.

Line 310: `self.assertEqual(state.optimizer_step, 1)` This calls 'self.assertEqual' with 'state.optimizer_step, 1' inside the function test_complete_spikingformer_topology_forward_backward_and_update, which handles test complete spikingformer topology forward backward and update. The call advances the host-side job that checks spikingformer training runtime behavior independently with Python assertions.

Line 313: `if __name__ == "__main__":` This executes the following indented host-code branch only when '___name___ == "___main___"' is true. The important operands are ___name___: the value named 'name' in this block; ___main___: the value named 'main' in this block. Context: the file whose role is to checks spikingformer training runtime behavior independently with Python assertions.

Line 314: `unittest.main()` This calls 'unittest.main' with " inside the file whose role is to checks spikingformer training runtime behavior independently with Python assertions. The call advances the host-side job that checks spikingformer training runtime behavior independently with Python assertions.

76 tests/test_train_spikingformer_pynq.py

Role in the complete system: checks train spikingformer pynq behavior independently with Python assertions.

76.1 Beginner architecture map

Dataflow responsibility This file's end-to-end responsibility is to checks train spikingformer pynq behavior independently with Python assertions.

Where it runs This is sequential host software. Python objects live in CPU memory; they become FPGA work only when the compiler packs a command or payload and the PYNQ driver transfers those bytes through AXI DMA or AXI-Lite.

Public structure Classes: PynqTrainingJobTests. Functions: sha256, test_shards_are_integrity_checked_deterministic_and_r test_augmentation_and_cosine_schedule_are_reproducible. Each function annotation below names its enclosing function so an array operation is tied to the model, compiler, driver, test, or report phase that uses it.

Numeric and failure boundary Shapes, signedness, byte order, scaling, and saturation are part of the hardware contract. Validation exceptions are functional safety checks: rejecting malformed input before DMA is different from silently clipping, reshaping, or continuing with an incompatible artifact.

76.2 Complete source

```

76.3 Line annotations

Line 1: `from __future__ import annotations` This imports the named Python API so the file whose role is to checks train spikingformer pynq behavior independently with Python assertions can use it explicitly. Imports execute on the host processor and create no FPGA hardware.

Line 3: `import hashlib` This imports the named Python API so the file whose role is to checks train spikingformer pynq behavior independently with Python assertions can use it explicitly. Imports execute on the host processor and create no FPGA hardware.

Line 4: `import json` This imports the named Python API so the file whose role is to checks train spikingformer pynq behavior independently with Python assertions can use it explicitly. Imports execute on the host processor and create no FPGA hardware.

Line 5: `import tempfile` This imports the named Python API so the file whose role is to checks train spikingformer pynq behavior independently with Python assertions can use it explicitly. Imports execute on the host processor and create no FPGA hardware.

Line 6: `import unittest` This imports the named Python API so the file whose role is to checks train spikingformer pynq behavior independently with Python assertions can use it explicitly. Imports execute on the host processor and create no FPGA hardware.

Line 7: `from pathlib import Path` This imports the named Python API so the file whose role is to checks train spikingformer pynq behavior independently with Python assertions can use it explicitly. Imports execute on the host processor and create no FPGA hardware.

Line 9: `import numpy as np` This imports the named Python API so the file whose role is to checks train spikingformer pynq behavior independently with Python assertions can use it explicitly. Imports execute on the host processor and create no FPGA hardware.

Line 11: `from train_spikingformer_pynq import (` This statement continues through source line 15; the explanation uses the complete expression rather than only the first visual fragment. This imports the named Python API so the file whose role is to checks train spikingformer pynq behavior independently with Python assertions can use it explicitly. Imports execute on the host processor and create no FPGA hardware.

Line 12: `Cifar10ShardSet,` This is continuation line 2 of the 5-line logical statement that begins at source line 11. Its exact fragment is 'Cifar10ShardSet,'. The important operands are Cifar10ShardSet: the value named 'cifar10 shard set' in this block. Read together, the complete operation is: This imports the named Python API so the file whose role is to checks train spikingformer pynq behavior independently with Python assertions can use it explicitly. Imports execute on the host processor and create no FPGA hardware.

Line 13: `augment_cifar10,` This is continuation line 3 of the 5-line logical statement that begins at source line 11. Its exact fragment is 'augment_cifar10,'. The important operands are augment_cifar10: the value named 'augment cifar10' in this block. Read together, the complete operation is: This imports the named Python API so the file whose role is to checks train spikingformer pynq behavior independently with Python assertions can use it explicitly. Imports execute on the host processor and create no FPGA hardware.

Line 14: `cosine_learning_rate,` This is continuation line 4 of the 5-line logical statement that begins at source line 11. Its exact fragment is 'cosine_learning_rate,'. The important operands are cosine_learning_rate: the fixed-point multiplier controlling update magnitude. Read together, the complete operation is: This imports the named Python API so the file whose role is to checks train spikingformer pynq behavior independently with Python assertions can use it explicitly. Imports execute on the host processor and create no FPGA hardware.

Line 15: `)` This is continuation line 5 of the 5-line logical statement that begins at source line 11. Its exact fragment is ')'. The expression is a literal or structural operator and has no hidden software state. Read together, the complete operation is: This imports the named Python API so the file whose role is to checks train spikingformer pynq behavior independently with Python assertions can use it explicitly. Imports execute on the host processor and create no FPGA hardware.

Line 18: `def sha256(path: Path) -> str:` This starts function sha256. Its indented body performs sha256 as part of the file that checks train spikingformer pynq behavior independently with Python assertions; it runs only when called.

Line 19: `return hashlib.sha256(path.read_bytes()).hexdigest()` This returns 'hashlib.sha256(path.read_bytes()).hexdige
to the caller of the function sha256, which handles sha256, ending this invocation. The important operands are hashlib: the value named 'hashlib' in this block; sha256: the value named 'sha256' in this block; path: the value named 'path' in this block.

Line 22: `class PynqTrainingJobTests(unittest.TestCase):` This defines class PynqTrainingJobTests, which groups data and methods for pynq training job tests. Instances exist in host memory and organize the flow that checks train spikingformer pynq behavior independently with Python assertions.

Line 23: `def test_shards_are_integrity_checked_deterministic_and_resumable(self) -> None:` This starts function test_shards_are_integrity_checked_deterministic_and_resumable. Its indented body performs test shards are integrity checked deterministic and resumable as part of the file that checks train spikingformer pynq behavior independently with Python assertions; it runs only when called.

Line 24: `with tempfile.TemporaryDirectory() as temporary:` This opens a managed resource scope for 'tempfile.TemporaryDirectory() as temporary' so files, tracing, or temporary state are finalized even if the function test_shards_are_integr
which handles test shards are integrity checked deterministic and resumable raises an error.

Line 25: `root = Path(temporary)` This assigns 'Path(temporary)' to 'root ' in host memory. Here root means the value named 'root' in this block. The important operands are Path: the value named 'path' in this block; temporary: the value named 'temporary' in this block. Context: the function test_shards_are_integrity_checked_deterministic_and_resumable, which handles test shards are integrity checked deterministic and resumable.

Line 26: `entries = []` This assigns '[]' to 'entries ' in host memory. Here entries means the value named 'entries' in this block. The expression is a literal or structural operator and has no hidden software state. Context: the function test_shards_are_integrity_checked_deterministic_and_resumable, which handles test shards are integrity checked deterministic and resumable.

Line 27: `first_index = 0` This assigns ‘0‘ to ‘first_index ‘ in host memory. Here first_index means an integer selecting one tensor element, lane, bank, or state entry. The expression is a literal or structural operator and has no hidden software state. Context: the function test_shards_are_integrity_checked_deterministic_and_resumable, which handles test shards are integrity checked deterministic and resumable.

Line 28: `for shard_index, samples in enumerate((5, 4)):` This iterates shard_index, samples over ‘enumerate((5, 4))‘. Each iteration repeats the indented host operation, commonly once per layer, tile, timestep, or test case in the function test_shards_are_integrity_checked_deterministic_and_resumable, which handles test shards are integrity checked deterministic and resumable.

Line 29: `path = root / f"cifar10_train_{shard_index:03d}.npz"` This assigns ‘root / f"cifar10_train_{shard_index:03d}.
to ‘path ‘ in host memory. Here path means the value named ’path’ in this block. The important operands are root: the value named ’root’ in this block; f: the value named ’f’ in this block; cifar10_train_: the value named ’cifar10 train’ in this block. Context: the function test_shards_are_integrity_checked_deterministic_and_resumable, which handles test shards are integrity checked deterministic and resumable.

Line 30: `images = np.full((samples, 32, 32, 3), shard_index * 40, dtype=np.uint8)` This assigns ‘np.full((samples, 32, 32, 3), shard_index * 40, dtype=np.uint8)‘ to ‘images ‘ in host memory. Here images means the value named ’images’ in this block. The important operands are full: the value named ’full’ in this block; samples: the value named ’samples’ in this block; shard_index: an integer selecting one tensor element, lane, bank, or state entry. Context: the function test_shards_are_integrity_checked_deterministic_and_resumable, which handles test shards are integrity checked deterministic and resumable.

Line 31: `labels = np.arange(first_index, first_index + samples, dtype=np.uint8) % 10` This assigns ‘np.arange(first_
first_index + samples, dtype=np.uint8) % 10‘ to ‘labels ‘ in host memory. Here labels means the value named ’labels’ in this block. The important operands are arange: the value named ’arange’ in this block; first_index: an integer selecting one tensor element, lane, bank, or state entry; samples: the value named ’samples’ in this block. Context: the function test_shards_are_integrity_checked_deterministic_and_resumable, which handles test shards are integrity checked deterministic and resumable.

Line 32: `np.savez_compressed(path, images=images, labels=labels)` This calls ‘np.savez_compressed‘ with ‘path, images=images, labels=labels‘ inside the function test_shards_are_integrity_checked_deterministic_and_resumable, which handles test shards are integrity checked deterministic and resumable. The call advances the host-side job that checks train spikingformer pynq behavior independently with Python assertions.

Line 33: `entries.append({` This statement continues through source line 40; the explanation uses the complete expression rather than only the first visual fragment. This calls ‘entries.append‘ with ‘{ "file": path.name, "samples": samples, "first_index": first_index, "last_index_exclusive": first_index + samples, "bytes": path.stat().st_size, "sha256": sha256(path), }‘ inside the function test_shards_are_integrity_checked_deterministic_and_resumable, which handles test shards are integrity checked deterministic and resumable. The call advances the host-side job that checks train spikingformer pynq behavior independently with Python assertions.

Line 34: `"file": path.name,` This is continuation line 2 of the 8-line logical statement that begins at source line 33. Its exact fragment is ‘"file": path.name,‘. The important operands are file: the value named ’file’ in this block; path: the value named ’path’ in this block; name: the value named ’name’ in this block. Read together, the complete operation is: This calls ‘entries.append‘ with ‘{ "file": path.name, "samples": samples, "first_index": first_index, "last_index_exclusive": first_index + samples, "bytes": path.stat().st_size, "sha256": sha256(path), }‘ inside the function test_shards_are_integrity_checked_deterministic_and_resumable, which handles test shards are integrity checked deterministic and resumable. The call advances the host-side job that checks train spikingformer pynq behavior independently with Python assertions.

Line 35: `"samples": samples,` This is continuation line 3 of the 8-line logical statement that begins at source line 33. Its exact fragment is ‘"samples": samples,‘. The important operands are samples: the value named ’samples’ in this block. Read together, the complete operation is: This calls ‘entries.append‘ with ‘{ "file": path.name, "samples": samples, "first_index": first_index, "last_index_exclusive": first_index + samples, "bytes": path.stat().st_size, "sha256":

sha256(path), }‘ inside the function test_shards_are_integrity_checked_deterministic_and_resumable, which handles test shards are integrity checked deterministic and resumable. The call advances the host-side job that checks train spikingformer pynq behavior independently with Python assertions.

Line 36: `"first_index": first_index,` This is continuation line 4 of the 8-line logical statement that begins at source line 33. Its exact fragment is ‘"first_index": first_index,‘. The important operands are first_index: an integer selecting one tensor element, lane, bank, or state entry. Read together, the complete operation is: This calls ‘entries.append‘ with ‘{ "file": path.name, "samples": samples, "first_index": first_index, "last_index_exclusive": first_index + samples, "bytes": path.stat().st_size, "sha256": sha256(path), }‘ inside the function test_shards_are_integrity_checked_deterministic_and_ which handles test shards are integrity checked deterministic and resumable. The call advances the host-side job that checks train spikingformer pynq behavior independently with Python assertions.

Line 37: `"last_index_exclusive": first_index + samples,` This is continuation line 5 of the 8-line logical statement that begins at source line 33. Its exact fragment is ‘"last_index_exclusive": first_index + samples,‘. The important operands are last_index_exclusive: the AXI-Stream marker for the final beat of a packet or command payload; first_index: an integer selecting one tensor element, lane, bank, or state entry; samples: the value named 'samples' in this block. Read together, the complete operation is: This calls ‘entries.append‘ with ‘{ "file": path.name, "samples": samples, "first_index": first_index, "last_index_exclusive": first_index + samples, "bytes": path.stat().st_size, "sha256": sha256(path), }‘ inside the function test_shards_are_integrity_checked_deterministic_and_resumable, which handles test shards are integrity checked deterministic and resumable. The call advances the host-side job that checks train spikingformer pynq behavior independently with Python assertions.

Line 38: `"bytes": path.stat().st_size,` This is continuation line 6 of the 8-line logical statement that begins at source line 33. Its exact fragment is ‘"bytes": path.stat().st_size,‘. The important operands are bytes: the value named 'bytes' in this block; path: the value named 'path' in this block; stat: the value named 'stat' in this block. Read together, the complete operation is: This calls ‘entries.append‘ with ‘{ "file": path.name, "samples": samples, "first_index": first_index, "last_index_exclusive": first_index + samples, "bytes": path.stat().st_size, "sha256": sha256(path), }‘ inside the function test_shards_are_integrity_checked_deterministic_and_resumable, which handles test shards are integrity checked deterministic and resumable. The call advances the host-side job that checks train spikingformer pynq behavior independently with Python assertions.

Line 39: `"sha256": sha256(path),` This is continuation line 7 of the 8-line logical statement that begins at source line 33. Its exact fragment is ‘"sha256": sha256(path),‘. The important operands are sha256: the value named 'sha256' in this block; path: the value named 'path' in this block. Read together, the complete operation is: This calls ‘entries.append‘ with ‘{ "file": path.name, "samples": samples, "first_index": first_index, "last_index_exclusive": first_index + samples, "bytes": path.stat().st_size, "sha256": sha256(path), }‘ inside the function test_shards_are_integrity_checked_deterministic_and_ which handles test shards are integrity checked deterministic and resumable. The call advances the host-side job that checks train spikingformer pynq behavior independently with Python assertions.

Line 40: `})` This is continuation line 8 of the 8-line logical statement that begins at source line 33. Its exact fragment is ‘})‘. The expression is a literal or structural operator and has no hidden software state. Read together, the complete operation is: This calls ‘entries.append‘ with ‘{ "file": path.name, "samples": samples, "first_index": first_index, "last_index_exclusive": first_index + samples, "bytes": path.stat().st_size, "sha256": sha256(path), }‘ inside the function test_shards_are_integrity_checked_deterministic_and_resumable, which handles test shards are integrity checked deterministic and resumable. The call advances the host-side job that checks train spikingformer pynq behavior independently with Python assertions.

Line 41: `first_index += samples` Inside the function test_shards_are_integrity_checked_deterministic_and_resumable, which handles test shards are integrity checked deterministic and resumable, this statement advances the host implementation that checks train spikingformer pynq behavior independently with Python assertions. The important operands are first_index: an integer selecting one tensor element, lane, bank, or state entry; samples: the value named 'samples' in this block.

Line 42: `manifest = {` This statement continues through source line 45; the explanation uses the complete expression rather than only the first visual fragment. This assigns ‘{ "format": "neuraedge-official-cifar10-shards-v1", "splits": {"train": entries, "test": entries}, }‘ to ‘manifest ‘ in host memory. Here manifest means the value named

'manifest' in this block. The important operands are format: the value named 'format' in this block; neuraedge: the value named 'neuraedge' in this block; official: the value named 'official' in this block. Context: the function test_shards_are_integrity_checked_deterministic_and_resumable, which handles test shards are integrity checked deterministic and resumable.

Line 43: `"format": "neuraedge-official-cifar10-shards-v1",` This is continuation line 2 of the 4-line logical statement that begins at source line 42. Its exact fragment is ‘"format": "neuraedge-official-cifar10-shards-v1",‘. The important operands are format: the value named 'format' in this block; neuraedge: the value named 'neuraedge' in this block; official: the value named 'official' in this block. Read together, the complete operation is: This assigns ‘{ "format": "neuraedge-official-cifar10-shards-v1", "splits": {"train": entries, "test": entries}, }‘ to ‘manifest ‘ in host memory. Here manifest means the value named 'manifest' in this block. The important operands are format: the value named 'format' in this block; neuraedge: the value named 'neuraedge' in this block; official: the value named 'official' in this block. Context: the function test_shards_are_integrity_checked_deterministic_and_resumable, which handles test shards are integrity checked deterministic and resumable.

Line 44: `"splits": {"train": entries, "test": entries},` This is continuation line 3 of the 4-line logical statement that begins at source line 42. Its exact fragment is ‘"splits": {"train": entries, "test": entries},‘. The important operands are splits: the value named 'splits' in this block; train: the value named 'train' in this block; entries: the value named 'entries' in this block. Read together, the complete operation is: This assigns ‘{ "format": "neuraedge-official-cifar10-shards-v1", "splits": {"train": entries, "test": entries}, }‘ to ‘manifest ‘ in host memory. Here manifest means the value named 'manifest' in this block. The important operands are format: the value named 'format' in this block; neuraedge: the value named 'neuraedge' in this block; official: the value named 'official' in this block. Context: the function test_shards_are_integrity_checked_deterministic_and_resumable, which handles test shards are integrity checked deterministic and resumable.

Line 45: `}` This is continuation line 4 of the 4-line logical statement that begins at source line 42. Its exact fragment is ‘}‘. The expression is a literal or structural operator and has no hidden software state. Read together, the complete operation is: This assigns ‘{ "format": "neuraedge-official-cifar10-shards-v1", "splits": {"train": entries, "test": entries}, }‘ to ‘manifest ‘ in host memory. Here manifest means the value named 'manifest' in this block. The important operands are format: the value named 'format' in this block; neuraedge: the value named 'neuraedge' in this block; official: the value named 'official' in this block. Context: the function test_shards_are_integrity_checked_deterministic_and_resumable, which handles test shards are integrity checked deterministic and resumable.

Line 46: `manifest_path = root / "cifar10_shards_manifest.json"` This assigns ‘root / "cifar10_shards_manifest.json"‘ to ‘manifest_path ‘ in host memory. Here manifest_path means the value named 'manifest path' in this block. The important operands are root: the value named 'root' in this block; cifar10_shards_manifest: the value named 'cifar10 shards manifest' in this block; json: the value named 'json' in this block. Context: the function test_shards_are_integrity_checked_determ which handles test shards are integrity checked deterministic and resumable.

Line 47: `manifest_path.write_text(json.dumps(manifest), encoding="ascii")` This calls ‘manifest_path.write_text‘ with ‘json.dumps(manifest), encoding="ascii"‘ inside the function test_shards_are_integrity_checked_deterministic_and_resumab which handles test shards are integrity checked deterministic and resumable. The call advances the host-side job that checks train spikingformer pynq behavior independently with Python assertions.

Line 48: `dataset = Cifar10ShardSet(manifest_path, "train")` This assigns ‘Cifar10ShardSet(manifest_path, "train")‘ to ‘dataset ‘ in host memory. Here dataset means the value named 'dataset' in this block. The important operands are Cifar10ShardSet: the value named 'cifar10 shard set' in this block; manifest_path: the value named 'manifest path' in this block; train: the value named 'train' in this block. Context: the function test_shards_are_integrity_checked_deterministic_an which handles test shards are integrity checked deterministic and resumable.

Line 49: `first = list(dataset.batches(` This statement continues through source line 50; the explanation uses the complete expression rather than only the first visual fragment. This assigns ‘list(dataset.batches(epoch=7, batch_size=2, seed=19, shuffle=True))‘ to ‘first ‘ in host memory. Here first means the value named 'first' in this block. The important operands are list: the value named 'list' in this block; dataset: the value named 'dataset' in this block; batches: the value named 'batches' in this block. Context: the function test_shards_are_integrity_checked_deterministic_and_resumable, which handles test shards are integrity checked deterministic and resumable.

Line 50: `epoch=7, batch_size=2, seed=19, shuffle=True))` This is continuation line 2 of the 2-line logical statement that begins at source line 49. Its exact fragment is 'epoch=7, batch_size=2, seed=19, shuffle=True))'. The important operands are epoch: the value named 'epoch' in this block; batch_size: the value named 'batch size' in this block; seed: the value named 'seed' in this block. Read together, the complete operation is: This assigns 'list(dataset.batches(epoch=7, batch_size=2, seed=19, shuffle=True))' to 'first ' in host memory. Here first means the value named 'first' in this block. The important operands are list: the value named 'list' in this block; dataset: the value named 'dataset' in this block; batches: the value named 'batches' in this block. Context: the function test_shards_are_integrity_checked_deterministic_and_resumable, which handles test shards are integrity checked deterministic and resumable.

Line 51: `second = list(dataset.batches(` This statement continues through source line 52; the explanation uses the complete expression rather than only the first visual fragment. This assigns 'list(dataset.batches(epoch=7, batch_size=2, seed=19, shuffle=True))' to 'second ' in host memory. Here second means the value named 'second' in this block. The important operands are list: the value named 'list' in this block; dataset: the value named 'dataset' in this block; batches: the value named 'batches' in this block. Context: the function test_shards_are_integrity_checked_deterministic_and_resumable, which handles test shards are integrity checked deterministic and resumable.

Line 52: `epoch=7, batch_size=2, seed=19, shuffle=True))` This is continuation line 2 of the 2-line logical statement that begins at source line 51. Its exact fragment is 'epoch=7, batch_size=2, seed=19, shuffle=True))'. The important operands are epoch: the value named 'epoch' in this block; batch_size: the value named 'batch size' in this block; seed: the value named 'seed' in this block. Read together, the complete operation is: This assigns 'list(dataset.batches(epoch=7, batch_size=2, seed=19, shuffle=True))' to 'second ' in host memory. Here second means the value named 'second' in this block. The important operands are list: the value named 'list' in this block; dataset: the value named 'dataset' in this block; batches: the value named 'batches' in this block. Context: the function test_shards_are_integrity_checked_deterministic_and_resumable, which handles test shards are integrity checked deterministic and resumable.

Line 53: `self.assertEqual([item[0] for item in first], list(range(len(first))))` This calls 'self.assertEqual' with '[item[0] for item in first], list(range(len(first)))' inside the function test_shards_are_integrity_checked_deterministic_and_re which handles test shards are integrity checked deterministic and resumable. The call advances the host-side job that checks train spikingformer pynq behavior independently with Python assertions.

Line 54: `self.assertEqual(` This statement continues through source line 57; the explanation uses the complete expression rather than only the first visual fragment. This calls 'self.assertEqual' with ' [item[2].tolist() for item in first], [item[2].tolist() for item in second], ' inside the function test_shards_are_integrity_checked_deterministic_and_resumable, which handles test shards are integrity checked deterministic and resumable. The call advances the host-side job that checks train spikingformer pynq behavior independently with Python assertions.

Line 55: `[item[2].tolist() for item in first],` This is continuation line 2 of the 4-line logical statement that begins at source line 54. Its exact fragment is '[item[2].tolist() for item in first],'. The important operands are item: the value named 'item' in this block; tolist: the value named 'tolist' in this block; for: the value named 'for' in this block. Read together, the complete operation is: This calls 'self.assertEqual' with ' [item[2].tolist() for item in first], [item[2].tolist() for item in second], ' inside the function test_shards_are_integrity_checked_deterministic_and_resumable, which handles test shards are integrity checked deterministic and resumable. The call advances the host-side job that checks train spikingformer pynq behavior independently with Python assertions.

Line 56: `[item[2].tolist() for item in second],` This is continuation line 3 of the 4-line logical statement that begins at source line 54. Its exact fragment is '[item[2].tolist() for item in second],'. The important operands are item: the value named 'item' in this block; tolist: the value named 'tolist' in this block; for: the value named 'for' in this block. Read together, the complete operation is: This calls 'self.assertEqual' with ' [item[2].tolist() for item in first], [item[2].tolist() for item in second], ' inside the function test_shards_are_integrity_checked_deterministic_and_resumable, which handles test shards are integrity checked deterministic and resumable. The call advances the host-side job that checks train spikingformer pynq behavior independently with Python assertions.

Line 57: `)` This is continuation line 4 of the 4-line logical statement that begins at source line 54. Its exact fragment is ')'. The expression is a literal or structural operator and has no hidden software state. Read together, the complete

operation is: This calls ‘self.assertEqual‘ with ‘ [item[2].tolist() for item in first], [item[2].tolist() for item in second], ‘ inside the function test_shards_are_integrity_checked_deterministic_and_resumable, which handles test shards are integrity checked deterministic and resumable. The call advances the host-side job that checks train spikingformer pynq behavior independently with Python assertions.

Line 58: `resumed = list(dataset.batches(` This statement continues through source line 59; the explanation uses the complete expression rather than only the first visual fragment. This assigns ‘list(dataset.batches(epoch=7, batch_size=2, seed=19, shuffle=True, start_batch=3))‘ to ‘resumed ‘ in host memory. Here resumed means the value named ’resumed’ in this block. The important operands are list: the value named ’list’ in this block; dataset: the value named ’dataset’ in this block; batches: the value named ’batches’ in this block. Context: the function test_shards_are_integrity_checked_deterministic_and_resumable, which handles test shards are integrity checked deterministic and resumable.

Line 59: `epoch=7, batch_size=2, seed=19, shuffle=True, start_batch=3))` This is continuation line 2 of the 2-line logical statement that begins at source line 58. Its exact fragment is ‘epoch=7, batch_size=2, seed=19, shuffle=True, start_batch=3))‘. The important operands are epoch: the value named ’epoch’ in this block; batch_size: the value named ’batch size’ in this block; seed: the value named ’seed’ in this block. Read together, the complete operation is: This assigns ‘list(dataset.batches(epoch=7, batch_size=2, seed=19, shuffle=True, start_batch=3))‘ to ‘resumed ‘ in host memory. Here resumed means the value named ’resumed’ in this block. The important operands are list: the value named ’list’ in this block; dataset: the value named ’dataset’ in this block; batches: the value named ’batches’ in this block. Context: the function test_shards_are_integrity_checked_deterministic_and_resumable, which handles test shards are integrity checked deterministic and resumable.

Line 60: `self.assertEqual([item[0] for item in resumed], list(range(3, len(first))))` This calls ‘self.assertEqual‘ with ‘[item[0] for item in resumed], list(range(3, len(first)))‘ inside the function test_shards_are_integrity_checked_deterministic_a which handles test shards are integrity checked deterministic and resumable. The call advances the host-side job that checks train spikingformer pynq behavior independently with Python assertions.

Line 61: `self.assertEqual(sum(len(item[2]) for item in first), 9)` This calls ‘self.assertEqual‘ with ‘sum(len(item[2]) for item in first), 9‘ inside the function test_shards_are_integrity_checked_deterministic_and_resumable, which handles test shards are integrity checked deterministic and resumable. The call advances the host-side job that checks train spikingformer pynq behavior independently with Python assertions.

Line 63: `manifest["splits"]["train"][0]["sha256"] = "0" * 64` Inside the function test_shards_are_integrity_checked_ which handles test shards are integrity checked deterministic and resumable, this statement advances the host implementation that checks train spikingformer pynq behavior independently with Python assertions. The important operands are manifest: the value named ’manifest’ in this block; splits: the value named ’splits’ in this block; train: the value named ’train’ in this block.

Line 64: `manifest_path.write_text(json.dumps(manifest), encoding="ascii")` This calls ‘manifest_path.write_text‘ with ‘json.dumps(manifest), encoding="ascii"‘ inside the function test_shards_are_integrity_checked_deterministic_and_resumab which handles test shards are integrity checked deterministic and resumable. The call advances the host-side job that checks train spikingformer pynq behavior independently with Python assertions.

Line 65: `with self.assertRaises(ValueError):` This opens a managed resource scope for ‘self.assertRaises(ValueError)‘ so files, tracing, or temporary state are finalized even if the function test_shards_are_integrity_checked_deterministic_and_resuma which handles test shards are integrity checked deterministic and resumable raises an error.

Line 66: `Cifar10ShardSet(manifest_path, "train")` This calls ‘Cifar10ShardSet‘ with ‘manifest_path, "train"‘ inside the function test_shards_are_integrity_checked_deterministic_and_resumable, which handles test shards are integrity checked deterministic and resumable. The call advances the host-side job that checks train spikingformer pynq behavior independently with Python assertions.

Line 68: `def test_augmentation_and_cosine_schedule_are_reproducible(self) -> None:` This starts function test_augmentation_and_cosine_schedule_are_reproducible. Its indented body performs test augmentation and cosine schedule are reproducible as part of the file that checks train spikingformer pynq behavior independently with Python assertions; it runs only when called.

Line 69: `images = np.arange(2 * 32 * 32 * 3, dtype=np.uint16).reshape(2, 32, 32, 3)` This assigns ‘np.arange(2 * 32 * 32 * 3, dtype=np.uint16).reshape(2, 32, 32, 3)‘ to ‘images ‘ in host memory. Here images means the value named ’images’ in this block. The important operands are arange: the value named ’arange’ in this block; dtype: the value named ’dtype’ in this block; uint16: the value named ’uint16’ in this block. Context: the function test_augmentation_and_cosine_schedule which handles test augmentation and cosine schedule are reproducible.

Line 70: `images = (images % 256).astype(np.uint8)` This assigns ‘(images % 256).astype(np.uint8)‘ to ‘images ‘ in host memory. Here images means the value named ’images’ in this block. The important operands are images: the value named ’images’ in this block; astype: the value named ’astype’ in this block; uint8: the value named ’uint8’ in this block. Context: the function test_augmentation_and_cosine_schedule_are_reproducible, which handles test augmentation and cosine schedule are reproducible.

Line 71: `first = augment_cifar10(images, 1234)` This assigns ‘augment_cifar10(images, 1234)‘ to ‘first ‘ in host memory. Here first means the value named ’first’ in this block. The important operands are augment_cifar10: the value named ’augment cifar10’ in this block; images: the value named ’images’ in this block. Context: the function test_augmentation_and_cosine_schedule_are_reproducible, which handles test augmentation and cosine schedule are reproducible.

Line 72: `second = augment_cifar10(images, 1234)` This assigns ‘augment_cifar10(images, 1234)‘ to ‘second ‘ in host memory. Here second means the value named ’second’ in this block. The important operands are augment_cifar10: the value named ’augment cifar10’ in this block; images: the value named ’images’ in this block. Context: the function test_augmentation_and_cosine_schedule_are_reproducible, which handles test augmentation and cosine schedule are reproducible.

Line 73: `np.testing.assert_array_equal(first, second)` This calls ‘np.testing.assert_array_equal‘ with ‘first, second‘ inside the function test_augmentation_and_cosine_schedule_are_reproducible, which handles test augmentation and cosine schedule are reproducible. The call advances the host-side job that checks train spikingformer pynq behavior independently with Python assertions.

Line 74: `self.assertEqual(first.shape, images.shape)` This calls ‘self.assertEqual‘ with ‘first.shape, images.shape‘ inside the function test_augmentation_and_cosine_schedule_are_reproducible, which handles test augmentation and cosine schedule are reproducible. The call advances the host-side job that checks train spikingformer pynq behavior independently with Python assertions.

Line 75: `self.assertEqual(cosine_learning_rate(0, 400, 0.25, 0.01), 0.25)` This calls ‘self.assertEqual‘ with ‘cosine_learning_rate(0, 400, 0.25, 0.01), 0.25‘ inside the function test_augmentation_and_cosine_schedule_are_reproducible, which handles test augmentation and cosine schedule are reproducible. The call advances the host-side job that checks train spikingformer pynq behavior independently with Python assertions.

Line 76: `self.assertAlmostEqual(cosine_learning_rate(399, 400, 0.25, 0.01), 0.01)` This calls ‘self.assertAlmostEqua with ‘cosine_learning_rate(399, 400, 0.25, 0.01), 0.01‘ inside the function test_augmentation_and_cosine_schedule_are_reproduci which handles test augmentation and cosine schedule are reproducible. The call advances the host-side job that checks train spikingformer pynq behavior independently with Python assertions.

Line 79: `if __name__ == "__main__":` This executes the following indented host-code branch only when ‘___name___ == "___main___"‘ is true. The important operands are ___name___: the value named ’name’ in this block; ___main___: the value named ’main’ in this block. Context: the file whose role is to checks train spikingformer pynq behavior independently with Python assertions.

Line 80: `unittest.main()` This calls ‘unittest.main‘ with “ inside the file whose role is to checks train spikingformer pynq behavior independently with Python assertions. The call advances the host-side job that checks train spikingformer pynq behavior independently with Python assertions.

77 scripts/capture_power_activity.ps1

Role in the complete system: orchestrates the repeatable Windows capture power activity command-line flow.

77.1 Beginner architecture map

Dataflow responsibility This file's end-to-end responsibility is to orchestrates the repeatable Windows capture power activity command-line flow.

Where it runs This is PowerShell orchestration, not accelerator datapath hardware. It makes tool inputs, versions, paths, stages, and failure propagation repeatable.

Reproducibility contract Every external command must be checked, every required artifact must exist and be nonempty, and measured values must be read from generated reports. Rerunning this file should either reproduce its declared outputs or stop at the first failed gate.

77.2 Complete source

77.3 Line annotations

Line 1: `[CmdletBinding()]` This batch-control line contributes to the flow that orchestrates the repeatable Windows capture power activity command-line flow. The important operands are CmdletBinding: the value named 'cmdlet binding' in this block.

Line 2: `param(` This declares a typed command-line parameter so the flow can be rerun with explicit, validated paths and options.

Line 3: `[string]$VivadoRoot = "D:\AMDDesignTools\2026.1\Vivado",` This declares a typed command-line parameter so the flow can be rerun with explicit, validated paths and options.

Line 4: `[string]$OutputDirectory = ""` This declares a typed command-line parameter so the flow can be rerun with explicit, validated paths and options.

Line 5: `)` This batch-control line contributes to the flow that orchestrates the repeatable Windows capture power activity command-line flow. The expression is a literal or structural operator and has no hidden software state.

Line 7: `$ErrorActionPreference = "Stop"` This makes PowerShell stop on errors so a failed prerequisite cannot be hidden by later successful commands.

Line 8: `Set-StrictMode -Version Latest` This batch-control line contributes to the flow that orchestrates the repeatable Windows capture power activity command-line flow. The important operands are Set: the value named 'set' in this block; StrictMode: the value named 'strict mode' in this block; Version: the value named 'version' in this block.

Line 10: `$ProjectRoot = (Resolve-Path (Join-Path $PSScriptRoot "..")).Path` This resolves a deterministic filesystem location for the flow that orchestrates the repeatable Windows capture power activity command-line flow. Literal/full paths prevent a different working directory from silently selecting the wrong source, checkpoint, or output.

Line 11: `if ([string]::IsNullOrWhiteSpace($OutputDirectory)) {` This batch-control line contributes to the flow that orchestrates the repeatable Windows capture power activity command-line flow. The important operands are string: the value named 'string' in this block; IsNullOrWhiteSpace: the value named 'is null or white space' in this block; OutputDirectory: the value named 'output directory' in this block.

Line 12: `$OutputDirectory = Join-Path $ProjectRoot "outputs\power_activity"` This batch-control line contributes to the flow that orchestrates the repeatable Windows capture power activity command-line flow. The important operands are OutputDirectory: the value named 'output directory' in this block; Join: the value named 'join' in this block; Path: the value named 'path' in this block.

Line 13: `}` This batch-control line contributes to the flow that orchestrates the repeatable Windows capture power activity command-line flow. The expression is a literal or structural operator and has no hidden software state.

Line 14: `$OutputDirectory = [System.IO.Path]::GetFullPath($OutputDirectory)` This resolves a deterministic filesystem location for the flow that orchestrates the repeatable Windows capture power activity command-line flow. Literal/full paths prevent a different working directory from silently selecting the wrong source, checkpoint, or output.

Line 15: `$WorkDirectory = Join-Path $OutputDirectory "xsim_work"` This locates or invokes a required tool as part of the script that orchestrates the repeatable Windows capture power activity command-line flow; the exact command and arguments remain visible here for reproducibility.

Line 16: `$LogDirectory = Join-Path $OutputDirectory "logs"` This batch-control line contributes to the flow that orchestrates the repeatable Windows capture power activity command-line flow. The important operands are LogDirectory: the value named 'log directory' in this block; Join: the value named 'join' in this block; Path: the value named 'path' in this block.

Line 17: `$SaifDirectory = Join-Path $OutputDirectory "saif"` This batch-control line contributes to the flow that orchestrates the repeatable Windows capture power activity command-line flow. The important operands are SaifDirectory: the value named 'saif directory' in this block; Join: the value named 'join' in this block; Path: the value named 'path' in this block.

Line 18: `foreach ($Directory in @($OutputDirectory, $WorkDirectory, $LogDirectory, $SaifDirectory)) {` This batch-control line contributes to the flow that orchestrates the repeatable Windows capture power activity command-line flow. The important operands are foreach: the value named 'foreach' in this block; Directory: the value named 'directory' in this block; in: the value named 'in' in this block.

Line 19: `New-Item -ItemType Directory -Force -Path $Directory | Out-Null` This creates the declared output directory before a tool writes into it. '-Force' permits an existing directory but does not make an external tool failure succeed.

Line 20: `}` This batch-control line contributes to the flow that orchestrates the repeatable Windows capture power activity command-line flow. The expression is a literal or structural operator and has no hidden software state.

Line 21: `$FixtureStage = Join-Path $WorkDirectory "tb\fixtures"` This batch-control line contributes to the flow that orchestrates the repeatable Windows capture power activity command-line flow. The important operands are FixtureStage: the value named 'fixture stage' in this block; Join: the value named 'join' in this block; Path: the value named 'path' in this block.

Line 22: `New-Item -ItemType Directory -Force -Path $FixtureStage | Out-Null` This creates the declared output directory before a tool writes into it. '-Force' permits an existing directory but does not make an external tool failure succeed.

Line 23: `Copy-Item -Path (Join-Path $ProjectRoot "tb\fixtures\*") -Destination $FixtureStage -Force` This batch-control line contributes to the flow that orchestrates the repeatable Windows capture power activity command-line flow. The important operands are Copy: the value named 'copy' in this block; Item: the value named 'item' in this block; Path: the value named 'path' in this block.

Line 25: `$VivadoBin = Join-Path $VivadoRoot "bin"` This locates or invokes a required tool as part of the script that orchestrates the repeatable Windows capture power activity command-line flow; the exact command and arguments remain visible here for reproducibility.

Line 26: `$Xvlog = Join-Path $VivadoBin "xvlog.bat"` This locates or invokes a required tool as part of the script that orchestrates the repeatable Windows capture power activity command-line flow; the exact command and arguments remain visible here for reproducibility.

Line 27: `$Xelab = Join-Path $VivadoBin "xelab.bat"` This locates or invokes a required tool as part of the script that orchestrates the repeatable Windows capture power activity command-line flow; the exact command and arguments remain visible here for reproducibility.

Line 28: `$Xsim = Join-Path $VivadoBin "xsim.bat"` This locates or invokes a required tool as part of the script that orchestrates the repeatable Windows capture power activity command-line flow; the exact command and arguments remain visible here for reproducibility.

Line 29: `foreach ($Tool in @($Xvlog, $Xelab, $Xsim)) {` This locates or invokes a required tool as part of the script that orchestrates the repeatable Windows capture power activity command-line flow; the exact command and arguments remain visible here for reproducibility.

Line 30: `if (-not (Test-Path -LiteralPath $Tool)) {` This batch-control line contributes to the flow that orchestrates the repeatable Windows capture power activity command-line flow. The important operands are not: the value named 'not' in this block; Test: the value named 'test' in this block; Path: the value named 'path' in this block.

Line 31: `throw "Required Vivado simulator tool was not found: $Tool"` This locates or invokes a required tool as part of the script that orchestrates the repeatable Windows capture power activity command-line flow; the exact command and arguments remain visible here for reproducibility.

Line 32: `}` This batch-control line contributes to the flow that orchestrates the repeatable Windows capture power activity command-line flow. The expression is a literal or structural operator and has no hidden software state.

Line 33: `}` This batch-control line contributes to the flow that orchestrates the repeatable Windows capture power activity command-line flow. The expression is a literal or structural operator and has no hidden software state.

Line 35: `$PackageFile = Join-Path $ProjectRoot "rtl\neuraedge_command_pkg.sv"` This batch-control line contributes to the flow that orchestrates the repeatable Windows capture power activity command-line flow. The important operands are PackageFile: the value named 'package file' in this block; Join: the value named 'join' in this block; Path: the value named 'path' in this block.

Line 36: `$RtlFiles = @($PackageFile) + @(` This batch-control line contributes to the flow that orchestrates the repeatable Windows capture power activity command-line flow. The important operands are RtlFiles: the value named 'rtl files' in this block; PackageFile: the value named 'package file' in this block.

Line 37: `Get-ChildItem -LiteralPath (Join-Path $ProjectRoot "rtl") -Filter "*.sv" -File |` This batch-control line contributes to the flow that orchestrates the repeatable Windows capture power activity command-line flow. The important operands are Get: the value named 'get' in this block; ChildItem: the value named 'child item' in this block; LiteralPath: the value named 'literal path' in this block.

Line 38: `Where-Object { $_.FullName -ne $PackageFile } |` This batch-control line contributes to the flow that orchestrates the repeatable Windows capture power activity command-line flow. The important operands are Where: the value named 'where' in this block; Object: the value named 'object' in this block; _: the value named '' in this block.

Line 39: `Sort-Object Name |` This batch-control line contributes to the flow that orchestrates the repeatable Windows capture power activity command-line flow. The important operands are Sort: the value named 'sort' in this block; Object: the value named 'object' in this block; Name: the value named 'name' in this block.

Line 40: `ForEach-Object FullName` This batch-control line contributes to the flow that orchestrates the repeatable Windows capture power activity command-line flow. The important operands are ForEach: the value named 'for each' in this block; Object: the value named 'object' in this block; FullName: the value named 'full name' in this block.

Line 41: `)` This batch-control line contributes to the flow that orchestrates the repeatable Windows capture power activity command-line flow. The expression is a literal or structural operator and has no hidden software state.

Line 42: `$CaptureTcl = (Join-Path $PSScriptRoot "capture_power_activity.tcl").Replace('\', '/')` This batch-control line contributes to the flow that orchestrates the repeatable Windows capture power activity command-line flow. The important operands are CaptureTcl: the value named 'capture tcl' in this block; Join: the value named 'join' in this block; Path: the value named 'path' in this block.

Line 43: `$Scenarios = @(` This batch-control line contributes to the flow that orchestrates the repeatable Windows capture power activity command-line flow. The important operands are Scenarios: the value named 'scenarios' in this block.

Line 44: `[PSCustomObject]@{` This batch-control line contributes to the flow that orchestrates the repeatable Windows capture power activity command-line flow. The important operands are PSCustomObject: the value named 'pscustom object' in this block.

Line 45: `Top = "tb_neuraedge_pynq_axi_top"` This batch-control line contributes to the flow that orchestrates the repeatable Windows capture power activity command-line flow. The important operands are Top: the value named 'top' in this block; tb_neuraedge_pynq_axi_top: the value named 'tb neuraedge pynq axi top' in this block.

Line 46: `Scope = "/tb_neuraedge_pynq_axi_top/dut"` This batch-control line contributes to the flow that orchestrates the repeatable Windows capture power activity command-line flow. The important operands are Scope: the value named 'scope' in this block; tb_neuraedge_pynq_axi_top: the value named 'tb neuraedge pynq axi top' in this block; dut: the value named 'dut' in this block.

Line 47: `Amount = 5` This batch-control line contributes to the flow that orchestrates the repeatable Windows capture power activity command-line flow. The important operands are Amount: the value named 'amount' in this block.

Line 48: `Unit = "us"` This batch-control line contributes to the flow that orchestrates the repeatable Windows capture power activity command-line flow. The important operands are Unit: the value named 'unit' in this block; us: the value named 'us' in this block.

Line 49: `},` This batch-control line contributes to the flow that orchestrates the repeatable Windows capture power activity command-line flow. The expression is a literal or structural operator and has no hidden software state.

Line 50: `[PSCustomObject]@{` This batch-control line contributes to the flow that orchestrates the repeatable Windows capture power activity command-line flow. The important operands are PSCustomObject: the value named 'pscustom object' in this block.

Line 51: `Top = "tb_neuraedge_universal_core"` This batch-control line contributes to the flow that orchestrates the repeatable Windows capture power activity command-line flow. The important operands are Top: the value named 'top' in this block; tb_neuraedge_universal_core: the value named 'tb neuraedge universal core' in this block.

Line 52: `Scope = "/tb_neuraedge_universal_core/dut"` This batch-control line contributes to the flow that orchestrates the repeatable Windows capture power activity command-line flow. The important operands are Scope: the value named 'scope' in this block; tb_neuraedge_universal_core: the value named 'tb neuraedge universal core' in this block; dut: the value named 'dut' in this block.

Line 53: `Amount = 50` This batch-control line contributes to the flow that orchestrates the repeatable Windows capture power activity command-line flow. The important operands are Amount: the value named 'amount' in this block.

Line 54: `Unit = "us"` This batch-control line contributes to the flow that orchestrates the repeatable Windows capture power activity command-line flow. The important operands are Unit: the value named 'unit' in this block; us: the value named 'us' in this block.

Line 55: `}` This batch-control line contributes to the flow that orchestrates the repeatable Windows capture power activity command-line flow. The expression is a literal or structural operator and has no hidden software state.

Line 56: `)` This batch-control line contributes to the flow that orchestrates the repeatable Windows capture power activity command-line flow. The expression is a literal or structural operator and has no hidden software state.

Line 57: `$ManifestRows = [System.Collections.Generic.List[object]]::new()` This batch-control line contributes to the flow that orchestrates the repeatable Windows capture power activity command-line flow. The important operands are ManifestRows: one output-row position processed by the tensor tile; System: the value named 'system' in this block; Collections: the value named 'collections' in this block.

Line 59: `Push-Location $WorkDirectory` This batch-control line contributes to the flow that orchestrates the repeatable Windows capture power activity command-line flow. The important operands are Push: the value named 'push' in this block; Location: the value named 'location' in this block; WorkDirectory: the value named 'work directory' in this block.

Line 60: `try {` This batch-control line contributes to the flow that orchestrates the repeatable Windows capture power activity command-line flow. The important operands are try: the value named 'try' in this block.

Line 61: `& $Xvlog -sv -i $ProjectRoot @RtlFiles 2>&1 |` This locates or invokes a required tool as part of the script that orchestrates the repeatable Windows capture power activity command-line flow; the exact command and arguments remain visible here for reproducibility.

Line 62: `Tee-Object -FilePath (Join-Path $LogDirectory "rtl_compile.log")` This batch-control line contributes to the flow that orchestrates the repeatable Windows capture power activity command-line flow. The important operands are Tee: the value named 'tee' in this block; Object: the value named 'object' in this block; FilePath: the value named 'file path' in this block.

Line 63: `if ($LASTEXITCODE -ne 0) {` This checks the external program's process exit code and turns a failed compiler, simulator, or Vivado run into a failed pipeline.

Line 64: `throw "RTL xvlog compilation failed with exit code $LASTEXITCODE"` This checks the external program's process exit code and turns a failed compiler, simulator, or Vivado run into a failed pipeline.

Line 65: `}` This batch-control line contributes to the flow that orchestrates the repeatable Windows capture power activity command-line flow. The expression is a literal or structural operator and has no hidden software state.

Line 67: `foreach ($Scenario in $Scenarios) {` This batch-control line contributes to the flow that orchestrates the repeatable Windows capture power activity command-line flow. The important operands are foreach: the value named 'foreach' in this block; Scenario: the value named 'scenario' in this block; in: the value named 'in' in this block.

Line 68: `$Top = $Scenario.Top` This batch-control line contributes to the flow that orchestrates the repeatable Windows capture power activity command-line flow. The important operands are Top: the value named 'top' in this block; Scenario: the value named 'scenario' in this block.

Line 69: `$Snapshot = "${Top}_power_snapshot"` This batch-control line contributes to the flow that orchestrates the repeatable Windows capture power activity command-line flow. The important operands are Snapshot: the value named 'snapshot' in this block; Top: the value named 'top' in this block; _power_snapshot: the value named 'power snapshot' in this block.

Line 70: `$SaifPath = Join-Path $SaifDirectory "$Top.saif"` This batch-control line contributes to the flow that orchestrates the repeatable Windows capture power activity command-line flow. The important operands are SaifPath: the value named 'saif path' in this block; Join: the value named 'join' in this block; Path: the value named 'path' in this block.

Line 71: `Remove-Item -LiteralPath $SaifPath -Force -ErrorAction SilentlyContinue` This removes the explicitly named rebuildable artifact. The script uses a literal path so wildcard expansion cannot delete an unintended neighboring file.

Line 72: `& $Xvlog -sv -i $ProjectRoot (Join-Path $ProjectRoot "tb\$Top.sv") 2>&1 |` This locates or invokes a required tool as part of the script that orchestrates the repeatable Windows capture power activity command-line flow; the exact command and arguments remain visible here for reproducibility.

Line 73: `Tee-Object -FilePath (Join-Path $LogDirectory "$Top.compile.log")` This batch-control line contributes to the flow that orchestrates the repeatable Windows capture power activity command-line flow. The important operands are Tee: the value named 'tee' in this block; Object: the value named 'object' in this block; FilePath: the value named 'file path' in this block.

Line 74: `if ($LASTEXITCODE -ne 0) {` This checks the external program's process exit code and turns a failed compiler, simulator, or Vivado run into a failed pipeline.

Line 75: `throw "$Top xvlog compilation failed with exit code $LASTEXITCODE"` This checks the external program's process exit code and turns a failed compiler, simulator, or Vivado run into a failed pipeline.

Line 76: `}` This batch-control line contributes to the flow that orchestrates the repeatable Windows capture power activity command-line flow. The expression is a literal or structural operator and has no hidden software state.

Line 77: `& $Xelab -debug typical -timescale 1ns/1ps -snapshot $Snapshot "work.$Top" 2>&1 |` This locates or invokes a required tool as part of the script that orchestrates the repeatable Windows capture power activity command-line flow; the exact command and arguments remain visible here for reproducibility.

Line 78: `Tee-Object -FilePath (Join-Path $LogDirectory "$Top.elaborate.log")` This batch-control line contributes to the flow that orchestrates the repeatable Windows capture power activity command-line flow. The important operands are Tee: the value named 'tee' in this block; Object: the value named 'object' in this block; FilePath: the value named 'file path' in this block.

Line 79: `if ($LASTEXITCODE -ne 0) {` This checks the external program's process exit code and turns a failed compiler, simulator, or Vivado run into a failed pipeline.

Line 80: `throw "$Top xelab failed with exit code $LASTEXITCODE"` This checks the external program's process exit code and turns a failed compiler, simulator, or Vivado run into a failed pipeline.

Line 81: `}` This batch-control line contributes to the flow that orchestrates the repeatable Windows capture power activity command-line flow. The expression is a literal or structural operator and has no hidden software state.

Line 83: `$env:NEURAEDGE_SAIF_PATH = $SaifPath` This batch-control line contributes to the flow that orchestrates the repeatable Windows capture power activity command-line flow. The important operands are env: the value named 'env' in this block; NEURAEDGE_SAIF_PATH: the value named 'neuraedge saif path' in this block; SaifPath: the value named 'saif path' in this block.

Line 84: `$env:NEURAEDGE_SAIF_SCOPE = $Scenario.Scope` This batch-control line contributes to the flow that orchestrates the repeatable Windows capture power activity command-line flow. The important operands are env: the value named 'env' in this block; NEURAEDGE_SAIF_SCOPE: the value named 'neuraedge saif scope' in this block; Scenario: the value named 'scenario' in this block.

Line 85: `$env:NEURAEDGE_SAIF_AMOUNT = [string]$Scenario.Amount` This batch-control line contributes to the flow that orchestrates the repeatable Windows capture power activity command-line flow. The important operands are env: the value named 'env' in this block; NEURAEDGE_SAIF_AMOUNT: the value named 'neuraedge saif amount' in this block; string: the value named 'string' in this block.

Line 86: `$env:NEURAEDGE_SAIF_UNIT = $Scenario.Unit` This batch-control line contributes to the flow that orchestrates the repeatable Windows capture power activity command-line flow. The important operands are env: the value named 'env' in this block; NEURAEDGE_SAIF_UNIT: the value named 'neuraedge saif unit' in this block; Scenario: the value named 'scenario' in this block.

Line 87: `& $Xsim $Snapshot -onerror quit -onfinish quit -tclbatch $CaptureTcl 2>&1 |` This locates or invokes a required tool as part of the script that orchestrates the repeatable Windows capture power activity command-line flow; the exact command and arguments remain visible here for reproducibility.

Line 88: `Tee-Object -FilePath (Join-Path $LogDirectory "$Top.simulate.log")` This batch-control line contributes to the flow that orchestrates the repeatable Windows capture power activity command-line flow. The important operands are Tee: the value named 'tee' in this block; Object: the value named 'object' in this block; FilePath: the value named 'file path' in this block.

Line 89: `if ($LASTEXITCODE -ne 0) {` This checks the external program's process exit code and turns a failed compiler, simulator, or Vivado run into a failed pipeline.

Line 90: `throw "$Top XSim SAIF capture failed with exit code $LASTEXITCODE"` This checks the external program's process exit code and turns a failed compiler, simulator, or Vivado run into a failed pipeline.

Line 91: `}` This batch-control line contributes to the flow that orchestrates the repeatable Windows capture power activity command-line flow. The expression is a literal or structural operator and has no hidden software state.

Line 92: `if (-not (Test-Path -LiteralPath $SaifPath) -or` This batch-control line contributes to the flow that orchestrates the repeatable Windows capture power activity command-line flow. The important operands are not: the value named 'not' in this block; Test: the value named 'test' in this block; Path: the value named 'path' in this block.

Line 93: `(Get-Item -LiteralPath $SaifPath).Length -eq 0) {` This batch-control line contributes to the flow that orchestrates the repeatable Windows capture power activity command-line flow. The important operands are Get: the value named 'get' in this block; Item: the value named 'item' in this block; LiteralPath: the value named 'literal path' in this block.

Line 94: `throw "$Top did not produce a nonempty SAIF"` This batch-control line contributes to the flow that orchestrates the repeatable Windows capture power activity command-line flow. The important operands are throw: one output-row position processed by the tensor tile; Top: the value named 'top' in this block; did: the value named 'did' in this block.

Line 95: `}` This batch-control line contributes to the flow that orchestrates the repeatable Windows capture power activity command-line flow. The expression is a literal or structural operator and has no hidden software state.

Line 96: `$ManifestRows.Add([PSCustomObject]@{` This batch-control line contributes to the flow that orchestrates the repeatable Windows capture power activity command-line flow. The important operands are ManifestRows: one output-row position processed by the tensor tile; Add: the value named 'add' in this block; PSCustomObject: the value named 'pscustom object' in this block.

Line 97: `testbench = $Top` This batch-control line contributes to the flow that orchestrates the repeatable Windows capture power activity command-line flow. The important operands are testbench: the value named 'testbench' in this block; Top: the value named 'top' in this block.

Line 98: `scope = $Scenario.Scope` This batch-control line contributes to the flow that orchestrates the repeatable Windows capture power activity command-line flow. The important operands are scope: the value named 'scope' in this block; Scenario: the value named 'scenario' in this block; Scope: the value named 'scope' in this block.

Line 99: `duration = $Scenario.Amount` This batch-control line contributes to the flow that orchestrates the repeatable Windows capture power activity command-line flow. The important operands are duration: the value named 'duration' in this block; Scenario: the value named 'scenario' in this block; Amount: the value named 'amount' in this block.

Line 100: `unit = $Scenario.Unit` This batch-control line contributes to the flow that orchestrates the repeatable Windows capture power activity command-line flow. The important operands are unit: the value named 'unit' in this block; Scenario: the value named 'scenario' in this block; Unit: the value named 'unit' in this block.

Line 101: `saif = [System.IO.Path]::GetRelativePath($OutputDirectory, $SaifPath)` This batch-control line contributes to the flow that orchestrates the repeatable Windows capture power activity command-line flow. The important operands are saif: the value named 'saif' in this block; System: the value named 'system' in this block; IO: the value named 'io' in this block.

Line 102: `saif_bytes = (Get-Item -LiteralPath $SaifPath).Length` This batch-control line contributes to the flow that orchestrates the repeatable Windows capture power activity command-line flow. The important operands are saif_bytes: the value named 'saif bytes' in this block; Get: the value named 'get' in this block; Item: the value named 'item' in this block.

Line 103: `})` This batch-control line contributes to the flow that orchestrates the repeatable Windows capture power activity command-line flow. The expression is a literal or structural operator and has no hidden software state.

Line 104: `}` This batch-control line contributes to the flow that orchestrates the repeatable Windows capture power activity command-line flow. The expression is a literal or structural operator and has no hidden software state.

Line 105: `} finally {` This batch-control line contributes to the flow that orchestrates the repeatable Windows capture power activity command-line flow. The important operands are finally: the value named 'finally' in this block.

Line 106: `foreach ($Name in @("NEURAEDGE_SAIF_PATH", "NEURAEDGE_SAIF_SCOPE",` This batch-control line contributes to the flow that orchestrates the repeatable Windows capture power activity command-line flow. The important operands are foreach: the value named 'foreach' in this block; Name: the value named 'name' in this block; in: the value named 'in' in this block.

Line 107: `"NEURAEDGE_SAIF_AMOUNT", "NEURAEDGE_SAIF_UNIT")) {` This batch-control line contributes to the flow that orchestrates the repeatable Windows capture power activity command-line flow. The important operands are NEURAEDGE_SAIF_AMOUNT: the value named 'neuraedge saif amount' in this block; NEURAEDGE_SAIF_UNIT: the value named 'neuraedge saif unit' in this block.

Line 108: `Remove-Item "Env:$Name" -ErrorAction SilentlyContinue` This removes the explicitly named rebuildable artifact. The script uses a literal path so wildcard expansion cannot delete an unintended neighboring file.

Line 109: `}` This batch-control line contributes to the flow that orchestrates the repeatable Windows capture power activity command-line flow. The expression is a literal or structural operator and has no hidden software state.

Line 110: `Pop-Location` This batch-control line contributes to the flow that orchestrates the repeatable Windows capture power activity command-line flow. The important operands are Pop: the value named 'pop' in this block; Location: the value named 'location' in this block.

Line 111: `}` This batch-control line contributes to the flow that orchestrates the repeatable Windows capture power activity command-line flow. The expression is a literal or structural operator and has no hidden software state.

Line 113: `$Manifest = [ordered]@{` This batch-control line contributes to the flow that orchestrates the repeatable Windows capture power activity command-line flow. The important operands are Manifest: the value named 'manifest' in this block; ordered: the value named 'ordered' in this block.

Line 114: `format = "neuraedge-xsim-saif-v1"` This locates or invokes a required tool as part of the script that orchestrates the repeatable Windows capture power activity command-line flow; the exact command and arguments remain visible here for reproducibility.

Line 115: `vivado_root = $VivadoRoot` This locates or invokes a required tool as part of the script that orchestrates the repeatable Windows capture power activity command-line flow; the exact command and arguments remain visible here for reproducibility.

Line 116: `target_part = "xc7z020clg400-1"` This batch-control line contributes to the flow that orchestrates the repeatable Windows capture power activity command-line flow. The important operands are target_part: the value named 'target part' in this block; xc7z020clg400: the value named 'xc7z020clg400' in this block.

Line 117: `target_clock_mhz = 200` This batch-control line contributes to the flow that orchestrates the repeatable Windows capture power activity command-line flow. The important operands are target_clock_mhz: the value named 'target clock mhz' in this block.

Line 118: `captures = @($ManifestRows)` This batch-control line contributes to the flow that orchestrates the repeatable Windows capture power activity command-line flow. The important operands are captures: the value named 'captures' in this block; ManifestRows: one output-row position processed by the tensor tile.

Line 119: `}` This batch-control line contributes to the flow that orchestrates the repeatable Windows capture power activity command-line flow. The expression is a literal or structural operator and has no hidden software state.

Line 120: `$ManifestPath = Join-Path $OutputDirectory "power_activity_manifest.json"` This batch-control line contributes to the flow that orchestrates the repeatable Windows capture power activity command-line flow. The important operands are ManifestPath: the value named 'manifest path' in this block; Join: the value named 'join' in this block; Path: the value named 'path' in this block.

Line 121: `$Manifest | ConvertTo-Json -Depth 5 | Set-Content -LiteralPath $ManifestPath -Encoding utf8` This batch-control line contributes to the flow that orchestrates the repeatable Windows capture power activity command-line flow. The important operands are Manifest: the value named 'manifest' in this block; ConvertTo: the value named 'convert to' in this block; Json: the value named 'json' in this block.

Line 122: `Write-Output "NEURAEDGE_POWER_ACTIVITY_CAPTURED count=$($ManifestRows.Count) manifest=$ManifestPath` This batch-control line contributes to the flow that orchestrates the repeatable Windows capture power activity command-line flow. The important operands are Write: the value named 'write' in this block; Output: the value named 'output' in this block; NEURAEDGE_POWER_ACTIVITY_CAPTURED: the value named 'neuraedge power activity captured' in this block.

78 scripts/capture_waveforms.ps1

Role in the complete system: orchestrates the repeatable Windows capture waveforms command-line flow.

78.1 Beginner architecture map

Dataflow responsibility This file's end-to-end responsibility is to orchestrates the repeatable Windows capture waveforms command-line flow.

Where it runs This is PowerShell orchestration, not accelerator datapath hardware. It makes tool inputs, versions, paths, stages, and failure propagation repeatable.

Reproducibility contract Every external command must be checked, every required artifact must exist and be nonempty, and measured values must be read from generated reports. Rerunning this file should either reproduce its declared outputs or stop at the first failed gate.

78.2 Complete source

