During compute, the scheduler presents reduction indices and this memory returns one activation vector per selected row; keeping the tile local avoids rereading DDR for every output column.", "rtl/neuraedge_activation_lut8.sv": "Software first streams address/value pairs into the 256-entry table. A later execute command reads eight addresses in parallel, returns eight programmed nonlinear values, and counts only newly initialized addresses so duplicate writes cannot falsely report a complete table.", "rtl/neuraedge_active_index_buffer.sv": "While activations load, the tensor core tests whether a reduction position is all zero across active rows. Only nonzero positions are written here; compute

later walks this compact list, so sparse positions remove issue cycles rather than performing useless zero arithmetic.", "rtl/neuraedge_alpha_xnor.sv": "The input stream supplies packed query and key spike masks. The block counts matching one bits and matching zero bits, weights zero matches by programmable alpha, accumulates across chunks, and emits one fixed-point attention score under valid/ready backpressure.", "rtl/neuraedge_buffered_tensor_core.sv": "This is the tile-level controller around memories and the physical array. Commands are predecoded, validated, and then routed through activation load, weight load, sparse-index formation, issue FIFO, accumulation, and ordered result output states. A two-entry skid FIFO reserves one beat for registered READY latency, decouples the tile's 128-entry result store from parent backpressure, and delays command completion until the buffered final result is actually transferred.", "rtl/neuraedge_descriptor_sequencer.sv": "A DMA record header declares one command's payload and result lengths. The sequencer captures both halves of the 128-bit command, forwards exactly the declared payload, counts accepted results, regenerates final TLAST, and drains malformed packets so the next descriptor starts aligned.", "rtl/neuraedge_integer_layernorm.sv": "The block first stores a vector while accumulating its sum and squared sum. It derives integer mean and variance, invokes the iterative square-root and divider, applies per-element gamma and beta, saturates the result, and preserves output data whenever downstream ready is low.", "rtl/neuraedge_isqrt64.sv": "One iteration examines the next two radicand bits, shifts the partial remainder, conditionally subtracts the trial divisor, and appends one root bit. After 32 iterations the 32-bit result is exactly floor(sqrt(radicand)); a widened subtraction bit makes borrow detection explicit.", "rtl/neuraedge_lif_bank.sv": "Each of 32 lanes reads persistent membrane state, applies the leak shift, adds signed input current, compares against threshold, emits a spike, and writes either reset or integrated membrane back. Segmented counters avoid a long telemetry carry chain on the 200 MHz datapath.", "rtl/neuraedge_linear_backward8.sv": "A command declares up to eight rows, input features, and output features. Streamed activations, signed weights, and output gradients are buffered in four-lane halves; sixteen signed DSP products are accumulated per cycle. The controller first reduces dY times transposed W into dX, then transposed X times dY into dW, retaining 47-bit partial sums across tiled commands when requested. Separate magnitude, rounding-bias, shift, sign, and saturation states preserve the reference round-once result while breaking the long FPGA timing path.", "rtl/neuraedge_log_softmax.sv": "The engine buffers logits, finds their maximum, converts bounded negative differences to power-of-two terms, sums the denominator, divides each term into a fixed probability scale, and streams normalized outputs without a floating-point exponential unit.", "rtl/neuraedge_mac2_u8.sv": "Two unsigned byte weights are separated by a guard bit and multiplied by one activation in a DSP48E1. Registered correction handles the DSP's signed interpretation, then slices recover two independent exact 16-bit products without cross-field carry.", "rtl/neuraedge_pynq_axi_top.sv": "This is the software-visible shell. AXI-Lite writes configure command and descriptor registers, AXI-Stream carries DMA data, registered credit boundaries break READY timing paths, and status/interrupt registers expose completion, errors, and telemetry.", "rtl/neuraedge_sgd_optimizer8.sv": "For eight lanes, the engine reads weight, gradient, and momentum velocity, computes the fixed-point momentum update, rounds the learning-rate product symmetrically, saturates the new signed weight, stores new velocity/weight state, and streams the result.", "rtl/neuraedge_tensor_tile.sv": "The 8-by-16 tile schedules 64 packed DSP blocks as 128 dense byte MAC lanes, or bypasses multipliers for binary/ternary conditional additions. Per-row active masks, registered sparse popcount, issue/result FIFOs, and deterministic row/column output order make backpressure safe.", "rtl/neuraedge_udivider.sv": "A restoring divider shifts one dividend bit into the remainder each cycle, compares/subtracts the divisor, and writes one quotient bit. Divide-by-zero is reported explicitly instead of producing an accidental numeric value.", "rtl/neuraedge_universal_core.sv": "This command arbiter gives exactly one engine ownership of the shared streams. It stages LUT loads, LIF input, and other multibeat commands, then captures each engine into a source-local result bank before a registered shared output stage. Completion waits for the final AXI transfer, so stalls cannot acknowledge a command early; local accept signals prevent an inactive engine's counters from entering another engine's timing cone.", "rtl/neuraedge_vector_alu.sv": "Eight signed lanes execute residual add, ReLU, requantization, spike conversion, surrogate-gradient gating, maximum, Q15 multiply, or clamp. Wide intermediate products are registered before rounding and saturation so fixed-point behavior is deterministic.", "rtl/neuraedge_weight_bank.sv": "Each bank stores sixteen weight bytes for every reduction position. Eight banks feed outer mode rows or adjacent reduction groups, allowing the same memory organization to support matrix tiles and narrow dot-product schedules.", "software/neuraedge_compiler.py": "Validated NumPy tensors are tiled into hardware-sized activation and weight loads followed by compute records. The compiler chooses outer or dot8 reuse from traffic, lowers grouped convolution through im2col, packs little-endian stream beats, and rejects dimensions the RTL cannot represent.", "software/neuraedge_protocol.py": "This file is the bit-level contract shared with RTL. It packs each 128-bit command field, declares exact payload/result lengths, wraps records in descriptor headers, and decodes signed results so a software integer has the same bit meaning as FPGA wires.", "software/neuraedge_pynq.py": "The board driver loads the BIT/HWH overlay, allocates physically contiguous DMA buffers, writes AXI-Lite registers, arms receive before send, waits with timeouts, checks hardware errors, and returns telemetry beside result words.", "software/neuraedge_training.py": "The training compiler converts saved forward activations and class loss derivatives into descriptor programs. It emits surrogate-gradient gates for spike nonlinearities, exact tiled linear-backward commands for dX and dW, and Q16 optimizer commands for persistent weight and momentum state. Every payload