```

78.3 Line annotations

Line 1: `[CmdletBinding()]` This batch-control line contributes to the flow that orchestrates the repeatable Windows capture waveforms command-line flow. The important operands are CmdletBinding: the value named 'cmdlet binding' in this block.

Line 2: `param(` This declares a typed command-line parameter so the flow can be rerun with explicit, validated paths and options.

Line 3: `[string]$VivadoRoot = "D:\AMDDesignTools\2026.1\Vivado",` This declares a typed command-line parameter so the flow can be rerun with explicit, validated paths and options.

Line 4: `[string]$OutputDirectory = "",` This declares a typed command-line parameter so the flow can be rerun with explicit, validated paths and options.

Line 5: `[string[]]$Testbench = @()` This batch-control line contributes to the flow that orchestrates the repeatable Windows capture waveforms command-line flow. The important operands are string: the value named 'string' in this block; Testbench: the value named 'testbench' in this block.

Line 6: `)` This batch-control line contributes to the flow that orchestrates the repeatable Windows capture waveforms command-line flow. The expression is a literal or structural operator and has no hidden software state.

Line 8: `$ErrorActionPreference = "Stop"` This makes PowerShell stop on errors so a failed prerequisite cannot be hidden by later successful commands.

Line 9: `Set-StrictMode -Version Latest` This batch-control line contributes to the flow that orchestrates the repeatable Windows capture waveforms command-line flow. The important operands are Set: the value named 'set' in this block; StrictMode: the value named 'strict mode' in this block; Version: the value named 'version' in this block.

Line 11: `$ProjectRoot = (Resolve-Path (Join-Path $PSScriptRoot "..")).Path` This resolves a deterministic filesystem location for the flow that orchestrates the repeatable Windows capture waveforms command-line flow. Literal/full paths prevent a different working directory from silently selecting the wrong source, checkpoint, or output.

Line 12: `if ([string]::IsNullOrWhiteSpace($OutputDirectory)) {` This batch-control line contributes to the flow that orchestrates the repeatable Windows capture waveforms command-line flow. The important operands are string: the value named 'string' in this block; IsNullOrWhiteSpace: the value named 'is null or white space' in this block; OutputDirectory: the value named 'output directory' in this block.

Line 13: `$OutputDirectory = Join-Path $ProjectRoot "outputs\waveforms"` This batch-control line contributes to the flow that orchestrates the repeatable Windows capture waveforms command-line flow. The important operands are OutputDirectory: the value named 'output directory' in this block; Join: the value named 'join' in this block; Path: the value named 'path' in this block.

Line 14: `}` This batch-control line contributes to the flow that orchestrates the repeatable Windows capture waveforms command-line flow. The expression is a literal or structural operator and has no hidden software state.

Line 15: `$OutputDirectory = [System.IO.Path]::GetFullPath($OutputDirectory)` This resolves a deterministic filesystem location for the flow that orchestrates the repeatable Windows capture waveforms command-line flow. Literal/full paths prevent a different working directory from silently selecting the wrong source, checkpoint, or output.

Line 16: `$WorkDirectory = Join-Path $OutputDirectory "xsim_work"` This locates or invokes a required tool as part of the script that orchestrates the repeatable Windows capture waveforms command-line flow; the exact command and arguments remain visible here for reproducibility.

Line 17: `$VcdDirectory = Join-Path $OutputDirectory "vcd"` This batch-control line contributes to the flow that orchestrates the repeatable Windows capture waveforms command-line flow. The important operands are VcdDirectory: the value named 'vcd directory' in this block; Join: the value named 'join' in this block; Path: the value named 'path' in this block.

Line 18: `$WdbDirectory = Join-Path $OutputDirectory "wdb"` This batch-control line contributes to the flow that orchestrates the repeatable Windows capture waveforms command-line flow. The important operands are WdbDirectory: the value named 'wdb directory' in this block; Join: the value named 'join' in this block; Path: the value named 'path' in this block.

Line 19: `$LogDirectory = Join-Path $OutputDirectory "logs"` This batch-control line contributes to the flow that orchestrates the repeatable Windows capture waveforms command-line flow. The important operands are LogDirectory: the value named 'log directory' in this block; Join: the value named 'join' in this block; Path: the value named 'path' in this block.

Line 20: `foreach ($Directory in @($OutputDirectory, $WorkDirectory, $VcdDirectory, $WdbDirectory, $LogDirecto`
`{` This batch-control line contributes to the flow that orchestrates the repeatable Windows capture waveforms command-line flow. The important operands are foreach: the value named 'foreach' in this block; Directory: the value named 'directory' in this block; in: the value named 'in' in this block.

Line 21: `New-Item -ItemType Directory -Force -Path $Directory | Out-Null` This creates the declared output directory before a tool writes into it. '-Force' permits an existing directory but does not make an external tool failure succeed.

Line 22: `}` This batch-control line contributes to the flow that orchestrates the repeatable Windows capture waveforms command-line flow. The expression is a literal or structural operator and has no hidden software state.

Line 23: `$FixtureStage = Join-Path $WorkDirectory "tb\fixtures"` This batch-control line contributes to the flow that orchestrates the repeatable Windows capture waveforms command-line flow. The important operands are FixtureStage: the value named 'fixture stage' in this block; Join: the value named 'join' in this block; Path: the value named 'path' in this block.

Line 24: `New-Item -ItemType Directory -Force -Path $FixtureStage | Out-Null` This creates the declared output directory before a tool writes into it. '-Force' permits an existing directory but does not make an external tool failure succeed.

Line 25: `Copy-Item -Path (Join-Path $ProjectRoot "tb\fixtures\*") -Destination $FixtureStage -Force`
This batch-control line contributes to the flow that orchestrates the repeatable Windows capture waveforms command-line flow. The important operands are Copy: the value named 'copy' in this block; Item: the value named 'item' in this block; Path: the value named 'path' in this block.

Line 27: `$VivadoBin = Join-Path $VivadoRoot "bin"` This locates or invokes a required tool as part of the script that orchestrates the repeatable Windows capture waveforms command-line flow; the exact command and arguments remain visible here for reproducibility.

Line 28: `$Xvlog = Join-Path $VivadoBin "xvlog.bat"` This locates or invokes a required tool as part of the script that orchestrates the repeatable Windows capture waveforms command-line flow; the exact command and arguments remain visible here for reproducibility.

Line 29: `$Xelab = Join-Path $VivadoBin "xelab.bat"` This locates or invokes a required tool as part of the script that orchestrates the repeatable Windows capture waveforms command-line flow; the exact command and arguments remain visible here for reproducibility.

Line 30: `$Xsim = Join-Path $VivadoBin "xsim.bat"` This locates or invokes a required tool as part of the script that orchestrates the repeatable Windows capture waveforms command-line flow; the exact command and arguments remain visible here for reproducibility.

Line 31: `foreach ($Tool in @($Xvlog, $Xelab, $Xsim)) {` This locates or invokes a required tool as part of the script that orchestrates the repeatable Windows capture waveforms command-line flow; the exact command and arguments remain visible here for reproducibility.

Line 32: `if (-not (Test-Path -LiteralPath $Tool)) {` This batch-control line contributes to the flow that orchestrates the repeatable Windows capture waveforms command-line flow. The important operands are not: the value named 'not' in this block; Test: the value named 'test' in this block; Path: the value named 'path' in this block.

Line 33: `throw "Required Vivado simulator tool was not found: $Tool"` This locates or invokes a required tool as part of the script that orchestrates the repeatable Windows capture waveforms command-line flow; the exact command and arguments remain visible here for reproducibility.

Line 34: `}` This batch-control line contributes to the flow that orchestrates the repeatable Windows capture waveforms command-line flow. The expression is a literal or structural operator and has no hidden software state.

Line 35: `}` This batch-control line contributes to the flow that orchestrates the repeatable Windows capture waveforms command-line flow. The expression is a literal or structural operator and has no hidden software state.

Line 37: `$Windows = [ordered]@{` This batch-control line contributes to the flow that orchestrates the repeatable Windows capture waveforms command-line flow. The important operands are Windows: the value named 'windows' in this block; ordered: the value named 'ordered' in this block.

Line 38: `"tb_neuraedge_mac2_u8" = @(2, "us")` This batch-control line contributes to the flow that orchestrates the repeatable Windows capture waveforms command-line flow. The important operands are tb_neuraedge_mac2_u8: the value named 'tb neuraedge mac2 u8' in this block; us: the value named 'us' in this block.

Line 39: `"tb_neuraedge_tensor_tile" = @(3, "us")` This batch-control line contributes to the flow that orchestrates the repeatable Windows capture waveforms command-line flow. The important operands are tb_neuraedge_tensor_tile: the value named 'tb neuraedge tensor tile' in this block; us: the value named 'us' in this block.

Line 40: `"tb_neuraedge_buffered_tensor_core" = @(4, "us")` This batch-control line contributes to the flow that orchestrates the repeatable Windows capture waveforms command-line flow. The important operands are tb_neuraedge_buffered_te local storage that decouples producer and consumer timing; us: the value named 'us' in this block.

Line 41: `"tb_neuraedge_alpha_xnor" = @(40, "us")` This batch-control line contributes to the flow that orchestrates the repeatable Windows capture waveforms command-line flow. The important operands are tb_neuraedge_alpha_xnor: the programmable weight assigned to matching zero spikes in alpha-XNOR attention; us: the value named 'us' in this block.

Line 42: `"tb_neuraedge_vector_alu" = @(170, "us")` This batch-control line contributes to the flow that orchestrates the repeatable Windows capture waveforms command-line flow. The important operands are tb_neuraedge_vector_alu: the value named 'tb neuraedge vector alu' in this block; us: the value named 'us' in this block.

Line 43: `"tb_neuraedge_integer_primitives" = @(90, "us")` This batch-control line contributes to the flow that orchestrates the repeatable Windows capture waveforms command-line flow. The important operands are tb_neuraedge_integer_pri the value named 'tb neuraedge integer primitives' in this block; us: the value named 'us' in this block.

Line 44: `"tb_neuraedge_normalization_units" = @(405, "us")` This batch-control line contributes to the flow that orchestrates the repeatable Windows capture waveforms command-line flow. The important operands are tb_neuraedge_norma the value named 'tb neuraedge normalization units' in this block; us: the value named 'us' in this block.

Line 45: `"tb_neuraedge_lif_bank" = @(20, "us")` This batch-control line contributes to the flow that orchestrates the repeatable Windows capture waveforms command-line flow. The important operands are tb_neuraedge_lif_bank: the value named 'tb neuraedge lif bank' in this block; us: the value named 'us' in this block.

Line 46: `"tb_neuraedge_linear_backward8" = @(1, "ms")` This batch-control line contributes to the flow that orchestrates the repeatable Windows capture waveforms command-line flow. The important operands are tb_neuraedge_linear_backw the value named 'tb neuraedge linear backward8' in this block; ms: the value named 'ms' in this block.

Line 47: `"tb_neuraedge_sgd_optimizer8" = @(20, "us")` This batch-control line contributes to the flow that orchestrates the repeatable Windows capture waveforms command-line flow. The important operands are tb_neuraedge_sgd_optimize the value named 'tb neuraedge sgd optimizer8' in this block; us: the value named 'us' in this block.

Line 48: `"tb_neuraedge_activation_lut8" = @(20, "us")` This batch-control line contributes to the flow that orchestrates the repeatable Windows capture waveforms command-line flow. The important operands are tb_neuraedge_activation_lu an input feature value consumed by a neuron or multiply-accumulate operation; us: the value named 'us' in this block.

Line 49: `"tb_neuraedge_universal_core" = @(50, "us")` This batch-control line contributes to the flow that orchestrates the repeatable Windows capture waveforms command-line flow. The important operands are tb_neuraedge_universal_co the value named 'tb neuraedge universal core' in this block; us: the value named 'us' in this block.

Line 50: `"tb_neuraedge_descriptor_sequencer" = @(2, "us")` This batch-control line contributes to the flow that orchestrates the repeatable Windows capture waveforms command-line flow. The important operands are tb_neuraedge_descriptor_ a DMA record header plus one command and its declared payload; us: the value named 'us' in this block.

Line 51: `"tb_neuraedge_pynq_descriptor" = @(2, "us")` This batch-control line contributes to the flow that orchestrates the repeatable Windows capture waveforms command-line flow. The important operands are tb_neuraedge_pynq_descrip a DMA record header plus one command and its declared payload; us: the value named 'us' in this block.

Line 52: `"tb_neuraedge_pynq_axi_top" = @(5, "us")` This batch-control line contributes to the flow that orchestrates the repeatable Windows capture waveforms command-line flow. The important operands are tb_neuraedge_pynq_axi_top: the value named 'tb neuraedge pynq axi top' in this block; us: the value named 'us' in this block.

Line 53: `}` This batch-control line contributes to the flow that orchestrates the repeatable Windows capture waveforms command-line flow. The expression is a literal or structural operator and has no hidden software state.

Line 66: `$PackageFile = Join-Path $ProjectRoot "rtl\neuraedge_command_pkg.sv"` This batch-control line contributes to the flow that orchestrates the repeatable Windows capture waveforms command-line flow. The important operands are PackageFile: the value named 'package file' in this block; Join: the value named 'join' in this block; Path: the value named 'path' in this block.

Line 67: `$RtlFiles = @($PackageFile) + @(` This batch-control line contributes to the flow that orchestrates the repeatable Windows capture waveforms command-line flow. The important operands are RtlFiles: the value named 'rtl files' in this block; PackageFile: the value named 'package file' in this block.

Line 68: `Get-ChildItem -LiteralPath (Join-Path $ProjectRoot "rtl") -Filter "*.sv" -File |` This batch-control line contributes to the flow that orchestrates the repeatable Windows capture waveforms command-line flow. The important operands are Get: the value named 'get' in this block; ChildItem: the value named 'child item' in this block; LiteralPath: the value named 'literal path' in this block.

Line 69: `Where-Object { $_.FullName -ne $PackageFile } |` This batch-control line contributes to the flow that orchestrates the repeatable Windows capture waveforms command-line flow. The important operands are Where: the value named 'where' in this block; Object: the value named 'object' in this block; _: the value named '' in this block.

Line 70: `Sort-Object Name |` This batch-control line contributes to the flow that orchestrates the repeatable Windows capture waveforms command-line flow. The important operands are Sort: the value named 'sort' in this block; Object: the value named 'object' in this block; Name: the value named 'name' in this block.

Line 71: `ForEach-Object FullName` This batch-control line contributes to the flow that orchestrates the repeatable Windows capture waveforms command-line flow. The important operands are ForEach: the value named 'for each' in this block; Object: the value named 'object' in this block; FullName: the value named 'full name' in this block.

Line 72: `)` This batch-control line contributes to the flow that orchestrates the repeatable Windows capture waveforms command-line flow. The expression is a literal or structural operator and has no hidden software state.

Line 73: `$CaptureTcl = Join-Path $PSScriptRoot "capture_waveform.tcl"` This batch-control line contributes to the flow that orchestrates the repeatable Windows capture waveforms command-line flow. The important operands are CaptureTcl: the value named 'capture tcl' in this block; Join: the value named 'join' in this block; Path: the value named 'path' in this block.

Line 74: `$CaptureTclArgument = $CaptureTcl.Replace('\', '/')` This batch-control line contributes to the flow that orchestrates the repeatable Windows capture waveforms command-line flow. The important operands are CaptureTclArgument: the value named 'capture tcl argument' in this block; CaptureTcl: the value named 'capture tcl' in this block; Replace: the value named 'replace' in this block.

Line 75: `$ManifestRows = [System.Collections.Generic.List[object]]::new()` This batch-control line contributes to the flow that orchestrates the repeatable Windows capture waveforms command-line flow. The important operands are ManifestRows: one output-row position processed by the tensor tile; System: the value named 'system' in this block; Collections: the value named 'collections' in this block.

Line 77: `Push-Location $WorkDirectory` This batch-control line contributes to the flow that orchestrates the repeatable Windows capture waveforms command-line flow. The important operands are Push: the value named 'push' in this block; Location: the value named 'location' in this block; WorkDirectory: the value named 'work directory' in this block.

Line 78: `try {` This batch-control line contributes to the flow that orchestrates the repeatable Windows capture waveforms command-line flow. The important operands are try: the value named 'try' in this block.

Line 79: `& $Xvlog -sv -i $ProjectRoot @RtlFiles 2>&1 |` This locates or invokes a required tool as part of the script that orchestrates the repeatable Windows capture waveforms command-line flow; the exact command and arguments remain visible here for reproducibility.

Line 80: `Tee-Object -FilePath (Join-Path $LogDirectory "rtl_compile.log")` This batch-control line contributes to the flow that orchestrates the repeatable Windows capture waveforms command-line flow. The important operands are Tee: the value named 'tee' in this block; Object: the value named 'object' in this block; FilePath: the value named 'file path' in this block.

Line 81: `if ($LASTEXITCODE -ne 0) {` This checks the external program's process exit code and turns a failed compiler, simulator, or Vivado run into a failed pipeline.

Line 82: `throw "RTL xvlog compilation failed with exit code $LASTEXITCODE"` This checks the external program's process exit code and turns a failed compiler, simulator, or Vivado run into a failed pipeline.

Line 83: `}` This batch-control line contributes to the flow that orchestrates the repeatable Windows capture waveforms command-line flow. The expression is a literal or structural operator and has no hidden software state.

Line 85: `foreach ($Top in $Selected) {` This batch-control line contributes to the flow that orchestrates the repeatable Windows capture waveforms command-line flow. The important operands are foreach: the value named 'foreach' in this block; Top: the value named 'top' in this block; in: the value named 'in' in this block.

Line 86: `$TestbenchFile = Join-Path $ProjectRoot "tb\$Top.sv"` This batch-control line contributes to the flow that orchestrates the repeatable Windows capture waveforms command-line flow. The important operands are TestbenchFile: the value named 'testbench file' in this block; Join: the value named 'join' in this block; Path: the value named 'path' in this block.

Line 87: `$CompileLog = Join-Path $LogDirectory "$Top.compile.log"` This batch-control line contributes to the flow that orchestrates the repeatable Windows capture waveforms command-line flow. The important operands are CompileLog: the value named 'compile log' in this block; Join: the value named 'join' in this block; Path: the value named 'path' in this block.

Line 88: `$ElaborateLog = Join-Path $LogDirectory "$Top.elaborate.log"` This batch-control line contributes to the flow that orchestrates the repeatable Windows capture waveforms command-line flow. The important operands are ElaborateLog: the value named 'elaborate log' in this block; Join: the value named 'join' in this block; Path: the value named 'path' in this block.

Line 89: `$SimulationLog = Join-Path $LogDirectory "$Top.simulate.log"` This batch-control line contributes to the flow that orchestrates the repeatable Windows capture waveforms command-line flow. The important operands are SimulationLog: the value named 'simulation log' in this block; Join: the value named 'join' in this block; Path: the value named 'path' in this block.

Line 90: `$Snapshot = "${Top}_wave_snapshot"` This batch-control line contributes to the flow that orchestrates the repeatable Windows capture waveforms command-line flow. The important operands are Snapshot: the value named 'snapshot' in this block; Top: the value named 'top' in this block; _wave_snapshot: the value named 'wave snapshot' in this block.

Line 91: `$VcdPath = Join-Path $VcdDirectory "$Top.vcd"` This batch-control line contributes to the flow that orchestrates the repeatable Windows capture waveforms command-line flow. The important operands are VcdPath: the value named 'vcd path' in this block; Join: the value named 'join' in this block; Path: the value named 'path' in this block.

Line 92: `$WdbPath = Join-Path $WdbDirectory "$Top.wdb"` This batch-control line contributes to the flow that orchestrates the repeatable Windows capture waveforms command-line flow. The important operands are WdbPath: the value named 'wdb path' in this block; Join: the value named 'join' in this block; Path: the value named 'path' in this block.

Line 93: `$Amount = [int]$Windows[$Top][0]` This batch-control line contributes to the flow that orchestrates the repeatable Windows capture waveforms command-line flow. The important operands are Amount: the value named 'amount' in this block; Windows: the value named 'windows' in this block; Top: the value named 'top' in this block.

Line 94: `$Unit = [string]$Windows[$Top][1]` This batch-control line contributes to the flow that orchestrates the repeatable Windows capture waveforms command-line flow. The important operands are Unit: the value named 'unit' in this block; string: the value named 'string' in this block; Windows: the value named 'windows' in this block.

Line 95: `Remove-Item -LiteralPath $VcdPath -Force -ErrorAction SilentlyContinue` This removes the explicitly named rebuildable artifact. The script uses a literal path so wildcard expansion cannot delete an unintended neighboring file.

Line 96: `Remove-Item -LiteralPath $WdbPath -Force -ErrorAction SilentlyContinue` This removes the explicitly named rebuildable artifact. The script uses a literal path so wildcard expansion cannot delete an unintended neighboring file.

Line 98: `& $Xvlog -sv -i $ProjectRoot $TestbenchFile 2>&1 |` This locates or invokes a required tool as part of the script that orchestrates the repeatable Windows capture waveforms command-line flow; the exact command and arguments remain visible here for reproducibility.

Line 99: `Tee-Object -FilePath $CompileLog` This batch-control line contributes to the flow that orchestrates the repeatable Windows capture waveforms command-line flow. The important operands are Tee: the value named 'tee' in this block; Object: the value named 'object' in this block; FilePath: the value named 'file path' in this block.

Line 100: `if ($LASTEXITCODE -ne 0) {` This checks the external program's process exit code and turns a failed compiler, simulator, or Vivado run into a failed pipeline.

Line 101: `throw "$Top xvlog compilation failed with exit code $LASTEXITCODE"` This checks the external program's process exit code and turns a failed compiler, simulator, or Vivado run into a failed pipeline.

Line 102: `}` This batch-control line contributes to the flow that orchestrates the repeatable Windows capture waveforms command-line flow. The expression is a literal or structural operator and has no hidden software state.

Line 104: `& $Xelab -debug typical -timescale 1ns/1ps -snapshot $Snapshot "work.$Top" 2>&1 |` This locates or invokes a required tool as part of the script that orchestrates the repeatable Windows capture waveforms command-line flow; the exact command and arguments remain visible here for reproducibility.

Line 105: `Tee-Object -FilePath $ElaborateLog` This batch-control line contributes to the flow that orchestrates the repeatable Windows capture waveforms command-line flow. The important operands are Tee: the value named 'tee' in this block; Object: the value named 'object' in this block; FilePath: the value named 'file path' in this block.

Line 106: `if ($LASTEXITCODE -ne 0) {` This checks the external program's process exit code and turns a failed compiler, simulator, or Vivado run into a failed pipeline.

Line 107: `throw "$Top xelab failed with exit code $LASTEXITCODE"` This checks the external program's process exit code and turns a failed compiler, simulator, or Vivado run into a failed pipeline.

Line 108: `}` This batch-control line contributes to the flow that orchestrates the repeatable Windows capture waveforms command-line flow. The expression is a literal or structural operator and has no hidden software state.

Line 110: `$env:NEURAEDGE_VCD_PATH = $VcdPath` This batch-control line contributes to the flow that orchestrates the repeatable Windows capture waveforms command-line flow. The important operands are env: the value named 'env' in this block; NEURAEDGE_VCD_PATH: the value named 'neuraedge vcd path' in this block; VcdPath: the value named 'vcd path' in this block.

Line 111: `$env:NEURAEDGE_WAVE_AMOUNT = [string]$Amount` This batch-control line contributes to the flow that orchestrates the repeatable Windows capture waveforms command-line flow. The important operands are env: the value named 'env' in this block; NEURAEDGE_WAVE_AMOUNT: the value named 'neuraedge wave amount' in this block; string: the value named 'string' in this block.

Line 112: `$env:NEURAEDGE_WAVE_UNIT = $Unit` This batch-control line contributes to the flow that orchestrates the repeatable Windows capture waveforms command-line flow. The important operands are env: the value named 'env' in this block; NEURAEDGE_WAVE_UNIT: the value named 'neuraedge wave unit' in this block; Unit: the value named 'unit' in this block.

Line 113: `& $Xsim $Snapshot -onerror quit -onfinish quit -wdb $WdbPath ‘` This locates or invokes a required tool as part of the script that orchestrates the repeatable Windows capture waveforms command-line flow; the exact command and arguments remain visible here for reproducibility.

Line 114: `-tclbatch $CaptureTclArgument 2>&1 |` This batch-control line contributes to the flow that orchestrates the repeatable Windows capture waveforms command-line flow. The important operands are tclbatch: the value named 'tclbatch' in this block; CaptureTclArgument: the value named 'capture tcl argument' in this block.

Line 115: `Tee-Object -FilePath $SimulationLog` This batch-control line contributes to the flow that orchestrates the repeatable Windows capture waveforms command-line flow. The important operands are Tee: the value named 'tee' in this block; Object: the value named 'object' in this block; FilePath: the value named 'file path' in this block.

Line 116: `if ($LASTEXITCODE -ne 0) {` This checks the external program's process exit code and turns a failed compiler, simulator, or Vivado run into a failed pipeline.

Line 117: `throw "$Top XSim waveform capture failed with exit code $LASTEXITCODE"` This checks the external program's process exit code and turns a failed compiler, simulator, or Vivado run into a failed pipeline.

Line 118: `}` This batch-control line contributes to the flow that orchestrates the repeatable Windows capture waveforms command-line flow. The expression is a literal or structural operator and has no hidden software state.

Line 119: `if (-not (Test-Path -LiteralPath $VcdPath) -or (Get-Item -LiteralPath $VcdPath).Length -eq 0) {` This batch-control line contributes to the flow that orchestrates the repeatable Windows capture waveforms command-line flow. The important operands are not: the value named 'not' in this block; Test: the value named 'test' in this block; Path: the value named 'path' in this block.

Line 120: `throw "$Top did not produce a nonempty VCD"` This batch-control line contributes to the flow that orchestrates the repeatable Windows capture waveforms command-line flow. The important operands are throw: one output-row position processed by the tensor tile; Top: the value named 'top' in this block; did: the value named 'did' in this block.

Line 121: `}` This batch-control line contributes to the flow that orchestrates the repeatable Windows capture waveforms command-line flow. The expression is a literal or structural operator and has no hidden software state.

Line 123: `$ManifestRows.Add([PSCustomObject]@{` This batch-control line contributes to the flow that orchestrates the repeatable Windows capture waveforms command-line flow. The important operands are ManifestRows: one output-row position processed by the tensor tile; Add: the value named 'add' in this block; PSCustomObject: the value named 'pscustom object' in this block.

Line 124: `testbench = $Top` This batch-control line contributes to the flow that orchestrates the repeatable Windows capture waveforms command-line flow. The important operands are testbench: the value named 'testbench' in this block; Top: the value named 'top' in this block.

Line 125: `duration = $Amount` This batch-control line contributes to the flow that orchestrates the repeatable Windows capture waveforms command-line flow. The important operands are duration: the value named 'duration' in this block; Amount: the value named 'amount' in this block.

Line 126: `unit = $Unit` This batch-control line contributes to the flow that orchestrates the repeatable Windows capture waveforms command-line flow. The important operands are unit: the value named 'unit' in this block; Unit: the value named 'unit' in this block.

Line 127: `vcd = [System.IO.Path]::GetRelativePath($OutputDirectory, $VcdPath)` This batch-control line contributes to the flow that orchestrates the repeatable Windows capture waveforms command-line flow. The important operands are vcd: the value named 'vcd' in this block; System: the value named 'system' in this block; IO: the value named 'io' in this block.

Line 128: `vcd_bytes = (Get-Item -LiteralPath $VcdPath).Length` This batch-control line contributes to the flow that orchestrates the repeatable Windows capture waveforms command-line flow. The important operands are vcd_bytes: the value named 'vcd bytes' in this block; Get: the value named 'get' in this block; Item: the value named 'item' in this block.

Line 129: `wdb = [System.IO.Path]::GetRelativePath($OutputDirectory, $WdbPath)` This batch-control line contributes to the flow that orchestrates the repeatable Windows capture waveforms command-line flow. The important operands are wdb: the value named 'wdb' in this block; System: the value named 'system' in this block; IO: the value named 'io' in this block.

Line 130: `wdb_bytes = (Get-Item -LiteralPath $WdbPath).Length` This batch-control line contributes to the flow that orchestrates the repeatable Windows capture waveforms command-line flow. The important operands are wdb_bytes: the value named 'wdb bytes' in this block; Get: the value named 'get' in this block; Item: the value named 'item' in this block.

Line 131: `simulation_log = [System.IO.Path]::GetRelativePath($OutputDirectory, $SimulationLog)` This batch-control line contributes to the flow that orchestrates the repeatable Windows capture waveforms command-line flow. The important operands are simulation_log: the value named 'simulation log' in this block; System: the value named 'system' in this block; IO: the value named 'io' in this block.

Line 132: `})` This batch-control line contributes to the flow that orchestrates the repeatable Windows capture waveforms command-line flow. The expression is a literal or structural operator and has no hidden software state.

Line 133: `}` This batch-control line contributes to the flow that orchestrates the repeatable Windows capture waveforms command-line flow. The expression is a literal or structural operator and has no hidden software state.

Line 134: `} finally {` This batch-control line contributes to the flow that orchestrates the repeatable Windows capture waveforms command-line flow. The important operands are finally: the value named 'finally' in this block.

Line 135: `Remove-Item Env:NEURAEDGE_VCD_PATH -ErrorAction SilentlyContinue` This removes the explicitly named rebuildable artifact. The script uses a literal path so wildcard expansion cannot delete an unintended neighboring file.

Line 136: `Remove-Item Env:NEURAEDGE_WAVE_AMOUNT -ErrorAction SilentlyContinue` This removes the explicitly named rebuildable artifact. The script uses a literal path so wildcard expansion cannot delete an unintended neighboring file.

Line 137: `Remove-Item Env:NEURAEDGE_WAVE_UNIT -ErrorAction SilentlyContinue` This removes the explicitly named rebuildable artifact. The script uses a literal path so wildcard expansion cannot delete an unintended neighboring file.

Line 138: `Pop-Location` This batch-control line contributes to the flow that orchestrates the repeatable Windows capture waveforms command-line flow. The important operands are Pop: the value named 'pop' in this block; Location: the value named 'location' in this block.

Line 139: `}` This batch-control line contributes to the flow that orchestrates the repeatable Windows capture waveforms command-line flow. The expression is a literal or structural operator and has no hidden software state.

Line 141: `$Manifest = [ordered]@{` This batch-control line contributes to the flow that orchestrates the repeatable Windows capture waveforms command-line flow. The important operands are Manifest: the value named 'manifest' in this block; ordered: the value named 'ordered' in this block.

Line 142: `format = "neuraedge-xsim-waveforms-v1"` This locates or invokes a required tool as part of the script that orchestrates the repeatable Windows capture waveforms command-line flow; the exact command and arguments remain visible here for reproducibility.

Line 143: `vivado_root = $VivadoRoot` This locates or invokes a required tool as part of the script that orchestrates the repeatable Windows capture waveforms command-line flow; the exact command and arguments remain visible here for reproducibility.

Line 144: `target_part = "xc7z020clg400-1"` This batch-control line contributes to the flow that orchestrates the repeatable Windows capture waveforms command-line flow. The important operands are target_part: the value named 'target part' in this block; xc7z020clg400: the value named 'xc7z020clg400' in this block.

Line 145: `target_clock_mhz = 200` This batch-control line contributes to the flow that orchestrates the repeatable Windows capture waveforms command-line flow. The important operands are target_clock_mhz: the value named 'target clock mhz' in this block.

Line 146: `captures = @($ManifestRows)` This batch-control line contributes to the flow that orchestrates the repeatable Windows capture waveforms command-line flow. The important operands are captures: the value named 'captures' in this block; ManifestRows: one output-row position processed by the tensor tile.

Line 147: `}` This batch-control line contributes to the flow that orchestrates the repeatable Windows capture waveforms command-line flow. The expression is a literal or structural operator and has no hidden software state.

Line 148: `$ManifestPath = Join-Path $OutputDirectory "waveform_manifest.json"` This batch-control line contributes to the flow that orchestrates the repeatable Windows capture waveforms command-line flow. The important operands are ManifestPath: the value named 'manifest path' in this block; Join: the value named 'join' in this block; Path: the value named 'path' in this block.

Line 149: `$Manifest | ConvertTo-Json -Depth 5 | Set-Content -LiteralPath $ManifestPath -Encoding utf8` This batch-control line contributes to the flow that orchestrates the repeatable Windows capture waveforms command-line flow. The important operands are Manifest: the value named 'manifest' in this block; ConvertTo: the value named 'convert to' in this block; Json: the value named 'json' in this block.

Line 150: `Write-Output "NEURAEDGE_WAVEFORMS_CAPTURED count=$($ManifestRows.Count) manifest=$ManifestPath"` This batch-control line contributes to the flow that orchestrates the repeatable Windows capture waveforms command-line flow. The important operands are Write: the value named 'write' in this block; Output: the value named 'output' in this block; NEURAEDGE_WAVEFORMS_CAPTURED: the value named 'neuraedge waveforms captured' in this block.

79 scripts/deploy_to_pynq.ps1

Role in the complete system: orchestrates the repeatable Windows deploy to pynq command-line flow.

79.1 Beginner architecture map

Dataflow responsibility This file's end-to-end responsibility is to orchestrates the repeatable Windows deploy to pynq command-line flow.

Where it runs This is PowerShell orchestration, not accelerator datapath hardware. It makes tool inputs, versions, paths, stages, and failure propagation repeatable.

Reproducibility contract Every external command must be checked, every required artifact must exist and be nonempty, and measured values must be read from generated reports. Rerunning this file should either reproduce its declared outputs or stop at the first failed gate.

79.3 Line annotations

Line 1: `param(` This declares a typed command-line parameter so the flow can be rerun with explicit, validated paths and options.

Line 2: `[string]$BoardHost = "xilinx@192.168.2.99",` This declares a typed command-line parameter so the flow can be rerun with explicit, validated paths and options.

Line 3: `[string]$RemoteRoot = "/home/xilinx/neuraedge_universal",` This declares a typed command-line parameter so the flow can be rerun with explicit, validated paths and options.

Line 4: `[string]$DataDirectory = ""` This declares a typed command-line parameter so the flow can be rerun with explicit, validated paths and options.

Line 5: `)` This batch-control line contributes to the flow that orchestrates the repeatable Windows deploy to pynq command-line flow. The expression is a literal or structural operator and has no hidden software state.

Line 7: `$ErrorActionPreference = "Stop"` This makes PowerShell stop on errors so a failed prerequisite cannot be hidden by later successful commands.

Line 8: `Set-StrictMode -Version Latest` This batch-control line contributes to the flow that orchestrates the repeatable Windows deploy to pynq command-line flow. The important operands are Set: the value named 'set' in this block; StrictMode: the value named 'strict mode' in this block; Version: the value named 'version' in this block.

Line 10: `$ProjectRoot = (Resolve-Path (Join-Path $PSScriptRoot "..")).Path` This resolves a deterministic filesystem location for the flow that orchestrates the repeatable Windows deploy to pynq command-line flow. Literal/full paths prevent a different working directory from silently selecting the wrong source, checkpoint, or output.

Line 11: `if ([string]::IsNullOrWhiteSpace($DataDirectory)) {` This batch-control line contributes to the flow that orchestrates the repeatable Windows deploy to pynq command-line flow. The important operands are string: the value named 'string' in this block; IsNullOrWhiteSpace: the value named 'is null or white space' in this block; DataDirectory: the value named 'data directory' in this block.

Line 12: `$DataDirectory = Join-Path $ProjectRoot "outputs\cifar10_shards"` This batch-control line contributes to the flow that orchestrates the repeatable Windows deploy to pynq command-line flow. The important operands are DataDirectory: the value named 'data directory' in this block; Join: the value named 'join' in this block; Path: the value named 'path' in this block.

Line 13: `}` This batch-control line contributes to the flow that orchestrates the repeatable Windows deploy to pynq command-line flow. The expression is a literal or structural operator and has no hidden software state.

Line 14: `$DataDirectory = (Resolve-Path -LiteralPath $DataDirectory).Path` This batch-control line contributes to the flow that orchestrates the repeatable Windows deploy to pynq command-line flow. The important operands are DataDirectory: the value named 'data directory' in this block; Resolve: the value named 'resolve' in this block; Path: the value named 'path' in this block.

Line 15: `$Bitfile = Join-Path $ProjectRoot "outputs\pynq_full\neuraedge_pynq_full.bit"` This batch-control line contributes to the flow that orchestrates the repeatable Windows deploy to pynq command-line flow. The important operands are Bitfile: the value named 'bitfile' in this block; Join: the value named 'join' in this block; Path: the value named 'path' in this block.

Line 16: `$Hwh = Join-Path $ProjectRoot "outputs\pynq_full\neuraedge_pynq_full.hwh"` This batch-control line contributes to the flow that orchestrates the repeatable Windows deploy to pynq command-line flow. The important operands are Hwh: the value named 'hwh' in this block; Join: the value named 'join' in this block; Path: the value named 'path' in this block.

Line 17: `$ParameterDirectory = Join-Path $ProjectRoot "outputs\spikingformer_hardware_parameters"` This batch-control line contributes to the flow that orchestrates the repeatable Windows deploy to pynq command-line flow. The important operands are ParameterDirectory: the value named 'parameter directory' in this block; Join: the value named 'join' in this block; Path: the value named 'path' in this block.

Line 18: `$ParameterManifest = Join-Path $ParameterDirectory "spikingformer_neuraedge_weights.json"` This batch-control line contributes to the flow that orchestrates the repeatable Windows deploy to pynq command-line flow. The important operands are ParameterManifest: the value named 'parameter manifest' in this block; Join: the value named 'join' in this block; Path: the value named 'path' in this block.

Line 19: `$ParameterBinary = Join-Path $ParameterDirectory "spikingformer_neuraedge_weights.bin"` This batch-control line contributes to the flow that orchestrates the repeatable Windows deploy to pynq command-line flow. The important operands are ParameterBinary: the value named 'parameter binary' in this block; Join: the value named 'join' in this block; Path: the value named 'path' in this block.

Line 20: `$DataManifest = Join-Path $DataDirectory "cifar10_shards_manifest.json"` This batch-control line contributes to the flow that orchestrates the repeatable Windows deploy to pynq command-line flow. The important operands are DataManifest: the value named 'data manifest' in this block; Join: the value named 'join' in this block; Path: the value named 'path' in this block.

Line 21: `foreach ($Required in @($Bitfile, $Hwh, $ParameterManifest, $ParameterBinary, $DataManifest)) {` This batch-control line contributes to the flow that orchestrates the repeatable Windows deploy to pynq command-line flow. The important operands are foreach: the value named 'foreach' in this block; Required: the value named 'required' in this block; in: the value named 'in' in this block.

Line 22: `if (-not (Test-Path -LiteralPath $Required -PathType Leaf)) {` This batch-control line contributes to the flow that orchestrates the repeatable Windows deploy to pynq command-line flow. The important operands are not: the value named 'not' in this block; Test: the value named 'test' in this block; Path: the value named 'path' in this block.

Line 23: `throw "Required deployment artifact is missing: $Required"` This batch-control line contributes to the flow that orchestrates the repeatable Windows deploy to pynq command-line flow. The important operands are throw: one output-row position processed by the tensor tile; Required: the value named 'required' in this block; deployment: the value named 'deployment' in this block.

Line 24: `}` This batch-control line contributes to the flow that orchestrates the repeatable Windows deploy to pynq command-line flow. The expression is a literal or structural operator and has no hidden software state.

Line 25: `}` This batch-control line contributes to the flow that orchestrates the repeatable Windows deploy to pynq command-line flow. The expression is a literal or structural operator and has no hidden software state.

Line 27: `$RemoteDirectories = @(` This batch-control line contributes to the flow that orchestrates the repeatable Windows deploy to pynq command-line flow. The important operands are RemoteDirectories: the value named 'remote directories' in this block.

Line 28: `"$RemoteRoot/software",` This batch-control line contributes to the flow that orchestrates the repeatable Windows deploy to pynq command-line flow. The important operands are RemoteRoot: the value named 'remote root' in this block; software: the value named 'software' in this block.

Line 29: `"$RemoteRoot/outputs/pynq_full",` This batch-control line contributes to the flow that orchestrates the repeatable Windows deploy to pynq command-line flow. The important operands are RemoteRoot: the value named 'remote root' in this block; outputs: the value named 'outputs' in this block; pynq_full: the value named 'pynq full' in this block.

Line 30: `"$RemoteRoot/outputs/spikingformer_hardware_parameters",` This batch-control line contributes to the flow that orchestrates the repeatable Windows deploy to pynq command-line flow. The important operands are RemoteRoot: the value named 'remote root' in this block; outputs: the value named 'outputs' in this block; spikingformer_hardware_parameters: the value named 'spikingformer hardware parameters' in this block.

Line 31: `"$RemoteRoot/outputs/cifar10_shards",` This batch-control line contributes to the flow that orchestrates the repeatable Windows deploy to pynq command-line flow. The important operands are RemoteRoot: the value named 'remote root' in this block; outputs: the value named 'outputs' in this block; cifar10_shards: the value named 'cifar10 shards' in this block.

Line 32: `"$RemoteRoot/outputs/pynq_training"` This batch-control line contributes to the flow that orchestrates the repeatable Windows deploy to pynq command-line flow. The important operands are RemoteRoot: the value named 'remote root' in this block; outputs: the value named 'outputs' in this block; pynq_training: the value named 'pynq training' in this block.

Line 33: `) -join " "` This batch-control line contributes to the flow that orchestrates the repeatable Windows deploy to pynq command-line flow. The important operands are join: the value named 'join' in this block.

Line 34: `& ssh $BoardHost "mkdir -p $RemoteDirectories"` This batch-control line contributes to the flow that orchestrates the repeatable Windows deploy to pynq command-line flow. The important operands are ssh: the value named 'ssh' in this block; BoardHost: the value named 'board host' in this block; mkdir: the value named 'mkdir' in this block.

Line 35: `if ($LASTEXITCODE -ne 0) { throw "Could not create remote PYNQ directories" }` This checks the external program's process exit code and turns a failed compiler, simulator, or Vivado run into a failed pipeline.

Line 37: `$SoftwareFiles = Get-ChildItem -LiteralPath (Join-Path $ProjectRoot "software") -Filter "*.py" -File |` This batch-control line contributes to the flow that orchestrates the repeatable Windows deploy to pynq command-line flow. The important operands are SoftwareFiles: the value named 'software files' in this block; Get: the value named 'get' in this block; ChildItem: the value named 'child item' in this block.

Line 38: `Sort-Object Name |` This batch-control line contributes to the flow that orchestrates the repeatable Windows deploy to pynq command-line flow. The important operands are Sort: the value named 'sort' in this block; Object: the value named 'object' in this block; Name: the value named 'name' in this block.

Line 39: `ForEach-Object FullName` This batch-control line contributes to the flow that orchestrates the repeatable Windows deploy to pynq command-line flow. The important operands are ForEach: the value named 'for each' in this block; Object: the value named 'object' in this block; FullName: the value named 'full name' in this block.

Line 40: `& scp @SoftwareFiles "${BoardHost}:$RemoteRoot/software/"` This batch-control line contributes to the flow that orchestrates the repeatable Windows deploy to pynq command-line flow. The important operands are scp: the value named 'scp' in this block; SoftwareFiles: the value named 'software files' in this block; BoardHost: the value named 'board host' in this block.

Line 41: `if ($LASTEXITCODE -ne 0) { throw "PYNQ software transfer failed" }` This checks the external program's process exit code and turns a failed compiler, simulator, or Vivado run into a failed pipeline.

Line 42: `& scp $Bitfile $Hwh "${BoardHost}:$RemoteRoot/outputs/pynq_full/"` This batch-control line contributes to the flow that orchestrates the repeatable Windows deploy to pynq command-line flow. The important operands are scp: the value named 'scp' in this block; Bitfile: the value named 'bitfile' in this block; Hwh: the value named 'hwh' in this block.

Line 43: `if ($LASTEXITCODE -ne 0) { throw "PYNQ overlay transfer failed" }` This checks the external program's process exit code and turns a failed compiler, simulator, or Vivado run into a failed pipeline.

Line 44: `& scp $ParameterManifest $ParameterBinary ‘` This batch-control line contributes to the flow that orchestrates the repeatable Windows deploy to pynq command-line flow. The important operands are scp: the value named 'scp' in this block; ParameterManifest: the value named 'parameter manifest' in this block; ParameterBinary: the value named 'parameter binary' in this block.

Line 45: `"${BoardHost}:$RemoteRoot/outputs/spikingformer_hardware_parameters/"` This batch-control line contributes to the flow that orchestrates the repeatable Windows deploy to pynq command-line flow. The important operands are BoardHost: the value named 'board host' in this block; RemoteRoot: the value named 'remote root' in this block; outputs: the value named 'outputs' in this block.

Line 46: `if ($LASTEXITCODE -ne 0) { throw "PYNQ parameter transfer failed" }` This checks the external program's process exit code and turns a failed compiler, simulator, or Vivado run into a failed pipeline.

Line 47: `$DataFiles = Get-ChildItem -LiteralPath $DataDirectory -Filter "*.npz" -File |` This batch-control line contributes to the flow that orchestrates the repeatable Windows deploy to pynq command-line flow. The important operands are DataFiles: the value named 'data files' in this block; Get: the value named 'get' in this block; ChildItem: the value named 'child item' in this block.

Line 48: `Sort-Object Name |` This batch-control line contributes to the flow that orchestrates the repeatable Windows deploy to pynq command-line flow. The important operands are Sort: the value named 'sort' in this block; Object: the value named 'object' in this block; Name: the value named 'name' in this block.

Line 49: `ForEach-Object FullName` This batch-control line contributes to the flow that orchestrates the repeatable Windows deploy to pynq command-line flow. The important operands are ForEach: the value named 'for each' in this block; Object: the value named 'object' in this block; FullName: the value named 'full name' in this block.

Line 50: `& scp $DataManifest @DataFiles "${BoardHost}:$RemoteRoot/outputs/cifar10_shards/"` This batch-control line contributes to the flow that orchestrates the repeatable Windows deploy to pynq command-line flow. The important operands are scp: the value named 'scp' in this block; DataManifest: the value named 'data manifest' in this block; DataFiles: the value named 'data files' in this block.

Line 51: `if ($LASTEXITCODE -ne 0) { throw "PYNQ CIFAR-10 transfer failed" }` This checks the external program's process exit code and turns a failed compiler, simulator, or Vivado run into a failed pipeline.

Line 52: `Write-Host "NEURAEDGE_PYNQ_DEPLOYED host=$BoardHost root=$RemoteRoot"` This batch-control line contributes to the flow that orchestrates the repeatable Windows deploy to pynq command-line flow. The important operands are Write: the value named 'write' in this block; Host: the value named 'host' in this block; NEURAEDGE_PYNQ_DEPLOYED: the value named 'neuraedge pynq deployed' in this block.

80 scripts/export_cifar10_shards.ps1

Role in the complete system: orchestrates the repeatable Windows export cifar10 shards command-line flow.

80.1 Beginner architecture map

Dataflow responsibility This file's end-to-end responsibility is to orchestrates the repeatable Windows export cifar10 shards command-line flow.

Where it runs This is PowerShell orchestration, not accelerator datapath hardware. It makes tool inputs, versions, paths, stages, and failure propagation repeatable.

Reproducibility contract Every external command must be checked, every required artifact must exist and be nonempty, and measured values must be read from generated reports. Rerunning this file should either reproduce its declared outputs or stop at the first failed gate.

80.2 Complete source

```
param(
    [string]$DatasetRoot = "",
    [string]$OutputDirectory = "",
    [int]$ShardSize = 1000
)

$ErrorActionPreference = "Stop"
Set-StrictMode -Version Latest

$ProjectRoot = (Resolve-Path (Join-Path $PSScriptRoot "..")).Path
if ([string]::IsNullOrWhiteSpace($DatasetRoot)) {
    $DatasetRoot = (Resolve-Path (Join-Path $ProjectRoot "..\datasets")).Path
}
if ([string]::IsNullOrWhiteSpace($OutputDirectory)) {
    $OutputDirectory = Join-Path $ProjectRoot "outputs\cifar10_shards"
}
$Python = (Resolve-Path (Join-Path $ProjectRoot "..\external_research\spikingformer_py310\Scripts\python.exe")).Path
& $Python (Join-Path $ProjectRoot "software\export_cifar10_shards.py") `
    --dataset-root $DatasetRoot `
    --output-dir $OutputDirectory `
    --shard-size $ShardSize `
    --no-download
if ($LASTEXITCODE -ne 0) {
    throw "CIFAR-10 shard export failed with exit code $LASTEXITCODE"
}
Write-Host "NEURAEDGE_CIFAR10_SHARDS_READY directory=$OutputDirectory"
```

80.3 Line annotations

Line 1: `param(` This declares a typed command-line parameter so the flow can be rerun with explicit, validated paths and options.

Line 2: `[string]$DatasetRoot = "",` This declares a typed command-line parameter so the flow can be rerun with explicit, validated paths and options.

Line 3: `[string]$OutputDirectory = "",` This declares a typed command-line parameter so the flow can be rerun with explicit, validated paths and options.

Line 4: `[int]$ShardSize = 1000` This declares a typed command-line parameter so the flow can be rerun with explicit, validated paths and options.

Line 5: `)` This batch-control line contributes to the flow that orchestrates the repeatable Windows export cifar10 shards command-line flow. The expression is a literal or structural operator and has no hidden software state.

Line 7: `$ErrorActionPreference = "Stop"` This makes PowerShell stop on errors so a failed prerequisite cannot be hidden by later successful commands.

Line 8: `Set-StrictMode -Version Latest` This batch-control line contributes to the flow that orchestrates the repeatable Windows export cifar10 shards command-line flow. The important operands are Set: the value named 'set' in this block; StrictMode: the value named 'strict mode' in this block; Version: the value named 'version' in this block.

Line 10: `$ProjectRoot = (Resolve-Path (Join-Path $PSScriptRoot "..")).Path` This resolves a deterministic filesystem location for the flow that orchestrates the repeatable Windows export cifar10 shards command-line flow. Literal/full paths prevent a different working directory from silently selecting the wrong source, checkpoint, or output.

Line 11: `if ([string]::IsNullOrWhiteSpace($DatasetRoot)) {` This batch-control line contributes to the flow that orchestrates the repeatable Windows export cifar10 shards command-line flow. The important operands are string: the value named 'string' in this block; IsNullOrWhiteSpace: the value named 'is null or white space' in this block; DatasetRoot: the value named 'dataset root' in this block.

Line 12: `$DatasetRoot = (Resolve-Path (Join-Path $ProjectRoot "..\datasets")).Path` This batch-control line contributes to the flow that orchestrates the repeatable Windows export cifar10 shards command-line flow. The important operands are DatasetRoot: the value named 'dataset root' in this block; Resolve: the value named 'resolve' in this block; Path: the value named 'path' in this block.

Line 13: `}` This batch-control line contributes to the flow that orchestrates the repeatable Windows export cifar10 shards command-line flow. The expression is a literal or structural operator and has no hidden software state.

Line 14: `if ([string]::IsNullOrWhiteSpace($OutputDirectory)) {` This batch-control line contributes to the flow that orchestrates the repeatable Windows export cifar10 shards command-line flow. The important operands are string: the value named 'string' in this block; IsNullOrWhiteSpace: the value named 'is null or white space' in this block; OutputDirectory: the value named 'output directory' in this block.

Line 15: `$OutputDirectory = Join-Path $ProjectRoot "outputs\cifar10_shards"` This batch-control line contributes to the flow that orchestrates the repeatable Windows export cifar10 shards command-line flow. The important operands are OutputDirectory: the value named 'output directory' in this block; Join: the value named 'join' in this block; Path: the value named 'path' in this block.

Line 16: `}` This batch-control line contributes to the flow that orchestrates the repeatable Windows export cifar10 shards command-line flow. The expression is a literal or structural operator and has no hidden software state.

Line 17: `$Python = (Resolve-Path (Join-Path $ProjectRoot "..\external_research\spikingformer_py310\Scripts\py`
This locates or invokes a required tool as part of the script that orchestrates the repeatable Windows export cifar10 shards command-line flow; the exact command and arguments remain visible here for reproducibility.

Line 18: `& $Python (Join-Path $ProjectRoot "software\export_cifar10_shards.py") ‘` This locates or invokes a required tool as part of the script that orchestrates the repeatable Windows export cifar10 shards command-line flow; the exact command and arguments remain visible here for reproducibility.

Line 19: `-dataset-root $DatasetRoot ‘` This batch-control line contributes to the flow that orchestrates the repeatable Windows export cifar10 shards command-line flow. The important operands are dataset: the value named 'dataset' in this block; root: the value named 'root' in this block; DatasetRoot: the value named 'dataset root' in this block.

Line 20: `-output-dir $OutputDirectory ‘` This batch-control line contributes to the flow that orchestrates the repeatable Windows export cifar10 shards command-line flow. The important operands are output: the value named 'output' in this block; dir: the value named 'dir' in this block; OutputDirectory: the value named 'output directory' in this block.

Line 21: `-shard-size $ShardSize ‘` This batch-control line contributes to the flow that orchestrates the repeatable Windows export cifar10 shards command-line flow. The important operands are shard: the value named 'shard' in this block; size: the value named 'size' in this block; ShardSize: the value named 'shard size' in this block.

Line 22: `-no-download` This batch-control line contributes to the flow that orchestrates the repeatable Windows export cifar10 shards command-line flow. The important operands are no: the value named 'no' in this block; download: the value named 'download' in this block.

Line 23: `if ($LASTEXITCODE -ne 0) {` This checks the external program's process exit code and turns a failed compiler, simulator, or Vivado run into a failed pipeline.

Line 24: `throw "CIFAR-10 shard export failed with exit code $LASTEXITCODE"` This checks the external program's process exit code and turns a failed compiler, simulator, or Vivado run into a failed pipeline.

Line 25: `}` This batch-control line contributes to the flow that orchestrates the repeatable Windows export cifar10 shards command-line flow. The expression is a literal or structural operator and has no hidden software state.

Line 26: `Write-Host "NEURAEDGE_CIFAR10_SHARDS_READY directory=$OutputDirectory"` This batch-control line contributes to the flow that orchestrates the repeatable Windows export cifar10 shards command-line flow. The important operands are Write: the value named 'write' in this block; Host: the value named 'host' in this block; NEURAEDGE_CIFAR10_SHARDS_READY: the consumer's statement that it can accept a payload this cycle.

81 scripts/manage_pynq_training.ps1

Role in the complete system: orchestrates the repeatable Windows manage pynq training command-line flow.

Line 7: `[int]$Epochs = 400,` This declares a typed command-line parameter so the flow can be rerun with explicit, validated paths and options.

Line 8: `[int]$BatchSize = 1,` This declares a typed command-line parameter so the flow can be rerun with explicit, validated paths and options.

Line 9: `[double]$LearningRate = 0.25,` This declares a typed command-line parameter so the flow can be rerun with explicit, validated paths and options.

Line 10: `[double]$MinimumLearningRate = 0.01,` This declares a typed command-line parameter so the flow can be rerun with explicit, validated paths and options.

Line 11: `[int]$CheckpointInterval = 1` This declares a typed command-line parameter so the flow can be rerun with explicit, validated paths and options.

Line 12: `)` This batch-control line contributes to the flow that orchestrates the repeatable Windows manage pynq training command-line flow. The expression is a literal or structural operator and has no hidden software state.

Line 14: `$ErrorActionPreference = "Stop"` This makes PowerShell stop on errors so a failed prerequisite cannot be hidden by later successful commands.

Line 15: `Set-StrictMode -Version Latest` This batch-control line contributes to the flow that orchestrates the repeatable Windows manage pynq training command-line flow. The important operands are Set: the value named 'set' in this block; StrictMode: the value named 'strict mode' in this block; Version: the value named 'version' in this block.

Line 17: `$Output = "$RemoteRoot/outputs/pynq_training"` This batch-control line contributes to the flow that orchestrates the repeatable Windows manage pynq training command-line flow. The important operands are Output: the value named 'output' in this block; RemoteRoot: the value named 'remote root' in this block; outputs: the value named 'outputs' in this block.

Line 18: `$PidFile = "$Output/training.pid"` This batch-control line contributes to the flow that orchestrates the repeatable Windows manage pynq training command-line flow. The important operands are PidFile: the value named 'pid file' in this block; Output: the value named 'output' in this block; training: the value named 'training' in this block.

Line 19: `$PauseFile = "$Output/PAUSE"` This batch-control line contributes to the flow that orchestrates the repeatable Windows manage pynq training command-line flow. The important operands are PauseFile: the value named 'pause file' in this block; Output: the value named 'output' in this block; PAUSE: the value named 'pause' in this block.

Line 20: `$StatusFile = "$Output/training_status.json"` This batch-control line contributes to the flow that orchestrates the repeatable Windows manage pynq training command-line flow. The important operands are StatusFile: the value named 'status file' in this block; Output: the value named 'output' in this block; training_status: the value named 'training status' in this block.

Line 21: `$OutLog = "$Output/train.out.log"` This batch-control line contributes to the flow that orchestrates the repeatable Windows manage pynq training command-line flow. The important operands are OutLog: the value named 'out log' in this block; Output: the value named 'output' in this block; train: the value named 'train' in this block.

Line 22: `$ErrLog = "$Output/train.err.log"` This batch-control line contributes to the flow that orchestrates the repeatable Windows manage pynq training command-line flow. The important operands are ErrLog: the value named 'err log' in this block; Output: the value named 'output' in this block; train: the value named 'train' in this block.

Line 24: `function Invoke-Remote([string]$Command) {` This batch-control line contributes to the flow that orchestrates the repeatable Windows manage pynq training command-line flow. The important operands are function: the value named 'function' in this block; Invoke: the value named 'invoke' in this block; Remote: the value named 'remote' in this block.

Line 25: `& ssh $BoardHost "sh -lc '$Command'"` This batch-control line contributes to the flow that orchestrates the repeatable Windows manage pynq training command-line flow. The important operands are ssh: the value named 'ssh' in this block; BoardHost: the value named 'board host' in this block; sh: the value named 'sh' in this block.

Line 26: `if ($LASTEXITCODE -ne 0) {` This checks the external program's process exit code and turns a failed compiler, simulator, or Vivado run into a failed pipeline.

Line 27: `throw "Remote PYNQ command failed with exit code $LASTEXITCODE"` This checks the external program's process exit code and turns a failed compiler, simulator, or Vivado run into a failed pipeline.

Line 28: `}` This batch-control line contributes to the flow that orchestrates the repeatable Windows manage pynq training command-line flow. The expression is a literal or structural operator and has no hidden software state.

Line 29: `}` This batch-control line contributes to the flow that orchestrates the repeatable Windows manage pynq training command-line flow. The expression is a literal or structural operator and has no hidden software state.

Line 31: `function Start-Training([switch]$Resume) {` This batch-control line contributes to the flow that orchestrates the repeatable Windows manage pynq training command-line flow. The important operands are function: the value named 'function' in this block; Start: the value named 'start' in this block; Training: the value named 'training' in this block.

Line 32: `$ResumeArgument = if ($Resume) { "-resume" } else { "" }` This batch-control line contributes to the flow that orchestrates the repeatable Windows manage pynq training command-line flow. The important operands are ResumeArgument: the value named 'resume argument' in this block; Resume: the value named 'resume' in this block; resume: the value named 'resume' in this block.

Line 33: `$Command = "mkdir -p $Output; " +` This batch-control line contributes to the flow that orchestrates the repeatable Windows manage pynq training command-line flow. The important operands are Command: the 128-bit instruction selecting an engine, shape, mode, and numeric parameters; mkdir: the value named 'mkdir' in this block; p: the value named 'p' in this block.

Line 34: `"if [ -f $PidFile ] && kill -0 ‘$(cat $PidFile) 2>/dev/null; then " +` This batch-control line contributes to the flow that orchestrates the repeatable Windows manage pynq training command-line flow. The important operands are f: the value named 'f' in this block; PidFile: the value named 'pid file' in this block; kill: the value named 'kill' in this block.

Line 35: `"echo already_running pid=‘$(cat $PidFile); exit 2; fi; " +` This batch-control line contributes to the flow that orchestrates the repeatable Windows manage pynq training command-line flow. The important operands are echo: the value named 'echo' in this block; already_running: the consumer's statement that it can accept a payload this cycle; pid: the value named 'pid' in this block.

Line 36: `"rm -f $PauseFile; " +` This batch-control line contributes to the flow that orchestrates the repeatable Windows manage pynq training command-line flow. The important operands are rm: the value named 'rm' in this block; f: the value named 'f' in this block; PauseFile: the value named 'pause file' in this block.

Line 37: `"cd $RemoteRoot; " +` This batch-control line contributes to the flow that orchestrates the repeatable Windows manage pynq training command-line flow. The important operands are cd: the value named 'cd' in this block; RemoteRoot: the value named 'remote root' in this block.

Line 38: `"nohup $Python software/train_spikingformer_pynq.py " +` This locates or invokes a required tool as part of the script that orchestrates the repeatable Windows manage pynq training command-line flow; the exact command and arguments remain visible here for reproducibility.

Line 39: `"-bitfile outputs/pynq_full/neuraedge_pynq_full.bit " +` This batch-control line contributes to the flow that orchestrates the repeatable Windows manage pynq training command-line flow. The important operands are bitfile: the value named 'bitfile' in this block; outputs: the value named 'outputs' in this block; pynq_full: the value named 'pynq full' in this block.

Line 40: `"-manifest outputs/spikingformer_hardware_parameters/spikingformer_neuraedge_weights.json " +` This batch-control line contributes to the flow that orchestrates the repeatable Windows manage pynq training command-line flow. The important operands are manifest: the value named 'manifest' in this block; outputs: the value named 'outputs' in this block; spikingformer_hardware_parameters: the value named 'spikingformer hardware parameters' in this block.

Line 41: `"-data-manifest outputs/cifar10_shards/cifar10_shards_manifest.json " +` This batch-control line contributes to the flow that orchestrates the repeatable Windows manage pynq training command-line flow. The important operands are data: the value named 'data' in this block; manifest: the value named 'manifest' in this block; outputs: the value named 'outputs' in this block.

Line 42: `"-output-dir outputs/pynq_training -epochs $Epochs -batch-size $BatchSize " +` This batch-control line contributes to the flow that orchestrates the repeatable Windows manage pynq training command-line flow. The important operands are output: the value named 'output' in this block; dir: the value named 'dir' in this block; outputs: the value named 'outputs' in this block.

Line 43: `"-learning-rate $LearningRate -minimum-learning-rate $MinimumLearningRate " +` This batch-control line contributes to the flow that orchestrates the repeatable Windows manage pynq training command-line flow. The important operands are learning: the value named 'learning' in this block; rate: the value named 'rate' in this block; LearningRate: the value named 'learning rate' in this block.

Line 44: `"-checkpoint-interval $CheckpointInterval $ResumeArgument " +` This batch-control line contributes to the flow that orchestrates the repeatable Windows manage pynq training command-line flow. The important operands are checkpoint: the value named 'checkpoint' in this block; interval: the value named 'interval' in this block; CheckpointInterval: the value named 'checkpoint interval' in this block.

Line 45: `">$OutLog 2>$ErrLog </dev/null & echo '$! >$PidFile; " +` This batch-control line contributes to the flow that orchestrates the repeatable Windows manage pynq training command-line flow. The important operands are OutLog: the value named 'out log' in this block; ErrLog: the value named 'err log' in this block; dev: the value named 'dev' in this block.

Line 46: `"echo started pid='$(cat $PidFile)"` This batch-control line contributes to the flow that orchestrates the repeatable Windows manage pynq training command-line flow. The important operands are echo: the value named 'echo' in this block; started: the value named 'started' in this block; pid: the value named 'pid' in this block.

Line 47: `Invoke-Remote $Command` This batch-control line contributes to the flow that orchestrates the repeatable Windows manage pynq training command-line flow. The important operands are Invoke: the value named 'invoke' in this block; Remote: the value named 'remote' in this block; Command: the 128-bit instruction selecting an engine, shape, mode, and numeric parameters.

Line 48: `}` This batch-control line contributes to the flow that orchestrates the repeatable Windows manage pynq training command-line flow. The expression is a literal or structural operator and has no hidden software state.

Line 50: `switch ($Action) {` This batch-control line contributes to the flow that orchestrates the repeatable Windows manage pynq training command-line flow. The important operands are switch: the value named 'switch' in this block; Action: the value named 'action' in this block.

Line 51: `"start" { Start-Training }` This batch-control line contributes to the flow that orchestrates the repeatable Windows manage pynq training command-line flow. The important operands are start: the value named 'start' in this block; Start: the value named 'start' in this block; Training: the value named 'training' in this block.

Line 52: `"resume" { Start-Training -Resume }` This batch-control line contributes to the flow that orchestrates the repeatable Windows manage pynq training command-line flow. The important operands are resume: the value named 'resume' in this block; Start: the value named 'start' in this block; Training: the value named 'training' in this block.

Line 53: `"pause" {` This batch-control line contributes to the flow that orchestrates the repeatable Windows manage pynq training command-line flow. The important operands are pause: the value named 'pause' in this block.

Line 54: `Invoke-Remote "mkdir -p $Output; touch $PauseFile; echo pause_requested=$PauseFile"` This batch-control line contributes to the flow that orchestrates the repeatable Windows manage pynq training command-line flow. The important operands are Invoke: the value named 'invoke' in this block; Remote: the value named 'remote' in this block; mkdir: the value named 'mkdir' in this block.

Line 55: `}` This batch-control line contributes to the flow that orchestrates the repeatable Windows manage pynq training command-line flow. The expression is a literal or structural operator and has no hidden software state.

Line 56: `"status" {` This batch-control line contributes to the flow that orchestrates the repeatable Windows manage pynq training command-line flow. The important operands are status: the value named 'status' in this block.

Line 57: `$Command = "if [ -f $PidFile ]; then pid=‘$(cat $PidFile); else pid=none; fi; " +` This batch-control line contributes to the flow that orchestrates the repeatable Windows manage pynq training command-line flow. The important operands are Command: the 128-bit instruction selecting an engine, shape, mode, and numeric parameters; f: the value named ’f’ in this block; PidFile: the value named ’pid file’ in this block.

Line 58: `"if [ ‘$pid != none ] && kill -0 ‘$pid 2>/dev/null; then alive=true; else alive=false; fi; " +` This batch-control line contributes to the flow that orchestrates the repeatable Windows manage pynq training command-line flow. The important operands are pid: the value named ’pid’ in this block; none: the value named ’none’ in this block; kill: the value named ’kill’ in this block.

Line 59: `"echo pid=‘$pid alive=‘$alive; " +` This batch-control line contributes to the flow that orchestrates the repeatable Windows manage pynq training command-line flow. The important operands are echo: the value named ’echo’ in this block; pid: the value named ’pid’ in this block; alive: the value named ’alive’ in this block.

Line 60: `"if [ -f $StatusFile ]; then cat $StatusFile; else echo no_status_file; fi; " +` This batch-control line contributes to the flow that orchestrates the repeatable Windows manage pynq training command-line flow. The important operands are f: the value named ’f’ in this block; StatusFile: the value named ’status file’ in this block; then: the value named ’then’ in this block.

Line 61: `"echo out_log=$OutLog; echo err_log=$ErrLog"` This batch-control line contributes to the flow that orchestrates the repeatable Windows manage pynq training command-line flow. The important operands are echo: the value named ’echo’ in this block; out_log: the value named ’out log’ in this block; OutLog: the value named ’out log’ in this block.

Line 62: `Invoke-Remote $Command` This batch-control line contributes to the flow that orchestrates the repeatable Windows manage pynq training command-line flow. The important operands are Invoke: the value named ’invoke’ in this block; Remote: the value named ’remote’ in this block; Command: the 128-bit instruction selecting an engine, shape, mode, and numeric parameters.

Line 63: `}` This batch-control line contributes to the flow that orchestrates the repeatable Windows manage pynq training command-line flow. The expression is a literal or structural operator and has no hidden software state.

Line 64: `}` This batch-control line contributes to the flow that orchestrates the repeatable Windows manage pynq training command-line flow. The expression is a literal or structural operator and has no hidden software state.

82 scripts/run_mac2_probe.ps1

Role in the complete system: orchestrates the repeatable Windows run mac2 probe command-line flow.

82.1 Beginner architecture map

Dataflow responsibility This file's end-to-end responsibility is to orchestrates the repeatable Windows run mac2 probe command-line flow.

Where it runs This is PowerShell orchestration, not accelerator datapath hardware. It makes tool inputs, versions, paths, stages, and failure propagation repeatable.

Reproducibility contract Every external command must be checked, every required artifact must exist and be nonempty, and measured values must be read from generated reports. Rerunning this file should either reproduce its declared outputs or stop at the first failed gate.

82.2 Complete source

```
param(
    [string]$VivadoBin = "D:\AMDDesignTools\2026.1\Vivado\bin"
)

$ErrorActionPreference = "Stop"
$ProjectDir = Resolve-Path (Join-Path $PSScriptRoot "..")
$Xvlog = Join-Path $VivadoBin "xvlog.bat"
$Xelab = Join-Path $VivadoBin "xelab.bat"
$Xsim = Join-Path $VivadoBin "xsim.bat"
$Vivado = Join-Path $VivadoBin "vivado.bat"

foreach ($tool in @($Xvlog, $Xelab, $Xsim, $Vivado)) {
    if (!(Test-Path $tool)) { throw "Required Vivado tool not found: $tool" }
}

Push-Location $ProjectDir
try {
    & $Xvlog -sv rtl\neuraedge_mac2_u8.sv tb\tb_neuraedge_mac2_u8.sv

} finally {
    Pop-Location
}

Write-Host "Packed MAC arithmetic and 128-DSP mapping probe passed."
```

82.3 Line annotations

Line 1: `param(` This declares a typed command-line parameter so the flow can be rerun with explicit, validated paths and options.

Line 2: `[string]$VivadoBin = "D:\AMDDesignTools\2026.1\Vivado\bin"` This declares a typed command-line parameter so the flow can be rerun with explicit, validated paths and options.

Line 3: `)` This batch-control line contributes to the flow that orchestrates the repeatable Windows run mac2 probe command-line flow. The expression is a literal or structural operator and has no hidden software state.

Line 5: `$ErrorActionPreference = "Stop"` This makes PowerShell stop on errors so a failed prerequisite cannot be hidden by later successful commands.

Line 6: `$ProjectDir = Resolve-Path (Join-Path $PSScriptRoot "..")` This batch-control line contributes to the flow that orchestrates the repeatable Windows run mac2 probe command-line flow. The important operands are ProjectDir: the value named 'project dir' in this block; Resolve: the value named 'resolve' in this block; Path: the value named 'path' in this block.

Line 7: `$Xvlog = Join-Path $VivadoBin "xvlog.bat"` This locates or invokes a required tool as part of the script that orchestrates the repeatable Windows run mac2 probe command-line flow; the exact command and arguments remain visible here for reproducibility.

Line 8: `$Xelab = Join-Path $VivadoBin "xelab.bat"` This locates or invokes a required tool as part of the script that orchestrates the repeatable Windows run mac2 probe command-line flow; the exact command and arguments remain visible here for reproducibility.

Line 9: `$Xsim = Join-Path $VivadoBin "xsim.bat"` This locates or invokes a required tool as part of the script that orchestrates the repeatable Windows run mac2 probe command-line flow; the exact command and arguments remain visible here for reproducibility.

Line 10: `$Vivado = Join-Path $VivadoBin "vivado.bat"` This locates or invokes a required tool as part of the script that orchestrates the repeatable Windows run mac2 probe command-line flow; the exact command and arguments remain visible here for reproducibility.

Line 12: `foreach ($tool in @($Xvlog, $Xelab, $Xsim, $Vivado)) {` This locates or invokes a required tool as part of the script that orchestrates the repeatable Windows run mac2 probe command-line flow; the exact command and arguments remain visible here for reproducibility.

Line 13: `if (!(Test-Path $tool)) { throw "Required Vivado tool not found: $tool" }` This locates or invokes a required tool as part of the script that orchestrates the repeatable Windows run mac2 probe command-line flow; the exact command and arguments remain visible here for reproducibility.

Line 14: `}` This batch-control line contributes to the flow that orchestrates the repeatable Windows run mac2 probe command-line flow. The expression is a literal or structural operator and has no hidden software state.

Line 16: `Push-Location $ProjectDir` This batch-control line contributes to the flow that orchestrates the repeatable Windows run mac2 probe command-line flow. The important operands are Push: the value named 'push' in this block; Location: the value named 'location' in this block; ProjectDir: the value named 'project dir' in this block.

Line 17: `try {` This batch-control line contributes to the flow that orchestrates the repeatable Windows run mac2 probe command-line flow. The important operands are try: the value named 'try' in this block.

Line 18: `& $Xvlog -sv rtl\neuraedge_mac2_u8.sv tb\tb_neuraedge_mac2_u8.sv` This locates or invokes a required tool as part of the script that orchestrates the repeatable Windows run mac2 probe command-line flow; the exact command and arguments remain visible here for reproducibility.

Line 19: `if ($LASTEXITCODE -ne 0) { throw "xvlog failed with exit code $LASTEXITCODE" }` This checks the external program's process exit code and turns a failed compiler, simulator, or Vivado run into a failed pipeline.

Line 20: `& $Xelab tb_neuraedge_mac2_u8 -debug typical` This locates or invokes a required tool as part of the script that orchestrates the repeatable Windows run mac2 probe command-line flow; the exact command and arguments remain visible here for reproducibility.

Line 21: `if ($LASTEXITCODE -ne 0) { throw "xelab failed with exit code $LASTEXITCODE" }` This checks the external program's process exit code and turns a failed compiler, simulator, or Vivado run into a failed pipeline.

Line 22: `& $Xsim tb_neuraedge_mac2_u8 -runall` This locates or invokes a required tool as part of the script that orchestrates the repeatable Windows run mac2 probe command-line flow; the exact command and arguments remain visible here for reproducibility.

Line 23: `if ($LASTEXITCODE -ne 0) { throw "xsim failed with exit code $LASTEXITCODE" }` This checks the external program's process exit code and turns a failed compiler, simulator, or Vivado run into a failed pipeline.

Line 24: `& $Vivado -mode batch -source scripts\synth_mac2_probe.tcl -notrace` This locates or invokes a required tool as part of the script that orchestrates the repeatable Windows run mac2 probe command-line flow; the exact command and arguments remain visible here for reproducibility.

Line 25: `if ($LASTEXITCODE -ne 0) { throw "Vivado probe implementation failed with exit code $LASTEXITCODE" }` This checks the external program's process exit code and turns a failed compiler, simulator, or Vivado run into a failed pipeline.

Line 26: `} finally {` This batch-control line contributes to the flow that orchestrates the repeatable Windows run mac2 probe command-line flow. The important operands are finally: the value named 'finally' in this block.

Line 27: `Pop-Location` This batch-control line contributes to the flow that orchestrates the repeatable Windows run mac2 probe command-line flow. The important operands are Pop: the value named 'pop' in this block; Location: the value named 'location' in this block.

Line 28: `}` This batch-control line contributes to the flow that orchestrates the repeatable Windows run mac2 probe command-line flow. The expression is a literal or structural operator and has no hidden software state.

Line 30: `Write-Host "Packed MAC arithmetic and 128-DSP mapping probe passed."` This batch-control line contributes to the flow that orchestrates the repeatable Windows run mac2 probe command-line flow. The important operands are Write: the value named 'write' in this block; Host: the value named 'host' in this block; Packed: the value named 'packed' in this block.

83 scripts/run_pynq_full.ps1

Role in the complete system: orchestrates the repeatable Windows run pynq full command-line flow.

83.1 Beginner architecture map

Dataflow responsibility This file's end-to-end responsibility is to orchestrates the repeatable Windows run pynq full command-line flow.

Where it runs This is PowerShell orchestration, not accelerator datapath hardware. It makes tool inputs, versions, paths, stages, and failure propagation repeatable.

Reproducibility contract Every external command must be checked, every required artifact must exist and be nonempty, and measured values must be read from generated reports. Rerunning this file should either reproduce its declared outputs or stop at the first failed gate.

83.3 Line annotations

Line 1: `[CmdletBinding()]` This batch-control line contributes to the flow that orchestrates the repeatable Windows run pynq full command-line flow. The important operands are CmdletBinding: the value named 'cmdlet binding' in this block.

Line 2: `param(` This declares a typed command-line parameter so the flow can be rerun with explicit, validated paths and options.

Line 3: `[string]$VivadoRoot = "D:\AMDDesignTools\2026.1\Vivado",` This declares a typed command-line parameter so the flow can be rerun with explicit, validated paths and options.

Line 4: `[ValidateSet("validate", "full")]` This batch-control line contributes to the flow that orchestrates the repeatable Windows run pynq full command-line flow. The important operands are ValidateSet: the producer's statement that its current payload is meaningful; validate: the producer's statement that its current payload is meaningful; full: the value named 'full' in this block.

Line 5: `[string]$Mode = "full",` This declares a typed command-line parameter so the flow can be rerun with explicit, validated paths and options.

Line 6: `[switch]$CleanLogs` This declares a typed command-line parameter so the flow can be rerun with explicit, validated paths and options.

Line 7: `)` This batch-control line contributes to the flow that orchestrates the repeatable Windows run pynq full command-line flow. The expression is a literal or structural operator and has no hidden software state.

Line 9: `$ErrorActionPreference = "Stop"` This makes PowerShell stop on errors so a failed prerequisite cannot be hidden by later successful commands.

Line 10: `$ProjectRoot = Split-Path -Parent $PSScriptRoot` This resolves a deterministic filesystem location for the flow that orchestrates the repeatable Windows run pynq full command-line flow. Literal/full paths prevent a different working directory from silently selecting the wrong source, checkpoint, or output.

Line 11: `$Vivado = Join-Path $VivadoRoot "bin\vivado.bat"` This locates or invokes a required tool as part of the script that orchestrates the repeatable Windows run pynq full command-line flow; the exact command and arguments remain visible here for reproducibility.

Line 12: `$Tcl = Join-Path $PSScriptRoot "build_pynq_full.tcl"` This batch-control line contributes to the flow that orchestrates the repeatable Windows run pynq full command-line flow. The important operands are Tcl: the value named 'tcl' in this block; Join: the value named 'join' in this block; Path: the value named 'path' in this block.

Line 13: `$DiagramTcl = Join-Path $PSScriptRoot "export_pynq_diagrams.tcl"` This batch-control line contributes to the flow that orchestrates the repeatable Windows run pynq full command-line flow. The important operands are DiagramTcl: the value named 'diagram tcl' in this block; Join: the value named 'join' in this block; Path: the value named 'path' in this block.

Line 14: `$OutputRoot = Join-Path $ProjectRoot "outputs\pynq_full"` This batch-control line contributes to the flow that orchestrates the repeatable Windows run pynq full command-line flow. The important operands are OutputRoot: the value named 'output root' in this block; Join: the value named 'join' in this block; Path: the value named 'path' in this block.

Line 15: `$Summary = Join-Path $ProjectRoot "outputs\pynq_full\full_implementation_summary.txt"` This batch-control line contributes to the flow that orchestrates the repeatable Windows run pynq full command-line flow. The important operands are Summary: the value named 'summary' in this block; Join: the value named 'join' in this block; Path: the value named 'path' in this block.

Line 16: `$BuildRoot = if ([string]::IsNullOrWhiteSpace($env:NEURAEDGE_VIVADO_BUILD_ROOT)) {` This locates or invokes a required tool as part of the script that orchestrates the repeatable Windows run pynq full command-line flow; the exact command and arguments remain visible here for reproducibility.

Line 17: `"D:\NeuraEdgeBuild"` This batch-control line contributes to the flow that orchestrates the repeatable Windows run pynq full command-line flow. The important operands are D: the value named 'd' in this block; NeuraEdgeBuild: the value named 'neura edge build' in this block.

Line 18: `} else {` This batch-control line contributes to the flow that orchestrates the repeatable Windows run pynq full command-line flow. The expression is a literal or structural operator and has no hidden software state.

Line 19: `[System.IO.Path]::GetFullPath($env:NEURAEDGE_VIVADO_BUILD_ROOT)` This locates or invokes a required tool as part of the script that orchestrates the repeatable Windows run pynq full command-line flow; the exact command and arguments remain visible here for reproducibility.

Line 20: `}` This batch-control line contributes to the flow that orchestrates the repeatable Windows run pynq full command-line flow. The expression is a literal or structural operator and has no hidden software state.

Line 21: `$VivadoProject = Join-Path $BuildRoot "pynq_full\neuraedge_pynq_full.xpr"` This locates or invokes a required tool as part of the script that orchestrates the repeatable Windows run pynq full command-line flow; the exact command and arguments remain visible here for reproducibility.

Line 23: `if (-not (Test-Path -LiteralPath $Vivado)) {` This locates or invokes a required tool as part of the script that orchestrates the repeatable Windows run pynq full command-line flow; the exact command and arguments remain visible here for reproducibility.

Line 24: `throw "Vivado was not found at $Vivado"` This locates or invokes a required tool as part of the script that orchestrates the repeatable Windows run pynq full command-line flow; the exact command and arguments remain visible here for reproducibility.

Line 25: `}` This batch-control line contributes to the flow that orchestrates the repeatable Windows run pynq full command-line flow. The expression is a literal or structural operator and has no hidden software state.

Line 27: `if ($CleanLogs) {` This batch-control line contributes to the flow that orchestrates the repeatable Windows run pynq full command-line flow. The important operands are CleanLogs: the value named 'clean logs' in this block.

Line 28: `foreach ($Name in @("vivado.jou", "vivado.log")) {` This locates or invokes a required tool as part of the script that orchestrates the repeatable Windows run pynq full command-line flow; the exact command and arguments remain visible here for reproducibility.

Line 29: `$Path = Join-Path $ProjectRoot $Name` This batch-control line contributes to the flow that orchestrates the repeatable Windows run pynq full command-line flow. The important operands are Path: the value named 'path' in this block; Join: the value named 'join' in this block; ProjectRoot: the value named 'project root' in this block.

Line 30: `if (Test-Path -LiteralPath $Path) {` This batch-control line contributes to the flow that orchestrates the repeatable Windows run pynq full command-line flow. The important operands are Test: the value named 'test' in this block; Path: the value named 'path' in this block; LiteralPath: the value named 'literal path' in this block.

Line 31: `Remove-Item -LiteralPath $Path -Force` This removes the explicitly named rebuildable artifact. The script uses a literal path so wildcard expansion cannot delete an unintended neighboring file.

Line 32: `}` This batch-control line contributes to the flow that orchestrates the repeatable Windows run pynq full command-line flow. The expression is a literal or structural operator and has no hidden software state.

Line 33: `}` This batch-control line contributes to the flow that orchestrates the repeatable Windows run pynq full command-line flow. The expression is a literal or structural operator and has no hidden software state.

Line 34: `}` This batch-control line contributes to the flow that orchestrates the repeatable Windows run pynq full command-line flow. The expression is a literal or structural operator and has no hidden software state.

Line 36: `Push-Location $ProjectRoot` This batch-control line contributes to the flow that orchestrates the repeatable Windows run pynq full command-line flow. The important operands are Push: the value named 'push' in this block; Location: the value named 'location' in this block; ProjectRoot: the value named 'project root' in this block.

Line 37: `try {` This batch-control line contributes to the flow that orchestrates the repeatable Windows run pynq full command-line flow. The important operands are try: the value named 'try' in this block.

Line 38: `New-Item -ItemType Directory -Force -Path $OutputRoot | Out-Null` This creates the declared output directory before a tool writes into it. '-Force' permits an existing directory but does not make an external tool failure succeed.

Line 39: `$Log = Join-Path $OutputRoot "vivado_${Mode}.log"` This locates or invokes a required tool as part of the script that orchestrates the repeatable Windows run pynq full command-line flow; the exact command and arguments remain visible here for reproducibility.

Line 40: `$Journal = Join-Path $OutputRoot "vivado_${Mode}.jou"` This locates or invokes a required tool as part of the script that orchestrates the repeatable Windows run pynq full command-line flow; the exact command and arguments remain visible here for reproducibility.

Line 41: `& $Vivado -mode batch -log $Log -journal $Journal -source $Tcl -tclargs $Mode` This locates or invokes a required tool as part of the script that orchestrates the repeatable Windows run pynq full command-line flow; the exact command and arguments remain visible here for reproducibility.

Line 42: `if ($LASTEXITCODE -ne 0) {` This checks the external program's process exit code and turns a failed compiler, simulator, or Vivado run into a failed pipeline.

Line 43: `throw "PYNQ $Mode build failed with exit code $LASTEXITCODE. See $Log"` This checks the external program's process exit code and turns a failed compiler, simulator, or Vivado run into a failed pipeline.

Line 44: `}` This batch-control line contributes to the flow that orchestrates the repeatable Windows run pynq full command-line flow. The expression is a literal or structural operator and has no hidden software state.

Line 46: `$DiagramLog = Join-Path $OutputRoot "vivado_diagrams.log"` This locates or invokes a required tool as part of the script that orchestrates the repeatable Windows run pynq full command-line flow; the exact command and arguments remain visible here for reproducibility.

Line 47: `$DiagramJournal = Join-Path $OutputRoot "vivado_diagrams.jou"` This locates or invokes a required tool as part of the script that orchestrates the repeatable Windows run pynq full command-line flow; the exact command and arguments remain visible here for reproducibility.

Line 48: `& $Vivado -mode gui -log $DiagramLog -journal $DiagramJournal ‘` This locates or invokes a required tool as part of the script that orchestrates the repeatable Windows run pynq full command-line flow; the exact command and arguments remain visible here for reproducibility.

Line 49: `-source $DiagramTcl -tclargs $VivadoProject $OutputRoot` This locates or invokes a required tool as part of the script that orchestrates the repeatable Windows run pynq full command-line flow; the exact command and arguments remain visible here for reproducibility.

Line 50: `if ($LASTEXITCODE -ne 0) {` This checks the external program's process exit code and turns a failed compiler, simulator, or Vivado run into a failed pipeline.

Line 51: `throw "PYNQ diagram export failed with exit code $LASTEXITCODE. See $DiagramLog"` This checks the external program's process exit code and turns a failed compiler, simulator, or Vivado run into a failed pipeline.

Line 52: `}` This batch-control line contributes to the flow that orchestrates the repeatable Windows run pynq full command-line flow. The expression is a literal or structural operator and has no hidden software state.

Line 53: `foreach ($Diagram in @("neuraedge_pynq_block_design.pdf",` This batch-control line contributes to the flow that orchestrates the repeatable Windows run pynq full command-line flow. The important operands are foreach: the value named 'foreach' in this block; Diagram: the value named 'diagram' in this block; in: the value named 'in' in this block.

Line 54: `"neuraedge_pynq_block_design.svg")) {` This batch-control line contributes to the flow that orchestrates the repeatable Windows run pynq full command-line flow. The important operands are neuraedge_pynq_block_design: the value named 'neuraedge pynq block design' in this block; svg: the value named 'svg' in this block.

Line 55: `$DiagramPath = Join-Path $OutputRoot $Diagram` This batch-control line contributes to the flow that orchestrates the repeatable Windows run pynq full command-line flow. The important operands are DiagramPath: the value named 'diagram path' in this block; Join: the value named 'join' in this block; Path: the value named 'path' in this block.

Line 56: `if (-not (Test-Path -LiteralPath $DiagramPath) -or` This batch-control line contributes to the flow that orchestrates the repeatable Windows run pynq full command-line flow. The important operands are not: the value named 'not' in this block; Test: the value named 'test' in this block; Path: the value named 'path' in this block.

Line 57: `(Get-Item -LiteralPath $DiagramPath).Length -eq 0) {` This batch-control line contributes to the flow that orchestrates the repeatable Windows run pynq full command-line flow. The important operands are Get: the value named 'get' in this block; Item: the value named 'item' in this block; LiteralPath: the value named 'literal path' in this block.

Line 58: `throw "PYNQ diagram export did not create $DiagramPath"` This batch-control line contributes to the flow that orchestrates the repeatable Windows run pynq full command-line flow. The important operands are throw: one output-row position processed by the tensor tile; PYNQ: the value named 'pynq' in this block; diagram: the value named 'diagram' in this block.

Line 59: `}` This batch-control line contributes to the flow that orchestrates the repeatable Windows run pynq full command-line flow. The expression is a literal or structural operator and has no hidden software state.

Line 60: `}` This batch-control line contributes to the flow that orchestrates the repeatable Windows run pynq full command-line flow. The expression is a literal or structural operator and has no hidden software state.

Line 61: `} finally {` This batch-control line contributes to the flow that orchestrates the repeatable Windows run pynq full command-line flow. The important operands are finally: the value named 'finally' in this block.

Line 62: `Pop-Location` This batch-control line contributes to the flow that orchestrates the repeatable Windows run pynq full command-line flow. The important operands are Pop: the value named 'pop' in this block; Location: the value named 'location' in this block.

Line 63: `}` This batch-control line contributes to the flow that orchestrates the repeatable Windows run pynq full command-line flow. The expression is a literal or structural operator and has no hidden software state.

Line 65: `if ($Mode -eq "full") {` This batch-control line contributes to the flow that orchestrates the repeatable Windows run pynq full command-line flow. The important operands are Mode: the value named 'mode' in this block; eq: the value named 'eq' in this block; full: the value named 'full' in this block.

Line 66: `Get-Content -LiteralPath $Summary` This batch-control line contributes to the flow that orchestrates the repeatable Windows run pynq full command-line flow. The important operands are Get: the value named 'get' in this block; Content: the value named 'content' in this block; LiteralPath: the value named 'literal path' in this block.

Line 67: `} else {` This batch-control line contributes to the flow that orchestrates the repeatable Windows run pynq full command-line flow. The expression is a literal or structural operator and has no hidden software state.

Line 68: `Write-Host "NEURAEDGE_PYNQ_VALIDATION_PASSED report=$OutputRoot\validated_ip_status.rpt"` This batch-control line contributes to the flow that orchestrates the repeatable Windows run pynq full command-line flow. The important operands are Write: the value named 'write' in this block; Host: the value named 'host' in this block; NEURAEDGE_PYNQ_VALIDATION_PASSED: the producer's statement that its current payload is meaningful.

Line 69: `}` This batch-control line contributes to the flow that orchestrates the repeatable Windows run pynq full command-line flow. The expression is a literal or structural operator and has no hidden software state.

84 scripts/run_regression.ps1

Role in the complete system: orchestrates the repeatable Windows run regression command-line flow.

84.1 Beginner architecture map

Dataflow responsibility This file's end-to-end responsibility is to orchestrates the repeatable Windows run regression command-line flow.

Where it runs This is PowerShell orchestration, not accelerator datapath hardware. It makes tool inputs, versions, paths, stages, and failure propagation repeatable.

Reproducibility contract Every external command must be checked, every required artifact must exist and be nonempty, and measured values must be read from generated reports. Rerunning this file should either reproduce its declared outputs or stop at the first failed gate.

84.2 Complete source

84.3 Line annotations

Line 1: `param(` This declares a typed command-line parameter so the flow can be rerun with explicit, validated paths and options.

Line 2: `[string]$IcarusRoot = "C:\msys64\ucrt64\bin",` This declares a typed command-line parameter so the flow can be rerun with explicit, validated paths and options.

Line 3: `[string]$MsysRoot = "C:\msys64",` This declares a typed command-line parameter so the flow can be rerun with explicit, validated paths and options.

Line 4: `[string]$PythonExe = "",` This declares a typed command-line parameter so the flow can be rerun with explicit, validated paths and options.