length, gradient shape, numeric shift, and returned update is checked against the same protocol helpers used by RTL tests.", "software/spikingformer_accelerator.py": "The exported model graph calls compiler primitives in checkpoint order: tokenizer convolutions and LIF, four Q/K/V attention and MLP blocks, residuals, reduction, and classifier. Tensor shapes and quantization records, rather than a hard-coded class result, determine every hardware program.", "software/export_spikingformer_hardware.py": "Checkpoint weights and BatchNorm statistics are folded into affine projections, calibrated, quantized, aligned to 64-byte sections, and hashed. The JSON manifest records offsets, shapes, dtypes, scales, and section digests consumed by both emulator and board runtime.", "software/generate_debug_report.py": "This evidence builder reads immutable result artifacts instead of rerunning or inventing measurements. It parses VCD transitions and Vivado text tables, plots all standard-test predictions and hardware reports, embeds the native block design, and records every plot's source artifact.", "software/spikingformer_reference.py": "The source checkpoint is reconstructed with its original timestep and spike behavior. A separate hardware-emulation path applies exported integer coefficients, allowing full-test accuracy and per-logit disagreement to be measured before board execution.", "software/spikingformer_training_runtime.py": "Each epoch loads deterministic CIFAR-10 shards, executes the quantized forward graph, forms the supervised loss gradient, and dispatches hardware backward and optimizer descriptor programs. Updated parameter and velocity arrays are checkpointed atomically with epoch, sample cursor, RNG state, hashes, and metrics, so pause or power loss resumes from a committed minibatch boundary instead of replaying an ambiguous update.", "software/train_spikingformer_pynq.py": "The command-line entry point validates the overlay, parameter archive, dataset shards, and ABI before constructing the runtime. It translates pause-file and resume options into explicit checkpoint behavior, reports board telemetry and validation accuracy, and exits nonzero when required physical artifacts or numerical checks fail.", }‘ to ‘FILE_DATAFLOWS ‘ in host memory. Here FILE_DATAFLOWS means the value named 'file dataflows' in this block. The important operands are rtl: the value named 'rtl' in this block; neuraedge_activation_buffer: an input feature value consumed by a neuron or multiply-accumulate operation; sv: the value named 'sv' in this block. Context: the file whose role is to generates this source-reference volume and its source-integrity manifest.