Line 5: `[switch]$KeepExecutables` This declares a typed command-line parameter so the flow can be rerun with explicit, validated paths and options.

Line 6: `)` This batch-control line contributes to the flow that orchestrates the repeatable Windows run regression command-line flow. The expression is a literal or structural operator and has no hidden software state.

Line 8: `$ErrorActionPreference = "Stop"` This makes PowerShell stop on errors so a failed prerequisite cannot be hidden by later successful commands.

Line 9: `Set-StrictMode -Version Latest` This batch-control line contributes to the flow that orchestrates the repeatable Windows run regression command-line flow. The important operands are Set: the value named 'set' in this block; StrictMode: the value named 'strict mode' in this block; Version: the value named 'version' in this block.

Line 11: `$ProjectRoot = (Resolve-Path (Join-Path $PSScriptRoot "..")).Path` This resolves a deterministic filesystem location for the flow that orchestrates the repeatable Windows run regression command-line flow. Literal/full paths prevent a different working directory from silently selecting the wrong source, checkpoint, or output.

Line 12: `$OutputRoot = Join-Path $ProjectRoot "outputs\regression"` This batch-control line contributes to the flow that orchestrates the repeatable Windows run regression command-line flow. The important operands are OutputRoot: the value named 'output root' in this block; Join: the value named 'join' in this block; Path: the value named 'path' in this block.

Line 13: `New-Item -ItemType Directory -Force -Path $OutputRoot | Out-Null` This creates the declared output directory before a tool writes into it. '-Force' permits an existing directory but does not make an external tool failure succeed.

Line 14: `$SummaryPath = Join-Path $OutputRoot "regression_summary.txt"` This batch-control line contributes to the flow that orchestrates the repeatable Windows run regression command-line flow. The important operands are SummaryPath: the value named 'summary path' in this block; Join: the value named 'join' in this block; Path: the value named 'path' in this block.

Line 15: `@(` This batch-control line contributes to the flow that orchestrates the repeatable Windows run regression command-line flow. The expression is a literal or structural operator and has no hidden software state.

Line 16: `"result=RUNNING",` This batch-control line contributes to the flow that orchestrates the repeatable Windows run regression command-line flow. The important operands are result: the value named 'result' in this block; RUNNING: the value named 'running' in this block.

Line 17: `"started_utc=$([DateTime]::UtcNow.ToString('o'))"` This batch-control line contributes to the flow that orchestrates the repeatable Windows run regression command-line flow. The important operands are started_utc: the value named 'started utc' in this block; DateTime: the value named 'date time' in this block; UtcNow: the value named 'utc now' in this block.

Line 18: `) | Set-Content -LiteralPath $SummaryPath -Encoding ascii` This batch-control line contributes to the flow that orchestrates the repeatable Windows run regression command-line flow. The important operands are Set: the value named 'set' in this block; Content: the value named 'content' in this block; LiteralPath: the value named 'literal path' in this block.

Line 20: `$Iverilog = Join-Path $IcarusRoot "iverilog.exe"` This locates or invokes a required tool as part of the script that orchestrates the repeatable Windows run regression command-line flow; the exact command and arguments remain visible here for reproducibility.

Line 21: `$Vvp = Join-Path $IcarusRoot "vvp.exe"` This batch-control line contributes to the flow that orchestrates the repeatable Windows run regression command-line flow. The important operands are Vvp: the value named 'vvp' in this block; Join: the value named 'join' in this block; Path: the value named 'path' in this block.

Line 22: `if (-not (Test-Path -LiteralPath $Iverilog) -or -not (Test-Path -LiteralPath $Vvp)) {` This locates or invokes a required tool as part of the script that orchestrates the repeatable Windows run regression command-line flow; the exact command and arguments remain visible here for reproducibility.

Line 23: `throw "Icarus Verilog was not found under $IcarusRoot"` This batch-control line contributes to the flow that orchestrates the repeatable Windows run regression command-line flow. The important operands are throw: one output-row position processed by the tensor tile; Icarus: the value named 'icarus' in this block; Verilog: the value named 'verilog' in this block.

Line 24: `}` This batch-control line contributes to the flow that orchestrates the repeatable Windows run regression command-line flow. The expression is a literal or structural operator and has no hidden software state.

Line 26: `function Test-RegressionPython {` This locates or invokes a required tool as part of the script that orchestrates the repeatable Windows run regression command-line flow; the exact command and arguments remain visible here for reproducibility.

Line 27: `param([string]$Candidate)` This declares a typed command-line parameter so the flow can be rerun with explicit, validated paths and options.

Line 28: `if ([string]::IsNullOrWhiteSpace($Candidate)) {` This batch-control line contributes to the flow that orchestrates the repeatable Windows run regression command-line flow. The important operands are string: the value named 'string' in this block; IsNullOrWhiteSpace: the value named 'is null or white space' in this block; Candidate: the value named 'candidate' in this block.

Line 29: `return $false` This batch-control line contributes to the flow that orchestrates the repeatable Windows run regression command-line flow. The expression is a literal or structural operator and has no hidden software state.

Line 30: `}` This batch-control line contributes to the flow that orchestrates the repeatable Windows run regression command-line flow. The expression is a literal or structural operator and has no hidden software state.

Line 31: `$Command = Get-Command $Candidate -ErrorAction SilentlyContinue` This batch-control line contributes to the flow that orchestrates the repeatable Windows run regression command-line flow. The important operands are Command: the 128-bit instruction selecting an engine, shape, mode, and numeric parameters; Get: the value named 'get' in this block; Candidate: the value named 'candidate' in this block.

Line 32: `if ($null -eq $Command) {` This batch-control line contributes to the flow that orchestrates the repeatable Windows run regression command-line flow. The important operands are null: the value named 'null' in this block; eq: the value named 'eq' in this block; Command: the 128-bit instruction selecting an engine, shape, mode, and numeric parameters.

Line 33: `return $false` This batch-control line contributes to the flow that orchestrates the repeatable Windows run regression command-line flow. The expression is a literal or structural operator and has no hidden software state.

Line 34: `}` This batch-control line contributes to the flow that orchestrates the repeatable Windows run regression command-line flow. The expression is a literal or structural operator and has no hidden software state.

Line 35: `& $Command.Source -c "import numpy, torch" *> $null` This batch-control line contributes to the flow that orchestrates the repeatable Windows run regression command-line flow. The important operands are Command: the 128-bit instruction selecting an engine, shape, mode, and numeric parameters; Source: the value named 'source' in this block; c: the value named 'c' in this block.

Line 36: `return $LASTEXITCODE -eq 0` This checks the external program's process exit code and turns a failed compiler, simulator, or Vivado run into a failed pipeline.

Line 37: `}` This batch-control line contributes to the flow that orchestrates the repeatable Windows run regression command-line flow. The expression is a literal or structural operator and has no hidden software state.

Line 39: `if ([string]::IsNullOrWhiteSpace($PythonExe)) {` This locates or invokes a required tool as part of the script that orchestrates the repeatable Windows run regression command-line flow; the exact command and arguments remain visible here for reproducibility.

Line 40: `$Candidates = [System.Collections.Generic.List[string]]::new()` This batch-control line contributes to the flow that orchestrates the repeatable Windows run regression command-line flow. The important operands are Candidates: the value named 'candidates' in this block; System: the value named 'system' in this block; Collections: the value named 'collections' in this block.

Line 41: `$SearchRoot = Get-Item -LiteralPath $ProjectRoot` This batch-control line contributes to the flow that orchestrates the repeatable Windows run regression command-line flow. The important operands are SearchRoot: the value named 'search root' in this block; Get: the value named 'get' in this block; Item: the value named 'item' in this block.

Line 42: `for ($Depth = 0; $Depth -lt 5 -and $null -ne $SearchRoot; $Depth++) {` This batch-control line contributes to the flow that orchestrates the repeatable Windows run regression command-line flow. The important operands are for: the value named 'for' in this block; Depth: the value named 'depth' in this block; lt: the value named 'lt' in this block.

Line 43: `$PreferredPython = Join-Path $SearchRoot.FullName '` This locates or invokes a required tool as part of the script that orchestrates the repeatable Windows run regression command-line flow; the exact command and arguments remain visible here for reproducibility.

Line 44: `"external_research\spikingformer_py310\Scripts\python.exe"` This locates or invokes a required tool as part of the script that orchestrates the repeatable Windows run regression command-line flow; the exact command and arguments remain visible here for reproducibility.

Line 45: `if (Test-Path -LiteralPath $PreferredPython) {` This locates or invokes a required tool as part of the script that orchestrates the repeatable Windows run regression command-line flow; the exact command and arguments remain visible here for reproducibility.

Line 46: `$Candidates.Add((Resolve-Path $PreferredPython).Path)` This locates or invokes a required tool as part of the script that orchestrates the repeatable Windows run regression command-line flow; the exact command and arguments remain visible here for reproducibility.

Line 47: `}` This batch-control line contributes to the flow that orchestrates the repeatable Windows run regression command-line flow. The expression is a literal or structural operator and has no hidden software state.

Line 48: `$SearchRoot = $SearchRoot.Parent` This batch-control line contributes to the flow that orchestrates the repeatable Windows run regression command-line flow. The important operands are SearchRoot: the value named 'search root' in this block; Parent: the value named 'parent' in this block.

Line 49: `}` This batch-control line contributes to the flow that orchestrates the repeatable Windows run regression command-line flow. The expression is a literal or structural operator and has no hidden software state.

Line 50: `$Launcher = Get-Command py.exe -ErrorAction SilentlyContinue` This batch-control line contributes to the flow that orchestrates the repeatable Windows run regression command-line flow. The important operands are Launcher: the value named 'launcher' in this block; Get: the value named 'get' in this block; Command: the 128-bit instruction selecting an engine, shape, mode, and numeric parameters.

Line 51: `if ($null -ne $Launcher) {` This batch-control line contributes to the flow that orchestrates the repeatable Windows run regression command-line flow. The important operands are null: the value named 'null' in this block; ne: the value named 'ne' in this block; Launcher: the value named 'launcher' in this block.

Line 52: `foreach ($Version in @("3.14", "3.10")) {` This batch-control line contributes to the flow that orchestrates the repeatable Windows run regression command-line flow. The important operands are foreach: the value named 'foreach' in this block; Version: the value named 'version' in this block; in: the value named 'in' in this block.

Line 53: `$Discovered = & $Launcher.Source "-$Version" -c "import sys; print(sys.executable)" 2>$null` This batch-control line contributes to the flow that orchestrates the repeatable Windows run regression command-line flow. The important operands are Discovered: the value named 'discovered' in this block; Launcher: the value named 'launcher' in this block; Source: the value named 'source' in this block.

Line 54: `if ($LASTEXITCODE -eq 0 -and -not [string]::IsNullOrWhiteSpace($Discovered)) {` This checks the external program's process exit code and turns a failed compiler, simulator, or Vivado run into a failed pipeline.

Line 55: `$Candidates.Add([string]($Discovered | Select-Object -Last 1))` This batch-control line contributes to the flow that orchestrates the repeatable Windows run regression command-line flow. The important operands are Candidates: the value named 'candidates' in this block; Add: the value named 'add' in this block; string: the value named 'string' in this block.

Line 56: `}` This batch-control line contributes to the flow that orchestrates the repeatable Windows run regression command-line flow. The expression is a literal or structural operator and has no hidden software state.

Line 57: `}` This batch-control line contributes to the flow that orchestrates the repeatable Windows run regression command-line flow. The expression is a literal or structural operator and has no hidden software state.

The important operands are foreach: the value named 'foreach' in this block; Candidate: the value named 'candidate' in this block; in: the value named 'in' in this block.

Line 64: `if (Test-RegressionPython $Candidate) {` This locates or invokes a required tool as part of the script that orchestrates the repeatable Windows run regression command-line flow; the exact command and arguments remain visible here for reproducibility.

Line 65: `$PythonExe = (Get-Command $Candidate -ErrorAction Stop).Source` This locates or invokes a required tool as part of the script that orchestrates the repeatable Windows run regression command-line flow; the exact command and arguments remain visible here for reproducibility.

Line 66: `break` This batch-control line contributes to the flow that orchestrates the repeatable Windows run regression command-line flow. The important operands are break: the value named 'break' in this block.

Line 67: `}` This batch-control line contributes to the flow that orchestrates the repeatable Windows run regression command-line flow. The expression is a literal or structural operator and has no hidden software state.

Line 68: `}` This batch-control line contributes to the flow that orchestrates the repeatable Windows run regression command-line flow. The expression is a literal or structural operator and has no hidden software state.

Line 69: `if ([string]::IsNullOrWhiteSpace($PythonExe)) {` This locates or invokes a required tool as part of the script that orchestrates the repeatable Windows run regression command-line flow; the exact command and arguments remain visible here for reproducibility.

Line 70: `throw "No Python interpreter with NumPy and PyTorch was found. Pass -PythonExe explicitly."` This locates or invokes a required tool as part of the script that orchestrates the repeatable Windows run regression command-line flow; the exact command and arguments remain visible here for reproducibility.

Line 71: `}` This batch-control line contributes to the flow that orchestrates the repeatable Windows run regression command-line flow. The expression is a literal or structural operator and has no hidden software state.

Line 72: `} elseif (-not (Test-RegressionPython $PythonExe)) {` This locates or invokes a required tool as part of the script that orchestrates the repeatable Windows run regression command-line flow; the exact command and arguments remain visible here for reproducibility.

Line 73: `throw "The requested Python interpreter is unavailable or cannot import NumPy and PyTorch: $PythonExe"` This locates or invokes a required tool as part of the script that orchestrates the repeatable Windows run regression command-line flow; the exact command and arguments remain visible here for reproducibility.

Line 74: `}` This batch-control line contributes to the flow that orchestrates the repeatable Windows run regression command-line flow. The expression is a literal or structural operator and has no hidden software state.

Line 76: `$PackageFile = Join-Path $ProjectRoot "rtl\neuraedge_command_pkg.sv"` This batch-control line contributes to the flow that orchestrates the repeatable Windows run regression command-line flow. The important operands are PackageFile: the value named 'package file' in this block; Join: the value named 'join' in this block; Path: the value named 'path' in this block.

Line 77: `$RtlFiles = @($PackageFile) + @(` This batch-control line contributes to the flow that orchestrates the repeatable Windows run regression command-line flow. The important operands are RtlFiles: the value named 'rtl files' in this block; PackageFile: the value named 'package file' in this block.

Line 78: `Get-ChildItem -LiteralPath (Join-Path $ProjectRoot "rtl") -Filter "*.sv" -File |` This batch-control line contributes to the flow that orchestrates the repeatable Windows run regression command-line flow. The important operands are Get: the value named 'get' in this block; ChildItem: the value named 'child item' in this block; LiteralPath: the value named 'literal path' in this block.

Line 79: `Where-Object { $_.FullName -ne $PackageFile } |` This batch-control line contributes to the flow that orchestrates the repeatable Windows run regression command-line flow. The important operands are Where: the value named 'where' in this block; Object: the value named 'object' in this block; _: the value named '' in this block.

Line 80: `Sort-Object Name |` This batch-control line contributes to the flow that orchestrates the repeatable Windows run regression command-line flow. The important operands are Sort: the value named 'sort' in this block; Object: the value named 'object' in this block; Name: the value named 'name' in this block.

Line 81: `ForEach-Object FullName` This batch-control line contributes to the flow that orchestrates the repeatable Windows run regression command-line flow. The important operands are ForEach: the value named 'for each' in this block; Object: the value named 'object' in this block; FullName: the value named 'full name' in this block.

Line 82: `)` This batch-control line contributes to the flow that orchestrates the repeatable Windows run regression command-line flow. The expression is a literal or structural operator and has no hidden software state.

Line 83: `$Testbenches = @(` This batch-control line contributes to the flow that orchestrates the repeatable Windows run regression command-line flow. The important operands are Testbenches: the value named 'testbenches' in this block.

Line 84: `"tb_neuraedge_mac2_u8",` This batch-control line contributes to the flow that orchestrates the repeatable Windows run regression command-line flow. The important operands are tb_neuraedge_mac2_u8: the value named 'tb neuraedge mac2 u8' in this block.

Line 85: `"tb_neuraedge_tensor_tile",` This batch-control line contributes to the flow that orchestrates the repeatable Windows run regression command-line flow. The important operands are tb_neuraedge_tensor_tile: the value named 'tb neuraedge tensor tile' in this block.

Line 86: `"tb_neuraedge_buffered_tensor_core",` This batch-control line contributes to the flow that orchestrates the repeatable Windows run regression command-line flow. The important operands are tb_neuraedge_buffered_tensor_core: local storage that decouples producer and consumer timing.

Line 87: `"tb_neuraedge_alpha_xnor",` This batch-control line contributes to the flow that orchestrates the repeatable Windows run regression command-line flow. The important operands are tb_neuraedge_alpha_xnor: the programmable weight assigned to matching zero spikes in alpha-XNOR attention.

Line 88: `"tb_neuraedge_vector_alu",` This batch-control line contributes to the flow that orchestrates the repeatable Windows run regression command-line flow. The important operands are tb_neuraedge_vector_alu: the value named 'tb neuraedge vector alu' in this block.

Line 89: `"tb_neuraedge_integer_primitives",` This batch-control line contributes to the flow that orchestrates the repeatable Windows run regression command-line flow. The important operands are tb_neuraedge_integer_primitives: the value named 'tb neuraedge integer primitives' in this block.

Line 90: `"tb_neuraedge_normalization_units",` This batch-control line contributes to the flow that orchestrates the repeatable Windows run regression command-line flow. The important operands are tb_neuraedge_normalization_units: the value named 'tb neuraedge normalization units' in this block.

Line 91: `"tb_neuraedge_lif_bank",` This batch-control line contributes to the flow that orchestrates the repeatable Windows run regression command-line flow. The important operands are tb_neuraedge_lif_bank: the value named 'tb neuraedge lif bank' in this block.

Line 92: `"tb_neuraedge_sgd_optimizer8",` This batch-control line contributes to the flow that orchestrates the repeatable Windows run regression command-line flow. The important operands are tb_neuraedge_sgd_optimizer8: the value named 'tb neuraedge sgd optimizer8' in this block.

Line 93: `"tb_neuraedge_linear_backward8",` This batch-control line contributes to the flow that orchestrates the repeatable Windows run regression command-line flow. The important operands are tb_neuraedge_linear_backward8: the value named 'tb neuraedge linear backward8' in this block.

Line 94: `"tb_neuraedge_activation_lut8",` This batch-control line contributes to the flow that orchestrates the repeatable Windows run regression command-line flow. The important operands are tb_neuraedge_activation_lut8: an input feature value consumed by a neuron or multiply-accumulate operation.

Line 95: `"tb_neuraedge_universal_core",` This batch-control line contributes to the flow that orchestrates the repeatable Windows run regression command-line flow. The important operands are tb_neuraedge_universal_core: the value named 'tb neuraedge universal core' in this block.

Line 96: `"tb_neuraedge_descriptor_sequencer",` This batch-control line contributes to the flow that orchestrates the repeatable Windows run regression command-line flow. The important operands are tb_neuraedge_descriptor_sequencer: a DMA record header plus one command and its declared payload.

Line 97: `"tb_neuraedge_pynq_descriptor",` This batch-control line contributes to the flow that orchestrates the repeatable Windows run regression command-line flow. The important operands are tb_neuraedge_pynq_descriptor: a DMA record header plus one command and its declared payload.

Line 98: `"tb_neuraedge_pynq_axi_top"` This batch-control line contributes to the flow that orchestrates the repeatable Windows run regression command-line flow. The important operands are tb_neuraedge_pynq_axi_top: the value named 'tb neuraedge pynq axi top' in this block.

Line 99: `)` This batch-control line contributes to the flow that orchestrates the repeatable Windows run regression command-line flow. The expression is a literal or structural operator and has no hidden software state.

Line 101: `Push-Location $ProjectRoot` This batch-control line contributes to the flow that orchestrates the repeatable Windows run regression command-line flow. The important operands are Push: the value named 'push' in this block; Location: the value named 'location' in this block; ProjectRoot: the value named 'project root' in this block.

Line 102: `try {` This batch-control line contributes to the flow that orchestrates the repeatable Windows run regression command-line flow. The important operands are try: the value named 'try' in this block.

Line 103: `$env:PYTHONPATH = (Join-Path $ProjectRoot "software")` This locates or invokes a required tool as part of the script that orchestrates the repeatable Windows run regression command-line flow; the exact command and arguments remain visible here for reproducibility.

Line 104: `& $PythonExe (Join-Path $ProjectRoot "software\generate_tensor_tile_fixture.py") ‘` This locates or invokes a required tool as part of the script that orchestrates the repeatable Windows run regression command-line flow; the exact command and arguments remain visible here for reproducibility.

Line 105: `-output-dir (Join-Path $ProjectRoot "tb\fixtures") 2>&1 |` This batch-control line contributes to the flow that orchestrates the repeatable Windows run regression command-line flow. The important operands are output: the value named 'output' in this block; dir: the value named 'dir' in this block; Join: the value named 'join' in this block.

Line 106: `Tee-Object -FilePath (Join-Path $OutputRoot "tensor_fixture_generation.log")` This batch-control line contributes to the flow that orchestrates the repeatable Windows run regression command-line flow. The important operands are Tee: the value named 'tee' in this block; Object: the value named 'object' in this block; FilePath: the value named 'file path' in this block.

Line 107: `if ($LASTEXITCODE -ne 0) {` This checks the external program's process exit code and turns a failed compiler, simulator, or Vivado run into a failed pipeline.

Line 108: `throw "Tensor fixture generation failed with exit code $LASTEXITCODE"` This checks the external program's process exit code and turns a failed compiler, simulator, or Vivado run into a failed pipeline.

Line 109: `}` This batch-control line contributes to the flow that orchestrates the repeatable Windows run regression command-line flow. The expression is a literal or structural operator and has no hidden software state.

Line 110: `& $PythonExe (Join-Path $ProjectRoot "software\generate_operator_fixtures.py") ‘` This locates or invokes a required tool as part of the script that orchestrates the repeatable Windows run regression command-line flow; the exact command and arguments remain visible here for reproducibility.

Line 111: `-output-dir (Join-Path $ProjectRoot "tb\fixtures") 2>&1 |` This batch-control line contributes to the flow that orchestrates the repeatable Windows run regression command-line flow. The important operands are output: the value named 'output' in this block; dir: the value named 'dir' in this block; Join: the value named 'join' in this block.

Line 112: `Tee-Object -FilePath (Join-Path $OutputRoot "operator_fixture_generation.log")` This batch-control line contributes to the flow that orchestrates the repeatable Windows run regression command-line flow. The important operands are Tee: the value named 'tee' in this block; Object: the value named 'object' in this block; FilePath: the value named 'file path' in this block.

Line 113: `if ($LASTEXITCODE -ne 0) {` This checks the external program's process exit code and turns a failed compiler, simulator, or Vivado run into a failed pipeline.

Line 114: `throw "Operator fixture generation failed with exit code $LASTEXITCODE"` This checks the external program's process exit code and turns a failed compiler, simulator, or Vivado run into a failed pipeline.

Line 115: `}` This batch-control line contributes to the flow that orchestrates the repeatable Windows run regression command-line flow. The expression is a literal or structural operator and has no hidden software state.

Line 117: `& (Join-Path $PSScriptRoot "run_verilator_lint.ps1") -MsysRoot $MsysRoot 2>&1 |` This locates or invokes a required tool as part of the script that orchestrates the repeatable Windows run regression command-line flow; the exact command and arguments remain visible here for reproducibility.

Line 118: `Tee-Object -FilePath (Join-Path $OutputRoot "verilator_driver.log")` This locates or invokes a required tool as part of the script that orchestrates the repeatable Windows run regression command-line flow; the exact command and arguments remain visible here for reproducibility.

Line 119: `if ($LASTEXITCODE -ne 0) {` This checks the external program's process exit code and turns a failed compiler, simulator, or Vivado run into a failed pipeline.

Line 120: `throw "Verilator lint failed with exit code $LASTEXITCODE"` This checks the external program's process exit code and turns a failed compiler, simulator, or Vivado run into a failed pipeline.

Line 121: `}` This batch-control line contributes to the flow that orchestrates the repeatable Windows run regression command-line flow. The expression is a literal or structural operator and has no hidden software state.

Line 123: `& $PythonExe -m unittest discover -s tests -v 2>&1 |` This locates or invokes a required tool as part of the script that orchestrates the repeatable Windows run regression command-line flow; the exact command and arguments remain visible here for reproducibility.

Line 124: `Tee-Object -FilePath (Join-Path $OutputRoot "python_unittest.log")` This locates or invokes a required tool as part of the script that orchestrates the repeatable Windows run regression command-line flow; the exact command and arguments remain visible here for reproducibility.

Line 125: `if ($LASTEXITCODE -ne 0) {` This checks the external program's process exit code and turns a failed compiler, simulator, or Vivado run into a failed pipeline.

Line 126: `throw "Python regression failed with exit code $LASTEXITCODE"` This checks the external program's process exit code and turns a failed compiler, simulator, or Vivado run into a failed pipeline.

Line 127: `}` This batch-control line contributes to the flow that orchestrates the repeatable Windows run regression command-line flow. The expression is a literal or structural operator and has no hidden software state.

Line 129: `foreach ($Top in $Testbenches) {` This batch-control line contributes to the flow that orchestrates the repeatable Windows run regression command-line flow. The important operands are foreach: the value named 'foreach' in this block; Top: the value named 'top' in this block; in: the value named 'in' in this block.

Line 130: `$TestbenchFile = Join-Path $ProjectRoot "tb\$Top.sv"` This batch-control line contributes to the flow that orchestrates the repeatable Windows run regression command-line flow. The important operands are TestbenchFile: the value named 'testbench file' in this block; Join: the value named 'join' in this block; Path: the value named 'path' in this block.

Line 131: `$Executable = Join-Path $OutputRoot "$Top.vvp"` This batch-control line contributes to the flow that orchestrates the repeatable Windows run regression command-line flow. The important operands are Executable: the value named 'executable' in this block; Join: the value named 'join' in this block; Path: the value named 'path' in this block.

Line 132: `$CompileLog = Join-Path $OutputRoot "$Top.compile.log"` This batch-control line contributes to the flow that orchestrates the repeatable Windows run regression command-line flow. The important operands are CompileLog: the value named 'compile log' in this block; Join: the value named 'join' in this block; Path: the value named 'path' in this block.

Line 133: `$RunLog = Join-Path $OutputRoot "$Top.run.log"` This batch-control line contributes to the flow that orchestrates the repeatable Windows run regression command-line flow. The important operands are RunLog: the value named 'run log' in this block; Join: the value named 'join' in this block; Path: the value named 'path' in this block.

Line 135: `& $Iverilog -g2012 -I $ProjectRoot -s $Top -o $Executable @RtlFiles $TestbenchFile 2>&1 |` This locates or invokes a required tool as part of the script that orchestrates the repeatable Windows run regression command-line flow; the exact command and arguments remain visible here for reproducibility.

Line 136: `Tee-Object -FilePath $CompileLog` This batch-control line contributes to the flow that orchestrates the repeatable Windows run regression command-line flow. The important operands are Tee: the value named 'tee' in this block; Object: the value named 'object' in this block; FilePath: the value named 'file path' in this block.

Line 137: `if ($LASTEXITCODE -ne 0) {` This checks the external program's process exit code and turns a failed compiler, simulator, or Vivado run into a failed pipeline.

Line 138: `throw "$Top compilation failed with exit code $LASTEXITCODE"` This checks the external program's process exit code and turns a failed compiler, simulator, or Vivado run into a failed pipeline.

Line 139: `}` This batch-control line contributes to the flow that orchestrates the repeatable Windows run regression command-line flow. The expression is a literal or structural operator and has no hidden software state.

Line 141: `& $Vvp $Executable 2>&1 | Tee-Object -FilePath $RunLog` This batch-control line contributes to the flow that orchestrates the repeatable Windows run regression command-line flow. The important operands are Vvp: the value named 'vvp' in this block; Executable: the value named 'executable' in this block; Tee: the value named 'tee' in this block.

Line 142: `if ($LASTEXITCODE -ne 0) {` This checks the external program's process exit code and turns a failed compiler, simulator, or Vivado run into a failed pipeline.

Line 143: `throw "$Top simulation failed with exit code $LASTEXITCODE"` This checks the external program's process exit code and turns a failed compiler, simulator, or Vivado run into a failed pipeline.

Line 144: `}` This batch-control line contributes to the flow that orchestrates the repeatable Windows run regression command-line flow. The expression is a literal or structural operator and has no hidden software state.

Line 145: `$RunText = Get-Content -LiteralPath $RunLog -Raw` This batch-control line contributes to the flow that orchestrates the repeatable Windows run regression command-line flow. The important operands are RunText: the value named 'run text' in this block; Get: the value named 'get' in this block; Content: the value named 'content' in this block.

Line 146: `$PassPattern = "(?m)^$([regex]::Escape($Top)) PASSED\b"` This batch-control line contributes to the flow that orchestrates the repeatable Windows run regression command-line flow. The important operands are PassPattern: the value named 'pass pattern' in this block; m: the value named 'm' in this block; regex: the value named 'regex' in this block.

Line 147: `if ($RunText -notmatch $PassPattern) {` This batch-control line contributes to the flow that orchestrates the repeatable Windows run regression command-line flow. The important operands are RunText: the value named 'run text' in this block; notmatch: the value named 'notmatch' in this block; PassPattern: the value named 'pass pattern' in this block.

Line 148: `throw "$Top simulation did not emit its required PASSED marker"` This batch-control line contributes to the flow that orchestrates the repeatable Windows run regression command-line flow. The important operands are throw: one output-row position processed by the tensor tile; Top: the value named 'top' in this block; simulation: the value named 'simulation' in this block.

Line 149: `}` This batch-control line contributes to the flow that orchestrates the repeatable Windows run regression command-line flow. The expression is a literal or structural operator and has no hidden software state.

Line 150: `if ($RunText -match "(?im)^\s*ERROR\b|^.*\bFAILED\b") {` This batch-control line contributes to the flow that orchestrates the repeatable Windows run regression command-line flow. The important operands are RunText: the value named 'run text' in this block; match: the value named 'match' in this block; im: the value named 'im' in this block.

Line 151: `throw "$Top simulation emitted an ERROR or FAILED marker"` This batch-control line contributes to the flow that orchestrates the repeatable Windows run regression command-line flow. The important operands are throw: one output-row position processed by the tensor tile; Top: the value named 'top' in this block; simulation: the value named 'simulation' in this block.

Line 152: `}` This batch-control line contributes to the flow that orchestrates the repeatable Windows run regression command-line flow. The expression is a literal or structural operator and has no hidden software state.

Line 153: `if (-not $KeepExecutables) {` This batch-control line contributes to the flow that orchestrates the repeatable Windows run regression command-line flow. The important operands are not: the value named 'not' in this block; KeepExecutables: the value named 'keep executables' in this block.

Line 154: `Remove-Item -LiteralPath $Executable -Force` This removes the explicitly named rebuildable artifact. The script uses a literal path so wildcard expansion cannot delete an unintended neighboring file.

Line 155: `}` This batch-control line contributes to the flow that orchestrates the repeatable Windows run regression command-line flow. The expression is a literal or structural operator and has no hidden software state.

Line 156: `}` This batch-control line contributes to the flow that orchestrates the repeatable Windows run regression command-line flow. The expression is a literal or structural operator and has no hidden software state.

Line 157: `} catch {` This batch-control line contributes to the flow that orchestrates the repeatable Windows run regression command-line flow. The important operands are catch: the value named 'catch' in this block.

Line 158: `@(` This batch-control line contributes to the flow that orchestrates the repeatable Windows run regression command-line flow. The expression is a literal or structural operator and has no hidden software state.

Line 159: `"result=FAIL",` This batch-control line contributes to the flow that orchestrates the repeatable Windows run regression command-line flow. The important operands are result: the value named 'result' in this block; FAIL: the value named 'fail' in this block.

Line 160: `"message=$($_.Exception.Message)",` This batch-control line contributes to the flow that orchestrates the repeatable Windows run regression command-line flow. The important operands are message: the value named 'message' in this block; _: the value named '' in this block; Exception: the value named 'exception' in this block.

Line 161: `"completed_utc=$([DateTime]::UtcNow.ToString('o'))"` This batch-control line contributes to the flow that orchestrates the repeatable Windows run regression command-line flow. The important operands are completed_utc: the value named 'completed utc' in this block; DateTime: the value named 'date time' in this block; UtcNow: the value named 'utc now' in this block.

Line 162: `) | Set-Content -LiteralPath $SummaryPath -Encoding ascii` This batch-control line contributes to the flow that orchestrates the repeatable Windows run regression command-line flow. The important operands are Set: the value named 'set' in this block; Content: the value named 'content' in this block; LiteralPath: the value named 'literal path' in this block.

Line 163: `throw` This batch-control line contributes to the flow that orchestrates the repeatable Windows run regression command-line flow. The important operands are throw: one output-row position processed by the tensor tile.

Line 164: `} finally {` This batch-control line contributes to the flow that orchestrates the repeatable Windows run regression command-line flow. The important operands are finally: the value named 'finally' in this block.

Line 165: `Pop-Location` This batch-control line contributes to the flow that orchestrates the repeatable Windows run regression command-line flow. The important operands are Pop: the value named 'pop' in this block; Location: the value named 'location' in this block.

Line 166: `}` This batch-control line contributes to the flow that orchestrates the repeatable Windows run regression command-line flow. The expression is a literal or structural operator and has no hidden software state.

Line 168: `@(` This batch-control line contributes to the flow that orchestrates the repeatable Windows run regression command-line flow. The expression is a literal or structural operator and has no hidden software state.

Line 169: `"result=PASS",` This batch-control line contributes to the flow that orchestrates the repeatable Windows run regression command-line flow. The important operands are result: the value named 'result' in this block; PASS: the value named 'pass' in this block.

Line 170: `"python_executable=$PythonExe",` This locates or invokes a required tool as part of the script that orchestrates the repeatable Windows run regression command-line flow; the exact command and arguments remain visible here for reproducibility.

Line 171: `"iverilog_executable=$Iverilog",` This locates or invokes a required tool as part of the script that orchestrates the repeatable Windows run regression command-line flow; the exact command and arguments remain visible here for reproducibility.

Line 172: `"verilator_environment=$MsysRoot",` This locates or invokes a required tool as part of the script that orchestrates the repeatable Windows run regression command-line flow; the exact command and arguments remain visible here for reproducibility.

Line 173: `"rtl_testbench_count=$($Testbenches.Count)",` This batch-control line contributes to the flow that orchestrates the repeatable Windows run regression command-line flow. The important operands are rtl_testbench_count: an integer count retained for control or measurable telemetry; Testbenches: the value named 'testbenches' in this block; Count: the value named 'count' in this block.

Line 174: `"completed_utc=$([DateTime]::UtcNow.ToString('o'))"` This batch-control line contributes to the flow that orchestrates the repeatable Windows run regression command-line flow. The important operands are completed_utc: the value named 'completed utc' in this block; DateTime: the value named 'date time' in this block; UtcNow: the value named 'utc now' in this block.

Line 175: `) | Set-Content -LiteralPath $SummaryPath -Encoding ascii` This batch-control line contributes to the flow that orchestrates the repeatable Windows run regression command-line flow. The important operands are Set: the value named 'set' in this block; Content: the value named 'content' in this block; LiteralPath: the value named 'literal path' in this block.

Line 176: `Write-Host "NEURAEDGE_REGRESSION_PASSED tests=$($Testbenches.Count) summary=$SummaryPath"` This batch-control line contributes to the flow that orchestrates the repeatable Windows run regression command-line flow. The important operands are Write: the value named 'write' in this block; Host: the value named 'host' in this block; NEURAEDGE_REGRESSION_PASSED: the value named 'neuraedge regression passed' in this block.

85 scripts/run_saif_power.ps1

Role in the complete system: orchestrates the repeatable Windows run saif power command-line flow.

85.1 Beginner architecture map

Dataflow responsibility This file's end-to-end responsibility is to orchestrates the repeatable Windows run saif power command-line flow.

Where it runs This is PowerShell orchestration, not accelerator datapath hardware. It makes tool inputs, versions, paths, stages, and failure propagation repeatable.

Reproducibility contract Every external command must be checked, every required artifact must exist and be nonempty, and measured values must be read from generated reports. Rerunning this file should either reproduce its declared outputs or stop at the first failed gate.

Line 1: `[CmdletBinding()]` This batch-control line contributes to the flow that orchestrates the repeatable Windows run saif power command-line flow. The important operands are CmdletBinding: the value named 'cmdlet binding' in

this block.

Line 2: `param(` This declares a typed command-line parameter so the flow can be rerun with explicit, validated paths and options.

Line 3: `[string]$VivadoRoot = "D:\AMDDesignTools\2026.1\Vivado",` This declares a typed command-line parameter so the flow can be rerun with explicit, validated paths and options.

Line 4: `[string]$Checkpoint = "",` This declares a typed command-line parameter so the flow can be rerun with explicit, validated paths and options.

Line 5: `[string]$OutputDirectory = "",` This declares a typed command-line parameter so the flow can be rerun with explicit, validated paths and options.

Line 6: `[string]$SaifDirectory = "",` This declares a typed command-line parameter so the flow can be rerun with explicit, validated paths and options.

Line 7: `[string]$AcceleratorInstance = "__ROOT__",` This declares a typed command-line parameter so the flow can be rerun with explicit, validated paths and options.

Line 8: `[switch]$ReuseSaif` This declares a typed command-line parameter so the flow can be rerun with explicit, validated paths and options.

Line 9: `)` This batch-control line contributes to the flow that orchestrates the repeatable Windows run saif power command-line flow. The expression is a literal or structural operator and has no hidden software state.

Line 11: `$ErrorActionPreference = "Stop"` This makes PowerShell stop on errors so a failed prerequisite cannot be hidden by later successful commands.

Line 12: `Set-StrictMode -Version Latest` This batch-control line contributes to the flow that orchestrates the repeatable Windows run saif power command-line flow. The important operands are Set: the value named 'set' in this block; StrictMode: the value named 'strict mode' in this block; Version: the value named 'version' in this block.

Line 13: `$ProjectRoot = (Resolve-Path (Join-Path $PSScriptRoot "..")).Path` This resolves a deterministic filesystem location for the flow that orchestrates the repeatable Windows run saif power command-line flow. Literal/full paths prevent a different working directory from silently selecting the wrong source, checkpoint, or output.

Line 14: `if ([string]::IsNullOrWhiteSpace($Checkpoint)) {` This batch-control line contributes to the flow that orchestrates the repeatable Windows run saif power command-line flow. The important operands are string: the value named 'string' in this block; IsNullOrWhiteSpace: the value named 'is null or white space' in this block; Checkpoint: the value named 'checkpoint' in this block.

Line 15: `$Checkpoint = Join-Path $ProjectRoot "outputs\pynq_ooc\neuraedge_pynq_axi_top_routed.dcp"` This batch-control line contributes to the flow that orchestrates the repeatable Windows run saif power command-line flow. The important operands are Checkpoint: the value named 'checkpoint' in this block; Join: the value named 'join' in this block; Path: the value named 'path' in this block.

Line 16: `}` This batch-control line contributes to the flow that orchestrates the repeatable Windows run saif power command-line flow. The expression is a literal or structural operator and has no hidden software state.

Line 17: `if ([string]::IsNullOrWhiteSpace($OutputDirectory)) {` This batch-control line contributes to the flow that orchestrates the repeatable Windows run saif power command-line flow. The important operands are string: the value named 'string' in this block; IsNullOrWhiteSpace: the value named 'is null or white space' in this block; OutputDirectory: the value named 'output directory' in this block.

Line 18: `$OutputDirectory = Join-Path $ProjectRoot "outputs\power_activity"` This batch-control line contributes to the flow that orchestrates the repeatable Windows run saif power command-line flow. The important operands are OutputDirectory: the value named 'output directory' in this block; Join: the value named 'join' in this block; Path: the value named 'path' in this block.

Line 19: `}` This batch-control line contributes to the flow that orchestrates the repeatable Windows run saif power command-line flow. The expression is a literal or structural operator and has no hidden software state.

Line 20: `$Checkpoint = [System.IO.Path]::GetFullPath($Checkpoint)` This resolves a deterministic filesystem location for the flow that orchestrates the repeatable Windows run saif power command-line flow. Literal/full paths prevent a different working directory from silently selecting the wrong source, checkpoint, or output.

Line 21: `$OutputDirectory = [System.IO.Path]::GetFullPath($OutputDirectory)` This resolves a deterministic filesystem location for the flow that orchestrates the repeatable Windows run saif power command-line flow. Literal/full paths prevent a different working directory from silently selecting the wrong source, checkpoint, or output.

Line 22: `if ([string]::IsNullOrWhiteSpace($SaifDirectory)) {` This batch-control line contributes to the flow that orchestrates the repeatable Windows run saif power command-line flow. The important operands are string: the value named 'string' in this block; IsNullOrWhiteSpace: the value named 'is null or white space' in this block; SaifDirectory: the value named 'saif directory' in this block.

Line 23: `$SaifDirectory = $OutputDirectory` This batch-control line contributes to the flow that orchestrates the repeatable Windows run saif power command-line flow. The important operands are SaifDirectory: the value named 'saif directory' in this block; OutputDirectory: the value named 'output directory' in this block.

Line 24: `}` This batch-control line contributes to the flow that orchestrates the repeatable Windows run saif power command-line flow. The expression is a literal or structural operator and has no hidden software state.

Line 25: `$SaifDirectory = [System.IO.Path]::GetFullPath($SaifDirectory)` This resolves a deterministic filesystem location for the flow that orchestrates the repeatable Windows run saif power command-line flow. Literal/full paths prevent a different working directory from silently selecting the wrong source, checkpoint, or output.

Line 27: `$Vivado = Join-Path $VivadoRoot "bin\vivado.bat"` This locates or invokes a required tool as part of the script that orchestrates the repeatable Windows run saif power command-line flow; the exact command and arguments remain visible here for reproducibility.

Line 28: `$Tcl = Join-Path $PSScriptRoot "annotate_saif_power.tcl"` This batch-control line contributes to the flow that orchestrates the repeatable Windows run saif power command-line flow. The important operands are Tcl: the value named 'tcl' in this block; Join: the value named 'join' in this block; Path: the value named 'path' in this block.

Line 29: `$WrapperSaif = Join-Path $SaifDirectory "saif\tb_neuraedge_pynq_axi_top.saif"` This batch-control line contributes to the flow that orchestrates the repeatable Windows run saif power command-line flow. The important operands are WrapperSaif: the value named 'wrapper saif' in this block; Join: the value named 'join' in this block; Path: the value named 'path' in this block.

Line 30: `$CoreSaif = Join-Path $SaifDirectory "saif\tb_neuraedge_universal_core.saif"` This batch-control line contributes to the flow that orchestrates the repeatable Windows run saif power command-line flow. The important operands are CoreSaif: the value named 'core saif' in this block; Join: the value named 'join' in this block; Path: the value named 'path' in this block.

Line 31: `if (-not $ReuseSaif) {` This batch-control line contributes to the flow that orchestrates the repeatable Windows run saif power command-line flow. The important operands are not: the value named 'not' in this block; ReuseSaif: the value named 'reuse saif' in this block.

Line 32: `& (Join-Path $PSScriptRoot "capture_power_activity.ps1") ‘` This batch-control line contributes to the flow that orchestrates the repeatable Windows run saif power command-line flow. The important operands are Join: the value named 'join' in this block; Path: the value named 'path' in this block; PSScriptRoot: the value named 'psscript root' in this block.

Line 33: `-VivadoRoot $VivadoRoot -OutputDirectory $SaifDirectory` This locates or invokes a required tool as part of the script that orchestrates the repeatable Windows run saif power command-line flow; the exact command and arguments remain visible here for reproducibility.

Line 34: `if ($LASTEXITCODE -ne 0) {` This checks the external program's process exit code and turns a failed compiler, simulator, or Vivado run into a failed pipeline.

Line 35: `throw "SAIF capture failed with exit code $LASTEXITCODE"` This checks the external program's process exit code and turns a failed compiler, simulator, or Vivado run into a failed pipeline.

Line 36: `}` This batch-control line contributes to the flow that orchestrates the repeatable Windows run saif power command-line flow. The expression is a literal or structural operator and has no hidden software state.

Line 37: `}` This batch-control line contributes to the flow that orchestrates the repeatable Windows run saif power command-line flow. The expression is a literal or structural operator and has no hidden software state.

Line 38: `foreach ($Saif in @($WrapperSaif, $CoreSaif)) {` This batch-control line contributes to the flow that orchestrates the repeatable Windows run saif power command-line flow. The important operands are foreach: the value named 'foreach' in this block; Saif: the value named 'saif' in this block; in: the value named 'in' in this block.

Line 39: `if (-not (Test-Path -LiteralPath $Saif -PathType Leaf)) {` This batch-control line contributes to the flow that orchestrates the repeatable Windows run saif power command-line flow. The important operands are not: the value named 'not' in this block; Test: the value named 'test' in this block; Path: the value named 'path' in this block.

Line 40: `throw "Required SAIF does not exist: $Saif"` This batch-control line contributes to the flow that orchestrates the repeatable Windows run saif power command-line flow. The important operands are throw: one output-row position processed by the tensor tile; Required: the value named 'required' in this block; SAIF: the value named 'saif' in this block.

Line 41: `}` This batch-control line contributes to the flow that orchestrates the repeatable Windows run saif power command-line flow. The expression is a literal or structural operator and has no hidden software state.

Line 42: `if ((Get-Item -LiteralPath $Saif).Length -eq 0) {` This batch-control line contributes to the flow that orchestrates the repeatable Windows run saif power command-line flow. The important operands are Get: the value named 'get' in this block; Item: the value named 'item' in this block; LiteralPath: the value named 'literal path' in this block.

Line 43: `throw "Required SAIF is empty: $Saif"` This batch-control line contributes to the flow that orchestrates the repeatable Windows run saif power command-line flow. The important operands are throw: one output-row position processed by the tensor tile; Required: the value named 'required' in this block; SAIF: the value named 'saif' in this block.

Line 44: `}` This batch-control line contributes to the flow that orchestrates the repeatable Windows run saif power command-line flow. The expression is a literal or structural operator and has no hidden software state.

Line 45: `}` This batch-control line contributes to the flow that orchestrates the repeatable Windows run saif power command-line flow. The expression is a literal or structural operator and has no hidden software state.

Line 46: `$ReportDirectory = Join-Path $OutputDirectory "vivado_reports"` This locates or invokes a required tool as part of the script that orchestrates the repeatable Windows run saif power command-line flow; the exact command and arguments remain visible here for reproducibility.

Line 47: `& $Vivado -mode batch -nojournal -nolog -source $Tcl -tclargs ‘` This locates or invokes a required tool as part of the script that orchestrates the repeatable Windows run saif power command-line flow; the exact command and arguments remain visible here for reproducibility.

Line 48: `$Checkpoint $WrapperSaif $CoreSaif $ReportDirectory $AcceleratorInstance` This batch-control line contributes to the flow that orchestrates the repeatable Windows run saif power command-line flow. The important operands are Checkpoint: the value named 'checkpoint' in this block; WrapperSaif: the value named 'wrapper saif' in this block; CoreSaif: the value named 'core saif' in this block.

Line 49: `if ($LASTEXITCODE -ne 0) {` This checks the external program's process exit code and turns a failed compiler, simulator, or Vivado run into a failed pipeline.

Line 50: `throw "Vivado SAIF power analysis failed with exit code $LASTEXITCODE"` This checks the external program's process exit code and turns a failed compiler, simulator, or Vivado run into a failed pipeline.

Line 51: `}` This batch-control line contributes to the flow that orchestrates the repeatable Windows run saif power command-line flow. The expression is a literal or structural operator and has no hidden software state.

Line 52: `Write-Output "NEURAEDGE_SAIF_POWER_COMPLETE report=$ReportDirectory\routed_saif_power.rpt"` This batch-control line contributes to the flow that orchestrates the repeatable Windows run saif power command-line flow. The important operands are Write: the value named 'write' in this block; Output: the value named 'output' in this block; NEURAEDGE_SAIF_POWER_COMPLETE: the value named 'neuraedge saif power complete' in this block.

86 scripts/run_verilator_lint.ps1

Role in the complete system: orchestrates the repeatable Windows run verilator lint command-line flow.

86.1 Beginner architecture map

Dataflow responsibility This file's end-to-end responsibility is to orchestrates the repeatable Windows run verilator lint command-line flow.

Where it runs This is PowerShell orchestration, not accelerator datapath hardware. It makes tool inputs, versions, paths, stages, and failure propagation repeatable.

Reproducibility contract Every external command must be checked, every required artifact must exist and be nonempty, and measured values must be read from generated reports. Rerunning this file should either reproduce its declared outputs or stop at the first failed gate.

86.2 Complete source

```
param(
    [string]$MsysRoot = "C:\msys64"
)

$ErrorActionPreference = "Stop"
Set-StrictMode -Version Latest

$ProjectRoot = (Resolve-Path (Join-Path $PSScriptRoot "..")).Path
$MsysShell = Join-Path $MsysRoot "msys2_shell.cmd"
if (-not (Test-Path -LiteralPath $MsysShell)) {
    throw "MSYS2 shell was not found at $MsysShell"
}

Push-Location $ProjectRoot
try {
    & $MsysShell -defterm -no-start -ucrt64 -here -c "bash scripts/run_verilator_lint.sh"
    if ($LASTEXITCODE -ne 0) {
        throw "Verilator lint failed with exit code $LASTEXITCODE"
    }
} finally {
    Pop-Location
}

Write-Host "NEURAEDGE_VERILATOR_LINT_PASSED"
```

86.3 Line annotations

Line 1: `param(` This declares a typed command-line parameter so the flow can be rerun with explicit, validated paths and options.

Line 2: `[string]$MsysRoot = "C:\msys64"` This declares a typed command-line parameter so the flow can be rerun with explicit, validated paths and options.

Line 3: `)` This batch-control line contributes to the flow that orchestrates the repeatable Windows run verilator lint command-line flow. The expression is a literal or structural operator and has no hidden software state.

Line 5: `$ErrorActionPreference = "Stop"` This makes PowerShell stop on errors so a failed prerequisite cannot be hidden by later successful commands.

Line 5: `[switch]$Resume,` This declares a typed command-line parameter so the flow can be rerun with explicit, validated paths and options.

Line 6: `[ValidateSet("Explore", "AggressiveExplore", "Default")]` This batch-control line contributes to the flow that orchestrates the repeatable Windows run vivado build command-line flow. The important operands are ValidateSet: the producer's statement that its current payload is meaningful; Explore: the value named 'explore' in this block; AggressiveExplore: the value named 'aggressive explore' in this block.

Line 7: `[string]$ResumeDirective = "Explore"` This declares a typed command-line parameter so the flow can be rerun with explicit, validated paths and options.

Line 8: `)` This batch-control line contributes to the flow that orchestrates the repeatable Windows run vivado build command-line flow. The expression is a literal or structural operator and has no hidden software state.

Line 10: `$ErrorActionPreference = "Stop"` This makes PowerShell stop on errors so a failed prerequisite cannot be hidden by later successful commands.

Line 11: `$ProjectRoot = Split-Path -Parent $PSScriptRoot` This resolves a deterministic filesystem location for the flow that orchestrates the repeatable Windows run vivado build command-line flow. Literal/full paths prevent a different working directory from silently selecting the wrong source, checkpoint, or output.

Line 12: `$Vivado = Join-Path $VivadoRoot "bin\vivado.bat"` This locates or invokes a required tool as part of the script that orchestrates the repeatable Windows run vivado build command-line flow; the exact command and arguments remain visible here for reproducibility.

Line 13: `$Tcl = Join-Path $PSScriptRoot "build_pynq_ooc.tcl"` This batch-control line contributes to the flow that orchestrates the repeatable Windows run vivado build command-line flow. The important operands are Tcl: the value named 'tcl' in this block; Join: the value named 'join' in this block; Path: the value named 'path' in this block.

Line 14: `$ResumeTcl = Join-Path $PSScriptRoot "resume_pynq_ooc.tcl"` This batch-control line contributes to the flow that orchestrates the repeatable Windows run vivado build command-line flow. The important operands are ResumeTcl: the value named 'resume tcl' in this block; Join: the value named 'join' in this block; Path: the value named 'path' in this block.

Line 15: `$OutputRoot = Join-Path $ProjectRoot "outputs\pynq_ooc"` This batch-control line contributes to the flow that orchestrates the repeatable Windows run vivado build command-line flow. The important operands are OutputRoot: the value named 'output root' in this block; Join: the value named 'join' in this block; Path: the value named 'path' in this block.

Line 16: `$ResumeCheckpoint = Join-Path $OutputRoot "pre_postroute_physopt.dcp"` This batch-control line contributes to the flow that orchestrates the repeatable Windows run vivado build command-line flow. The important operands are ResumeCheckpoint: the value named 'resume checkpoint' in this block; Join: the value named 'join' in this block; Path: the value named 'path' in this block.

Line 18: `if (-not (Test-Path -LiteralPath $Vivado)) {` This locates or invokes a required tool as part of the script that orchestrates the repeatable Windows run vivado build command-line flow; the exact command and arguments remain visible here for reproducibility.

Line 19: `throw "Vivado was not found at $Vivado"` This locates or invokes a required tool as part of the script that orchestrates the repeatable Windows run vivado build command-line flow; the exact command and arguments remain visible here for reproducibility.

Line 20: `}` This batch-control line contributes to the flow that orchestrates the repeatable Windows run vivado build command-line flow. The expression is a literal or structural operator and has no hidden software state.

Line 22: `if ($CleanLogs) {` This batch-control line contributes to the flow that orchestrates the repeatable Windows run vivado build command-line flow. The important operands are CleanLogs: the value named 'clean logs' in this block.

Line 23: `foreach ($Name in @("vivado.jou", "vivado.log")) {` This locates or invokes a required tool as part of the script that orchestrates the repeatable Windows run vivado build command-line flow; the exact command and arguments remain visible here for reproducibility.

Line 24: `$Path = Join-Path $ProjectRoot $Name` This batch-control line contributes to the flow that orchestrates the repeatable Windows run vivado build command-line flow. The important operands are Path: the value named 'path' in this block; Join: the value named 'join' in this block; ProjectRoot: the value named 'project root' in this block.

Line 25: `if (Test-Path -LiteralPath $Path) {` This batch-control line contributes to the flow that orchestrates the repeatable Windows run vivado build command-line flow. The important operands are Test: the value named 'test' in this block; Path: the value named 'path' in this block; LiteralPath: the value named 'literal path' in this block.

Line 26: `Remove-Item -LiteralPath $Path -Force` This removes the explicitly named rebuildable artifact. The script uses a literal path so wildcard expansion cannot delete an unintended neighboring file.

Line 27: `}` This batch-control line contributes to the flow that orchestrates the repeatable Windows run vivado build command-line flow. The expression is a literal or structural operator and has no hidden software state.

Line 28: `}` This batch-control line contributes to the flow that orchestrates the repeatable Windows run vivado build command-line flow. The expression is a literal or structural operator and has no hidden software state.

Line 29: `if (-not $Resume) {` This batch-control line contributes to the flow that orchestrates the repeatable Windows run vivado build command-line flow. The important operands are not: the value named 'not' in this block; Resume: the value named 'resume' in this block.

Line 30: `foreach ($Name in @(` This batch-control line contributes to the flow that orchestrates the repeatable Windows run vivado build command-line flow. The important operands are foreach: the value named 'foreach' in this block; Name: the value named 'name' in this block; in: the value named 'in' in this block.

Line 31: `"pre_postroute_physopt.dcp",` This batch-control line contributes to the flow that orchestrates the repeatable Windows run vivado build command-line flow. The important operands are pre_postroute_physopt: the value named 'pre postroute physopt' in this block; dcp: the value named 'dcp' in this block.

Line 32: `"postroute_physopt_unrouted.dcp",` This batch-control line contributes to the flow that orchestrates the repeatable Windows run vivado build command-line flow. The important operands are postroute_physopt_unrouted: the value named 'postroute physopt unrouted' in this block; dcp: the value named 'dcp' in this block.

Line 33: `"implementation_summary.txt"` This batch-control line contributes to the flow that orchestrates the repeatable Windows run vivado build command-line flow. The important operands are implementation_summary: the value named 'implementation summary' in this block; txt: the value named 'txt' in this block.

Line 34: `)) {` This batch-control line contributes to the flow that orchestrates the repeatable Windows run vivado build command-line flow. The expression is a literal or structural operator and has no hidden software state.

Line 35: `$Path = Join-Path $OutputRoot $Name` This batch-control line contributes to the flow that orchestrates the repeatable Windows run vivado build command-line flow. The important operands are Path: the value named 'path' in this block; Join: the value named 'join' in this block; OutputRoot: the value named 'output root' in this block.

Line 36: `if (Test-Path -LiteralPath $Path) {` This batch-control line contributes to the flow that orchestrates the repeatable Windows run vivado build command-line flow. The important operands are Test: the value named 'test' in this block; Path: the value named 'path' in this block; LiteralPath: the value named 'literal path' in this block.

Line 37: `Remove-Item -LiteralPath $Path -Force` This removes the explicitly named rebuildable artifact. The script uses a literal path so wildcard expansion cannot delete an unintended neighboring file.

Line 38: `}` This batch-control line contributes to the flow that orchestrates the repeatable Windows run vivado build command-line flow. The expression is a literal or structural operator and has no hidden software state.

Line 39: `}` This batch-control line contributes to the flow that orchestrates the repeatable Windows run vivado build command-line flow. The expression is a literal or structural operator and has no hidden software state.

Line 40: `}` This batch-control line contributes to the flow that orchestrates the repeatable Windows run vivado build command-line flow. The expression is a literal or structural operator and has no hidden software state.

Line 41: `}` This batch-control line contributes to the flow that orchestrates the repeatable Windows run vivado build command-line flow. The expression is a literal or structural operator and has no hidden software state.

Line 43: `Push-Location $ProjectRoot` This batch-control line contributes to the flow that orchestrates the repeatable Windows run vivado build command-line flow. The important operands are Push: the value named 'push' in this block; Location: the value named 'location' in this block; ProjectRoot: the value named 'project root' in this block.

Line 44: `try {` This batch-control line contributes to the flow that orchestrates the repeatable Windows run vivado build command-line flow. The important operands are try: the value named 'try' in this block.

Line 45: `if ($Resume) {` This batch-control line contributes to the flow that orchestrates the repeatable Windows run vivado build command-line flow. The important operands are Resume: the value named 'resume' in this block.

Line 46: `if (-not (Test-Path -LiteralPath $ResumeCheckpoint)) {` This batch-control line contributes to the flow that orchestrates the repeatable Windows run vivado build command-line flow. The important operands are not: the value named 'not' in this block; Test: the value named 'test' in this block; Path: the value named 'path' in this block.

Line 47: `throw "No routed resume checkpoint was found at $ResumeCheckpoint"` This batch-control line contributes to the flow that orchestrates the repeatable Windows run vivado build command-line flow. The important operands are throw: one output-row position processed by the tensor tile; No: the value named 'no' in this block; routed: the value named 'routed' in this block.

Line 48: `}` This batch-control line contributes to the flow that orchestrates the repeatable Windows run vivado build command-line flow. The expression is a literal or structural operator and has no hidden software state.

Line 49: `& $Vivado -mode batch -nojournal -nolog -source $ResumeTcl ‘` This locates or invokes a required tool as part of the script that orchestrates the repeatable Windows run vivado build command-line flow; the exact command and arguments remain visible here for reproducibility.

Line 50: `-tclargs pynq_ooc $ResumeDirective` This batch-control line contributes to the flow that orchestrates the repeatable Windows run vivado build command-line flow. The important operands are tclargs: the value named 'tclargs' in this block; pynq_ooc: the value named 'pynq ooc' in this block; ResumeDirective: the value named 'resume directive' in this block.

Line 51: `if ($LASTEXITCODE -ne 0) {` This checks the external program's process exit code and turns a failed compiler, simulator, or Vivado run into a failed pipeline.

Line 52: `throw "Vivado resume failed with exit code $LASTEXITCODE"` This checks the external program's process exit code and turns a failed compiler, simulator, or Vivado run into a failed pipeline.

Line 53: `}` This batch-control line contributes to the flow that orchestrates the repeatable Windows run vivado build command-line flow. The expression is a literal or structural operator and has no hidden software state.

Line 54: `} else {` This batch-control line contributes to the flow that orchestrates the repeatable Windows run vivado build command-line flow. The expression is a literal or structural operator and has no hidden software state.

Line 55: `& $Vivado -mode batch -nojournal -nolog -source $Tcl` This locates or invokes a required tool as part of the script that orchestrates the repeatable Windows run vivado build command-line flow; the exact command and arguments remain visible here for reproducibility.

Line 56: `$BuildExitCode = $LASTEXITCODE` This checks the external program's process exit code and turns a failed compiler, simulator, or Vivado run into a failed pipeline.

Line 57: `if ($BuildExitCode -ne 0 -and (Test-Path -LiteralPath $ResumeCheckpoint)) {` This batch-control line contributes to the flow that orchestrates the repeatable Windows run vivado build command-line flow. The important operands are BuildExitCode: the value named 'build exit code' in this block; ne: the value named 'ne' in this block; and: the value named 'and' in this block.

Line 58: `Write-Host "Primary Vivado flow exited with $BuildExitCode; resuming the saved route with $ResumeDir` This locates or invokes a required tool as part of the script that orchestrates the repeatable Windows run vivado build command-line flow; the exact command and arguments remain visible here for reproducibility.

Line 59: `& $Vivado -mode batch -nojournal -nolog -source $ResumeTcl ‘` This locates or invokes a required tool as part of the script that orchestrates the repeatable Windows run vivado build command-line flow; the exact command and arguments remain visible here for reproducibility.

Line 60: `-tclargs pynq_ooc $ResumeDirective` This batch-control line contributes to the flow that orchestrates the repeatable Windows run vivado build command-line flow. The important operands are tclargs: the value named 'tclargs' in this block; pynq_ooc: the value named 'pynq ooc' in this block; ResumeDirective: the value named 'resume directive' in this block.

Line 61: `if ($LASTEXITCODE -ne 0) {` This checks the external program's process exit code and turns a failed compiler, simulator, or Vivado run into a failed pipeline.

Line 62: `throw "Vivado implementation and routed-checkpoint resume both failed; primary=$BuildExitCode resume=$LASTE...` This checks the external program's process exit code and turns a failed compiler, simulator, or Vivado run into a failed pipeline.

Line 63: `}` This batch-control line contributes to the flow that orchestrates the repeatable Windows run vivado build command-line flow. The expression is a literal or structural operator and has no hidden software state.

Line 64: `} elseif ($BuildExitCode -ne 0) {` This batch-control line contributes to the flow that orchestrates the repeatable Windows run vivado build command-line flow. The important operands are elseif: the value named 'elseif' in this block; BuildExitCode: the value named 'build exit code' in this block; ne: the value named 'ne' in this block.

Line 65: `throw "Vivado implementation failed with exit code $BuildExitCode before a routed checkpoint was available"` This locates or invokes a required tool as part of the script that orchestrates the repeatable Windows run vivado build command-line flow; the exact command and arguments remain visible here for reproducibility.

Line 66: `}` This batch-control line contributes to the flow that orchestrates the repeatable Windows run vivado build command-line flow. The expression is a literal or structural operator and has no hidden software state.

Line 67: `}` This batch-control line contributes to the flow that orchestrates the repeatable Windows run vivado build command-line flow. The expression is a literal or structural operator and has no hidden software state.

Line 68: `} finally {` This batch-control line contributes to the flow that orchestrates the repeatable Windows run vivado build command-line flow. The important operands are finally: the value named 'finally' in this block.

Line 69: `Pop-Location` This batch-control line contributes to the flow that orchestrates the repeatable Windows run vivado build command-line flow. The important operands are Pop: the value named 'pop' in this block; Location: the value named 'location' in this block.

Line 70: `}` This batch-control line contributes to the flow that orchestrates the repeatable Windows run vivado build command-line flow. The expression is a literal or structural operator and has no hidden software state.

Line 72: `Get-Content -LiteralPath (Join-Path $ProjectRoot "outputs\pynq_ooc\implementation_summary.txt")` This batch-control line contributes to the flow that orchestrates the repeatable Windows run vivado build command-line flow. The important operands are Get: the value named 'get' in this block; Content: the value named 'content' in this block; LiteralPath: the value named 'literal path' in this block.

88 scripts/analyze_routed_timing.tcl

Role in the complete system: runs the reproducible Vivado analyze routed timing hardware flow.

88.1 Beginner architecture map

Dataflow responsibility This file's end-to-end responsibility is to runs the reproducible Vivado analyze routed timing hardware flow.

Where it runs This is Vivado Tcl orchestration, not accelerator datapath hardware. It makes tool inputs, versions, paths, stages, and failure propagation repeatable.

Reproducibility contract Every external command must be checked, every required artifact must exist and be nonempty, and measured values must be read from generated reports. Rerunning this file should either reproduce its declared outputs or stop at the first failed gate.

88.2 Complete source

```
set script_dir [file dirname [file normalize [info script]]]
set project_dir [file dirname $script_dir]
set output_dir [file join $project_dir "outputs" "pynq_ooc"]

open_checkpoint [file join $output_dir "neuraedge_pynq_axi_top_routed.dcp"]
report_timing -delay_type max -max_paths 250 -nworst 1 -input_pins \
    -file [file join $output_dir "routed_timing_paths_250.rpt"]
report_methodology -file [file join $output_dir "routed_methodology.rpt"]
close_design
```

88.3 Line annotations

Line 1: `set script_dir [file dirname [file normalize [info script]]]` This batch-control line contributes to the flow that runs the reproducible Vivado analyze routed timing hardware flow. The important operands are set: the value named 'set' in this block; script_dir: the value named 'script dir' in this block; file: the value named 'file' in this block.

Line 2: `set project_dir [file dirname $script_dir]` This batch-control line contributes to the flow that runs the reproducible Vivado analyze routed timing hardware flow. The important operands are set: the value named 'set' in this block; project_dir: the value named 'project dir' in this block; file: the value named 'file' in this block.

Line 3: `set output_dir [file join $project_dir "outputs" "pynq_ooc"]` This batch-control line contributes to the flow that runs the reproducible Vivado analyze routed timing hardware flow. The important operands are set: the value named 'set' in this block; output_dir: the value named 'output dir' in this block; file: the value named 'file' in this block.

Line 5: `open_checkpoint [file join $output_dir "neuraedge_pynq_axi_top_routed.dcp"]` This batch-control line contributes to the flow that runs the reproducible Vivado analyze routed timing hardware flow. The important operands are open_checkpoint: the value named 'open checkpoint' in this block; file: the value named 'file' in this block; join: the value named 'join' in this block.

Line 6: `report_timing -delay_type max -max_paths 250 -nworst 1 -input_pins \` This writes an auditable Vivado artifact using 'report_timing -delay_type max -max_paths 250 -nworst 1 -input_pins \'; later documentation reads the resulting report rather than inventing a metric.

Line 7: `-file [file join $output_dir "routed_timing_paths_250.rpt"]` This batch-control line contributes to the flow that runs the reproducible Vivado analyze routed timing hardware flow. The important operands are file: the value named 'file' in this block; join: the value named 'join' in this block; output_dir: the value named 'output dir' in this block.

Line 8: `report_methodology -file [file join $output_dir "routed_methodology.rpt"]` This writes an auditable Vivado artifact using ‘report_methodology -file [file join $output_dir "routed_methodology.rpt"]‘; later documentation reads the resulting report rather than inventing a metric.

Line 9: `close_design` This batch-control line contributes to the flow that runs the reproducible Vivado analyze routed timing hardware flow. The important operands are close_design: the value named ’close design’ in this block.

89 scripts/annotate_saif_power.tcl

Role in the complete system: runs the reproducible Vivado annotate saif power hardware flow.

89.1 Beginner architecture map

89.3 Line annotations

Line 1: `if {$argc != 5} {` This batch-control line contributes to the flow that runs the reproducible Vivado annotate saif power hardware flow. The important operands are argc: the value named 'argc' in this block.

Line 2: `error "Usage: annotate_saif_power.tcl <routed.dcp> <wrapper.saif> <core.saif> <output_dir> <accelerat` This batch-control line contributes to the flow that runs the reproducible Vivado annotate saif power hardware flow. The important operands are error: the value named 'error' in this block; Usage: the value named 'usage' in this block; annotate_saif_power: the value named 'annotate saif power' in this block.

Line 3: `}` This batch-control line contributes to the flow that runs the reproducible Vivado annotate saif power hardware flow. The expression is a literal or structural operator and has no hidden software state.

Line 4: `set checkpoint [file normalize [lindex $argv 0]]` This batch-control line contributes to the flow that runs the reproducible Vivado annotate saif power hardware flow. The important operands are set: the value named 'set' in this block; checkpoint: the value named 'checkpoint' in this block; file: the value named 'file' in this block.

Line 5: `set wrapper_saif [file normalize [lindex $argv 1]]` This batch-control line contributes to the flow that runs the reproducible Vivado annotate saif power hardware flow. The important operands are set: the value named 'set' in this block; wrapper_saif: the value named 'wrapper saif' in this block; file: the value named 'file' in this block.

Line 6: `set core_saif [file normalize [lindex $argv 2]]` This batch-control line contributes to the flow that runs the reproducible Vivado annotate saif power hardware flow. The important operands are set: the value named 'set' in this block; core_saif: the value named 'core saif' in this block; file: the value named 'file' in this block.

Line 7: `set output_dir [file normalize [lindex $argv 3]]` This batch-control line contributes to the flow that runs the reproducible Vivado annotate saif power hardware flow. The important operands are set: the value named 'set' in this block; output_dir: the value named 'output dir' in this block; file: the value named 'file' in this block.

Line 8: `set accelerator_instance [lindex $argv 4]` This batch-control line contributes to the flow that runs the reproducible Vivado annotate saif power hardware flow. The important operands are set: the value named 'set' in this block; accelerator_instance: the value named 'accelerator instance' in this block; lindex: an integer selecting one tensor element, lane, bank, or state entry.

Line 9: `file mkdir $output_dir` This batch-control line contributes to the flow that runs the reproducible Vivado annotate saif power hardware flow. The important operands are file: the value named 'file' in this block; mkdir: the value named 'mkdir' in this block; output_dir: the value named 'output dir' in this block.

Line 10: `foreach required_file [list $checkpoint $wrapper_saif $core_saif] {` This batch-control line contributes to the flow that runs the reproducible Vivado annotate saif power hardware flow. The important operands are foreach: the value named 'foreach' in this block; required_file: the value named 'required file' in this block; list: the value named 'list' in this block.

Line 11: `if {![file exists $required_file]} {` This batch-control line contributes to the flow that runs the reproducible Vivado annotate saif power hardware flow. The important operands are file: the value named 'file' in this block; exists: the value named 'exists' in this block; required_file: the value named 'required file' in this block.

Line 12: `error "Required power-analysis input does not exist: $required_file"` This batch-control line contributes to the flow that runs the reproducible Vivado annotate saif power hardware flow. The important operands are error: the value named 'error' in this block; Required: the value named 'required' in this block; power: the value named 'power' in this block.

Line 13: `}` This batch-control line contributes to the flow that runs the reproducible Vivado annotate saif power hardware flow. The expression is a literal or structural operator and has no hidden software state.

Line 14: `}` This batch-control line contributes to the flow that runs the reproducible Vivado annotate saif power hardware flow. The expression is a literal or structural operator and has no hidden software state.

Line 16: `proc relocate_saif {source_path destination_path target_path} {` This batch-control line contributes to the flow that runs the reproducible Vivado annotate saif power hardware flow. The important operands are proc: the value named 'proc' in this block; relocate_saif: the value named 'relocate saif' in this block; source_path: the value named 'source path' in this block.

Line 17: `set target_parts [split $target_path "/"]` This batch-control line contributes to the flow that runs the reproducible Vivado annotate saif power hardware flow. The important operands are set: the value named 'set' in this block; target_parts: the value named 'target parts' in this block; split: the value named 'split' in this block.

Line 18: `if {[llength $target_parts] < 2} {` This batch-control line contributes to the flow that runs the reproducible Vivado annotate saif power hardware flow. The important operands are llength: the value named 'llength' in this block; target_parts: the value named 'target parts' in this block.

Line 19: `error "Relocated SAIF target must contain at least two hierarchy levels"` This batch-control line contributes to the flow that runs the reproducible Vivado annotate saif power hardware flow. The important operands are error: the value named 'error' in this block; Relocated: the value named 'relocated' in this block; SAIF: the value named 'saif' in this block.

Line 20: `}` This batch-control line contributes to the flow that runs the reproducible Vivado annotate saif power hardware flow. The expression is a literal or structural operator and has no hidden software state.

Line 21: `set source_handle [open $source_path "r"]` This batch-control line contributes to the flow that runs the reproducible Vivado annotate saif power hardware flow. The important operands are set: the value named 'set' in this block; source_handle: the value named 'source handle' in this block; open: the value named 'open' in this block.

Line 22: `set destination_handle [open $destination_path "w"]` This batch-control line contributes to the flow that runs the reproducible Vivado annotate saif power hardware flow. The important operands are set: the value named 'set' in this block; destination_handle: the value named 'destination handle' in this block; open: the value named 'open' in this block.

Line 23: `set replaced_instances 0` This batch-control line contributes to the flow that runs the reproducible Vivado annotate saif power hardware flow. The important operands are set: the value named 'set' in this block; replaced_instances: the value named 'replaced instances' in this block.

Line 24: `try {` This batch-control line contributes to the flow that runs the reproducible Vivado annotate saif power hardware flow. The important operands are try: the value named 'try' in this block.

Line 25: `while {[gets $source_handle line] >= 0} {` This batch-control line contributes to the flow that runs the reproducible Vivado annotate saif power hardware flow. The important operands are while: the value named 'while' in this block; gets: the value named 'gets' in this block; source_handle: the value named 'source handle' in this block.

Line 26: `if {$replaced_instances < 2 &&` This batch-control line contributes to the flow that runs the reproducible Vivado annotate saif power hardware flow. The important operands are replaced_instances: the value named 'replaced instances' in this block.

Line 27: `[regexp {^(\s*)\(INSTANCE\s+\S+\s*$} $line -> indent]} {` This batch-control line contributes to the flow that runs the reproducible Vivado annotate saif power hardware flow. The important operands are regexp: the value named 'regexp' in this block; s: the value named 's' in this block; INSTANCE: the value named 'instance' in this block.

Line 28: `puts $destination_handle "${indent}(INSTANCE [lindex $target_parts $replaced_instances]"` This batch-control line contributes to the flow that runs the reproducible Vivado annotate saif power hardware flow. The important operands are puts: the value named 'puts' in this block; destination_handle: the value named 'destination handle' in this block; indent: the value named 'indent' in this block.

Line 29: `incr replaced_instances` This batch-control line contributes to the flow that runs the reproducible Vivado annotate saif power hardware flow. The important operands are incr: the value named 'incr' in this block; replaced_instances: the value named 'replaced instances' in this block.

Line 30: `if {$replaced_instances == 2} {` This batch-control line contributes to the flow that runs the reproducible Vivado annotate saif power hardware flow. The important operands are replaced_instances: the value named 'replaced instances' in this block.

Line 31: `for {set index 2} {$index < [llength $target_parts]} {incr index} {` This batch-control line contributes to the flow that runs the reproducible Vivado annotate saif power hardware flow. The important operands are for: the value named 'for' in this block; set: the value named 'set' in this block; index: an integer selecting one tensor element, lane, bank, or state entry.

Line 32: `append indent " "` This batch-control line contributes to the flow that runs the reproducible Vivado annotate saif power hardware flow. The important operands are append: the value named 'append' in this block; indent: the value named 'indent' in this block.

Line 33: `puts $destination_handle "${indent}(INSTANCE [lindex $target_parts $index]"` This batch-control line contributes to the flow that runs the reproducible Vivado annotate saif power hardware flow. The important operands are puts: the value named 'puts' in this block; destination_handle: the value named 'destination handle' in this block; indent: the value named 'indent' in this block.

Line 34: `}` This batch-control line contributes to the flow that runs the reproducible Vivado annotate saif power hardware flow. The expression is a literal or structural operator and has no hidden software state.

Line 35: `}` This batch-control line contributes to the flow that runs the reproducible Vivado annotate saif power hardware flow. The expression is a literal or structural operator and has no hidden software state.

Line 36: `} else {` This batch-control line contributes to the flow that runs the reproducible Vivado annotate saif power hardware flow. The expression is a literal or structural operator and has no hidden software state.

Line 37: `puts $destination_handle $line` This batch-control line contributes to the flow that runs the reproducible Vivado annotate saif power hardware flow. The important operands are puts: the value named 'puts' in this block; destination_handle: the value named 'destination handle' in this block; line: the value named 'line' in this block.

Line 38: `}` This batch-control line contributes to the flow that runs the reproducible Vivado annotate saif power hardware flow. The expression is a literal or structural operator and has no hidden software state.

Line 39: `}` This batch-control line contributes to the flow that runs the reproducible Vivado annotate saif power hardware flow. The expression is a literal or structural operator and has no hidden software state.

Line 40: `if {$replaced_instances != 2} {` This batch-control line contributes to the flow that runs the reproducible Vivado annotate saif power hardware flow. The important operands are replaced_instances: the value named 'replaced instances' in this block.

Line 41: `error "Could not find the two simulated SAIF wrapper instances in $source_path"` This batch-control line contributes to the flow that runs the reproducible Vivado annotate saif power hardware flow. The important operands are error: the value named 'error' in this block; Could: the value named 'could' in this block; not: the value named 'not' in this block.

Line 42: `}` This batch-control line contributes to the flow that runs the reproducible Vivado annotate saif power hardware flow. The expression is a literal or structural operator and has no hidden software state.

Line 43: `for {set index 2} {$index < [llength $target_parts]} {incr index} {` This batch-control line contributes to the flow that runs the reproducible Vivado annotate saif power hardware flow. The important operands are for: the value named 'for' in this block; set: the value named 'set' in this block; index: an integer selecting one tensor element, lane, bank, or state entry.

Line 44: `puts $destination_handle ")"` This batch-control line contributes to the flow that runs the reproducible Vivado annotate saif power hardware flow. The important operands are puts: the value named 'puts' in this block; destination_handle: the value named 'destination handle' in this block.

Line 45: `}` This batch-control line contributes to the flow that runs the reproducible Vivado annotate saif power hardware flow. The expression is a literal or structural operator and has no hidden software state.

Line 46: `} finally {` This batch-control line contributes to the flow that runs the reproducible Vivado annotate saif power hardware flow. The important operands are finally: the value named 'finally' in this block.

Line 47: `close $source_handle` This batch-control line contributes to the flow that runs the reproducible Vivado annotate saif power hardware flow. The important operands are close: the value named 'close' in this block; source_handle: the value named 'source handle' in this block.

Line 48: `close $destination_handle` This batch-control line contributes to the flow that runs the reproducible Vivado annotate saif power hardware flow. The important operands are close: the value named 'close' in this block; destination_handle: the value named 'destination handle' in this block.

Line 49: `}` This batch-control line contributes to the flow that runs the reproducible Vivado annotate saif power hardware flow. The expression is a literal or structural operator and has no hidden software state.

Line 50: `}` This batch-control line contributes to the flow that runs the reproducible Vivado annotate saif power hardware flow. The expression is a literal or structural operator and has no hidden software state.

Line 52: `open_checkpoint $checkpoint` This batch-control line contributes to the flow that runs the reproducible Vivado annotate saif power hardware flow. The important operands are open_checkpoint: the value named 'open checkpoint' in this block; checkpoint: the value named 'checkpoint' in this block.

Line 53: `if {$accelerator_instance eq "__ROOT__"} {` This batch-control line contributes to the flow that runs the reproducible Vivado annotate saif power hardware flow. The important operands are accelerator_instance: the value named 'accelerator instance' in this block; eq: the value named 'eq' in this block; ___ROOT___: the value named 'root' in this block.

Line 54: `read_saif -out_file [file join $output_dir "wrapper_saif_match.rpt"] \` This annotates implemented nets with measured XSim switching activity from the named SAIF file. The retained match report quantifies which simulated names mapped to routed nets: 'read_saif -out_file [file join $output_dir "wrapper_saif_match.rpt"] \'.

Line 55: `-strip_path tb_neuraedge_pynq_axi_top/dut -file $wrapper_saif` This batch-control line contributes to the flow that runs the reproducible Vivado annotate saif power hardware flow. The important operands are strip_path: the value named 'strip path' in this block; tb_neuraedge_pynq_axi_top: the value named 'tb neuraedge pynq axi top' in this block; dut: the value named 'dut' in this block.

Line 56: `current_instance u_core` This batch-control line contributes to the flow that runs the reproducible Vivado annotate saif power hardware flow. The important operands are current_instance: the value named 'current instance' in this block; u_core: the value named 'u core' in this block.

Line 57: `read_saif -out_file [file join $output_dir "core_saif_match.rpt"] \` This annotates implemented nets with measured XSim switching activity from the named SAIF file. The retained match report quantifies which simulated names mapped to routed nets: 'read_saif -out_file [file join $output_dir "core_saif_match.rpt"] \'.

Line 58: `-strip_path tb_neuraedge_universal_core/dut -file $core_saif` This batch-control line contributes to the flow that runs the reproducible Vivado annotate saif power hardware flow. The important operands are strip_path: the value named 'strip path' in this block; tb_neuraedge_universal_core: the value named 'tb neuraedge universal core' in this block; dut: the value named 'dut' in this block.

Line 59: `current_instance` This batch-control line contributes to the flow that runs the reproducible Vivado annotate saif power hardware flow. The important operands are current_instance: the value named 'current instance' in this block.

Line 60: `} else {` This batch-control line contributes to the flow that runs the reproducible Vivado annotate saif power hardware flow. The expression is a literal or structural operator and has no hidden software state.

Line 61: `set accelerator_cells [get_cells -quiet -hierarchical -filter \` This batch-control line contributes to the flow that runs the reproducible Vivado annotate saif power hardware flow. The important operands are set: the value named 'set' in this block; accelerator_cells: the value named 'accelerator cells' in this block; get_cells: the value named 'get cells' in this block.

Line 62: `"NAME == $accelerator_instance"]` This batch-control line contributes to the flow that runs the reproducible Vivado annotate saif power hardware flow. The important operands are NAME: the value named 'name' in this block; accelerator_instance: the value named 'accelerator instance' in this block.

Line 63: `if {[llength $accelerator_cells] != 1} {` This batch-control line contributes to the flow that runs the reproducible Vivado annotate saif power hardware flow. The important operands are llength: the value named 'llength' in this block; accelerator_cells: the value named 'accelerator cells' in this block.

Line 64: `error "Accelerator instance does not resolve uniquely: $accelerator_instance"` This batch-control line contributes to the flow that runs the reproducible Vivado annotate saif power hardware flow. The important operands are error: the value named 'error' in this block; Accelerator: the value named 'accelerator' in this block; instance: the value named 'instance' in this block.

Line 65: `}` This batch-control line contributes to the flow that runs the reproducible Vivado annotate saif power hardware flow. The expression is a literal or structural operator and has no hidden software state.

Line 66: `set relocated_wrapper [file join $output_dir "relocated_wrapper.saif"]` This batch-control line contributes to the flow that runs the reproducible Vivado annotate saif power hardware flow. The important operands are set: the value named 'set' in this block; relocated_wrapper: the value named 'relocated wrapper' in this block; file: the value named 'file' in this block.

Line 67: `set relocated_core [file join $output_dir "relocated_core.saif"]` This batch-control line contributes to the flow that runs the reproducible Vivado annotate saif power hardware flow. The important operands are set: the value named 'set' in this block; relocated_core: the value named 'relocated core' in this block; file: the value named 'file' in this block.

Line 68: `relocate_saif $wrapper_saif $relocated_wrapper $accelerator_instance` This batch-control line contributes to the flow that runs the reproducible Vivado annotate saif power hardware flow. The important operands are relocate_saif: the value named 'relocate saif' in this block; wrapper_saif: the value named 'wrapper saif' in this block; relocated_wrapper: the value named 'relocated wrapper' in this block.

Line 69: `relocate_saif $core_saif $relocated_core ${accelerator_instance}/u_core` This batch-control line contributes to the flow that runs the reproducible Vivado annotate saif power hardware flow. The important operands are relocate_saif: the value named 'relocate saif' in this block; core_saif: the value named 'core saif' in this block; relocated_core: the value named 'relocated core' in this block.

Line 70: `try {` This batch-control line contributes to the flow that runs the reproducible Vivado annotate saif power hardware flow. The important operands are try: the value named 'try' in this block.

Line 71: `read_saif -out_file [file join $output_dir "wrapper_saif_match.rpt"] \` This annotates implemented nets with measured XSim switching activity from the named SAIF file. The retained match report quantifies which simulated names mapped to routed nets: 'read_saif -out_file [file join $output_dir "wrapper_saif_match.rpt"] \'.

Line 72: `-no_strip -file $relocated_wrapper` This batch-control line contributes to the flow that runs the reproducible Vivado annotate saif power hardware flow. The important operands are no_strip: the value named 'no strip' in this block; file: the value named 'file' in this block; relocated_wrapper: the value named 'relocated wrapper' in this block.

Line 73: `read_saif -out_file [file join $output_dir "core_saif_match.rpt"] \` This annotates implemented nets with measured XSim switching activity from the named SAIF file. The retained match report quantifies which simulated names mapped to routed nets: 'read_saif -out_file [file join $output_dir "core_saif_match.rpt"] \'.

Line 74: `-no_strip -file $relocated_core` This batch-control line contributes to the flow that runs the reproducible Vivado annotate saif power hardware flow. The important operands are no_strip: the value named 'no strip' in this block; file: the value named 'file' in this block; relocated_core: the value named 'relocated core' in this block.

Line 75: `} finally {` This batch-control line contributes to the flow that runs the reproducible Vivado annotate saif power hardware flow. The important operands are finally: the value named 'finally' in this block.

Line 76: `file delete -force $relocated_wrapper $relocated_core` This batch-control line contributes to the flow that runs the reproducible Vivado annotate saif power hardware flow. The important operands are file: the value named 'file' in this block; delete: the value named 'delete' in this block; force: the value named 'force' in this block.

Line 77: `}` This batch-control line contributes to the flow that runs the reproducible Vivado annotate saif power hardware flow. The expression is a literal or structural operator and has no hidden software state.

Line 78: `}` This batch-control line contributes to the flow that runs the reproducible Vivado annotate saif power hardware flow. The expression is a literal or structural operator and has no hidden software state.

Line 79: `set_switching_activity -deassert_resets` This batch-control line contributes to the flow that runs the reproducible Vivado annotate saif power hardware flow. The important operands are set_switching_activity: the value named 'set switching activity' in this block; deassert_resets: the value named 'deassert resets' in this block.

Line 80: `if {$accelerator_instance eq "__ROOT__"} {` This batch-control line contributes to the flow that runs the reproducible Vivado annotate saif power hardware flow. The important operands are accelerator_instance: the value named 'accelerator instance' in this block; eq: the value named 'eq' in this block; ___ROOT___: the value named 'root' in this block.

Line 81: `set routed_nets [get_nets -hierarchical]` This batch-control line contributes to the flow that runs the reproducible Vivado annotate saif power hardware flow. The important operands are set: the value named 'set' in this block; routed_nets: the value named 'routed nets' in this block; get_nets: the value named 'get nets' in this block.

Line 82: `} else {` This batch-control line contributes to the flow that runs the reproducible Vivado annotate saif power hardware flow. The expression is a literal or structural operator and has no hidden software state.

Line 83: `current_instance $accelerator_instance` This batch-control line contributes to the flow that runs the reproducible Vivado annotate saif power hardware flow. The important operands are current_instance: the value named 'current instance' in this block; accelerator_instance: the value named 'accelerator instance' in this block.

Line 84: `set routed_nets [get_nets -hierarchical]` This batch-control line contributes to the flow that runs the reproducible Vivado annotate saif power hardware flow. The important operands are set: the value named 'set' in this block; routed_nets: the value named 'routed nets' in this block; get_nets: the value named 'get nets' in this block.

Line 85: `current_instance` This batch-control line contributes to the flow that runs the reproducible Vivado annotate saif power hardware flow. The important operands are current_instance: the value named 'current instance' in this block.

Line 86: `}` This batch-control line contributes to the flow that runs the reproducible Vivado annotate saif power hardware flow. The expression is a literal or structural operator and has no hidden software state.

Line 87: `if {[llength $routed_nets] == 0} {` This batch-control line contributes to the flow that runs the reproducible Vivado annotate saif power hardware flow. The important operands are llength: the value named 'llength' in this block; routed_nets: the value named 'routed nets' in this block.

Line 88: `error "The routed checkpoint contains no hierarchical nets to report"` This batch-control line contributes to the flow that runs the reproducible Vivado annotate saif power hardware flow. The important operands are error: the value named 'error' in this block; The: the value named 'the' in this block; routed: the value named 'routed' in this block.

Line 89: `}` This batch-control line contributes to the flow that runs the reproducible Vivado annotate saif power hardware flow. The expression is a literal or structural operator and has no hidden software state.

Line 90: `report_switching_activity -file \` This writes an auditable Vivado artifact using 'report_switching_activity -file \'; later documentation reads the resulting report rather than inventing a metric.

Line 91: `[file join $output_dir "annotated_switching_activity.rpt"] $routed_nets` This batch-control line contributes to the flow that runs the reproducible Vivado annotate saif power hardware flow. The important operands are file: the value named 'file' in this block; join: the value named 'join' in this block; output_dir: the value named 'output dir' in this block.

Line 92: `report_power -file [file join $output_dir "routed_saif_power.rpt"]` This writes an auditable Vivado artifact using 'report_power -file [file join $output_dir "routed_saif_power.rpt"]'; later documentation reads the resulting report rather than inventing a metric.

Line 93: `write_checkpoint -force [file join $output_dir "neuraedge_saif_annotated.dcp"]` This writes an auditable Vivado artifact using 'write_checkpoint -force [file join $output_dir "neuraedge_saif_annotated.dcp"]'; later documentation reads the resulting report rather than inventing a metric.

Line 94: `close_design` This batch-control line contributes to the flow that runs the reproducible Vivado annotate saif power hardware flow. The important operands are close_design: the value named 'close design' in this block.

90 scripts/build_pynq_full.tcl

Role in the complete system: runs the reproducible Vivado build pynq full hardware flow.

90.1 Beginner architecture map

Dataflow responsibility This file's end-to-end responsibility is to runs the reproducible Vivado build pynq full hardware flow.

Where it runs This is Vivado Tcl orchestration, not accelerator datapath hardware. It makes tool inputs, versions, paths, stages, and failure propagation repeatable.

Reproducibility contract Every external command must be checked, every required artifact must exist and be nonempty, and measured values must be read from generated reports. Rerunning this file should either reproduce its declared outputs or stop at the first failed gate.

90.2 Complete source

```
# Build the complete PYNQ-Z2 processing-system, DMA, and NeuraEdge overlay.
# The board preset is vendored from the AMD/Xilinx Board Store and configures
# the physical DDR3 and MIO pins. FCLK0 supplies 100 MHz control, FCLK1 supplies
# a timing-safe 125 MHz DMA/DDR path, and FCLK2 supplies the 200 MHz accelerator.

90.3 Line annotations

Line 1: `# Build the complete PYNQ-Z2 processing-system, DMA, and NeuraEdge overlay.` This comment documents the batch-flow intent: Build the complete PYNQ-Z2 processing-system, DMA, and NeuraEdge overlay.

Line 2: `# The board preset is vendored from the AMD/Xilinx Board Store and configures` This comment documents the batch-flow intent: The board preset is vendored from the AMD/Xilinx Board Store and configures

Line 3: `# the physical DDR3 and MIO pins. FCLK0 supplies 100 MHz control, FCLK1 supplies` This comment documents the batch-flow intent: the physical DDR3 and MIO pins. FCLK0 supplies 100 MHz control, FCLK1 supplies

Line 4: `# a timing-safe 125 MHz DMA/DDR path, and FCLK2 supplies the 200 MHz accelerator.` This comment documents the batch-flow intent: a timing-safe 125 MHz DMA/DDR path, and FCLK2 supplies the 200 MHz accelerator.

Line 6: `set script_dir [file normalize [file dirname [info script]]]` This batch-control line contributes to the flow that runs the reproducible Vivado build pynq full hardware flow. The important operands are set: the value named 'set' in this block; script_dir: the value named 'script dir' in this block; file: the value named 'file' in this block.

Line 7: `set project_dir [file normalize [file join $script_dir ".."]]` This batch-control line contributes to the flow that runs the reproducible Vivado build pynq full hardware flow. The important operands are set: the value named 'set' in this block; project_dir: the value named 'project dir' in this block; file: the value named 'file' in this block.

Line 8: `set board_store [file join $project_dir "third_party" "XilinxBoardStore" "boards"]` This batch-control line contributes to the flow that runs the reproducible Vivado build pynq full hardware flow. The important operands are set: the value named 'set' in this block; board_store: the value named 'board store' in this block; file: the value named 'file' in this block.

Line 9: `set output_dir [file join $project_dir "outputs" "pynq_full"]` This batch-control line contributes to the flow that runs the reproducible Vivado build pynq full hardware flow. The important operands are set: the value named 'set' in this block; output_dir: the value named 'output dir' in this block; file: the value named 'file' in this block.

Line 10: `if {[info exists ::env(NEURAEDGE_VIVADO_BUILD_ROOT)]} {` This batch-control line contributes to the flow that runs the reproducible Vivado build pynq full hardware flow. The important operands are info: the value named 'info' in this block; exists: the value named 'exists' in this block; env: the value named 'env' in this block.

Line 11: `set build_root [file normalize $::env(NEURAEDGE_VIVADO_BUILD_ROOT)]` This batch-control line contributes to the flow that runs the reproducible Vivado build pynq full hardware flow. The important operands are set: the value named 'set' in this block; build_root: the value named 'build root' in this block; file: the value named 'file' in this block.

Line 12: `} else {` This batch-control line contributes to the flow that runs the reproducible Vivado build pynq full hardware flow. The expression is a literal or structural operator and has no hidden software state.

Line 13: `set build_root [file normalize "D:/NeuraEdgeBuild"]` This batch-control line contributes to the flow that runs the reproducible Vivado build pynq full hardware flow. The important operands are set: the value named 'set' in this block; build_root: the value named 'build root' in this block; file: the value named 'file' in this block.

Line 14: `}` This batch-control line contributes to the flow that runs the reproducible Vivado build pynq full hardware flow. The expression is a literal or structural operator and has no hidden software state.

Line 15: `set vivado_project_dir [file join $build_root "pynq_full"]` This batch-control line contributes to the flow that runs the reproducible Vivado build pynq full hardware flow. The important operands are set: the value named 'set' in this block; vivado_project_dir: the value named 'vivado project dir' in this block; file: the value named 'file' in this block.

Line 16: `set build_mode "full"` This batch-control line contributes to the flow that runs the reproducible Vivado build pynq full hardware flow. The important operands are set: the value named 'set' in this block; build_mode: the value named 'build mode' in this block; full: the value named 'full' in this block.

Line 17: `if {$argc >= 1} {` This batch-control line contributes to the flow that runs the reproducible Vivado build pynq full hardware flow. The important operands are argc: the value named 'argc' in this block.

Line 18: `set build_mode [lindex $argv 0]` This batch-control line contributes to the flow that runs the reproducible Vivado build pynq full hardware flow. The important operands are set: the value named 'set' in this block; build_mode: the value named 'build mode' in this block; lindex: an integer selecting one tensor element, lane, bank, or state entry.

Line 19: `}` This batch-control line contributes to the flow that runs the reproducible Vivado build pynq full hardware flow. The expression is a literal or structural operator and has no hidden software state.

Line 20: `if {$build_mode ni {validate full}} {` This batch-control line contributes to the flow that runs the reproducible Vivado build pynq full hardware flow. The important operands are build_mode: the value named 'build mode' in this block; ni: the value named 'ni' in this block; validate: the producer's statement that its current payload is meaningful.

Line 21: `error "Build mode must be validate or full"` This batch-control line contributes to the flow that runs the reproducible Vivado build pynq full hardware flow. The important operands are error: the value named 'error' in this block; Build: the value named 'build' in this block; mode: the value named 'mode' in this block.

Line 22: `}` This batch-control line contributes to the flow that runs the reproducible Vivado build pynq full hardware flow. The expression is a literal or structural operator and has no hidden software state.

Line 23: `file mkdir $output_dir` This batch-control line contributes to the flow that runs the reproducible Vivado build pynq full hardware flow. The important operands are file: the value named 'file' in this block; mkdir: the value named 'mkdir' in this block; output_dir: the value named 'output dir' in this block.

Line 24: `if {$build_mode eq "full"} {` This batch-control line contributes to the flow that runs the reproducible Vivado build pynq full hardware flow. The important operands are build_mode: the value named 'build mode' in this block; eq: the value named 'eq' in this block; full: the value named 'full' in this block.

Line 25: `# A failed rebuild must never leave an older deployable image looking like` This comment documents the batch-flow intent: A failed rebuild must never leave an older deployable image looking like

Line 26: `# the result of the current source tree. Diagnostic reports are overwritten` This comment documents the batch-flow intent: the result of the current source tree. Diagnostic reports are overwritten

Line 27: `# in place, while accepted deployment artifacts are republished only after` This comment documents the batch-flow intent: in place, while accepted deployment artifacts are republished only after

Line 28: `# route, timing, and DRC gates pass below.` This comment documents the batch-flow intent: route, timing, and DRC gates pass below.

Line 29: `foreach stale_artifact {` This batch-control line contributes to the flow that runs the reproducible Vivado build pynq full hardware flow. The important operands are foreach: the value named 'foreach' in this block; stale_artifact: the value named 'stale artifact' in this block.

Line 30: `neuraedge_pynq_full.bit` This batch-control line contributes to the flow that runs the reproducible Vivado build pynq full hardware flow. The important operands are neuraedge_pynq_full: the value named 'neuraedge pynq full' in this block; bit: the value named 'bit' in this block.

Line 31: `neuraedge_pynq_full.hwh` This batch-control line contributes to the flow that runs the reproducible Vivado build pynq full hardware flow. The important operands are neuraedge_pynq_full: the value named 'neuraedge pynq full' in this block; hwh: the value named 'hwh' in this block.

Line 32: `neuraedge_pynq_full.xsa` This batch-control line contributes to the flow that runs the reproducible Vivado build pynq full hardware flow. The important operands are neuraedge_pynq_full: the value named 'neuraedge pynq full' in this block; xsa: the value named 'xsa' in this block.

Line 33: `full_implementation_summary.txt` This batch-control line contributes to the flow that runs the reproducible Vivado build pynq full hardware flow. The important operands are full_implementation_summary: the value named 'full implementation summary' in this block; txt: the value named 'txt' in this block.

Line 34: `} {` This batch-control line contributes to the flow that runs the reproducible Vivado build pynq full hardware flow. The expression is a literal or structural operator and has no hidden software state.

Line 35: `set stale_path [file join $output_dir $stale_artifact]` This batch-control line contributes to the flow that runs the reproducible Vivado build pynq full hardware flow. The important operands are set: the value named 'set' in this block; stale_path: the value named 'stale path' in this block; file: the value named 'file' in this block.

Line 36: `if {[file exists $stale_path]} {` This batch-control line contributes to the flow that runs the reproducible Vivado build pynq full hardware flow. The important operands are file: the value named 'file' in this block; exists: the value named 'exists' in this block; stale_path: the value named 'stale path' in this block.

Line 37: `file delete -force $stale_path` This batch-control line contributes to the flow that runs the reproducible Vivado build pynq full hardware flow. The important operands are file: the value named 'file' in this block; delete: the value named 'delete' in this block; force: the value named 'force' in this block.

Line 38: `}` This batch-control line contributes to the flow that runs the reproducible Vivado build pynq full hardware flow. The expression is a literal or structural operator and has no hidden software state.

Line 39: `}` This batch-control line contributes to the flow that runs the reproducible Vivado build pynq full hardware flow. The expression is a literal or structural operator and has no hidden software state.

Line 42: `set_param board.repoPaths [list $board_store]` This batch-control line contributes to the flow that runs the reproducible Vivado build pynq full hardware flow. The important operands are set_param: the value named 'set param' in this block; board: the value named 'board' in this block; repoPaths: the value named 'repo paths' in this block.

Line 43: `set board_part "tul.com.tw:pynq-z2:part0:1.0"` This batch-control line contributes to the flow that runs the reproducible Vivado build pynq full hardware flow. The important operands are set: the value named 'set' in this block; board_part: the value named 'board part' in this block; tul: the value named 'tul' in this block.

Line 44: `if {[llength [get_board_parts -quiet $board_part]] != 1} {` This batch-control line contributes to the flow that runs the reproducible Vivado build pynq full hardware flow. The important operands are llength: the value named 'llength' in this block; get_board_parts: the value named 'get board parts' in this block; quiet: the value named 'quiet' in this block.

Line 45: `error "Vendored PYNQ-Z2 board part was not discovered at $board_store"` This batch-control line contributes to the flow that runs the reproducible Vivado build pynq full hardware flow. The important operands are error: the value named 'error' in this block; Vendored: the value named 'vendored' in this block; PYNQ: the value named 'pynq' in this block.

Line 46: `}` This batch-control line contributes to the flow that runs the reproducible Vivado build pynq full hardware flow. The expression is a literal or structural operator and has no hidden software state.

Line 48: `create_project neuraedge_pynq_full $vivado_project_dir -force -part xc7z020clg400-1` This batch-control line contributes to the flow that runs the reproducible Vivado build pynq full hardware flow. The important operands are create_project: the value named 'create project' in this block; neuraedge_pynq_full: the value named 'neuraedge pynq full' in this block; vivado_project_dir: the value named 'vivado project dir' in this block.

Line 49: `set_property board_part $board_part [current_project]` This batch-control line contributes to the flow that runs the reproducible Vivado build pynq full hardware flow. The important operands are set_property: the value named 'set property' in this block; board_part: the value named 'board part' in this block; current_project: the value named 'current project' in this block.

Line 50: `set_property target_language Verilog [current_project]` This batch-control line contributes to the flow that runs the reproducible Vivado build pynq full hardware flow. The important operands are set_property: the value named 'set property' in this block; target_language: the value named 'target language' in this block; Verilog: the value named 'verilog' in this block.

Line 51: `set_property simulator_language Mixed [current_project]` This batch-control line contributes to the flow that runs the reproducible Vivado build pynq full hardware flow. The important operands are set_property: the value named 'set property' in this block; simulator_language: the value named 'simulator language' in this block; Mixed: the value named 'mixed' in this block.

Line 53: `set rtl_files [list \` This batch-control line contributes to the flow that runs the reproducible Vivado build pynq full hardware flow. The important operands are set: the value named 'set' in this block; rtl_files: the value named 'rtl files' in this block; list: the value named 'list' in this block.

Line 54: `[file join $project_dir "rtl" "neuraedge_command_pkg.sv"] \` This batch-control line contributes to the flow that runs the reproducible Vivado build pynq full hardware flow. The important operands are file: the value named 'file' in this block; join: the value named 'join' in this block; project_dir: the value named 'project dir' in this block.

Line 55: `[file join $project_dir "rtl" "neuraedge_mac2_u8.sv"] \` This batch-control line contributes to the flow that runs the reproducible Vivado build pynq full hardware flow. The important operands are file: the value named 'file' in this block; join: the value named 'join' in this block; project_dir: the value named 'project dir' in this block.

Line 56: `[file join $project_dir "rtl" "neuraedge_tensor_tile.sv"] \` This batch-control line contributes to the flow that runs the reproducible Vivado build pynq full hardware flow. The important operands are file: the value named 'file' in this block; join: the value named 'join' in this block; project_dir: the value named 'project dir' in this block.

Line 57: `[file join $project_dir "rtl" "neuraedge_active_index_buffer.sv"] \` This batch-control line contributes to the flow that runs the reproducible Vivado build pynq full hardware flow. The important operands are file: the value named 'file' in this block; join: the value named 'join' in this block; project_dir: the value named 'project dir' in this block.

Line 58: `[file join $project_dir "rtl" "neuraedge_activation_buffer.sv"] \` This batch-control line contributes to the flow that runs the reproducible Vivado build pynq full hardware flow. The important operands are file: the value named 'file' in this block; join: the value named 'join' in this block; project_dir: the value named 'project dir' in this block.

Line 59: `[file join $project_dir "rtl" "neuraedge_weight_bank.sv"] \` This batch-control line contributes to the flow that runs the reproducible Vivado build pynq full hardware flow. The important operands are file: the value named 'file' in this block; join: the value named 'join' in this block; project_dir: the value named 'project dir' in this block.

Line 60: `[file join $project_dir "rtl" "neuraedge_buffered_tensor_core.sv"] \` This batch-control line contributes to the flow that runs the reproducible Vivado build pynq full hardware flow. The important operands are file: the value named 'file' in this block; join: the value named 'join' in this block; project_dir: the value named 'project dir' in this block.

Line 61: `[file join $project_dir "rtl" "neuraedge_alpha_xnor.sv"] \` This batch-control line contributes to the flow that runs the reproducible Vivado build pynq full hardware flow. The important operands are file: the value named 'file' in this block; join: the value named 'join' in this block; project_dir: the value named 'project dir' in this block.

Line 62: `[file join $project_dir "rtl" "neuraedge_vector_alu.sv"] \` This batch-control line contributes to the flow that runs the reproducible Vivado build pynq full hardware flow. The important operands are file: the value named 'file' in this block; join: the value named 'join' in this block; project_dir: the value named 'project dir' in this block.

Line 63: `[file join $project_dir "rtl" "neuraedge_udivider.sv"] \` This batch-control line contributes to the flow that runs the reproducible Vivado build pynq full hardware flow. The important operands are file: the value named 'file' in this block; join: the value named 'join' in this block; project_dir: the value named 'project dir' in this block.

Line 64: `[file join $project_dir "rtl" "neuraedge_isqrt64.sv"] \` This batch-control line contributes to the flow that runs the reproducible Vivado build pynq full hardware flow. The important operands are file: the value named 'file' in this block; join: the value named 'join' in this block; project_dir: the value named 'project dir' in this block.

Line 65: `[file join $project_dir "rtl" "neuraedge_integer_layernorm.sv"] \` This batch-control line contributes to the flow that runs the reproducible Vivado build pynq full hardware flow. The important operands are file: the value named 'file' in this block; join: the value named 'join' in this block; project_dir: the value named 'project dir' in this block.

Line 66: `[file join $project_dir "rtl" "neuraedge_log_softmax.sv"] \` This batch-control line contributes to the flow that runs the reproducible Vivado build pynq full hardware flow. The important operands are file: the value named 'file' in this block; join: the value named 'join' in this block; project_dir: the value named 'project dir' in this block.

Line 67: `[file join $project_dir "rtl" "neuraedge_lif_bank.sv"] \` This batch-control line contributes to the flow that runs the reproducible Vivado build pynq full hardware flow. The important operands are file: the value named 'file' in this block; join: the value named 'join' in this block; project_dir: the value named 'project dir' in this block.

Line 68: `[file join $project_dir "rtl" "neuraedge_sgd_optimizer8.sv"] \` This batch-control line contributes to the flow that runs the reproducible Vivado build pynq full hardware flow. The important operands are file: the value named 'file' in this block; join: the value named 'join' in this block; project_dir: the value named 'project dir' in this block.

Line 69: `[file join $project_dir "rtl" "neuraedge_gradient_accumulator_bank.sv"] \` This batch-control line contributes to the flow that runs the reproducible Vivado build pynq full hardware flow. The important operands are file: the value named 'file' in this block; join: the value named 'join' in this block; project_dir: the value named 'project dir' in this block.

Line 70: `[file join $project_dir "rtl" "neuraedge_linear_backward8.sv"] \` This batch-control line contributes to the flow that runs the reproducible Vivado build pynq full hardware flow. The important operands are file: the value named 'file' in this block; join: the value named 'join' in this block; project_dir: the value named 'project dir' in this block.

Line 71: `[file join $project_dir "rtl" "neuraedge_activation_lut8.sv"] \` This batch-control line contributes to the flow that runs the reproducible Vivado build pynq full hardware flow. The important operands are file: the value named 'file' in this block; join: the value named 'join' in this block; project_dir: the value named 'project dir' in this block.

Line 72: `[file join $project_dir "rtl" "neuraedge_universal_core.sv"] \` This batch-control line contributes to the flow that runs the reproducible Vivado build pynq full hardware flow. The important operands are file: the value named 'file' in this block; join: the value named 'join' in this block; project_dir: the value named 'project dir' in this block.

Line 73: `[file join $project_dir "rtl" "neuraedge_descriptor_sequencer.sv"] \` This batch-control line contributes to the flow that runs the reproducible Vivado build pynq full hardware flow. The important operands are file: the value named 'file' in this block; join: the value named 'join' in this block; project_dir: the value named 'project dir' in this block.

Line 74: `[file join $project_dir "rtl" "neuraedge_pynq_axi_top.sv"]]` This batch-control line contributes to the flow that runs the reproducible Vivado build pynq full hardware flow. The important operands are file: the value named 'file' in this block; join: the value named 'join' in this block; project_dir: the value named 'project dir' in this block.

Line 75: `add_files -norecurse $rtl_files` This batch-control line contributes to the flow that runs the reproducible Vivado build pynq full hardware flow. The important operands are add_files: the value named 'add files' in this block; norecurse: the value named 'norecurse' in this block; rtl_files: the value named 'rtl files' in this block.

Line 76: `set_property file_type SystemVerilog [get_files $rtl_files]` This batch-control line contributes to the flow that runs the reproducible Vivado build pynq full hardware flow. The important operands are set_property: the value named 'set property' in this block; file_type: the value named 'file type' in this block; SystemVerilog: the value named 'system verilog' in this block.

Line 77: `set_property top neuraedge_pynq_axi_top [current_fileset]` This batch-control line contributes to the flow that runs the reproducible Vivado build pynq full hardware flow. The important operands are set_property: the value named 'set property' in this block; top: the value named 'top' in this block; neuraedge_pynq_axi_top: the value named 'neuraedge pynq axi top' in this block.

Line 78: `update_compile_order -fileset sources_1` This batch-control line contributes to the flow that runs the reproducible Vivado build pynq full hardware flow. The important operands are update_compile_order: the value named 'update compile order' in this block; fileset: the value named 'fileset' in this block; sources_1: the value named 'sources 1' in this block.

Line 80: `# Package the verified RTL with an explicit IP-XACT memory map. A raw module` This comment documents the batch-flow intent: Package the verified RTL with an explicit IP-XACT memory map. A raw module

Line 81: `# reference exposes AXI pins but has no address block, which prevents Vivado's` This comment documents the batch-flow intent: reference exposes AXI pins but has no address block, which prevents Vivado's

Line 82: `# Address Editor and PYNQ's HWH parser from describing the control registers.` This comment documents the batch-flow intent: Address Editor and PYNQ's HWH parser from describing the control registers.

Line 83: `set ip_repo [file join $output_dir "ip_repo" "neuraedge_universal_1_0"]` This batch-control line contributes to the flow that runs the reproducible Vivado build pynq full hardware flow. The important operands are set: the value named 'set' in this block; ip_repo: the value named 'ip repo' in this block; file: the value named 'file' in this block.

Line 84: `file mkdir $ip_repo` This batch-control line contributes to the flow that runs the reproducible Vivado build pynq full hardware flow. The important operands are file: the value named 'file' in this block; mkdir: the value named 'mkdir' in this block; ip_repo: the value named 'ip repo' in this block.

Line 85: `ipx::package_project -root_dir $ip_repo -vendor neuraedge.local \` This batch-control line contributes to the flow that runs the reproducible Vivado build pynq full hardware flow. The important operands are ipx: the value named 'ipx' in this block; package_project: the value named 'package project' in this block; root_dir: the value named 'root dir' in this block.

Line 86: `-library accelerator -taxonomy /UserIP -import_files -set_current true` This batch-control line contributes to the flow that runs the reproducible Vivado build pynq full hardware flow. The important operands are library: the value named 'library' in this block; accelerator: the value named 'accelerator' in this block; taxonomy: the value named 'taxonomy' in this block.

Line 87: `set packaged_core [ipx::current_core]` This batch-control line contributes to the flow that runs the reproducible Vivado build pynq full hardware flow. The important operands are set: the value named 'set' in this block; packaged_core: the value named 'packaged core' in this block; ipx: the value named 'ipx' in this block.

Line 88: `set_property name neuraedge_universal $packaged_core` This batch-control line contributes to the flow that runs the reproducible Vivado build pynq full hardware flow. The important operands are set_property: the value named 'set property' in this block; name: the value named 'name' in this block; neuraedge_universal: the value named 'neuraedge universal' in this block.

Line 89: `set_property display_name "NeuraEdge Universal Accelerator" $packaged_core` This batch-control line contributes to the flow that runs the reproducible Vivado build pynq full hardware flow. The important operands are set_property: the value named 'set property' in this block; display_name: the value named 'display name' in this block; NeuraEdge: the value named 'neura edge' in this block.

Line 90: `set_property description "INT8, sparse, spiking, transformer, and on-fabric optimizer accelerator" $package...` This batch-control line contributes to the flow that runs the reproducible Vivado build pynq full hardware flow. The important operands are set_property: the value named 'set property' in this block; description: the value named 'description' in this block; INT8: the value named 'int8' in this block.

Line 91: `set_property version 1.0 $packaged_core` This batch-control line contributes to the flow that runs the reproducible Vivado build pynq full hardware flow. The important operands are set_property: the value named 'set property' in this block; version: the value named 'version' in this block; packaged_core: the value named 'packaged core' in this block.

Line 92: `set_property core_revision 1 $packaged_core` This batch-control line contributes to the flow that runs the reproducible Vivado build pynq full hardware flow. The important operands are set_property: the value named 'set property' in this block; core_revision: the value named 'core revision' in this block; packaged_core: the value named 'packaged core' in this block.

Line 93: `set s_axi_interface [ipx::get_bus_interfaces S_AXI -of_objects $packaged_core]` This batch-control line contributes to the flow that runs the reproducible Vivado build pynq full hardware flow. The important operands are set: the value named 'set' in this block; s_axi_interface: the value named 's axi interface' in this block; ipx: the value named 'ipx' in this block.

Line 94: `ipx::add_memory_map S_AXI $packaged_core` This batch-control line contributes to the flow that runs the reproducible Vivado build pynq full hardware flow. The important operands are ipx: the value named 'ipx' in this block; add_memory_map: local FPGA storage addressed by surrounding index logic; S_AXI: the value named 's axi' in this block.

Line 95: `set_property slave_memory_map_ref S_AXI $s_axi_interface` This batch-control line contributes to the flow that runs the reproducible Vivado build pynq full hardware flow. The important operands are set_property: the value named 'set property' in this block; slave_memory_map_ref: local FPGA storage addressed by surrounding index logic; S_AXI: the value named 's axi' in this block.

Line 96: `set memory_map [ipx::get_memory_maps S_AXI -of_objects $packaged_core]` This batch-control line contributes to the flow that runs the reproducible Vivado build pynq full hardware flow. The important operands are set: the value named 'set' in this block; memory_map: local FPGA storage addressed by surrounding index logic; ipx: the value named 'ipx' in this block.

Line 97: `ipx::add_address_block Reg $memory_map` This batch-control line contributes to the flow that runs the reproducible Vivado build pynq full hardware flow. The important operands are ipx: the value named 'ipx' in this block; add_address_block: the value named 'add address block' in this block; Reg: the value named 'reg' in this block.

Line 98: `set register_block [ipx::get_address_blocks Reg -of_objects $memory_map]` This batch-control line contributes to the flow that runs the reproducible Vivado build pynq full hardware flow. The important operands are set: the value named 'set' in this block; register_block: the value named 'register block' in this block; ipx: the value named 'ipx' in this block.

Line 99: `set_property range 256 $register_block` This batch-control line contributes to the flow that runs the reproducible Vivado build pynq full hardware flow. The important operands are set_property: the value named 'set property' in this block; range: the value named 'range' in this block; register_block: the value named 'register block' in this block.

Line 100: `set_property width 32 $register_block` This batch-control line contributes to the flow that runs the reproducible Vivado build pynq full hardware flow. The important operands are set_property: the value named 'set property' in this block; width: the value named 'width' in this block; register_block: the value named 'register block' in this block.

Line 101: `ipx::associate_bus_interfaces -busif S_AXI -clock aclk $packaged_core` This batch-control line contributes to the flow that runs the reproducible Vivado build pynq full hardware flow. The important operands are ipx: the value named 'ipx' in this block; associate_bus_interfaces: the value named 'associate bus interfaces' in this block; busif: the value named 'busif' in this block.

Line 102: `ipx::associate_bus_interfaces -busif S_AXIS -clock aclk $packaged_core` This batch-control line contributes to the flow that runs the reproducible Vivado build pynq full hardware flow. The important operands are ipx: the value named 'ipx' in this block; associate_bus_interfaces: the value named 'associate bus interfaces' in this block; busif: the value named 'busif' in this block.

Line 103: `ipx::associate_bus_interfaces -busif M_AXIS -clock aclk $packaged_core` This batch-control line contributes to the flow that runs the reproducible Vivado build pynq full hardware flow. The important operands are ipx: the value named 'ipx' in this block; associate_bus_interfaces: the value named 'associate bus interfaces' in this block; busif: the value named 'busif' in this block.

Line 104: `ipx::create_xgui_files $packaged_core` This batch-control line contributes to the flow that runs the reproducible Vivado build pynq full hardware flow. The important operands are ipx: the value named 'ipx' in this block; create_xgui_files: the value named 'create xgui files' in this block; packaged_core: the value named 'packaged core' in this block.

Line 105: `ipx::update_checksums $packaged_core` This batch-control line contributes to the flow that runs the reproducible Vivado build pynq full hardware flow. The important operands are ipx: the value named 'ipx' in this block; update_checksums: the value named 'update checksums' in this block; packaged_core: the value named 'packaged core' in this block.

Line 106: `ipx::save_core $packaged_core` This batch-control line contributes to the flow that runs the reproducible Vivado build pynq full hardware flow. The important operands are ipx: the value named 'ipx' in this block; save_core: the value named 'save core' in this block; packaged_core: the value named 'packaged core' in this block.

Line 107: `set_property ip_repo_paths [list [file dirname $ip_repo]] [current_project]` This batch-control line contributes to the flow that runs the reproducible Vivado build pynq full hardware flow. The important operands are set_property: the value named 'set property' in this block; ip_repo_paths: the value named 'ip repo paths' in this block; list: the value named 'list' in this block.

Line 108: `update_ip_catalog` This batch-control line contributes to the flow that runs the reproducible Vivado build pynq full hardware flow. The important operands are update_ip_catalog: the value named 'update ip catalog' in this block.

Line 110: `create_bd_design system` This batch-control line contributes to the flow that runs the reproducible Vivado build pynq full hardware flow. The important operands are create_bd_design: the value named 'create bd design' in this block; system: the value named 'system' in this block.

Line 112: `set ps7 [create_bd_cell -type ip -vlnv xilinx.com:ip:processing_system7:5.5 ps7]` This batch-control line contributes to the flow that runs the reproducible Vivado build pynq full hardware flow. The important operands are set: the value named 'set' in this block; ps7: the value named 'ps7' in this block; create_bd_cell: the value named 'create bd cell' in this block.

Line 113: `apply_bd_automation -rule xilinx.com:bd_rule:processing_system7 \` This batch-control line contributes to the flow that runs the reproducible Vivado build pynq full hardware flow. The important operands are apply_bd_automation: the value named 'apply bd automation' in this block; rule: the value named 'rule' in this block; xilinx: the value named 'xilinx' in this block.

Line 114: `-config {apply_board_preset "1" make_external "FIXED_IO, DDR" Master "Disable" Slave "Disable"} \` This batch-control line contributes to the flow that runs the reproducible Vivado build pynq full hardware flow. The important operands are config: the value named 'config' in this block; apply_board_preset: the value named 'apply board preset' in this block; make_external: the value named 'make external' in this block.

Line 115: `$ps7` This batch-control line contributes to the flow that runs the reproducible Vivado build pynq full hardware flow. The important operands are ps7: the value named 'ps7' in this block.

Line 116: `set_property -dict [list \` This batch-control line contributes to the flow that runs the reproducible Vivado build pynq full hardware flow. The important operands are set_property: the value named 'set property' in this block; dict: the value named 'dict' in this block; list: the value named 'list' in this block.

Line 117: `CONFIG.PCW_USE_M_AXI_GP0 {1} \` This batch-control line contributes to the flow that runs the reproducible Vivado build pynq full hardware flow. The important operands are CONFIG: the value named 'config' in this block; PCW_USE_M_AXI_GP0: the value named 'pcw use m axi gp0' in this block.

Line 118: `CONFIG.PCW_USE_S_AXI_HP0 {1} \` This batch-control line contributes to the flow that runs the reproducible Vivado build pynq full hardware flow. The important operands are CONFIG: the value named 'config' in this block; PCW_USE_S_AXI_HP0: the value named 'pcw use s axi hp0' in this block.

Line 119: `CONFIG.PCW_S_AXI_HP0_DATA_WIDTH {64} \` This batch-control line contributes to the flow that runs the reproducible Vivado build pynq full hardware flow. The important operands are CONFIG: the value named 'config' in this block; PCW_S_AXI_HP0_DATA_WIDTH: the value named 'pcw s axi hp0 data width' in this block.

Line 120: `CONFIG.PCW_S_AXI_HP0_ID_WIDTH {1} \` This batch-control line contributes to the flow that runs the reproducible Vivado build pynq full hardware flow. The important operands are CONFIG: the value named 'config' in this block; PCW_S_AXI_HP0_ID_WIDTH: the value named 'pcw s axi hp0 id width' in this block.

Line 121: `CONFIG.PCW_USE_FABRIC_INTERRUPT {1} \` This batch-control line contributes to the flow that runs the reproducible Vivado build pynq full hardware flow. The important operands are CONFIG: the value named 'config' in this block; PCW_USE_FABRIC_INTERRUPT: the hardware notification that wakes software after completion or error.

Line 122: `CONFIG.PCW_IRQ_F2P_INTR {1} \` This batch-control line contributes to the flow that runs the reproducible Vivado build pynq full hardware flow. The important operands are CONFIG: the value named 'config' in this block; PCW_IRQ_F2P_INTR: the value named 'pcw irq f2 p intr' in this block.

Line 123: `CONFIG.PCW_EN_CLK0_PORT {1} \` This batch-control line contributes to the flow that runs the reproducible Vivado build pynq full hardware flow. The important operands are CONFIG: the value named 'config' in this block; PCW_EN_CLK0_PORT: the clock that makes all registers advance together.

Line 124: `CONFIG.PCW_EN_CLK1_PORT {1} \` This batch-control line contributes to the flow that runs the reproducible Vivado build pynq full hardware flow. The important operands are CONFIG: the value named 'config' in this block; PCW_EN_CLK1_PORT: the clock that makes all registers advance together.

Line 125: `CONFIG.PCW_EN_CLK2_PORT {1} \` This batch-control line contributes to the flow that runs the reproducible Vivado build pynq full hardware flow. The important operands are CONFIG: the value named 'config' in this block; PCW_EN_CLK2_PORT: the clock that makes all registers advance together.

Line 126: `CONFIG.PCW_FPGA0_PERIPHERAL_FREQMHZ {100.000000} \` This batch-control line contributes to the flow that runs the reproducible Vivado build pynq full hardware flow. The important operands are CONFIG: the value named 'config' in this block; PCW_FPGA0_PERIPHERAL_FREQMHZ: the value named 'pcw fpga0 peripheral freqmhz' in this block.

Line 127: `CONFIG.PCW_FPGA1_PERIPHERAL_FREQMHZ {125.000000} \` This batch-control line contributes to the flow that runs the reproducible Vivado build pynq full hardware flow. The important operands are CONFIG: the value named 'config' in this block; PCW_FPGA1_PERIPHERAL_FREQMHZ: the value named 'pcw fpga1 peripheral freqmhz' in this block.

Line 128: `CONFIG.PCW_FPGA2_PERIPHERAL_FREQMHZ {200.000000}] $ps7` This batch-control line contributes to the flow that runs the reproducible Vivado build pynq full hardware flow. The important operands are CONFIG: the value named 'config' in this block; PCW_FPGA2_PERIPHERAL_FREQMHZ: the value named 'pcw fpga2 peripheral freqmhz' in this block; ps7: the value named 'ps7' in this block.

Line 129: `# The board preset assigns 10 MHz to this disabled-by-default interface. Once` This comment documents the batch-flow intent: The board preset assigns 10 MHz to this disabled-by-default interface. Once

Line 130: `# GP0 is enabled, let block-design propagation derive its frequency from the` This comment documents the batch-flow intent: GP0 is enabled, let block-design propagation derive its frequency from the

Line 131: `# connected 100 MHz FCLK0 instead of retaining that stale user-strength value.` This comment documents the batch-flow intent: connected 100 MHz FCLK0 instead of retaining that stale user-strength value.

Line 132: `set_property CONFIG.PCW_M_AXI_GP0_FREQMHZ.VALUE_SRC auto $ps7` This batch-control line contributes to the flow that runs the reproducible Vivado build pynq full hardware flow. The important operands are set_property: the value named 'set property' in this block; CONFIG: the value named 'config' in this block; PCW_M_AXI_GP0_FREQMHZ: the value named 'pcw m axi gp0 freqmhz' in this block.

Line 134: `set reset_100 [create_bd_cell -type ip -vlnv xilinx.com:ip:proc_sys_reset:5.0 reset_100]` This batch-control line contributes to the flow that runs the reproducible Vivado build pynq full hardware flow. The important operands are set: the value named 'set' in this block; reset_100: the value named 'reset 100' in this block; create_bd_cell: the value named 'create bd cell' in this block.

Line 135: `set reset_125 [create_bd_cell -type ip -vlnv xilinx.com:ip:proc_sys_reset:5.0 reset_125]` This batch-control line contributes to the flow that runs the reproducible Vivado build pynq full hardware flow. The important operands are set: the value named 'set' in this block; reset_125: the value named 'reset 125' in this block; create_bd_cell: the value named 'create bd cell' in this block.

Line 136: `set reset_200 [create_bd_cell -type ip -vlnv xilinx.com:ip:proc_sys_reset:5.0 reset_200]` This batch-control line contributes to the flow that runs the reproducible Vivado build pynq full hardware flow. The important operands are set: the value named 'set' in this block; reset_200: the value named 'reset 200' in this block; create_bd_cell: the value named 'create bd cell' in this block.

Line 137: `set accelerator_control_cdc [create_bd_cell -type ip -vlnv xilinx.com:ip:axi_clock_converter:2.1 accelerato...` This batch-control line contributes to the flow that runs the reproducible Vivado build pynq full hardware flow. The important operands are set: the value named 'set' in this block; accelerator_control_cdc: the value named 'accelerator control cdc' in this block; create_bd_cell: the value named 'create bd cell' in this block.

Line 138: `set dma_control_cdc [create_bd_cell -type ip -vlnv xilinx.com:ip:axi_clock_converter:2.1 dma_contro` This batch-control line contributes to the flow that runs the reproducible Vivado build pynq full hardware flow. The important operands are set: the value named 'set' in this block; dma_control_cdc: the direct-memory-access engine moving contiguous buffers between DDR and FPGA logic; create_bd_cell: the value named 'create bd cell' in this block.

Line 139: `set control_interconnect [create_bd_cell -type ip -vlnv xilinx.com:ip:axi_interconnect:2.1 control_intercon...` This batch-control line contributes to the flow that runs the reproducible Vivado build pynq full hardware flow. The important operands are set: the value named 'set' in this block; control_interconnect: the value named 'control interconnect' in this block; create_bd_cell: the value named 'create bd cell' in this block.

Line 140: `set_property -dict [list CONFIG.NUM_SI {1} CONFIG.NUM_MI {2}] $control_interconnect` This batch-control line contributes to the flow that runs the reproducible Vivado build pynq full hardware flow. The important operands are set_property: the value named 'set property' in this block; dict: the value named 'dict' in this block; list: the value named 'list' in this block.

Line 142: `set dma [create_bd_cell -type ip -vlnv xilinx.com:ip:axi_dma:7.1 dma]` This batch-control line contributes to the flow that runs the reproducible Vivado build pynq full hardware flow. The important operands are set: the value named 'set' in this block; dma: the direct-memory-access engine moving contiguous buffers between DDR and FPGA logic; create_bd_cell: the value named 'create bd cell' in this block.

Line 143: `set_property -dict [list \` This batch-control line contributes to the flow that runs the reproducible Vivado build pynq full hardware flow. The important operands are set_property: the value named 'set property' in this block; dict: the value named 'dict' in this block; list: the value named 'list' in this block.

Line 144: `CONFIG.c_include_sg {0} \` This batch-control line contributes to the flow that runs the reproducible Vivado build pynq full hardware flow. The important operands are CONFIG: the value named 'config' in this block; c_include_sg: the value named 'c include sg' in this block.

Line 145: `CONFIG.c_sg_length_width {26} \` This batch-control line contributes to the flow that runs the reproducible Vivado build pynq full hardware flow. The important operands are CONFIG: the value named 'config' in this block; c_sg_length_width: the value named 'c sg length width' in this block.

Line 146: `CONFIG.c_include_mm2s {1} \` This batch-control line contributes to the flow that runs the reproducible Vivado build pynq full hardware flow. The important operands are CONFIG: the value named 'config' in this block; c_include_mm2s: the value named 'c include mm2s' in this block.

Line 147: `CONFIG.c_include_s2mm {1} \` This batch-control line contributes to the flow that runs the reproducible Vivado build pynq full hardware flow. The important operands are CONFIG: the value named 'config' in this block; c_include_s2mm: the value named 'c include s2mm' in this block.

Line 148: `CONFIG.c_include_mm2s_dre {1} \` This batch-control line contributes to the flow that runs the reproducible Vivado build pynq full hardware flow. The important operands are CONFIG: the value named 'config' in this block; c_include_mm2s_dre: the value named 'c include mm2s dre' in this block.

Line 149: `CONFIG.c_include_s2mm_dre {1} \` This batch-control line contributes to the flow that runs the reproducible Vivado build pynq full hardware flow. The important operands are CONFIG: the value named 'config' in this block; c_include_s2mm_dre: the value named 'c include s2mm dre' in this block.

Line 150: `CONFIG.c_m_axi_mm2s_data_width {64} \` This batch-control line contributes to the flow that runs the reproducible Vivado build pynq full hardware flow. The important operands are CONFIG: the value named 'config' in this block; c_m_axi_mm2s_data_width: the value named 'c m axi mm2s data width' in this block.

Line 151: `CONFIG.c_m_axi_s2mm_data_width {64} \` This batch-control line contributes to the flow that runs the reproducible Vivado build pynq full hardware flow. The important operands are CONFIG: the value named 'config' in this block; c_m_axi_s2mm_data_width: the value named 'c m axi s2mm data width' in this block.

Line 152: `CONFIG.c_m_axis_mm2s_tdata_width {64} \` This batch-control line contributes to the flow that runs the reproducible Vivado build pynq full hardware flow. The important operands are CONFIG: the value named 'config' in this block; c_m_axis_mm2s_tdata_width: the value named 'c m axis mm2s tdata width' in this block.

Line 153: `CONFIG.c_s_axis_s2mm_tdata_width {64} \` This batch-control line contributes to the flow that runs the reproducible Vivado build pynq full hardware flow. The important operands are CONFIG: the value named 'config' in this block; c_s_axis_s2mm_tdata_width: the value named 'c s axis s2mm tdata width' in this block.

Line 154: `CONFIG.c_mm2s_burst_size {256} \` This batch-control line contributes to the flow that runs the reproducible Vivado build pynq full hardware flow. The important operands are CONFIG: the value named 'config' in this block; c_mm2s_burst_size: the value named 'c mm2s burst size' in this block.

Line 155: `CONFIG.c_s2mm_burst_size {256}] $dma` This batch-control line contributes to the flow that runs the reproducible Vivado build pynq full hardware flow. The important operands are CONFIG: the value named 'config' in this block; c_s2mm_burst_size: the value named 'c s2mm burst size' in this block; dma: the direct-memory-access engine moving contiguous buffers between DDR and FPGA logic.

Line 157: `set memory_interconnect [create_bd_cell -type ip -vlnv xilinx.com:ip:axi_interconnect:2.1 memory_interconnect]` This batch-control line contributes to the flow that runs the reproducible Vivado build pynq full hardware flow. The important operands are set: the value named 'set' in this block; memory_interconnect: local FPGA storage addressed by surrounding index logic; create_bd_cell: the value named 'create bd cell' in this block.

Line 158: `set_property -dict [list CONFIG.NUM_SI {2} CONFIG.NUM_MI {1}] $memory_interconnect` This batch-control line contributes to the flow that runs the reproducible Vivado build pynq full hardware flow. The important operands are set_property: the value named 'set property' in this block; dict: the value named 'dict' in this block; list: the value named 'list' in this block.

Line 160: `set mm2s_cdc [create_bd_cell -type ip -vlnv xilinx.com:ip:axis_clock_converter:1.1 mm2s_cdc]` This batch-control line contributes to the flow that runs the reproducible Vivado build pynq full hardware flow. The important operands are set: the value named 'set' in this block; mm2s_cdc: the value named 'mm2s cdc' in this block; create_bd_cell: the value named 'create bd cell' in this block.

Line 161: `set s2mm_cdc [create_bd_cell -type ip -vlnv xilinx.com:ip:axis_clock_converter:1.1 s2mm_cdc]` This batch-control line contributes to the flow that runs the reproducible Vivado build pynq full hardware flow. The important operands are set: the value named 'set' in this block; s2mm_cdc: the value named 's2mm cdc' in this block; create_bd_cell: the value named 'create bd cell' in this block.

Line 162: `foreach stream_cdc [list $mm2s_cdc $s2mm_cdc] {` This batch-control line contributes to the flow that runs the reproducible Vivado build pynq full hardware flow. The important operands are foreach: the value named 'foreach' in this block; stream_cdc: the value named 'stream cdc' in this block; list: the value named 'list' in this block.

Line 163: `set_property -dict [list \` This batch-control line contributes to the flow that runs the reproducible Vivado build pynq full hardware flow. The important operands are set_property: the value named 'set property' in this block; dict: the value named 'dict' in this block; list: the value named 'list' in this block.

Line 164: `CONFIG.TDATA_NUM_BYTES {8} \` This batch-control line contributes to the flow that runs the reproducible Vivado build pynq full hardware flow. The important operands are CONFIG: the value named 'config' in this block; TDATA_NUM_BYTES: the value named 'tdata num bytes' in this block.

Line 165: `CONFIG.HAS_TKEEP {1} \` This batch-control line contributes to the flow that runs the reproducible Vivado build pynq full hardware flow. The important operands are CONFIG: the value named 'config' in this block; HAS_TKEEP: the value named 'has tkeep' in this block.

Line 166: `CONFIG.HAS_TLAST {1} \` This batch-control line contributes to the flow that runs the reproducible Vivado build pynq full hardware flow. The important operands are CONFIG: the value named 'config' in this block; HAS_TLAST: the AXI-Stream marker for the final beat of a packet or command payload.

Line 167: `CONFIG.IS_ACLK_ASYNC {1} \` This batch-control line contributes to the flow that runs the reproducible Vivado build pynq full hardware flow. The important operands are CONFIG: the value named 'config' in this block; IS_ACLK_ASYNC: the clock that makes all registers advance together.

Line 168: `CONFIG.SYNCHRONIZATION_STAGES {3}] $stream_cdc` This batch-control line contributes to the flow that runs the reproducible Vivado build pynq full hardware flow. The important operands are CONFIG: the value named 'config' in this block; SYNCHRONIZATION_STAGES: the value named 'synchronization stages' in this block; stream_cdc: the value named 'stream cdc' in this block.

Line 169: `}` This batch-control line contributes to the flow that runs the reproducible Vivado build pynq full hardware flow. The expression is a literal or structural operator and has no hidden software state.

Line 171: `set accelerator [create_bd_cell -type ip \` This batch-control line contributes to the flow that runs the reproducible Vivado build pynq full hardware flow. The important operands are set: the value named 'set' in this block; accelerator: the value named 'accelerator' in this block; create_bd_cell: the value named 'create bd cell' in this block.

Line 172: `-vlnv neuraedge.local:accelerator:neuraedge_universal:1.0 accelerator]` This batch-control line contributes to the flow that runs the reproducible Vivado build pynq full hardware flow. The important operands are vlnv: the value named 'vlnv' in this block; neuraedge: the value named 'neuraedge' in this block; local: the value named 'local' in this block.

Line 173: `set interrupt_concat [create_bd_cell -type inline_hdl \` This batch-control line contributes to the flow that runs the reproducible Vivado build pynq full hardware flow. The important operands are set: the value named 'set' in this block; interrupt_concat: the hardware notification that wakes software after completion or error; create_bd_cell: the value named 'create bd cell' in this block.

Line 174: `-vlnv xilinx.com:inline_hdl:ilconcat:1.0 interrupt_concat]` This batch-control line contributes to the flow that runs the reproducible Vivado build pynq full hardware flow. The important operands are vlnv: the value named 'vlnv' in this block; xilinx: the value named 'xilinx' in this block; com: the value named 'com' in this block.

Line 175: `set_property CONFIG.NUM_PORTS {16} $interrupt_concat` This batch-control line contributes to the flow that runs the reproducible Vivado build pynq full hardware flow. The important operands are set_property: the value named 'set property' in this block; CONFIG: the value named 'config' in this block; NUM_PORTS: the value named 'num ports' in this block.

Line 176: `set interrupt_zero [create_bd_cell -type inline_hdl \` This batch-control line contributes to the flow that runs the reproducible Vivado build pynq full hardware flow. The important operands are set: the value named 'set' in this block; interrupt_zero: the hardware notification that wakes software after completion or error; create_bd_cell: the value named 'create bd cell' in this block.

Line 177: `-vlnv xilinx.com:inline_hdl:ilconstant:1.0 interrupt_zero]` This batch-control line contributes to the flow that runs the reproducible Vivado build pynq full hardware flow. The important operands are vlnv: the value named 'vlnv' in this block; xilinx: the value named 'xilinx' in this block; com: the value named 'com' in this block.

Line 178: `set_property -dict [list CONFIG.CONST_WIDTH {1} CONFIG.CONST_VAL {0}] $interrupt_zero` This batch-control line contributes to the flow that runs the reproducible Vivado build pynq full hardware flow. The important operands are set_property: the value named 'set property' in this block; dict: the value named 'dict' in this block; list: the value named 'list' in this block.

Line 180: `# Control path: the 100 MHz GP0/interconnect fans out through explicit CDCs to` This comment documents the batch-flow intent: Control path: the 100 MHz GP0/interconnect fans out through explicit CDCs to

Line 181: `# the 200 MHz accelerator and the 125 MHz DMA register interface.` This comment documents the batch-flow intent: the 200 MHz accelerator and the 125 MHz DMA register interface.

Line 182: `connect_bd_intf_net [get_bd_intf_pins ps7/M_AXI_GP0] [get_bd_intf_pins control_interconnect/S00_AXI`
This connects two complete block-design interfaces, carrying all AXI channel signals defined by that interface. Vivado validates widths, directions, clocks, and protocol compatibility for 'connect_bd_intf_net [get_bd_intf_pins ps7/M_AXI_GP0] [get_bd_intf_pins control_interconnect/S00_AXI]'.

Line 183: `connect_bd_intf_net [get_bd_intf_pins control_interconnect/M00_AXI] [get_bd_intf_pins accelerator_c`
This connects two complete block-design interfaces, carrying all AXI channel signals defined by that interface. Vivado validates widths, directions, clocks, and protocol compatibility for 'connect_bd_intf_net [get_bd_intf_pins control_interconnect/M00_AXI] [get_bd_intf_pins accelerator_control_cdc/S_AXI]'.

Line 184: `connect_bd_intf_net [get_bd_intf_pins accelerator_control_cdc/M_AXI] [get_bd_intf_pins accelerator/`
This connects two complete block-design interfaces, carrying all AXI channel signals defined by that interface. Vivado validates widths, directions, clocks, and protocol compatibility for 'connect_bd_intf_net [get_bd_intf_pins accelerator_control_cdc/M_AXI] [get_bd_intf_pins accelerator/S_AXI]'.

Line 185: `connect_bd_intf_net [get_bd_intf_pins control_interconnect/M01_AXI] [get_bd_intf_pins dma_control_c`
This connects two complete block-design interfaces, carrying all AXI channel signals defined by that interface. Vivado validates widths, directions, clocks, and protocol compatibility for 'connect_bd_intf_net [get_bd_intf_pins control_interconnect/M01_AXI] [get_bd_intf_pins dma_control_cdc/S_AXI]'.

Line 218: `[get_bd_pins dma_control_cdc/m_axi_aclk] \` This batch-control line contributes to the flow that runs the reproducible Vivado build pynq full hardware flow. The important operands are get_bd_pins: the value named 'get bd pins' in this block; dma_control_cdc: the direct-memory-access engine moving contiguous buffers between DDR and FPGA logic; m_axi_aclk: the clock that makes all registers advance together.

Line 219: `[get_bd_pins mm2s_cdc/s_axis_aclk] \` This batch-control line contributes to the flow that runs the reproducible Vivado build pynq full hardware flow. The important operands are get_bd_pins: the value named 'get bd pins' in this block; mm2s_cdc: the value named 'mm2s cdc' in this block; s_axis_aclk: the clock that makes all registers advance together.

Line 220: `[get_bd_pins s2mm_cdc/m_axis_aclk]` This batch-control line contributes to the flow that runs the reproducible Vivado build pynq full hardware flow. The important operands are get_bd_pins: the value named 'get bd pins' in this block; s2mm_cdc: the value named 's2mm cdc' in this block; m_axis_aclk: the clock that makes all registers advance together.

Line 221: `connect_bd_net [get_bd_pins ps7/FCLK_CLK2] \` This connects scalar or bus pins in the block design. For clocks and resets, this exact connection decides the timing domain and reset island of every attached register: 'connect_bd_net [get_bd_pins ps7/FCLK_CLK2] \'.

Line 222: `[get_bd_pins reset_200/slowest_sync_clk] \` This batch-control line contributes to the flow that runs the reproducible Vivado build pynq full hardware flow. The important operands are get_bd_pins: the value named 'get bd pins' in this block; reset_200: the value named 'reset 200' in this block; slowest_sync_clk: the clock that makes all registers advance together.

Line 223: `[get_bd_pins accelerator_control_cdc/m_axi_aclk] \` This batch-control line contributes to the flow that runs the reproducible Vivado build pynq full hardware flow. The important operands are get_bd_pins: the value named 'get bd pins' in this block; accelerator_control_cdc: the value named 'accelerator control cdc' in this block; m_axi_aclk: the clock that makes all registers advance together.

Line 224: `[get_bd_pins mm2s_cdc/m_axis_aclk] \` This batch-control line contributes to the flow that runs the reproducible Vivado build pynq full hardware flow. The important operands are get_bd_pins: the value named 'get bd pins' in this block; mm2s_cdc: the value named 'mm2s cdc' in this block; m_axis_aclk: the clock that makes all registers advance together.

Line 225: `[get_bd_pins s2mm_cdc/s_axis_aclk] \` This batch-control line contributes to the flow that runs the reproducible Vivado build pynq full hardware flow. The important operands are get_bd_pins: the value named 'get bd pins' in this block; s2mm_cdc: the value named 's2mm cdc' in this block; s_axis_aclk: the clock that makes all registers advance together.

Line 226: `[get_bd_pins accelerator/aclk]` This batch-control line contributes to the flow that runs the reproducible Vivado build pynq full hardware flow. The important operands are get_bd_pins: the value named 'get bd pins' in this block; accelerator: the value named 'accelerator' in this block; aclk: the AXI and accelerator clock.

Line 227: `connect_bd_net [get_bd_pins ps7/FCLK_RESET0_N] \` This connects scalar or bus pins in the block design. For clocks and resets, this exact connection decides the timing domain and reset island of every attached register: 'connect_bd_net [get_bd_pins ps7/FCLK_RESET0_N] \'.

Line 228: `[get_bd_pins reset_100/ext_reset_in] \` This batch-control line contributes to the flow that runs the reproducible Vivado build pynq full hardware flow. The important operands are get_bd_pins: the value named 'get bd pins' in this block; reset_100: the value named 'reset 100' in this block; ext_reset_in: the value named 'ext reset in' in this block.

Line 229: `[get_bd_pins reset_125/ext_reset_in] \` This batch-control line contributes to the flow that runs the reproducible Vivado build pynq full hardware flow. The important operands are get_bd_pins: the value named 'get bd pins' in this block; reset_125: the value named 'reset 125' in this block; ext_reset_in: the value named 'ext reset in' in this block.

Line 230: `[get_bd_pins reset_200/ext_reset_in]` This batch-control line contributes to the flow that runs the reproducible Vivado build pynq full hardware flow. The important operands are get_bd_pins: the value named 'get bd pins' in this block; reset_200: the value named 'reset 200' in this block; ext_reset_in: the value named 'ext reset in' in this block.

Line 231: `connect_bd_net [get_bd_pins reset_100/interconnect_aresetn] \` This connects scalar or bus pins in the block design. For clocks and resets, this exact connection decides the timing domain and reset island of every attached register: 'connect_bd_net [get_bd_pins reset_100/interconnect_aresetn] \'.

Line 232: `[get_bd_pins control_interconnect/ARESETN] \` This batch-control line contributes to the flow that runs the reproducible Vivado build pynq full hardware flow. The important operands are get_bd_pins: the value named 'get bd pins' in this block; control_interconnect: the value named 'control interconnect' in this block; ARESETN: the active-low AXI reset.

Line 233: `[get_bd_pins control_interconnect/S00_ARESETN] \` This batch-control line contributes to the flow that runs the reproducible Vivado build pynq full hardware flow. The important operands are get_bd_pins: the value named 'get bd pins' in this block; control_interconnect: the value named 'control interconnect' in this block; S00_ARESETN: the active-low AXI reset.

Line 234: `[get_bd_pins control_interconnect/M00_ARESETN] \` This batch-control line contributes to the flow that runs the reproducible Vivado build pynq full hardware flow. The important operands are get_bd_pins: the value named 'get bd pins' in this block; control_interconnect: the value named 'control interconnect' in this block; M00_ARESETN: the active-low AXI reset.

Line 235: `[get_bd_pins control_interconnect/M01_ARESETN] \` This batch-control line contributes to the flow that runs the reproducible Vivado build pynq full hardware flow. The important operands are get_bd_pins: the value named 'get bd pins' in this block; control_interconnect: the value named 'control interconnect' in this block; M01_ARESETN: the active-low AXI reset.

Line 236: `[get_bd_pins accelerator_control_cdc/s_axi_aresetn] \` This batch-control line contributes to the flow that runs the reproducible Vivado build pynq full hardware flow. The important operands are get_bd_pins: the value named 'get bd pins' in this block; accelerator_control_cdc: the value named 'accelerator control cdc' in this block; s_axi_aresetn: the active-low AXI reset.

Line 237: `[get_bd_pins dma_control_cdc/s_axi_aresetn]` This batch-control line contributes to the flow that runs the reproducible Vivado build pynq full hardware flow. The important operands are get_bd_pins: the value named 'get bd pins' in this block; dma_control_cdc: the direct-memory-access engine moving contiguous buffers between DDR and FPGA logic; s_axi_aresetn: the active-low AXI reset.

Line 238: `connect_bd_net [get_bd_pins reset_125/interconnect_aresetn] \` This connects scalar or bus pins in the block design. For clocks and resets, this exact connection decides the timing domain and reset island of every attached register: 'connect_bd_net [get_bd_pins reset_125/interconnect_aresetn] \'.

Line 239: `[get_bd_pins dma_control_cdc/m_axi_aresetn] \` This batch-control line contributes to the flow that runs the reproducible Vivado build pynq full hardware flow. The important operands are get_bd_pins: the value named 'get bd pins' in this block; dma_control_cdc: the direct-memory-access engine moving contiguous buffers between DDR and FPGA logic; m_axi_aresetn: the active-low AXI reset.

Line 240: `[get_bd_pins memory_interconnect/ARESETN] \` This batch-control line contributes to the flow that runs the reproducible Vivado build pynq full hardware flow. The important operands are get_bd_pins: the value named 'get bd pins' in this block; memory_interconnect: local FPGA storage addressed by surrounding index logic; ARESETN: the active-low AXI reset.

Line 241: `[get_bd_pins memory_interconnect/S00_ARESETN] \` This batch-control line contributes to the flow that runs the reproducible Vivado build pynq full hardware flow. The important operands are get_bd_pins: the value named 'get bd pins' in this block; memory_interconnect: local FPGA storage addressed by surrounding index logic; S00_ARESETN: the active-low AXI reset.

Line 242: `[get_bd_pins memory_interconnect/S01_ARESETN] \` This batch-control line contributes to the flow that runs the reproducible Vivado build pynq full hardware flow. The important operands are get_bd_pins: the value named 'get bd pins' in this block; memory_interconnect: local FPGA storage addressed by surrounding index logic; S01_ARESETN: the active-low AXI reset.

Line 243: `[get_bd_pins memory_interconnect/M00_ARESETN]` This batch-control line contributes to the flow that runs the reproducible Vivado build pynq full hardware flow. The important operands are get_bd_pins: the value named 'get bd pins' in this block; memory_interconnect: local FPGA storage addressed by surrounding index logic; M00_ARESETN: the active-low AXI reset.

Line 244: `connect_bd_net [get_bd_pins reset_125/peripheral_aresetn] \` This connects scalar or bus pins in the block design. For clocks and resets, this exact connection decides the timing domain and reset island of every attached register: 'connect_bd_net [get_bd_pins reset_125/peripheral_aresetn] \'.

Line 245: `[get_bd_pins dma/axi_resetn] \` This batch-control line contributes to the flow that runs the reproducible Vivado build pynq full hardware flow. The important operands are get_bd_pins: the value named 'get bd pins' in this block; dma: the direct-memory-access engine moving contiguous buffers between DDR and FPGA logic; axi_resetn: the value named 'axi resetn' in this block.

Line 246: `[get_bd_pins mm2s_cdc/s_axis_aresetn] \` This batch-control line contributes to the flow that runs the reproducible Vivado build pynq full hardware flow. The important operands are get_bd_pins: the value named 'get bd pins' in this block; mm2s_cdc: the value named 'mm2s cdc' in this block; s_axis_aresetn: the active-low AXI reset.

Line 247: `[get_bd_pins s2mm_cdc/m_axis_aresetn]` This batch-control line contributes to the flow that runs the reproducible Vivado build pynq full hardware flow. The important operands are get_bd_pins: the value named 'get bd pins' in this block; s2mm_cdc: the value named 's2mm cdc' in this block; m_axis_aresetn: the active-low AXI reset.

Line 248: `connect_bd_net [get_bd_pins reset_200/interconnect_aresetn] \` This connects scalar or bus pins in the block design. For clocks and resets, this exact connection decides the timing domain and reset island of every attached register: 'connect_bd_net [get_bd_pins reset_200/interconnect_aresetn] \'.

Line 249: `[get_bd_pins accelerator_control_cdc/m_axi_aresetn]` This batch-control line contributes to the flow that runs the reproducible Vivado build pynq full hardware flow. The important operands are get_bd_pins: the value named 'get bd pins' in this block; accelerator_control_cdc: the value named 'accelerator control cdc' in this block; m_axi_aresetn: the active-low AXI reset.

Line 250: `connect_bd_net [get_bd_pins reset_200/peripheral_aresetn] \` This connects scalar or bus pins in the block design. For clocks and resets, this exact connection decides the timing domain and reset island of every attached register: 'connect_bd_net [get_bd_pins reset_200/peripheral_aresetn] \'.

Line 251: `[get_bd_pins mm2s_cdc/m_axis_aresetn] \` This batch-control line contributes to the flow that runs the reproducible Vivado build pynq full hardware flow. The important operands are get_bd_pins: the value named 'get bd pins' in this block; mm2s_cdc: the value named 'mm2s cdc' in this block; m_axis_aresetn: the active-low AXI reset.

Line 252: `[get_bd_pins s2mm_cdc/s_axis_aresetn] \` This batch-control line contributes to the flow that runs the reproducible Vivado build pynq full hardware flow. The important operands are get_bd_pins: the value named 'get bd pins' in this block; s2mm_cdc: the value named 's2mm cdc' in this block; s_axis_aresetn: the active-low AXI reset.

Line 253: `[get_bd_pins accelerator/aresetn]` This batch-control line contributes to the flow that runs the reproducible Vivado build pynq full hardware flow. The important operands are get_bd_pins: the value named 'get bd pins' in this block; accelerator: the value named 'accelerator' in this block; aresetn: the active-low AXI reset.

Line 255: `# Accelerator completion and both DMA channels are independently visible to Linux.` This comment documents the batch-flow intent: Accelerator completion and both DMA channels are independently visible to Linux.

Line 256: `connect_bd_net [get_bd_pins accelerator/interrupt] [get_bd_pins interrupt_concat/In0]` This connects scalar or bus pins in the block design. For clocks and resets, this exact connection decides the timing domain and reset island of every attached register: 'connect_bd_net [get_bd_pins accelerator/interrupt] [get_bd_pins interrupt_concat/In0]'.

Line 257: `connect_bd_net [get_bd_pins dma/mm2s_introut] [get_bd_pins interrupt_concat/In1]` This connects scalar or bus pins in the block design. For clocks and resets, this exact connection decides the timing domain and reset island of every attached register: 'connect_bd_net [get_bd_pins dma/mm2s_introut] [get_bd_pins interrupt_concat/In1]'.

Line 258: `connect_bd_net [get_bd_pins dma/s2mm_introut] [get_bd_pins interrupt_concat/In2]` This connects scalar or bus pins in the block design. For clocks and resets, this exact connection decides the timing domain and reset island of every attached register: 'connect_bd_net [get_bd_pins dma/s2mm_introut] [get_bd_pins interrupt_concat/In2]'.

Line 259: `for {set interrupt_index 3} {$interrupt_index < 16} {incr interrupt_index} {` This batch-control line contributes to the flow that runs the reproducible Vivado build pynq full hardware flow. The important operands are for: the value named 'for' in this block; set: the value named 'set' in this block; interrupt_index: the hardware notification that wakes software after completion or error.

Line 260: `connect_bd_net [get_bd_pins interrupt_zero/dout] \` This connects scalar or bus pins in the block design. For clocks and resets, this exact connection decides the timing domain and reset island of every attached register: 'connect_bd_net [get_bd_pins interrupt_zero/dout] \'.

Line 261: `[get_bd_pins interrupt_concat/In$interrupt_index]` This batch-control line contributes to the flow that runs the reproducible Vivado build pynq full hardware flow. The important operands are get_bd_pins: the value named 'get bd pins' in this block; interrupt_concat: the hardware notification that wakes software after completion or error; In$interrupt_index: the hardware notification that wakes software after completion or error.

Line 262: `}` This batch-control line contributes to the flow that runs the reproducible Vivado build pynq full hardware flow. The expression is a literal or structural operator and has no hidden software state.

Line 263: `connect_bd_net [get_bd_pins interrupt_concat/dout] [get_bd_pins ps7/IRQ_F2P]` This connects scalar or bus pins in the block design. For clocks and resets, this exact connection decides the timing domain and reset island of every attached register: 'connect_bd_net [get_bd_pins interrupt_concat/dout] [get_bd_pins ps7/IRQ_F2P]'.

Line 265: `assign_bd_address -offset 0x43C00000 -range 0x00010000 \` This asks Vivado to establish an AXI address map; following explicit offset/range settings make the software-visible register addresses stable across rebuilds.

Line 266: `-target_address_space [get_bd_addr_spaces ps7/Data] \` This batch-control line contributes to the flow that runs the reproducible Vivado build pynq full hardware flow. The important operands are target_address_space: the value named 'target address space' in this block; get_bd_addr_spaces: the value named 'get bd addr spaces' in this block; ps7: the value named 'ps7' in this block.

Line 267: `[get_bd_addr_segs accelerator/S_AXI/Reg] -force` This batch-control line contributes to the flow that runs the reproducible Vivado build pynq full hardware flow. The important operands are get_bd_addr_segs: the value named 'get bd addr segs' in this block; accelerator: the value named 'accelerator' in this block; S_AXI: the value named 's axi' in this block.

Line 268: `assign_bd_address -offset 0x40400000 -range 0x00010000 \` This asks Vivado to establish an AXI address map; following explicit offset/range settings make the software-visible register addresses stable across rebuilds.

Line 269: `-target_address_space [get_bd_addr_spaces ps7/Data] \` This batch-control line contributes to the flow that runs the reproducible Vivado build pynq full hardware flow. The important operands are target_address_space: the value named 'target address space' in this block; get_bd_addr_spaces: the value named 'get bd addr spaces' in this block; ps7: the value named 'ps7' in this block.

Line 270: `[get_bd_addr_segs dma/S_AXI_LITE/Reg] -force` This batch-control line contributes to the flow that runs the reproducible Vivado build pynq full hardware flow. The important operands are get_bd_addr_segs: the value named 'get bd addr segs' in this block; dma: the direct-memory-access engine moving contiguous buffers between DDR and FPGA logic; S_AXI_LITE: the value named 's axi lite' in this block.

Line 271: `assign_bd_address -offset 0x00000000 -range 0x20000000 \` This asks Vivado to establish an AXI address map; following explicit offset/range settings make the software-visible register addresses stable across rebuilds.

Line 272: `-target_address_space [get_bd_addr_spaces dma/Data_MM2S] \` This batch-control line contributes to the flow that runs the reproducible Vivado build pynq full hardware flow. The important operands are target_address_space: the value named 'target address space' in this block; get_bd_addr_spaces: the value named 'get bd addr spaces' in this block; dma: the direct-memory-access engine moving contiguous buffers between DDR and FPGA logic.

Line 273: `[get_bd_addr_segs ps7/S_AXI_HP0/HP0_DDR_LOWOCM] -force` This batch-control line contributes to the flow that runs the reproducible Vivado build pynq full hardware flow. The important operands are get_bd_addr_segs: the value named 'get bd addr segs' in this block; ps7: the value named 'ps7' in this block; S_AXI_HP0: the value named 's axi hp0' in this block.

Line 274: `assign_bd_address -offset 0x00000000 -range 0x20000000 \` This asks Vivado to establish an AXI address map; following explicit offset/range settings make the software-visible register addresses stable across rebuilds.

Line 275: `-target_address_space [get_bd_addr_spaces dma/Data_S2MM] \` This batch-control line contributes to the flow that runs the reproducible Vivado build pynq full hardware flow. The important operands are target_address_space: the value named 'target address space' in this block; get_bd_addr_spaces: the value named 'get bd addr spaces' in this block; dma: the direct-memory-access engine moving contiguous buffers between DDR and FPGA logic.

Line 276: `[get_bd_addr_segs ps7/S_AXI_HP0/HP0_DDR_LOWOCM] -force` This batch-control line contributes to the flow that runs the reproducible Vivado build pynq full hardware flow. The important operands are get_bd_addr_segs: the value named 'get bd addr segs' in this block; ps7: the value named 'ps7' in this block; S_AXI_HP0: the value named 's axi hp0' in this block.

Line 278: `validate_bd_design` This batch-control line contributes to the flow that runs the reproducible Vivado build pynq full hardware flow. The important operands are validate_bd_design: the producer's statement that its current payload is meaningful.

Line 279: `save_bd_design` This batch-control line contributes to the flow that runs the reproducible Vivado build pynq full hardware flow. The important operands are save_bd_design: the value named 'save bd design' in this block.

Line 280: `set bd_file [get_files system.bd]` This batch-control line contributes to the flow that runs the reproducible Vivado build pynq full hardware flow. The important operands are set: the value named 'set' in this block; bd_file: the value named 'bd file' in this block; get_files: the value named 'get files' in this block.

Line 281: `generate_target all $bd_file` This batch-control line contributes to the flow that runs the reproducible Vivado build pynq full hardware flow. The important operands are generate_target: the value named 'generate target' in this block; all: the value named 'all' in this block; bd_file: the value named 'bd file' in this block.

Line 282: `make_wrapper -files $bd_file -top` This batch-control line contributes to the flow that runs the reproducible Vivado build pynq full hardware flow. The important operands are make_wrapper: the value named 'make wrapper' in this block; files: the value named 'files' in this block; bd_file: the value named 'bd file' in this block.

Line 283: `set wrapper_file [file join $vivado_project_dir "neuraedge_pynq_full.gen" "sources_1" "bd" "system" "hdl" "...` This batch-control line contributes to the flow that runs the reproducible Vivado build pynq full hardware flow. The important operands are set: the value named 'set' in this block; wrapper_file: the value named 'wrapper file' in this block; file: the value named 'file' in this block.

Line 284: `add_files -norecurse $wrapper_file` This batch-control line contributes to the flow that runs the reproducible Vivado build pynq full hardware flow. The important operands are add_files: the value named 'add files' in this block; norecurse: the value named 'norecurse' in this block; wrapper_file: the value named 'wrapper file' in this block.

Line 285: `set_property top system_wrapper [current_fileset]` This batch-control line contributes to the flow that runs the reproducible Vivado build pynq full hardware flow. The important operands are set_property: the value named 'set property' in this block; top: the value named 'top' in this block; system_wrapper: the value named 'system wrapper' in this block.

Line 286: `update_compile_order -fileset sources_1` This batch-control line contributes to the flow that runs the reproducible Vivado build pynq full hardware flow. The important operands are update_compile_order: the value named 'update compile order' in this block; fileset: the value named 'fileset' in this block; sources_1: the value named 'sources 1' in this block.

Line 288: `write_bd_tcl -force [file join $output_dir "generated_system_bd.tcl"]` This writes an auditable Vivado artifact using 'write_bd_tcl -force [file join $output_dir "generated_system_bd.tcl"]'; later documentation reads the resulting report rather than inventing a metric.

Line 289: `if {$build_mode eq "validate"} {` This batch-control line contributes to the flow that runs the reproducible Vivado build pynq full hardware flow. The important operands are build_mode: the value named 'build mode' in this block; eq: the value named 'eq' in this block; validate: the producer's statement that its current payload is meaningful.

Line 290: `report_ip_status -file [file join $output_dir "validated_ip_status.rpt"]` This writes an auditable Vivado artifact using 'report_ip_status -file [file join $output_dir "validated_ip_status.rpt"]'; later documentation reads the resulting report rather than inventing a metric.

Line 291: `puts "NEURAEDGE_PYNQ_BD_VALIDATION_PASSED"` This batch-control line contributes to the flow that runs the reproducible Vivado build pynq full hardware flow. The important operands are puts: the value named 'puts' in this block; NEURAEDGE_PYNQ_BD_VALIDATION_PASSED: the producer's statement that its current payload is meaningful.

Line 292: `close_project` This batch-control line contributes to the flow that runs the reproducible Vivado build pynq full hardware flow. The important operands are close_project: the value named 'close project' in this block.

Line 293: `exit 0` This batch-control line contributes to the flow that runs the reproducible Vivado build pynq full hardware flow. The important operands are exit: the value named 'exit' in this block.

Line 294: `}` This batch-control line contributes to the flow that runs the reproducible Vivado build pynq full hardware flow. The expression is a literal or structural operator and has no hidden software state.

Line 296: `set synth_run [get_runs synth_1]` This batch-control line contributes to the flow that runs the reproducible Vivado build pynq full hardware flow. The important operands are set: the value named 'set' in this block; synth_run: the value named 'synth run' in this block; get_runs: the value named 'get runs' in this block.

Line 297: `set_property STEPS.SYNTH_DESIGN.ARGS.DIRECTIVE PerformanceOptimized $synth_run` This batch-control line contributes to the flow that runs the reproducible Vivado build pynq full hardware flow. The important operands are set_property: the value named 'set property' in this block; STEPS: the value named 'steps' in this block; SYNTH_DESIGN: the value named 'synth design' in this block.

Line 298: `set impl_run [get_runs impl_1]` This batch-control line contributes to the flow that runs the reproducible Vivado build pynq full hardware flow. The important operands are set: the value named 'set' in this block; impl_run: the value named 'impl run' in this block; get_runs: the value named 'get runs' in this block.

Line 299: `set_property STEPS.OPT_DESIGN.ARGS.DIRECTIVE Explore $impl_run` This batch-control line contributes to the flow that runs the reproducible Vivado build pynq full hardware flow. The important operands are set_property: the value named 'set property' in this block; STEPS: the value named 'steps' in this block; OPT_DESIGN: the value named 'opt design' in this block.

Line 300: `set_property STEPS.PLACE_DESIGN.ARGS.DIRECTIVE ExtraNetDelay_high $impl_run` This batch-control line contributes to the flow that runs the reproducible Vivado build pynq full hardware flow. The important operands are set_property: the value named 'set property' in this block; STEPS: the value named 'steps' in this block; PLACE_DESIGN: the value named 'place design' in this block.

Line 301: `set_property STEPS.PHYS_OPT_DESIGN.IS_ENABLED true $impl_run` This batch-control line contributes to the flow that runs the reproducible Vivado build pynq full hardware flow. The important operands are set_property: the value named 'set property' in this block; STEPS: the value named 'steps' in this block; PHYS_OPT_DESIGN: the value named 'phys opt design' in this block.

Line 302: `set_property STEPS.PHYS_OPT_DESIGN.ARGS.DIRECTIVE AggressiveExplore $impl_run` This batch-control line contributes to the flow that runs the reproducible Vivado build pynq full hardware flow. The important operands are set_property: the value named 'set property' in this block; STEPS: the value named 'steps' in this block; PHYS_OPT_DESIGN: the value named 'phys opt design' in this block.

Line 303: `set_property STEPS.ROUTE_DESIGN.ARGS.DIRECTIVE AggressiveExplore $impl_run` This batch-control line contributes to the flow that runs the reproducible Vivado build pynq full hardware flow. The important operands are set_property: the value named 'set property' in this block; STEPS: the value named 'steps' in this block; ROUTE_DESIGN: the value named 'route design' in this block.

Line 304: `set_property STEPS.POST_ROUTE_PHYS_OPT_DESIGN.IS_ENABLED true $impl_run` This batch-control line contributes to the flow that runs the reproducible Vivado build pynq full hardware flow. The important operands are set_property: the value named 'set property' in this block; STEPS: the value named 'steps' in this block; POST_ROUTE_PHYS_O the value named 'post route phys opt design' in this block.

Line 305: `# Vivado 2026.1 on Windows reproducibly faults in AggressiveExplore's` This comment documents the batch-flow intent: Vivado 2026.1 on Windows reproducibly faults in AggressiveExplore's

Line 306: `# post-route hold-fix phase for this design. Explore retains post-route setup` This comment documents the batch-flow intent: post-route hold-fix phase for this design. Explore retains post-route setup

Line 307: `# and hold repair without entering that unstable phase.` This comment documents the batch-flow intent: and hold repair without entering that unstable phase.

Line 308: `set_property STEPS.POST_ROUTE_PHYS_OPT_DESIGN.ARGS.DIRECTIVE Explore $impl_run` This batch-control line contributes to the flow that runs the reproducible Vivado build pynq full hardware flow. The important operands are set_property: the value named 'set property' in this block; STEPS: the value named 'steps' in this block; POST_ROUTE_PHYS_OPT_DESIGN: the value named 'post route phys opt design' in this block.

Line 310: `launch_runs synth_1 -jobs 2` This controls a named Vivado synthesis or implementation run with 'launch_runs synth_1 -jobs 2'. Waiting and opening the completed run prevents reports from reading an earlier or unfinished netlist.

Line 311: `wait_on_run synth_1` This controls a named Vivado synthesis or implementation run with 'wait_on_run synth_1'. Waiting and opening the completed run prevents reports from reading an earlier or unfinished netlist.

Line 312: `if {[get_property PROGRESS $synth_run] ne "100%"` This batch-control line contributes to the flow that runs the reproducible Vivado build pynq full hardware flow. The important operands are get_property: the value named 'get property' in this block; PROGRESS: the value named 'progress' in this block; synth_run: the value named 'synth run' in this block.

Line 313: `|| ![string match "*Complete*" [get_property STATUS $synth_run]]} {` This batch-control line contributes to the flow that runs the reproducible Vivado build pynq full hardware flow. The important operands are string: the value named 'string' in this block; match: the value named 'match' in this block; Complete: the value named 'complete' in this block.

Line 314: `error "Full PYNQ synthesis failed: [get_property STATUS $synth_run]"` This batch-control line contributes to the flow that runs the reproducible Vivado build pynq full hardware flow. The important operands are error: the value named 'error' in this block; Full: the value named 'full' in this block; PYNQ: the value named 'pynq' in this block.

Line 315: `}` This batch-control line contributes to the flow that runs the reproducible Vivado build pynq full hardware flow. The expression is a literal or structural operator and has no hidden software state.

Line 316: `launch_runs impl_1 -to_step write_bitstream -jobs 2` This controls a named Vivado synthesis or implementation run with 'launch_runs impl_1 -to_step write_bitstream -jobs 2'. Waiting and opening the completed run prevents reports from reading an earlier or unfinished netlist.

Line 317: `wait_on_run impl_1` This controls a named Vivado synthesis or implementation run with 'wait_on_run impl_1'. Waiting and opening the completed run prevents reports from reading an earlier or unfinished netlist.

Line 318: `if {[get_property PROGRESS $impl_run] ne "100%"` This batch-control line contributes to the flow that runs the reproducible Vivado build pynq full hardware flow. The important operands are get_property: the value named 'get property' in this block; PROGRESS: the value named 'progress' in this block; impl_run: the value named 'impl run' in this block.

Line 319: `|| ![string match "*Complete*" [get_property STATUS $impl_run]]} {` This batch-control line contributes to the flow that runs the reproducible Vivado build pynq full hardware flow. The important operands are string: the value named 'string' in this block; match: the value named 'match' in this block; Complete: the value named 'complete' in this block.

Line 320: `error "Full PYNQ implementation failed: [get_property STATUS $impl_run]"` This batch-control line contributes to the flow that runs the reproducible Vivado build pynq full hardware flow. The important operands are error: the value named 'error' in this block; Full: the value named 'full' in this block; PYNQ: the value named 'pynq' in this block.

Line 321: `}` This batch-control line contributes to the flow that runs the reproducible Vivado build pynq full hardware flow. The expression is a literal or structural operator and has no hidden software state.

Line 323: `open_run impl_1` This controls a named Vivado synthesis or implementation run with 'open_run impl_1'. Waiting and opening the completed run prevents reports from reading an earlier or unfinished netlist.

Line 324: `report_utilization -hierarchical -file [file join $output_dir "full_routed_utilization_hierarchical` This writes an auditable Vivado artifact using 'report_utilization -hierarchical -file [file join $output_dir "full_routed_utilization_hi later documentation reads the resulting report rather than inventing a metric.

Line 325: `report_timing_summary -delay_type min_max -max_paths 50 \` This writes an auditable Vivado artifact using 'report_timing_summary -delay_type min_max -max_paths 50 \'; later documentation reads the resulting report rather than inventing a metric.

Line 326: `-file [file join $output_dir "full_routed_timing_summary.rpt"]` This batch-control line contributes to the flow that runs the reproducible Vivado build pynq full hardware flow. The important operands are file: the value named 'file' in this block; join: the value named 'join' in this block; output_dir: the value named 'output dir' in this block.

Line 327: `report_timing -delay_type max -max_paths 250 -sort_by group \` This writes an auditable Vivado artifact using 'report_timing -delay_type max -max_paths 250 -sort_by group \'; later documentation reads the resulting report rather than inventing a metric.

Line 328: `-file [file join $output_dir "full_routed_timing_paths_250.rpt"]` This batch-control line contributes to the flow that runs the reproducible Vivado build pynq full hardware flow. The important operands are file: the value named 'file' in this block; join: the value named 'join' in this block; output_dir: the value named 'output dir' in this block.

Line 329: `report_clock_interaction -file [file join $output_dir "full_clock_interaction.rpt"]` This writes an auditable Vivado artifact using 'report_clock_interaction -file [file join $output_dir "full_clock_interaction.rpt"]'; later documentation reads the resulting report rather than inventing a metric.

Line 330: `report_cdc -details -file [file join $output_dir "full_cdc.rpt"]` This writes an auditable Vivado artifact using 'report_cdc -details -file [file join $output_dir "full_cdc.rpt"]'; later documentation reads the resulting report rather than inventing a metric.

Line 331: `set full_route_status_text [report_route_status -return_string]` This batch-control line contributes to the flow that runs the reproducible Vivado build pynq full hardware flow. The important operands are set: the value named 'set' in this block; full_route_status_text: the value named 'full route status text' in this block; report_route_status: the value named 'report route status' in this block.

Line 332: `set route_status_file [open [file join $output_dir "full_route_status.rpt"] "w"]` This batch-control line contributes to the flow that runs the reproducible Vivado build pynq full hardware flow. The important operands are set: the value named 'set' in this block; route_status_file: the value named 'route status file' in this block; open: the value named 'open' in this block.

Line 333: `puts -nonewline $route_status_file $full_route_status_text` This batch-control line contributes to the flow that runs the reproducible Vivado build pynq full hardware flow. The important operands are puts: the value named 'puts' in this block; nonewline: the value named 'nonewline' in this block; route_status_file: the value named 'route status file' in this block.

Line 334: `close $route_status_file` This batch-control line contributes to the flow that runs the reproducible Vivado build pynq full hardware flow. The important operands are close: the value named 'close' in this block; route_status_file: the value named 'route status file' in this block.

Line 335: `report_drc -file [file join $output_dir "full_drc.rpt"]` This writes an auditable Vivado artifact using 'report_drc -file [file join $output_dir "full_drc.rpt"]'; later documentation reads the resulting report rather than inventing a metric.

Line 336: `report_methodology -file [file join $output_dir "full_methodology.rpt"]` This writes an auditable Vivado artifact using 'report_methodology -file [file join $output_dir "full_methodology.rpt"]'; later documentation reads the resulting report rather than inventing a metric.

Line 337: `report_design_analysis -congestion -file [file join $output_dir "full_congestion.rpt"]` This writes an auditable Vivado artifact using 'report_design_analysis -congestion -file [file join $output_dir "full_congestion.rpt"]'; later documentation reads the resulting report rather than inventing a metric.

Line 338: `report_power -file [file join $output_dir "full_vectorless_power.rpt"]` This writes an auditable Vivado artifact using 'report_power -file [file join $output_dir "full_vectorless_power.rpt"]'; later documentation reads the resulting report rather than inventing a metric.

Line 339: `write_checkpoint -force [file join $output_dir "neuraedge_pynq_full_routed.dcp"]` This writes an auditable Vivado artifact using 'write_checkpoint -force [file join $output_dir "neuraedge_pynq_full_routed.dcp"]'; later documentation reads the resulting report rather than inventing a metric.

Line 341: `set setup_path [get_timing_paths -delay_type max -max_paths 1]` This batch-control line contributes to the flow that runs the reproducible Vivado build pynq full hardware flow. The important operands are set: the value named 'set' in this block; setup_path: the value named 'setup path' in this block; get_timing_paths: the value named 'get timing paths' in this block.

Line 342: `set hold_path [get_timing_paths -delay_type min -max_paths 1]` This batch-control line contributes to the flow that runs the reproducible Vivado build pynq full hardware flow. The important operands are set: the value named 'set' in this block; hold_path: the value named 'hold path' in this block; get_timing_paths: the value named 'get timing paths' in this block.

Line 343: `set setup_wns [get_property SLACK $setup_path]` This batch-control line contributes to the flow that runs the reproducible Vivado build pynq full hardware flow. The important operands are set: the value named 'set' in this block; setup_wns: the value named 'setup wns' in this block; get_property: the value named 'get property' in this block.

Line 344: `set hold_whs [get_property SLACK $hold_path]` This batch-control line contributes to the flow that runs the reproducible Vivado build pynq full hardware flow. The important operands are set: the value named 'set' in this block; hold_whs: the value named 'hold whs' in this block; get_property: the value named 'get property' in this block.

Line 345: `set route_error_count -1` This batch-control line contributes to the flow that runs the reproducible Vivado build pynq full hardware flow. The important operands are set: the value named 'set' in this block; route_error_count: an integer count retained for control or measurable telemetry.

Line 346: `if {[regexp {# of nets with routing errors\.*\s*:\s*([0-9]+)} \` This batch-control line contributes to the flow that runs the reproducible Vivado build pynq full hardware flow. The important operands are regexp: the value named 'regexp' in this block; of: the value named 'of' in this block; nets: the value named 'nets' in this block.

Line 347: `$full_route_status_text route_match route_count]} {` This batch-control line contributes to the flow that runs the reproducible Vivado build pynq full hardware flow. The important operands are full_route_status_text: the value named 'full route status text' in this block; route_match: the value named 'route match' in this block; route_count: an integer count retained for control or measurable telemetry.

Line 348: `set route_error_count $route_count` This batch-control line contributes to the flow that runs the reproducible Vivado build pynq full hardware flow. The important operands are set: the value named 'set' in this block; route_error_count: an integer count retained for control or measurable telemetry; route_count: an integer count retained for control or measurable telemetry.

Line 349: `}` This batch-control line contributes to the flow that runs the reproducible Vivado build pynq full hardware flow. The expression is a literal or structural operator and has no hidden software state.

Line 350: `set drc_error_count [llength [get_drc_violations -quiet -filter {SEVERITY == Error}]]` This batch-control line contributes to the flow that runs the reproducible Vivado build pynq full hardware flow. The important operands are set: the value named 'set' in this block; drc_error_count: an integer count retained for control or measurable telemetry; llength: the value named 'llength' in this block.

Line 351: `set summary_file [open [file join $output_dir "full_implementation_summary.txt"] "w"]` This batch-control line contributes to the flow that runs the reproducible Vivado build pynq full hardware flow. The important operands are set: the value named 'set' in this block; summary_file: the value named 'summary file' in this block; open: the value named 'open' in this block.

Line 352: `puts $summary_file "board_part=$board_part"` This batch-control line contributes to the flow that runs the reproducible Vivado build pynq full hardware flow. The important operands are puts: the value named 'puts' in this block; summary_file: the value named 'summary file' in this block; board_part: the value named 'board part' in this block.

Line 353: `puts $summary_file "part=xc7z020clg400-1"` This batch-control line contributes to the flow that runs the reproducible Vivado build pynq full hardware flow. The important operands are puts: the value named 'puts' in this block; summary_file: the value named 'summary file' in this block; part: the value named 'part' in this block.

Line 354: `puts $summary_file "accelerator_clock_mhz=200.0"` This batch-control line contributes to the flow that runs the reproducible Vivado build pynq full hardware flow. The important operands are puts: the value named 'puts' in this block; summary_file: the value named 'summary file' in this block; accelerator_clock_mhz: the value named 'accelerator clock mhz' in this block.

Line 355: `puts $summary_file "dma_clock_mhz=125.0"` This batch-control line contributes to the flow that runs the reproducible Vivado build pynq full hardware flow. The important operands are puts: the value named 'puts' in this block; summary_file: the value named 'summary file' in this block; dma_clock_mhz: the direct-memory-access engine moving contiguous buffers between DDR and FPGA logic.

Line 356: `puts $summary_file "control_clock_mhz=100.0"` This batch-control line contributes to the flow that runs the reproducible Vivado build pynq full hardware flow. The important operands are puts: the value named 'puts' in this block; summary_file: the value named 'summary file' in this block; control_clock_mhz: the value named 'control clock mhz' in this block.

Line 357: `puts $summary_file "lut_count=[llength [get_cells -hierarchical -filter {REF_NAME =~ LUT*}]]"` This batch-control line contributes to the flow that runs the reproducible Vivado build pynq full hardware flow. The important operands are puts: the value named 'puts' in this block; summary_file: the value named 'summary file' in this block; lut_count: an integer count retained for control or measurable telemetry.

Line 358: `puts $summary_file "ff_count=[llength [get_cells -hierarchical -filter {REF_NAME =~ FD*}]]"` This batch-control line contributes to the flow that runs the reproducible Vivado build pynq full hardware flow. The important operands are puts: the value named 'puts' in this block; summary_file: the value named 'summary file' in this block; ff_count: an integer count retained for control or measurable telemetry.

Line 359: `puts $summary_file "dsp48_count=[llength [get_cells -hierarchical -filter {REF_NAME =~ DSP48*}]]"` This batch-control line contributes to the flow that runs the reproducible Vivado build pynq full hardware flow. The important operands are puts: the value named 'puts' in this block; summary_file: the value named 'summary file' in this block; dsp48_count: an integer count retained for control or measurable telemetry.

Line 360: `puts $summary_file "bram36_count=[llength [get_cells -hierarchical -filter {REF_NAME == RAMB36E1}]]` This batch-control line contributes to the flow that runs the reproducible Vivado build pynq full hardware flow. The important operands are puts: the value named 'puts' in this block; summary_file: the value named 'summary file' in this block; bram36_count: an integer count retained for control or measurable telemetry.

Line 361: `puts $summary_file "bram18_count=[llength [get_cells -hierarchical -filter {REF_NAME == RAMB18E1}]]` This batch-control line contributes to the flow that runs the reproducible Vivado build pynq full hardware flow. The important operands are puts: the value named 'puts' in this block; summary_file: the value named 'summary file' in this block; bram18_count: an integer count retained for control or measurable telemetry.

Line 362: `puts $summary_file "setup_wns_ns=$setup_wns"` This batch-control line contributes to the flow that runs the reproducible Vivado build pynq full hardware flow. The important operands are puts: the value named 'puts' in this block; summary_file: the value named 'summary file' in this block; setup_wns_ns: the value named 'setup wns ns' in this block.

Line 363: `puts $summary_file "hold_whs_ns=$hold_whs"` This batch-control line contributes to the flow that runs the reproducible Vivado build pynq full hardware flow. The important operands are puts: the value named 'puts' in this block; summary_file: the value named 'summary file' in this block; hold_whs_ns: the value named 'hold whs ns' in this block.

Line 364: `puts $summary_file "route_error_count=$route_error_count"` This batch-control line contributes to the flow that runs the reproducible Vivado build pynq full hardware flow. The important operands are puts: the value named 'puts' in this block; summary_file: the value named 'summary file' in this block; route_error_count: an integer count retained for control or measurable telemetry.

Line 365: `puts $summary_file "drc_error_count=$drc_error_count"` This batch-control line contributes to the flow that runs the reproducible Vivado build pynq full hardware flow. The important operands are puts: the value named 'puts' in this block; summary_file: the value named 'summary file' in this block; drc_error_count: an integer count retained for control or measurable telemetry.

Line 366: `close $summary_file` This batch-control line contributes to the flow that runs the reproducible Vivado build pynq full hardware flow. The important operands are close: the value named 'close' in this block; summary_file: the value named 'summary file' in this block.

Line 368: `if {$route_error_count != 0} {` This batch-control line contributes to the flow that runs the reproducible Vivado build pynq full hardware flow. The important operands are route_error_count: an integer count retained for control or measurable telemetry.

Line 369: `error "Full PYNQ routing is incomplete: route_error_count=$route_error_count"` This batch-control line contributes to the flow that runs the reproducible Vivado build pynq full hardware flow. The important operands are error: the value named 'error' in this block; Full: the value named 'full' in this block; PYNQ: the value named 'pynq' in this block.

Line 370: `}` This batch-control line contributes to the flow that runs the reproducible Vivado build pynq full hardware flow. The expression is a literal or structural operator and has no hidden software state.

Line 371: `if {$drc_error_count != 0} {` This batch-control line contributes to the flow that runs the reproducible Vivado build pynq full hardware flow. The important operands are drc_error_count: an integer count retained for control or measurable telemetry.

Line 372: `error "Full PYNQ design has DRC errors: drc_error_count=$drc_error_count"` This batch-control line contributes to the flow that runs the reproducible Vivado build pynq full hardware flow. The important operands are error: the value named 'error' in this block; Full: the value named 'full' in this block; PYNQ: the value named 'pynq' in this block.

Line 373: `}` This batch-control line contributes to the flow that runs the reproducible Vivado build pynq full hardware flow. The expression is a literal or structural operator and has no hidden software state.

Line 374: `if {$setup_wns < 0.0} {` This batch-control line contributes to the flow that runs the reproducible Vivado build pynq full hardware flow. The important operands are setup_wns: the value named 'setup wns' in this block.

Line 375: `error "Full PYNQ design missed setup timing: WNS=$setup_wns ns"` This batch-control line contributes to the flow that runs the reproducible Vivado build pynq full hardware flow. The important operands are error: the value named 'error' in this block; Full: the value named 'full' in this block; PYNQ: the value named 'pynq' in this block.

Line 376: `}` This batch-control line contributes to the flow that runs the reproducible Vivado build pynq full hardware flow. The expression is a literal or structural operator and has no hidden software state.

Line 377: `if {$hold_whs < 0.0} {` This batch-control line contributes to the flow that runs the reproducible Vivado build pynq full hardware flow. The important operands are hold_whs: the value named 'hold whs' in this block.

Line 378: `error "Full PYNQ design missed hold timing: WHS=$hold_whs ns"` This batch-control line contributes to the flow that runs the reproducible Vivado build pynq full hardware flow. The important operands are error: the value named 'error' in this block; Full: the value named 'full' in this block; PYNQ: the value named 'pynq' in this block.

Line 379: `}` This batch-control line contributes to the flow that runs the reproducible Vivado build pynq full hardware flow. The expression is a literal or structural operator and has no hidden software state.

Line 381: `set generated_bit [file join $vivado_project_dir \` This batch-control line contributes to the flow that runs the reproducible Vivado build pynq full hardware flow. The important operands are set: the value named 'set' in this block; generated_bit: the value named 'generated bit' in this block; file: the value named 'file' in this block.

Line 382: `"neuraedge_pynq_full.runs" "impl_1" "system_wrapper.bit"]` This batch-control line contributes to the flow that runs the reproducible Vivado build pynq full hardware flow. The important operands are neuraedge_pynq_full: the value named 'neuraedge pynq full' in this block; runs: the value named 'runs' in this block; impl_1: the value named 'impl 1' in this block.

Line 383: `if {![file exists $generated_bit]} {` This batch-control line contributes to the flow that runs the reproducible Vivado build pynq full hardware flow. The important operands are file: the value named 'file' in this block; exists: the value named 'exists' in this block; generated_bit: the value named 'generated bit' in this block.

Line 384: `error "Implementation completed but bitstream was not found at $generated_bit"` This batch-control line contributes to the flow that runs the reproducible Vivado build pynq full hardware flow. The important operands are error: the value named 'error' in this block; Implementation: the value named 'implementation' in this block; completed: the value named 'completed' in this block.

Line 385: `}` This batch-control line contributes to the flow that runs the reproducible Vivado build pynq full hardware flow. The expression is a literal or structural operator and has no hidden software state.

Line 386: `file copy -force $generated_bit [file join $output_dir "neuraedge_pynq_full.bit"]` This batch-control line contributes to the flow that runs the reproducible Vivado build pynq full hardware flow. The important operands are file: the value named 'file' in this block; copy: the value named 'copy' in this block; force: the value named 'force' in this block.

Line 387: `set generated_hwh [file join $vivado_project_dir "neuraedge_pynq_full.gen" "sources_1" "bd" "system" "hw_ha...` This batch-control line contributes to the flow that runs the reproducible Vivado build pynq full hardware flow. The important operands are set: the value named 'set' in this block; generated_hwh: the value named 'generated hwh' in this block; file: the value named 'file' in this block.

Line 388: `if {![file exists $generated_hwh]} {` This batch-control line contributes to the flow that runs the reproducible Vivado build pynq full hardware flow. The important operands are file: the value named 'file' in this block; exists: the value named 'exists' in this block; generated_hwh: the value named 'generated hwh' in this block.

Line 389: `error "Block design completed but hardware handoff was not found at $generated_hwh"` This batch-control line contributes to the flow that runs the reproducible Vivado build pynq full hardware flow. The important operands are error: the value named 'error' in this block; Block: the value named 'block' in this block; design: the value named 'design' in this block.

Line 390: `}` This batch-control line contributes to the flow that runs the reproducible Vivado build pynq full hardware flow. The expression is a literal or structural operator and has no hidden software state.

Line 391: `file copy -force $generated_hwh [file join $output_dir "neuraedge_pynq_full.hwh"]` This batch-control line contributes to the flow that runs the reproducible Vivado build pynq full hardware flow. The important operands are file: the value named 'file' in this block; copy: the value named 'copy' in this block; force: the value named 'force' in this block.

Line 392: `write_hw_platform -fixed -include_bit -force \` This writes an auditable Vivado artifact using 'write_hw_platform -fixed -include_bit -force \'; later documentation reads the resulting report rather than inventing a metric.

Line 393: `-file [file join $output_dir "neuraedge_pynq_full.xsa"]` This batch-control line contributes to the flow that runs the reproducible Vivado build pynq full hardware flow. The important operands are file: the value named 'file' in this block; join: the value named 'join' in this block; output_dir: the value named 'output dir' in this block.

91 scripts/build_pynq_ooc.tcl

Role in the complete system: runs the reproducible Vivado build pynq ooc hardware flow.

91.1 Beginner architecture map

Dataflow responsibility This file's end-to-end responsibility is to runs the reproducible Vivado build pynq ooc hardware flow.

Where it runs This is Vivado Tcl orchestration, not accelerator datapath hardware. It makes tool inputs, versions, paths, stages, and failure propagation repeatable.

Reproducibility contract Every external command must be checked, every required artifact must exist and be nonempty, and measured values must be read from generated reports. Rerunning this file should either reproduce its declared outputs or stop at the first failed gate.

Line 28: `[file join $project_dir "rtl" "neuraedge_activation_lut8.sv"] \` This batch-control line contributes to the flow that runs the reproducible Vivado build pynq ooc hardware flow. The important operands are file: the value named 'file' in this block; join: the value named 'join' in this block; project_dir: the value named 'project dir' in this block.

Line 29: `[file join $project_dir "rtl" "neuraedge_universal_core.sv"] \` This batch-control line contributes to the flow that runs the reproducible Vivado build pynq ooc hardware flow. The important operands are file: the value named 'file' in this block; join: the value named 'join' in this block; project_dir: the value named 'project dir' in this block.

Line 30: `[file join $project_dir "rtl" "neuraedge_descriptor_sequencer.sv"] \` This batch-control line contributes to the flow that runs the reproducible Vivado build pynq ooc hardware flow. The important operands are file: the value named 'file' in this block; join: the value named 'join' in this block; project_dir: the value named 'project dir' in this block.

Line 31: `[file join $project_dir "rtl" "neuraedge_pynq_axi_top.sv"]]` This batch-control line contributes to the flow that runs the reproducible Vivado build pynq ooc hardware flow. The important operands are file: the value named 'file' in this block; join: the value named 'join' in this block; project_dir: the value named 'project dir' in this block.

Line 33: `read_verilog -sv $rtl_files` This loads the listed RTL into Vivado's in-memory design so the subsequent synthesis uses the repository source.

Line 34: `synth_design -top neuraedge_pynq_axi_top -part xc7z020clg400-1 \` This invokes Vivado synthesis for the named top and FPGA part, mapping behavioral RTL into LUT, flip-flop, BRAM, and DSP primitives.

Line 35: `-mode out_of_context -flatten_hierarchy rebuilt -directive PerformanceOptimized` This batch-control line contributes to the flow that runs the reproducible Vivado build pynq ooc hardware flow. The important operands are mode: the value named 'mode' in this block; out_of_context: the value named 'out of context' in this block; flatten_hierarchy: the value named 'flatten hierarchy' in this block.

Line 36: `create_clock -name aclk -period 5.000 [get_ports aclk]` This declares the clock period against which Vivado checks every synchronous setup and hold path.

Line 37: `set_clock_uncertainty 0.100 [get_clocks aclk]` This batch-control line contributes to the flow that runs the reproducible Vivado build pynq ooc hardware flow. The important operands are set_clock_uncertainty: the value named 'set clock uncertainty' in this block; get_clocks: the value named 'get clocks' in this block; aclk: the AXI and accelerator clock.

Line 38: `set_property HD.CLK_SRC BUFGCTRL_X0Y0 [get_ports aclk]` This batch-control line contributes to the flow that runs the reproducible Vivado build pynq ooc hardware flow. The important operands are set_property: the value named 'set property' in this block; HD: the value named 'hd' in this block; CLK_SRC: the clock that makes all registers advance together.

Line 39: `set_false_path -from [get_ports aresetn]` This batch-control line contributes to the flow that runs the reproducible Vivado build pynq ooc hardware flow. The important operands are set_false_path: the value named 'set false path' in this block; from: the value named 'from' in this block; get_ports: the value named 'get ports' in this block.

Line 40: `set data_inputs [get_ports -filter {DIRECTION == IN && NAME != "aclk" && NAME != "aresetn"}]` This batch-control line contributes to the flow that runs the reproducible Vivado build pynq ooc hardware flow. The important operands are set: the value named 'set' in this block; data_inputs: the value named 'data inputs' in this block; get_ports: the value named 'get ports' in this block.

Line 41: `set data_outputs [get_ports -filter {DIRECTION == OUT}]` This batch-control line contributes to the flow that runs the reproducible Vivado build pynq ooc hardware flow. The important operands are set: the value named 'set' in this block; data_outputs: the value named 'data outputs' in this block; get_ports: the value named 'get ports' in this block.

Line 42: `set_input_delay -clock aclk 1.000 $data_inputs` This batch-control line contributes to the flow that runs the reproducible Vivado build pynq ooc hardware flow. The important operands are set_input_delay: the value named 'set input delay' in this block; clock: the value named 'clock' in this block; aclk: the AXI and accelerator clock.

Line 43: `set_output_delay -clock aclk 1.000 $data_outputs` This batch-control line contributes to the flow that runs the reproducible Vivado build pynq ooc hardware flow. The important operands are set_output_delay: the value named 'set output delay' in this block; clock: the value named 'clock' in this block; aclk: the AXI and accelerator clock.

Line 45: `report_utilization -hierarchical -file [file join $output_dir "post_synth_utilization_hierarchical.r`
This writes an auditable Vivado artifact using ‘report_utilization -hierarchical -file [file join $output_dir "post_synth_utilization_hi later documentation reads the resulting report rather than inventing a metric.

Line 46: `report_timing_summary -file [file join $output_dir "post_synth_timing.rpt"]` This writes an auditable Vivado artifact using ‘report_timing_summary -file [file join $output_dir "post_synth_timing.rpt"]‘; later documentation reads the resulting report rather than inventing a metric.

Line 47: `write_checkpoint -force [file join $output_dir "post_synth.dcp"]` This writes an auditable Vivado artifact using ‘write_checkpoint -force [file join $output_dir "post_synth.dcp"]‘; later documentation reads the resulting report rather than inventing a metric.

Line 49: `opt_design -directive Explore` This runs Vivado implementation command ‘opt_design -directive Explore‘, changing the physical netlist or placement/routing needed for real timing.

Line 50: `place_design -directive ExtraNetDelay_high` This runs Vivado implementation command ‘place_design -directive ExtraNetDelay_high‘, changing the physical netlist or placement/routing needed for real timing.

Line 51: `phys_opt_design -directive AggressiveExplore` This runs Vivado implementation command ‘phys_opt_design -directive AggressiveExplore‘, changing the physical netlist or placement/routing needed for real timing.

Line 52: `route_design -directive AggressiveExplore` This runs Vivado implementation command 'route_design -directive AggressiveExplore', changing the physical netlist or placement/routing needed for real timing.

Line 53: `# Persist the expensive placed-and-routed solution before post-route physical` This comment documents the batch-flow intent: Persist the expensive placed-and-routed solution before post-route physical

Line 54: `# synthesis. Vivado can then resume without repeating placement if its` This comment documents the batch-flow intent: synthesis. Vivado can then resume without repeating placement if its

Line 55: `# optimizer process terminates unexpectedly.` This comment documents the batch-flow intent: optimizer process terminates unexpectedly.

Line 56: `write_checkpoint -force [file join $output_dir "pre_postroute_physopt.dcp"]` This writes an auditable Vivado artifact using 'write_checkpoint -force [file join $output_dir "pre_postroute_physopt.dcp"]'; later documentation reads the resulting report rather than inventing a metric.

Line 57: `# Vivado 2026.1 on Windows reproducibly faults in AggressiveExplore's` This comment documents the batch-flow intent: Vivado 2026.1 on Windows reproducibly faults in AggressiveExplore's

Line 58: `# post-route hold-fix phase. Explore performs the same critical-path repair` This comment documents the batch-flow intent: post-route hold-fix phase. Explore performs the same critical-path repair

Line 59: `# without entering that faulty phase; aggressive optimization remains enabled` This comment documents the batch-flow intent: without entering that faulty phase; aggressive optimization remains enabled

Line 60: `# before routing, where it completes normally.` This comment documents the batch-flow intent: before routing, where it completes normally.

Line 61: `phys_opt_design -directive Explore` This runs Vivado implementation command 'phys_opt_design -directive Explore', changing the physical netlist or placement/routing needed for real timing.

Line 62: `write_checkpoint -force [file join $output_dir "postroute_physopt_unrouted.dcp"]` This writes an auditable Vivado artifact using 'write_checkpoint -force [file join $output_dir "postroute_physopt_unrouted.dcp"]'; later documentation reads the resulting report rather than inventing a metric.

Line 63: `# Post-route physical optimization may move cells or insert hold buffers. Route` This comment documents the batch-flow intent: Post-route physical optimization may move cells or insert hold buffers. Route

Line 64: `# those edits before reporting timing so setup and hold are both physically real.` This comment documents the batch-flow intent: those edits before reporting timing so setup and hold are both physically real.

Line 65: `route_design -directive Quick` This runs Vivado implementation command 'route_design -directive Quick', changing the physical netlist or placement/routing needed for real timing.

Line 66: `source [file join $script_dir "finalize_pynq_ooc.tcl"]` This batch-control line contributes to the flow that runs the reproducible Vivado build pynq ooc hardware flow. The important operands are source: the value named 'source' in this block; file: the value named 'file' in this block; join: the value named 'join' in this block.

92 scripts/capture_power_activity.tcl

Role in the complete system: runs the reproducible Vivado capture power activity hardware flow.

92.1 Beginner architecture map

Dataflow responsibility This file's end-to-end responsibility is to runs the reproducible Vivado capture power activity hardware flow.

Where it runs This is Vivado Tcl orchestration, not accelerator datapath hardware. It makes tool inputs, versions, paths, stages, and failure propagation repeatable.

Reproducibility contract Every external command must be checked, every required artifact must exist and be nonempty, and measured values must be read from generated reports. Rerunning this file should either reproduce its declared outputs or stop at the first failed gate.

92.2 Complete source

```
foreach required_variable {
    NEURAEDGE_SAIF_PATH
    NEURAEDGE_SAIF_SCOPE
    NEURAEDGE_SAIF_AMOUNT
    NEURAEDGE_SAIF_UNIT
} {
    if {![info exists ::env($required_variable)]} {
        error "$required_variable is required"
    }
}

set saif_path [file normalize $::env(NEURAEDGE_SAIF_PATH)]
set saif_scope $::env(NEURAEDGE_SAIF_SCOPE)
set run_amount $::env(NEURAEDGE_SAIF_AMOUNT)
set run_unit $::env(NEURAEDGE_SAIF_UNIT)

close_saif
quit
```

92.3 Line annotations

Line 1: `foreach required_variable {` This batch-control line contributes to the flow that runs the reproducible Vivado capture power activity hardware flow. The important operands are foreach: the value named 'foreach' in this block; required_variable: the value named 'required variable' in this block.

Line 2: `NEURAEDGE_SAIF_PATH` This batch-control line contributes to the flow that runs the reproducible Vivado capture power activity hardware flow. The important operands are NEURAEDGE_SAIF_PATH: the value named 'neuraedge saif path' in this block.

Line 3: `NEURAEDGE_SAIF_SCOPE` This batch-control line contributes to the flow that runs the reproducible Vivado capture power activity hardware flow. The important operands are NEURAEDGE_SAIF_SCOPE: the value named 'neuraedge saif scope' in this block.

Line 4: `NEURAEDGE_SAIF_AMOUNT` This batch-control line contributes to the flow that runs the reproducible Vivado capture power activity hardware flow. The important operands are NEURAEDGE_SAIF_AMOUNT: the value named 'neuraedge saif amount' in this block.

Line 5: `NEURAEDGE_SAIF_UNIT` This batch-control line contributes to the flow that runs the reproducible Vivado capture power activity hardware flow. The important operands are NEURAEDGE_SAIF_UNIT: the value named 'neuraedge saif unit' in this block.

Line 6: `} {` This batch-control line contributes to the flow that runs the reproducible Vivado capture power activity hardware flow. The expression is a literal or structural operator and has no hidden software state.

Line 7: `if {![info exists ::env($required_variable)]} {` This batch-control line contributes to the flow that runs the reproducible Vivado capture power activity hardware flow. The important operands are info: the value named 'info' in this block; exists: the value named 'exists' in this block; env: the value named 'env' in this block.

Line 8: `error "$required_variable is required"` This batch-control line contributes to the flow that runs the reproducible Vivado capture power activity hardware flow. The important operands are error: the value named 'error' in this block; required_variable: the value named 'required variable' in this block; is: the value named 'is' in this block.

Line 9: `}` This batch-control line contributes to the flow that runs the reproducible Vivado capture power activity hardware flow. The expression is a literal or structural operator and has no hidden software state.

Line 10: `}` This batch-control line contributes to the flow that runs the reproducible Vivado capture power activity hardware flow. The expression is a literal or structural operator and has no hidden software state.

Line 12: `set saif_path [file normalize $::env(NEURAEDGE_SAIF_PATH)]` This batch-control line contributes to the flow that runs the reproducible Vivado capture power activity hardware flow. The important operands are set: the value named 'set' in this block; saif_path: the value named 'saif path' in this block; file: the value named 'file' in this block.

Line 13: `set saif_scope $::env(NEURAEDGE_SAIF_SCOPE)` This batch-control line contributes to the flow that runs the reproducible Vivado capture power activity hardware flow. The important operands are set: the value named 'set' in this block; saif_scope: the value named 'saif scope' in this block; env: the value named 'env' in this block.

Line 14: `set run_amount $::env(NEURAEDGE_SAIF_AMOUNT)` This batch-control line contributes to the flow that runs the reproducible Vivado capture power activity hardware flow. The important operands are set: the value named 'set' in this block; run_amount: the value named 'run amount' in this block; env: the value named 'env' in this block.

Line 15: `set run_unit $::env(NEURAEDGE_SAIF_UNIT)` This batch-control line contributes to the flow that runs the reproducible Vivado capture power activity hardware flow. The important operands are set: the value named 'set' in this block; run_unit: the value named 'run unit' in this block; env: the value named 'env' in this block.

Line 16: `set activity_objects [get_objects -r "${saif_scope}/*"]` This batch-control line contributes to the flow that runs the reproducible Vivado capture power activity hardware flow. The important operands are set: the value named 'set' in this block; activity_objects: the value named 'activity objects' in this block; get_objects: the value named 'get objects' in this block.

Line 17: `if {[llength $activity_objects] == 0} {` This batch-control line contributes to the flow that runs the reproducible Vivado capture power activity hardware flow. The important operands are llength: the value named 'llength' in this block; activity_objects: the value named 'activity objects' in this block.

Line 18: `error "No simulation objects matched SAIF scope $saif_scope"` This batch-control line contributes to the flow that runs the reproducible Vivado capture power activity hardware flow. The important operands are error: the value named 'error' in this block; No: the value named 'no' in this block; simulation: the value named 'simulation' in this block.

Line 19: `}` This batch-control line contributes to the flow that runs the reproducible Vivado capture power activity hardware flow. The expression is a literal or structural operator and has no hidden software state.

Line 21: `open_saif $saif_path` This batch-control line contributes to the flow that runs the reproducible Vivado capture power activity hardware flow. The important operands are open_saif: the value named 'open saif' in this block; saif_path: the value named 'saif path' in this block.

Line 22: `log_saif $activity_objects` This batch-control line contributes to the flow that runs the reproducible Vivado capture power activity hardware flow. The important operands are log_saif: the value named 'log saif' in this block; activity_objects: the value named 'activity objects' in this block.

Line 23: `run $run_amount $run_unit` This batch-control line contributes to the flow that runs the reproducible Vivado capture power activity hardware flow. The important operands are run: the value named 'run' in this block; run_amount: the value named 'run amount' in this block; run_unit: the value named 'run unit' in this block.

Line 24: `close_saif` This batch-control line contributes to the flow that runs the reproducible Vivado capture power activity hardware flow. The important operands are close_saif: the value named 'close saif' in this block.

Line 25: `quit` This batch-control line contributes to the flow that runs the reproducible Vivado capture power activity hardware flow. The important operands are quit: the value named 'quit' in this block.

The important operands are info: the value named 'info' in this block; exists: the value named 'exists' in this block; env: the value named 'env' in this block.

Line 2: `error "NEURAEDGE_VCD_PATH is required"` This batch-control line contributes to the flow that runs the reproducible Vivado capture waveform hardware flow. The important operands are error: the value named 'error' in this block; NEURAEDGE_VCD_PATH: the value named 'neuraedge vcd path' in this block; is: the value named 'is' in this block.

Line 3: `}` This batch-control line contributes to the flow that runs the reproducible Vivado capture waveform hardware flow. The expression is a literal or structural operator and has no hidden software state.

Line 4: `if {![info exists ::env(NEURAEDGE_WAVE_AMOUNT)]} {` This batch-control line contributes to the flow that runs the reproducible Vivado capture waveform hardware flow. The important operands are info: the value named 'info' in this block; exists: the value named 'exists' in this block; env: the value named 'env' in this block.

Line 5: `error "NEURAEDGE_WAVE_AMOUNT is required"` This batch-control line contributes to the flow that runs the reproducible Vivado capture waveform hardware flow. The important operands are error: the value named 'error' in this block; NEURAEDGE_WAVE_AMOUNT: the value named 'neuraedge wave amount' in this block; is: the value named 'is' in this block.

Line 6: `}` This batch-control line contributes to the flow that runs the reproducible Vivado capture waveform hardware flow. The expression is a literal or structural operator and has no hidden software state.

Line 7: `if {![info exists ::env(NEURAEDGE_WAVE_UNIT)]} {` This batch-control line contributes to the flow that runs the reproducible Vivado capture waveform hardware flow. The important operands are info: the value named 'info' in this block; exists: the value named 'exists' in this block; env: the value named 'env' in this block.

Line 8: `error "NEURAEDGE_WAVE_UNIT is required"` This batch-control line contributes to the flow that runs the reproducible Vivado capture waveform hardware flow. The important operands are error: the value named 'error' in this block; NEURAEDGE_WAVE_UNIT: the value named 'neuraedge wave unit' in this block; is: the value named 'is' in this block.

Line 9: `}` This batch-control line contributes to the flow that runs the reproducible Vivado capture waveform hardware flow. The expression is a literal or structural operator and has no hidden software state.

Line 11: `set vcd_path [file normalize $::env(NEURAEDGE_VCD_PATH)]` This batch-control line contributes to the flow that runs the reproducible Vivado capture waveform hardware flow. The important operands are set: the value named 'set' in this block; vcd_path: the value named 'vcd path' in this block; file: the value named 'file' in this block.

Line 12: `set run_amount $::env(NEURAEDGE_WAVE_AMOUNT)` This batch-control line contributes to the flow that runs the reproducible Vivado capture waveform hardware flow. The important operands are set: the value named 'set' in this block; run_amount: the value named 'run amount' in this block; env: the value named 'env' in this block.

Line 13: `set run_unit $::env(NEURAEDGE_WAVE_UNIT)` This batch-control line contributes to the flow that runs the reproducible Vivado capture waveform hardware flow. The important operands are set: the value named 'set' in this block; run_unit: the value named 'run unit' in this block; env: the value named 'env' in this block.

Line 15: `open_vcd $vcd_path` This batch-control line contributes to the flow that runs the reproducible Vivado capture waveform hardware flow. The important operands are open_vcd: the value named 'open vcd' in this block; vcd_path: the value named 'vcd path' in this block.

Line 16: `log_vcd [get_objects -r /*]` This batch-control line contributes to the flow that runs the reproducible Vivado capture waveform hardware flow. The important operands are log_vcd: the value named 'log vcd' in this block; get_objects: the value named 'get objects' in this block; r: the value named 'r' in this block.

Line 17: `log_wave -r /*` This batch-control line contributes to the flow that runs the reproducible Vivado capture waveform hardware flow. The important operands are log_wave: the value named 'log wave' in this block; r: the value named 'r' in this block.

Line 18: `run $run_amount $run_unit` This batch-control line contributes to the flow that runs the reproducible Vivado capture waveform hardware flow. The important operands are run: the value named 'run' in this block; run_amount: the value named 'run amount' in this block; run_unit: the value named 'run unit' in this block.

Line 19: `close_vcd` This batch-control line contributes to the flow that runs the reproducible Vivado capture waveform hardware flow. The important operands are close_vcd: the value named 'close vcd' in this block.

Line 20: `quit` This batch-control line contributes to the flow that runs the reproducible Vivado capture waveform hardware flow. The important operands are quit: the value named 'quit' in this block.

94 scripts/export_pynq_diagrams.tcl

Role in the complete system: runs the reproducible Vivado export pynq diagrams hardware flow.

94.1 Beginner architecture map

Dataflow responsibility This file's end-to-end responsibility is to runs the reproducible Vivado export pynq diagrams hardware flow.

Where it runs This is Vivado Tcl orchestration, not accelerator datapath hardware. It makes tool inputs, versions, paths, stages, and failure propagation repeatable.

Reproducibility contract Every external command must be checked, every required artifact must exist and be nonempty, and measured values must be read from generated reports. Rerunning this file should either reproduce its declared outputs or stop at the first failed gate.

94.2 Complete source

```
if {$argc != 2} {

94.3 Line annotations

Line 1: `if {$argc != 2} {` This batch-control line contributes to the flow that runs the reproducible Vivado export pynq diagrams hardware flow. The important operands are argc: the value named 'argc' in this block.

Line 2: `error "Usage: export_pynq_diagrams.tcl <project.xpr> <output_dir>"` This batch-control line contributes to the flow that runs the reproducible Vivado export pynq diagrams hardware flow. The important operands are error: the value named 'error' in this block; Usage: the value named 'usage' in this block; export_pynq_diagrams: the value named 'export pynq diagrams' in this block.

Line 3: `}` This batch-control line contributes to the flow that runs the reproducible Vivado export pynq diagrams hardware flow. The expression is a literal or structural operator and has no hidden software state.

Line 5: `set project_file [file normalize [lindex $argv 0]]` This batch-control line contributes to the flow that runs the reproducible Vivado export pynq diagrams hardware flow. The important operands are set: the value named 'set' in this block; project_file: the value named 'project file' in this block; file: the value named 'file' in this block.

Line 6: `set output_dir [file normalize [lindex $argv 1]]` This batch-control line contributes to the flow that runs the reproducible Vivado export pynq diagrams hardware flow. The important operands are set: the value named 'set' in this block; output_dir: the value named 'output dir' in this block; file: the value named 'file' in this block.

Line 7: `if {![file exists $project_file]} {` This batch-control line contributes to the flow that runs the reproducible Vivado export pynq diagrams hardware flow. The important operands are file: the value named 'file' in this block; exists: the value named 'exists' in this block; project_file: the value named 'project file' in this block.

Line 8: `error "Vivado project does not exist: $project_file"` This batch-control line contributes to the flow that runs the reproducible Vivado export pynq diagrams hardware flow. The important operands are error: the value named 'error' in this block; Vivado: the value named 'vivado' in this block; project: the value named 'project' in this block.

Line 9: `}` This batch-control line contributes to the flow that runs the reproducible Vivado export pynq diagrams hardware flow. The expression is a literal or structural operator and has no hidden software state.

Line 10: `file mkdir $output_dir` This batch-control line contributes to the flow that runs the reproducible Vivado export pynq diagrams hardware flow. The important operands are file: the value named 'file' in this block; mkdir: the value named 'mkdir' in this block; output_dir: the value named 'output dir' in this block.

Line 12: `open_project $project_file` This batch-control line contributes to the flow that runs the reproducible Vivado export pynq diagrams hardware flow. The important operands are open_project: the value named 'open project' in this block; project_file: the value named 'project file' in this block.

Line 13: `set bd_files [get_files -quiet system.bd]` This batch-control line contributes to the flow that runs the reproducible Vivado export pynq diagrams hardware flow. The important operands are set: the value named 'set' in this block; bd_files: the value named 'bd files' in this block; get_files: the value named 'get files' in this block.

Line 14: `if {[llength $bd_files] != 1} {` This batch-control line contributes to the flow that runs the reproducible Vivado export pynq diagrams hardware flow. The important operands are llength: the value named 'llength' in this block; bd_files: the value named 'bd files' in this block.

Line 15: `error "Expected exactly one system.bd, found [llength $bd_files]"` This batch-control line contributes to the flow that runs the reproducible Vivado export pynq diagrams hardware flow. The important operands are error: the value named 'error' in this block; Expected: the value named 'expected' in this block; exactly: the value named 'exactly' in this block.

Line 16: `}` This batch-control line contributes to the flow that runs the reproducible Vivado export pynq diagrams hardware flow. The expression is a literal or structural operator and has no hidden software state.

Line 17: `open_bd_design [lindex $bd_files 0]` This batch-control line contributes to the flow that runs the reproducible Vivado export pynq diagrams hardware flow. The important operands are open_bd_design: the value named 'open bd design' in this block; lindex: an integer selecting one tensor element, lane, bank, or state entry; bd_files: the value named 'bd files' in this block.

Line 19: `set pdf_path [file join $output_dir "neuraedge_pynq_block_design.pdf"]` This batch-control line contributes to the flow that runs the reproducible Vivado export pynq diagrams hardware flow. The important operands are set: the value named 'set' in this block; pdf_path: the value named 'pdf path' in this block; file: the value named 'file' in this block.

Line 20: `set svg_path [file join $output_dir "neuraedge_pynq_block_design.svg"]` This batch-control line contributes to the flow that runs the reproducible Vivado export pynq diagrams hardware flow. The important operands are set: the value named 'set' in this block; svg_path: the value named 'svg path' in this block; file: the value named 'file' in this block.

Line 21: `write_bd_layout -force -format pdf -orientation landscape -scope all $pdf_path` This writes an auditable Vivado artifact using ‘write_bd_layout -force -format pdf -orientation landscape -scope all $pdf_path‘; later documentation reads the resulting report rather than inventing a metric.

Line 22: `write_bd_layout -force -format svg -orientation landscape -scope all $svg_path` This writes an auditable Vivado artifact using ‘write_bd_layout -force -format svg -orientation landscape -scope all $svg_path‘; later documentation reads the resulting report rather than inventing a metric.

Line 23: `foreach diagram [list $pdf_path $svg_path] {` This batch-control line contributes to the flow that runs the reproducible Vivado export pynq diagrams hardware flow. The important operands are foreach: the value named ’foreach’ in this block; diagram: the value named ’diagram’ in this block; list: the value named ’list’ in this block.

Line 24: `if {![file exists $diagram] || [file size $diagram] == 0} {` This batch-control line contributes to the flow that runs the reproducible Vivado export pynq diagrams hardware flow. The important operands are file: the value named ’file’ in this block; exists: the value named ’exists’ in this block; diagram: the value named ’diagram’ in this block.

Line 25: `error "Block-design diagram was not generated: $diagram"` This batch-control line contributes to the flow that runs the reproducible Vivado export pynq diagrams hardware flow. The important operands are error: the value named ’error’ in this block; Block: the value named ’block’ in this block; design: the value named ’design’ in this block.

Line 26: `}` This batch-control line contributes to the flow that runs the reproducible Vivado export pynq diagrams hardware flow. The expression is a literal or structural operator and has no hidden software state.

Line 27: `}` This batch-control line contributes to the flow that runs the reproducible Vivado export pynq diagrams hardware flow. The expression is a literal or structural operator and has no hidden software state.

Line 29: `puts "NEURAEDGE_PYNQ_DIAGRAMS_EXPORTED pdf=$pdf_path svg=$svg_path"` This batch-control line contributes to the flow that runs the reproducible Vivado export pynq diagrams hardware flow. The important operands are puts: the value named ’puts’ in this block; NEURAEDGE_PYNQ_DIAGRAMS_EXPORTED: the value named ’neuraedge pynq diagrams exported’ in this block; pdf: the value named ’pdf’ in this block.

Line 30: `close_project` This batch-control line contributes to the flow that runs the reproducible Vivado export pynq diagrams hardware flow. The important operands are close_project: the value named ’close project’ in this block.

Line 31: `exit 0` This batch-control line contributes to the flow that runs the reproducible Vivado export pynq diagrams hardware flow. The important operands are exit: the value named ’exit’ in this block.

The important operands are set: the value named ’set’ in this block; bram18_count: an integer count retained for control or measurable telemetry; llength: the value named ’llength’ in this block.

Line 25: `set setup_path [get_timing_paths -delay_type max -max_paths 1]` This batch-control line contributes to the flow that runs the reproducible Vivado finalize pynq ooc hardware flow. The important operands are set: the value named ’set’ in this block; setup_path: the value named ’setup path’ in this block; get_timing_paths: the value named ’get timing paths’ in this block.

Line 26: `set hold_path [get_timing_paths -delay_type min -max_paths 1]` This batch-control line contributes to the flow that runs the reproducible Vivado finalize pynq ooc hardware flow. The important operands are set: the value named 'set' in this block; hold_path: the value named 'hold path' in this block; get_timing_paths: the value named 'get timing paths' in this block.

Line 27: `set setup_wns [get_property SLACK $setup_path]` This batch-control line contributes to the flow that runs the reproducible Vivado finalize pynq ooc hardware flow. The important operands are set: the value named 'set' in this block; setup_wns: the value named 'setup wns' in this block; get_property: the value named 'get property' in this block.

Line 28: `set hold_whs [get_property SLACK $hold_path]` This batch-control line contributes to the flow that runs the reproducible Vivado finalize pynq ooc hardware flow. The important operands are set: the value named 'set' in this block; hold_whs: the value named 'hold whs' in this block; get_property: the value named 'get property' in this block.

Line 29: `set route_error_count -1` This batch-control line contributes to the flow that runs the reproducible Vivado finalize pynq ooc hardware flow. The important operands are set: the value named 'set' in this block; route_error_count: an integer count retained for control or measurable telemetry.

Line 30: `if {[regexp {# of nets with routing errors\.*\s*:\s*([0-9]+)} \` This batch-control line contributes to the flow that runs the reproducible Vivado finalize pynq ooc hardware flow. The important operands are regexp: the value named 'regexp' in this block; of: the value named 'of' in this block; nets: the value named 'nets' in this block.

Line 31: `$route_status_text route_match route_count]} {` This batch-control line contributes to the flow that runs the reproducible Vivado finalize pynq ooc hardware flow. The important operands are route_status_text: the value named 'route status text' in this block; route_match: the value named 'route match' in this block; route_count: an integer count retained for control or measurable telemetry.

Line 32: `set route_error_count $route_count` This batch-control line contributes to the flow that runs the reproducible Vivado finalize pynq ooc hardware flow. The important operands are set: the value named 'set' in this block; route_error_count: an integer count retained for control or measurable telemetry; route_count: an integer count retained for control or measurable telemetry.

Line 33: `}` This batch-control line contributes to the flow that runs the reproducible Vivado finalize pynq ooc hardware flow. The expression is a literal or structural operator and has no hidden software state.

Line 34: `set drc_error_count [llength [get_drc_violations -quiet -filter {SEVERITY == Error}]]` This batch-control line contributes to the flow that runs the reproducible Vivado finalize pynq ooc hardware flow. The important operands are set: the value named 'set' in this block; drc_error_count: an integer count retained for control or measurable telemetry; llength: the value named 'llength' in this block.

Line 36: `set summary_file [open [file join $output_dir "implementation_summary.txt"] "w"]` This batch-control line contributes to the flow that runs the reproducible Vivado finalize pynq ooc hardware flow. The important operands are set: the value named 'set' in this block; summary_file: the value named 'summary file' in this block; open: the value named 'open' in this block.

Line 37: `puts $summary_file "part=xc7z020clg400-1"` This batch-control line contributes to the flow that runs the reproducible Vivado finalize pynq ooc hardware flow. The important operands are puts: the value named 'puts' in this block; summary_file: the value named 'summary file' in this block; part: the value named 'part' in this block.

Line 38: `puts $summary_file "target_clock_mhz=200.0"` This batch-control line contributes to the flow that runs the reproducible Vivado finalize pynq ooc hardware flow. The important operands are puts: the value named 'puts' in this block; summary_file: the value named 'summary file' in this block; target_clock_mhz: the value named 'target clock mhz' in this block.

Line 39: `puts $summary_file "lut_count=$lut_count"` This batch-control line contributes to the flow that runs the reproducible Vivado finalize pynq ooc hardware flow. The important operands are puts: the value named 'puts' in this block; summary_file: the value named 'summary file' in this block; lut_count: an integer count retained for control or measurable telemetry.

Line 40: `puts $summary_file "ff_count=$ff_count"` This batch-control line contributes to the flow that runs the reproducible Vivado finalize pynq ooc hardware flow. The important operands are puts: the value named 'puts' in this block; summary_file: the value named 'summary file' in this block; ff_count: an integer count retained for control or measurable telemetry.

Line 41: `puts $summary_file "dsp48_count=$dsp_count"` This batch-control line contributes to the flow that runs the reproducible Vivado finalize pynq ooc hardware flow. The important operands are puts: the value named 'puts' in this block; summary_file: the value named 'summary file' in this block; dsp48_count: an integer count retained for control or measurable telemetry.

Line 42: `puts $summary_file "bram36_count=$bram36_count"` This batch-control line contributes to the flow that runs the reproducible Vivado finalize pynq ooc hardware flow. The important operands are puts: the value named 'puts' in this block; summary_file: the value named 'summary file' in this block; bram36_count: an integer count retained for control or measurable telemetry.

Line 43: `puts $summary_file "bram18_count=$bram18_count"` This batch-control line contributes to the flow that runs the reproducible Vivado finalize pynq ooc hardware flow. The important operands are puts: the value named 'puts' in this block; summary_file: the value named 'summary file' in this block; bram18_count: an integer count retained for control or measurable telemetry.

Line 44: `puts $summary_file "setup_wns_ns=$setup_wns"` This batch-control line contributes to the flow that runs the reproducible Vivado finalize pynq ooc hardware flow. The important operands are puts: the value named 'puts' in this block; summary_file: the value named 'summary file' in this block; setup_wns_ns: the value named 'setup wns ns' in this block.

Line 45: `puts $summary_file "hold_whs_ns=$hold_whs"` This batch-control line contributes to the flow that runs the reproducible Vivado finalize pynq ooc hardware flow. The important operands are puts: the value named 'puts' in this block; summary_file: the value named 'summary file' in this block; hold_whs_ns: the value named 'hold whs ns' in this block.

Line 46: `puts $summary_file "route_error_count=$route_error_count"` This batch-control line contributes to the flow that runs the reproducible Vivado finalize pynq ooc hardware flow. The important operands are puts: the value named 'puts' in this block; summary_file: the value named 'summary file' in this block; route_error_count: an integer count retained for control or measurable telemetry.

Line 47: `puts $summary_file "drc_error_count=$drc_error_count"` This batch-control line contributes to the flow that runs the reproducible Vivado finalize pynq ooc hardware flow. The important operands are puts: the value named 'puts' in this block; summary_file: the value named 'summary file' in this block; drc_error_count: an integer count retained for control or measurable telemetry.

Line 48: `puts $summary_file "hold_context=ooc_top_ports_without_hd_partpin_locs"` This batch-control line contributes to the flow that runs the reproducible Vivado finalize pynq ooc hardware flow. The important operands are puts: the value named 'puts' in this block; summary_file: the value named 'summary file' in this block; hold_context: the value named 'hold context' in this block.

Line 49: `close $summary_file` This batch-control line contributes to the flow that runs the reproducible Vivado finalize pynq ooc hardware flow. The important operands are close: the value named 'close' in this block; summary_file: the value named 'summary file' in this block.

Line 51: `if {$route_error_count != 0} {` This batch-control line contributes to the flow that runs the reproducible Vivado finalize pynq ooc hardware flow. The important operands are route_error_count: an integer count retained for control or measurable telemetry.

Line 52: `error "Routed design is incomplete: route_error_count=$route_error_count"` This batch-control line contributes to the flow that runs the reproducible Vivado finalize pynq ooc hardware flow. The important operands are error: the value named 'error' in this block; Routed: the value named 'routed' in this block; design: the value named 'design' in this block.

Line 53: `}` This batch-control line contributes to the flow that runs the reproducible Vivado finalize pynq ooc hardware flow. The expression is a literal or structural operator and has no hidden software state.

Line 54: `if {$drc_error_count != 0} {` This batch-control line contributes to the flow that runs the reproducible Vivado finalize pynq ooc hardware flow. The important operands are drc_error_count: an integer count retained for control or measurable telemetry.

Line 55: `error "Routed design has DRC errors: drc_error_count=$drc_error_count"` This batch-control line contributes to the flow that runs the reproducible Vivado finalize pynq ooc hardware flow. The important operands are error: the value named 'error' in this block; Routed: the value named 'routed' in this block; design: the value named 'design' in this block.

Line 56: `}` This batch-control line contributes to the flow that runs the reproducible Vivado finalize pynq ooc hardware flow. The expression is a literal or structural operator and has no hidden software state.

Line 57: `if {$setup_wns < 0.0} {` This batch-control line contributes to the flow that runs the reproducible Vivado finalize pynq ooc hardware flow. The important operands are setup_wns: the value named 'setup wns' in this block.

Line 58: `error "Routed design missed the 5.0 ns target: WNS=$setup_wns ns"` This batch-control line contributes to the flow that runs the reproducible Vivado finalize pynq ooc hardware flow. The important operands are error: the value named 'error' in this block; Routed: the value named 'routed' in this block; design: the value named 'design' in this block.

Line 59: `}` This batch-control line contributes to the flow that runs the reproducible Vivado finalize pynq ooc hardware flow. The expression is a literal or structural operator and has no hidden software state.

Line 60: `# Min-delay paths at OOC AXI/stream ports are inaccurate without physical` This comment documents the batch-flow intent: Min-delay paths at OOC AXI/stream ports are inaccurate without physical

Line 61: `# partition pins. Preserve the diagnostic and enforce hold in the full shell.` This comment documents the batch-flow intent: partition pins. Preserve the diagnostic and enforce hold in the full shell.

Line 62: `if {$hold_whs < 0.0} {` This batch-control line contributes to the flow that runs the reproducible Vivado finalize pynq ooc hardware flow. The important operands are hold_whs: the value named 'hold whs' in this block.

Line 63: `puts "NEURAEDGE_OOC_HOLD_CONTEXT_ONLY WHS=$hold_whs ns"` This batch-control line contributes to the flow that runs the reproducible Vivado finalize pynq ooc hardware flow. The important operands are puts: the value named 'puts' in this block; NEURAEDGE_OOC_HOLD_CONTEXT_ONLY: the value named 'neuraedge ooc hold context only' in this block; WHS: the value named 'whs' in this block.

Line 64: `}` This batch-control line contributes to the flow that runs the reproducible Vivado finalize pynq ooc hardware flow. The expression is a literal or structural operator and has no hidden software state.

96 scripts/report_checkpoint_hierarchy.tcl

Role in the complete system: runs the reproducible Vivado report checkpoint hierarchy hardware flow.

96.1 Beginner architecture map

Dataflow responsibility This file's end-to-end responsibility is to runs the reproducible Vivado report checkpoint hierarchy hardware flow.

Where it runs This is Vivado Tcl orchestration, not accelerator datapath hardware. It makes tool inputs, versions, paths, stages, and failure propagation repeatable.

Reproducibility contract Every external command must be checked, every required artifact must exist and be nonempty, and measured values must be read from generated reports. Rerunning this file should either reproduce its declared outputs or stop at the first failed gate.

96.2 Complete source

```
# Report module-level area and control-set pressure from any synthesized DCP.
if {$argc != 2} {
    error "Usage: report_checkpoint_hierarchy.tcl <checkpoint.dcp> <output_dir>"
}

set checkpoint [file normalize [lindex $argv 0]]
set output_dir [file normalize [lindex $argv 1]]
if {![file exists $checkpoint]} {
    error "Checkpoint does not exist: $checkpoint"
}
file mkdir $output_dir

open_checkpoint $checkpoint
report_utilization -hierarchical -hierarchical_depth 8 \
    -file [file join $output_dir "hierarchical_utilization.rpt"]
report_control_sets -verbose \
    -file [file join $output_dir "control_sets.rpt"]
report_design_analysis -complexity -congestion \
    -file [file join $output_dir "design_complexity_congestion.rpt"]
puts "NEURAEDGE_CHECKPOINT_HIERARCHY_REPORTED output=$output_dir"
close_design
exit 0
```

Line 1: `# Report module-level area and control-set pressure from any synthesized DCP.` This comment documents the batch-flow intent: Report module-level area and control-set pressure from any synthesized DCP.

Line 2: `if {$argc != 2} {` This batch-control line contributes to the flow that runs the reproducible Vivado report checkpoint hierarchy hardware flow. The important operands are argc: the value named 'argc' in this block.

Line 3: `error "Usage: report_checkpoint_hierarchy.tcl <checkpoint.dcp> <output_dir>"` This batch-control line contributes to the flow that runs the reproducible Vivado report checkpoint hierarchy hardware flow. The important operands are error: the value named 'error' in this block; Usage: the value named 'usage' in this block; report_checkpoint_hierarchy: the value named 'report checkpoint hierarchy' in this block.

Line 4: `}` This batch-control line contributes to the flow that runs the reproducible Vivado report checkpoint hierarchy hardware flow. The expression is a literal or structural operator and has no hidden software state.

Line 6: `set checkpoint [file normalize [lindex $argv 0]]` This batch-control line contributes to the flow that runs the reproducible Vivado report checkpoint hierarchy hardware flow. The important operands are set: the value named 'set' in this block; checkpoint: the value named 'checkpoint' in this block; file: the value named 'file' in this block.

Line 7: `set output_dir [file normalize [lindex $argv 1]]` This batch-control line contributes to the flow that runs the reproducible Vivado report checkpoint hierarchy hardware flow. The important operands are set: the value named 'set' in this block; output_dir: the value named 'output dir' in this block; file: the value named 'file' in this block.

Line 8: `if {![file exists $checkpoint]} {` This batch-control line contributes to the flow that runs the reproducible Vivado report checkpoint hierarchy hardware flow. The important operands are file: the value named 'file' in this block; exists: the value named 'exists' in this block; checkpoint: the value named 'checkpoint' in this block.

Line 9: `error "Checkpoint does not exist: $checkpoint"` This batch-control line contributes to the flow that runs the reproducible Vivado report checkpoint hierarchy hardware flow. The important operands are error: the value named 'error' in this block; Checkpoint: the value named 'checkpoint' in this block; does: the value named 'does' in this block.

Line 10: `}` This batch-control line contributes to the flow that runs the reproducible Vivado report checkpoint hierarchy hardware flow. The expression is a literal or structural operator and has no hidden software state.

Line 11: `file mkdir $output_dir` This batch-control line contributes to the flow that runs the reproducible Vivado report checkpoint hierarchy hardware flow. The important operands are file: the value named 'file' in this block; mkdir: the value named 'mkdir' in this block; output_dir: the value named 'output dir' in this block.

Line 13: `open_checkpoint $checkpoint` This batch-control line contributes to the flow that runs the reproducible Vivado report checkpoint hierarchy hardware flow. The important operands are open_checkpoint: the value named 'open checkpoint' in this block; checkpoint: the value named 'checkpoint' in this block.

Line 14: `report_utilization -hierarchical -hierarchical_depth 8 \` This writes an auditable Vivado artifact using 'report_utilization -hierarchical -hierarchical_depth 8 \'; later documentation reads the resulting report rather than inventing a metric.

Line 15: `-file [file join $output_dir "hierarchical_utilization.rpt"]` This batch-control line contributes to the flow that runs the reproducible Vivado report checkpoint hierarchy hardware flow. The important operands are file: the value named 'file' in this block; join: the value named 'join' in this block; output_dir: the value named 'output dir' in this block.

Line 16: `report_control_sets -verbose \` This writes an auditable Vivado artifact using 'report_control_sets -verbose \'; later documentation reads the resulting report rather than inventing a metric.

Line 17: `-file [file join $output_dir "control_sets.rpt"]` This batch-control line contributes to the flow that runs the reproducible Vivado report checkpoint hierarchy hardware flow. The important operands are file: the value named 'file' in this block; join: the value named 'join' in this block; output_dir: the value named 'output dir' in this block.

Line 18: `report_design_analysis -complexity -congestion \` This writes an auditable Vivado artifact using 'report_design_analysis -complexity -congestion \'; later documentation reads the resulting report rather than inventing a metric.

Line 19: `-file [file join $output_dir "design_complexity_congestion.rpt"]` This batch-control line contributes to the flow that runs the reproducible Vivado report checkpoint hierarchy hardware flow. The important operands are file: the value named 'file' in this block; join: the value named 'join' in this block; output_dir: the value named 'output dir' in this block.

Line 20: `puts "NEURAEDGE_CHECKPOINT_HIERARCHY_REPORTED output=$output_dir"` This batch-control line contributes to the flow that runs the reproducible Vivado report checkpoint hierarchy hardware flow. The important operands are puts: the value named 'puts' in this block; NEURAEDGE_CHECKPOINT_HIERARCHY_REPORTED: the value named 'neuraedge checkpoint hierarchy reported' in this block; output: the value named 'output' in this block.

Line 21: `close_design` This batch-control line contributes to the flow that runs the reproducible Vivado report checkpoint hierarchy hardware flow. The important operands are close_design: the value named 'close design' in this block.

Line 22: `exit 0` This batch-control line contributes to the flow that runs the reproducible Vivado report checkpoint hierarchy hardware flow. The important operands are exit: the value named 'exit' in this block.

The important operands are puts: the value named 'puts' in this block; NEURAEDGE_OPTIMIZER_DSP_REPORTED: the value named 'neuraedge optimizer dsp reported' in this block; count: the value named 'count' in this block.

Line 43: `close_design` This batch-control line contributes to the flow that runs the reproducible Vivado report optimizer dsp hardware flow. The important operands are close_design: the value named 'close design' in this block.

Line 44: `exit 0` This batch-control line contributes to the flow that runs the reproducible Vivado report optimizer dsp hardware flow. The important operands are exit: the value named 'exit' in this block.

98 scripts/resume_pynq_ooc.tcl

Role in the complete system: runs the reproducible Vivado resume pynq ooc hardware flow.

98.1 Beginner architecture map

Dataflow responsibility This file's end-to-end responsibility is to runs the reproducible Vivado resume pynq ooc hardware flow.

Where it runs This is Vivado Tcl orchestration, not accelerator datapath hardware. It makes tool inputs, versions, paths, stages, and failure propagation repeatable.

Reproducibility contract Every external command must be checked, every required artifact must exist and be nonempty, and measured values must be read from generated reports. Rerunning this file should either reproduce its declared outputs or stop at the first failed gate.

98.2 Complete source

```
set script_dir [file normalize [file dirname [info script]]]

if {![file exists $checkpoint]} {
    error "Routed resume checkpoint does not exist: $checkpoint"
}

open_checkpoint $checkpoint
phys_opt_design -directive $directive
write_checkpoint -force [file join $output_dir "postroute_physopt_unrouted.dcp"]
route_design -directive Quick
source [file join $script_dir "finalize_pynq_ooc.tcl"]
```

98.3 Line annotations

Line 1: `set script_dir [file normalize [file dirname [info script]]]` This batch-control line contributes to the flow that runs the reproducible Vivado resume pynq ooc hardware flow. The important operands are set: the value named 'set' in this block; script_dir: the value named 'script dir' in this block; file: the value named 'file' in this block.

Line 2: `set project_dir [file normalize [file join $script_dir ".."]]` This batch-control line contributes to the flow that runs the reproducible Vivado resume pynq ooc hardware flow. The important operands are set: the value named 'set' in this block; project_dir: the value named 'project dir' in this block; file: the value named 'file' in this block.

Line 3: `set output_name "pynq_ooc"` This batch-control line contributes to the flow that runs the reproducible Vivado resume pynq ooc hardware flow. The important operands are set: the value named 'set' in this block; output_name: the value named 'output name' in this block; pynq_ooc: the value named 'pynq ooc' in this block.

Line 4: `set directive "Explore"` This batch-control line contributes to the flow that runs the reproducible Vivado resume pynq ooc hardware flow. The important operands are set: the value named 'set' in this block; directive: the value named 'directive' in this block; Explore: the value named 'explore' in this block.

Line 5: `if {$argc >= 1} {` This batch-control line contributes to the flow that runs the reproducible Vivado resume pynq ooc hardware flow. The important operands are argc: the value named 'argc' in this block.

Line 6: `set output_name [lindex $argv 0]` This batch-control line contributes to the flow that runs the reproducible Vivado resume pynq ooc hardware flow. The important operands are set: the value named 'set' in this block; output_name: the value named 'output name' in this block; lindex: an integer selecting one tensor element, lane, bank, or state entry.

Line 7: `}` This batch-control line contributes to the flow that runs the reproducible Vivado resume pynq ooc hardware flow. The expression is a literal or structural operator and has no hidden software state.

Line 8: `if {$argc >= 2} {` This batch-control line contributes to the flow that runs the reproducible Vivado resume pynq ooc hardware flow. The important operands are argc: the value named 'argc' in this block.

Line 9: `set directive [lindex $argv 1]` This batch-control line contributes to the flow that runs the reproducible Vivado resume pynq ooc hardware flow. The important operands are set: the value named 'set' in this block; directive: the value named 'directive' in this block; lindex: an integer selecting one tensor element, lane, bank, or state entry.

Line 10: `}` This batch-control line contributes to the flow that runs the reproducible Vivado resume pynq ooc hardware flow. The expression is a literal or structural operator and has no hidden software state.

Line 11: `set output_dir [file join $project_dir "outputs" $output_name]` This batch-control line contributes to the flow that runs the reproducible Vivado resume pynq ooc hardware flow. The important operands are set: the value named 'set' in this block; output_dir: the value named 'output dir' in this block; file: the value named 'file' in this block.

Line 12: `set checkpoint [file join $output_dir "pre_postroute_physopt.dcp"]` This batch-control line contributes to the flow that runs the reproducible Vivado resume pynq ooc hardware flow. The important operands are set: the value named 'set' in this block; checkpoint: the value named 'checkpoint' in this block; file: the value named 'file' in this block.

Line 14: `if {![file exists $checkpoint]} {` This batch-control line contributes to the flow that runs the reproducible Vivado resume pynq ooc hardware flow. The important operands are file: the value named 'file' in this block; exists: the value named 'exists' in this block; checkpoint: the value named 'checkpoint' in this block.

Line 15: `error "Routed resume checkpoint does not exist: $checkpoint"` This batch-control line contributes to the flow that runs the reproducible Vivado resume pynq ooc hardware flow. The important operands are error: the value named 'error' in this block; Routed: the value named 'routed' in this block; resume: the value named 'resume' in this block.

Line 16: `}` This batch-control line contributes to the flow that runs the reproducible Vivado resume pynq ooc hardware flow. The expression is a literal or structural operator and has no hidden software state.

Line 18: `open_checkpoint $checkpoint` This batch-control line contributes to the flow that runs the reproducible Vivado resume pynq ooc hardware flow. The important operands are open_checkpoint: the value named 'open checkpoint' in this block; checkpoint: the value named 'checkpoint' in this block.

Line 19: `phys_opt_design -directive $directive` This runs Vivado implementation command 'phys_opt_design -directive $directive', changing the physical netlist or placement/routing needed for real timing.

Line 20: `write_checkpoint -force [file join $output_dir "postroute_physopt_unrouted.dcp"]` This writes an auditable Vivado artifact using 'write_checkpoint -force [file join $output_dir "postroute_physopt_unrouted.dcp"]'; later documentation reads the resulting report rather than inventing a metric.

Line 21: `route_design -directive Quick` This runs Vivado implementation command 'route_design -directive Quick', changing the physical netlist or placement/routing needed for real timing.

Line 22: `source [file join $script_dir "finalize_pynq_ooc.tcl"]` This batch-control line contributes to the flow that runs the reproducible Vivado resume pynq ooc hardware flow. The important operands are source: the value named 'source' in this block; file: the value named 'file' in this block; join: the value named 'join' in this block.

99 scripts/synth_mac2_probe.tcl

Role in the complete system: runs the reproducible Vivado synth mac2 probe hardware flow.

99.1 Beginner architecture map

Dataflow responsibility This file's end-to-end responsibility is to runs the reproducible Vivado synth mac2 probe hardware flow.

Where it runs This is Vivado Tcl orchestration, not accelerator datapath hardware. It makes tool inputs, versions, paths, stages, and failure propagation repeatable.

99.3 Line annotations

Line 1: `set script_dir [file normalize [file dirname [info script]]]` This batch-control line contributes to the flow that runs the reproducible Vivado synth mac2 probe hardware flow. The important operands are set: the value named 'set' in this block; script_dir: the value named 'script dir' in this block; file: the value named 'file' in this block.

Line 2: `set project_dir [file normalize [file join $script_dir ".."]]` This batch-control line contributes to the flow that runs the reproducible Vivado synth mac2 probe hardware flow. The important operands are set: the value named 'set' in this block; project_dir: the value named 'project dir' in this block; file: the value named 'file' in this block.

Line 3: `set out_dir [file join $project_dir "outputs" "mac2_probe"]` This batch-control line contributes to the flow that runs the reproducible Vivado synth mac2 probe hardware flow. The important operands are set: the value named 'set' in this block; out_dir: the value named 'out dir' in this block; file: the value named 'file' in this block.

Line 4: `file mkdir $out_dir` This batch-control line contributes to the flow that runs the reproducible Vivado synth mac2 probe hardware flow. The important operands are file: the value named 'file' in this block; mkdir: the value named 'mkdir' in this block; out_dir: the value named 'out dir' in this block.

Line 6: `read_verilog -sv [file join $project_dir "rtl" "neuraedge_mac2_u8.sv"]` This loads the listed RTL into Vivado's in-memory design so the subsequent synthesis uses the repository source.

Line 7: `read_verilog -sv [file join $project_dir "rtl" "neuraedge_mac2_array_probe.sv"]` This loads the listed RTL into Vivado's in-memory design so the subsequent synthesis uses the repository source.

Line 8: `synth_design -top neuraedge_mac2_array_probe -part xc7z020clg400-1 -generic PAIRS=128` This invokes Vivado synthesis for the named top and FPGA part, mapping behavioral RTL into LUT, flip-flop, BRAM, and DSP primitives.

Line 9: `create_clock -period 5.0 -name clk [get_ports clk]` This declares the clock period against which Vivado checks every synchronous setup and hold path.

Line 11: `opt_design` This runs Vivado implementation command 'opt_design', changing the physical netlist or placement/routing needed for real timing.

Line 12: `place_design` This runs Vivado implementation command 'place_design', changing the physical netlist or placement/routing needed for real timing.

Line 13: `route_design` This runs Vivado implementation command 'route_design', changing the physical netlist or placement/routing needed for real timing.

Line 15: `report_utilization -file [file join $out_dir "mac2_probe_utilization.rpt"]` This writes an auditable Vivado artifact using 'report_utilization -file [file join $out_dir "mac2_probe_utilization.rpt"]'; later documentation reads the resulting report rather than inventing a metric.

Line 16: `report_timing_summary -file [file join $out_dir "mac2_probe_timing.rpt"]` This writes an auditable Vivado artifact using 'report_timing_summary -file [file join $out_dir "mac2_probe_timing.rpt"]'; later documentation reads the resulting report rather than inventing a metric.

Line 17: `report_drc -file [file join $out_dir "mac2_probe_drc.rpt"]` This writes an auditable Vivado artifact using 'report_drc -file [file join $out_dir "mac2_probe_drc.rpt"]'; later documentation reads the resulting report rather than inventing a metric.

Line 18: `write_checkpoint -force [file join $out_dir "mac2_probe_routed.dcp"]` This writes an auditable Vivado artifact using 'write_checkpoint -force [file join $out_dir "mac2_probe_routed.dcp"]'; later documentation reads the resulting report rather than inventing a metric.

Line 20: `set dsp_count [llength [get_cells -hierarchical -filter {REF_NAME =~ DSP48*}]]` This batch-control line contributes to the flow that runs the reproducible Vivado synth mac2 probe hardware flow. The important operands are set: the value named 'set' in this block; dsp_count: an integer count retained for control or measurable telemetry; llength: the value named 'llength' in this block.

Line 21: `set wns [get_property SLACK [get_timing_paths -max_paths 1 -setup]]` This batch-control line contributes to the flow that runs the reproducible Vivado synth mac2 probe hardware flow. The important operands are set: the value named 'set' in this block; wns: the value named 'wns' in this block; get_property: the value named 'get property' in this block.

Line 22: `set fh [open [file join $out_dir "mac2_probe_summary.txt"] "w"]` This batch-control line contributes to the flow that runs the reproducible Vivado synth mac2 probe hardware flow. The important operands are set: the value named 'set' in this block; fh: the value named 'fh' in this block; open: the value named 'open' in this block.

Line 23: `puts $fh "pairs=128"` This batch-control line contributes to the flow that runs the reproducible Vivado synth mac2 probe hardware flow. The important operands are puts: the value named 'puts' in this block; fh: the value named 'fh' in this block; pairs: the value named 'pairs' in this block.

Line 24: `puts $fh "products_per_cycle=256"` This batch-control line contributes to the flow that runs the reproducible Vivado synth mac2 probe hardware flow. The important operands are puts: the value named 'puts' in this block; fh: the value named 'fh' in this block; products_per_cycle: the value named 'products per cycle' in this block.

Line 25: `puts $fh "dsp48_count=$dsp_count"` This batch-control line contributes to the flow that runs the reproducible Vivado synth mac2 probe hardware flow. The important operands are puts: the value named 'puts' in this block; fh: the value named 'fh' in this block; dsp48_count: an integer count retained for control or measurable telemetry.

Line 26: `puts $fh "wns_ns=$wns"` This batch-control line contributes to the flow that runs the reproducible Vivado synth mac2 probe hardware flow. The important operands are puts: the value named 'puts' in this block; fh: the value named 'fh' in this block; wns_ns: the value named 'wns ns' in this block.

Line 27: `close $fh` This batch-control line contributes to the flow that runs the reproducible Vivado synth mac2 probe hardware flow. The important operands are close: the value named 'close' in this block; fh: the value named 'fh' in this block.

Line 29: `if {$dsp_count != 128} {` This batch-control line contributes to the flow that runs the reproducible Vivado synth mac2 probe hardware flow. The important operands are dsp_count: an integer count retained for control or measurable telemetry.

Line 30: `error "Packed MAC probe expected exactly 128 DSP48 cells, got $dsp_count"` This batch-control line contributes to the flow that runs the reproducible Vivado synth mac2 probe hardware flow. The important operands are error: the value named 'error' in this block; Packed: the value named 'packed' in this block; MAC: the value named 'mac' in this block.

Line 31: `}` This batch-control line contributes to the flow that runs the reproducible Vivado synth mac2 probe hardware flow. The expression is a literal or structural operator and has no hidden software state.

Line 32: `if {$wns < 0.0} {` This batch-control line contributes to the flow that runs the reproducible Vivado synth mac2 probe hardware flow. The important operands are wns: the value named 'wns' in this block.

Line 33: `error "Packed MAC probe failed the 5.0 ns timing target: WNS=$wns"` This batch-control line contributes to the flow that runs the reproducible Vivado synth mac2 probe hardware flow. The important operands are error: the value named 'error' in this block; Packed: the value named 'packed' in this block; MAC: the value named 'mac' in this block.

Line 34: `}` This batch-control line contributes to the flow that runs the reproducible Vivado synth mac2 probe hardware flow. The expression is a literal or structural operator and has no hidden software state.

The important operands are file: the value named 'file' in this block; join: the value named 'join' in this block; project_dir: the value named 'project dir' in this block.

Line 23: `[file join $project_dir "rtl" "neuraedge_log_softmax.sv"] \` This batch-control line contributes to the flow that runs the reproducible Vivado synth timing iteration hardware flow. The important operands are file: the value named 'file' in this block; join: the value named 'join' in this block; project_dir: the value named 'project dir' in this block.

Line 24: `[file join $project_dir "rtl" "neuraedge_lif_bank.sv"] \` This batch-control line contributes to the flow that runs the reproducible Vivado synth timing iteration hardware flow. The important operands are file: the value named 'file' in this block; join: the value named 'join' in this block; project_dir: the value named 'project dir' in this block.

Line 25: `[file join $project_dir "rtl" "neuraedge_sgd_optimizer8.sv"] \` This batch-control line contributes to the flow that runs the reproducible Vivado synth timing iteration hardware flow. The important operands are file: the value named 'file' in this block; join: the value named 'join' in this block; project_dir: the value named 'project dir' in this block.

Line 26: `[file join $project_dir "rtl" "neuraedge_gradient_accumulator_bank.sv"] \` This batch-control line contributes to the flow that runs the reproducible Vivado synth timing iteration hardware flow. The important operands are file: the value named 'file' in this block; join: the value named 'join' in this block; project_dir: the value named 'project dir' in this block.

Line 27: `[file join $project_dir "rtl" "neuraedge_linear_backward8.sv"] \` This batch-control line contributes to the flow that runs the reproducible Vivado synth timing iteration hardware flow. The important operands are file: the value named 'file' in this block; join: the value named 'join' in this block; project_dir: the value named 'project dir' in this block.

Line 28: `[file join $project_dir "rtl" "neuraedge_activation_lut8.sv"] \` This batch-control line contributes to the flow that runs the reproducible Vivado synth timing iteration hardware flow. The important operands are file: the value named 'file' in this block; join: the value named 'join' in this block; project_dir: the value named 'project dir' in this block.

Line 29: `[file join $project_dir "rtl" "neuraedge_universal_core.sv"] \` This batch-control line contributes to the flow that runs the reproducible Vivado synth timing iteration hardware flow. The important operands are file: the value named 'file' in this block; join: the value named 'join' in this block; project_dir: the value named 'project dir' in this block.

Line 30: `[file join $project_dir "rtl" "neuraedge_descriptor_sequencer.sv"] \` This batch-control line contributes to the flow that runs the reproducible Vivado synth timing iteration hardware flow. The important operands are file: the value named 'file' in this block; join: the value named 'join' in this block; project_dir: the value named 'project dir' in this block.

Line 31: `[file join $project_dir "rtl" "neuraedge_pynq_axi_top.sv"]]` This batch-control line contributes to the flow that runs the reproducible Vivado synth timing iteration hardware flow. The important operands are file: the value named 'file' in this block; join: the value named 'join' in this block; project_dir: the value named 'project dir' in this block.

Line 33: `read_verilog -sv $rtl_files` This loads the listed RTL into Vivado's in-memory design so the subsequent synthesis uses the repository source.

Line 34: `synth_design -top neuraedge_pynq_axi_top -part xc7z020clg400-1 \` This invokes Vivado synthesis for the named top and FPGA part, mapping behavioral RTL into LUT, flip-flop, BRAM, and DSP primitives.

Line 35: `-mode out_of_context -flatten_hierarchy rebuilt -directive PerformanceOptimized` This batch-control line contributes to the flow that runs the reproducible Vivado synth timing iteration hardware flow. The important operands are mode: the value named 'mode' in this block; out_of_context: the value named 'out of context' in this block; flatten_hierarchy: the value named 'flatten hierarchy' in this block.

Line 36: `create_clock -name aclk -period 5.000 [get_ports aclk]` This declares the clock period against which Vivado checks every synchronous setup and hold path.

Line 37: `set_clock_uncertainty 0.100 [get_clocks aclk]` This batch-control line contributes to the flow that runs the reproducible Vivado synth timing iteration hardware flow. The important operands are set_clock_uncertainty: the value named 'set clock uncertainty' in this block; get_clocks: the value named 'get clocks' in this block; aclk: the AXI and accelerator clock.

Line 38: `set_property HD.CLK_SRC BUFGCTRL_X0Y0 [get_ports aclk]` This batch-control line contributes to the flow that runs the reproducible Vivado synth timing iteration hardware flow. The important operands are set_property: the value named 'set property' in this block; HD: the value named 'hd' in this block; CLK_SRC: the clock that makes all registers advance together.

Line 39: `set_false_path -from [get_ports aresetn]` This batch-control line contributes to the flow that runs the reproducible Vivado synth timing iteration hardware flow. The important operands are set_false_path: the value named 'set false path' in this block; from: the value named 'from' in this block; get_ports: the value named 'get ports' in this block.

Line 40: `set data_inputs [get_ports -filter {DIRECTION == IN && NAME != "aclk" && NAME != "aresetn"}]` This batch-control line contributes to the flow that runs the reproducible Vivado synth timing iteration hardware flow. The important operands are set: the value named 'set' in this block; data_inputs: the value named 'data inputs' in this block; get_ports: the value named 'get ports' in this block.

Line 41: `set data_outputs [get_ports -filter {DIRECTION == OUT}]` This batch-control line contributes to the flow that runs the reproducible Vivado synth timing iteration hardware flow. The important operands are set: the value named 'set' in this block; data_outputs: the value named 'data outputs' in this block; get_ports: the value named 'get ports' in this block.

Line 42: `set_input_delay -clock aclk 1.000 $data_inputs` This batch-control line contributes to the flow that runs the reproducible Vivado synth timing iteration hardware flow. The important operands are set_input_delay: the value named 'set input delay' in this block; clock: the value named 'clock' in this block; aclk: the AXI and accelerator clock.

Line 43: `set_output_delay -clock aclk 1.000 $data_outputs` This batch-control line contributes to the flow that runs the reproducible Vivado synth timing iteration hardware flow. The important operands are set_output_delay: the value named 'set output delay' in this block; clock: the value named 'clock' in this block; aclk: the AXI and accelerator clock.

Line 45: `report_utilization -hierarchical \` This writes an auditable Vivado artifact using 'report_utilization -hierarchical \'; later documentation reads the resulting report rather than inventing a metric.

Line 46: `-file [file join $output_dir "post_synth_utilization_hierarchical.rpt"]` This batch-control line contributes to the flow that runs the reproducible Vivado synth timing iteration hardware flow. The important operands are file: the value named 'file' in this block; join: the value named 'join' in this block; output_dir: the value named 'output dir' in this block.

Line 47: `report_timing -delay_type max -max_paths 250 -nworst 1 -input_pins \` This writes an auditable Vivado artifact using 'report_timing -delay_type max -max_paths 250 -nworst 1 -input_pins \'; later documentation reads the resulting report rather than inventing a metric.

Line 48: `-file [file join $output_dir "post_synth_timing_paths_250.rpt"]` This batch-control line contributes to the flow that runs the reproducible Vivado synth timing iteration hardware flow. The important operands are file: the value named 'file' in this block; join: the value named 'join' in this block; output_dir: the value named 'output dir' in this block.

Line 49: `report_timing_summary -delay_type min_max -max_paths 20 \` This writes an auditable Vivado artifact using 'report_timing_summary -delay_type min_max -max_paths 20 \'; later documentation reads the resulting report rather than inventing a metric.

Line 50: `-file [file join $output_dir "post_synth_timing_summary.rpt"]` This batch-control line contributes to the flow that runs the reproducible Vivado synth timing iteration hardware flow. The important operands are file: the value named 'file' in this block; join: the value named 'join' in this block; output_dir: the value named 'output dir' in this block.

Line 51: `write_checkpoint -force [file join $output_dir "post_synth.dcp"]` This writes an auditable Vivado artifact using ‘write_checkpoint -force [file join $output_dir "post_synth.dcp"]‘; later documentation reads the resulting report rather than inventing a metric.

101 Coverage statement

This volume contains 99 source files, 28,915 physical source lines, and an explanation for all 26,565 nonblank lines. The companion JSON manifest records each source SHA-256 digest.