Its exact fragment is ‘"COUNT": "updates a segmented telemetry counter without a long carry chain",‘. The important operands are COUNT: the value named ’count’ in this block; updates: the value named ’updates’ in this block; a: the value named ’a’ in this block. Read together, the complete operation is: This assigns ‘{ "IDLE": "waits for a new operation and does not consume payload data", "HEADER": "accepts and validates the descriptor record header", "COMMAND_LOW": "captures command bits 63 through 0", "COMMAND_HIGH": "captures command bits 127 through 64 and checks input TLAST", "SUBMIT": "holds command-valid until the universal core accepts the instruction", "PAYLOAD": "forwards exactly the declared number of input beats to the selected engine", "WAIT": "waits for both command completion and the declared output count", "ERROR_DRAIN": "discards remaining DMA input until TLAST so the next transfer starts aligned", "LOAD": "stores incoming operands into local FPGA memory", "COMPUTE": "issues arithmetic work using values already held on chip", "OUTPUT": "presents computed results under valid/ready backpressure", "COUNT": "updates a segmented telemetry counter without a long carry chain", "DONE": "raises completion for one cycle and returns control to idle", }‘ to ‘STATE_MEANINGS ‘ in host memory. Here STATE_MEANINGS means the finite-state-machine phase retained in flip-flops. The important operands are IDLE: the value named ’idle’ in this block; waits: the value named ’waits’ in this block; for: the value named ’for’ in this block. Context: the file whose role is to generates this source-reference volume and its source-integrity manifest.

Line 169: `"DONE": "raises completion for one cycle and returns control to idle",` This is continuation line 14 of the 15-line logical statement that begins at source line 156. Its exact fragment is ‘"DONE": "raises completion for one cycle and returns control to idle",‘. The important operands are DONE: the value named ’done’ in this block; raises: the value named ’raises’ in this block; completion: the value named ’completion’ in this block. Read together, the complete operation is: This assigns ‘{ "IDLE": "waits for a new operation and does not consume payload data", "HEADER": "accepts and validates the descriptor record header", "COMMAND_LOW": "captures command bits 63 through 0", "COMMAND_HIGH": "captures command bits 127 through 64 and checks input TLAST", "SUBMIT": "holds command-valid until the universal core accepts the instruction", "PAYLOAD": "forwards exactly the declared number of input beats to the selected engine", "WAIT": "waits for both command completion and the declared output count", "ERROR_DRAIN": "discards remaining DMA input until TLAST so the next transfer starts aligned", "LOAD": "stores incoming operands into local FPGA memory", "COMPUTE": "issues arithmetic work using values already held on chip", "OUTPUT": "presents computed results under valid/ready backpressure", "COUNT": "updates a segmented telemetry counter without a long carry chain", "DONE": "raises completion for one cycle and returns control to idle", }‘ to ‘STATE_MEANINGS ‘ in host memory. Here STATE_MEANINGS means the finite-state-machine phase retained in flip-flops. The important operands are IDLE: the value named ’idle’ in this block; waits: the value named ’waits’ in this block; for: the value named ’for’ in this block. Context: the file whose role is to generates this source-reference volume and its source-integrity manifest.

Line 170: `}` This is continuation line 15 of the 15-line logical statement that begins at source line 156. Its exact fragment is ‘}‘. The expression is a literal or structural operator and has no hidden software state. Read together, the complete operation is: This assigns ‘{ "IDLE": "waits for a new operation and does not consume payload data", "HEADER": "accepts and validates the descriptor record header", "COMMAND_LOW": "captures command bits 63 through 0", "COMMAND_HIGH": "captures command bits 127 through 64 and checks input TLAST", "SUBMIT": "holds command-valid until the universal core accepts the instruction", "PAYLOAD": "forwards exactly the declared number of input beats to the selected engine", "WAIT": "waits for both command completion and the declared output count", "ERROR_DRAIN": "discards remaining DMA input until TLAST so the next transfer starts aligned", "LOAD": "stores incoming operands into local FPGA memory", "COMPUTE": "issues arithmetic work using values already held on chip", "OUTPUT": "presents computed results under valid/ready backpressure", "COUNT": "updates a segmented telemetry counter without a long carry chain", "DONE": "raises completion for one cycle and returns control to idle", }‘ to ‘STATE_MEANINGS ‘ in host memory. Here STATE_MEANINGS means the finite-state-machine phase retained in flip-flops. The important operands are IDLE: the value named ’idle’ in this block; waits: the value named ’waits’ in this

block; for: the value named 'for' in this block. Context: the file whose role is to generates this source-reference volume and its source-integrity manifest.

Line 173: `@dataclass(frozen=True)` This decorator changes how the following class or function is constructed. '@dataclass(frozen=True)' is applied at import time on the host and is part of the file whose role is to generates this source-reference volume and its source-integrity manifest; it creates no FPGA circuit by itself.

Line 174: `class SourceEntry:` This defines class SourceEntry, which groups data and methods for source entry. Instances exist in host memory and organize the flow that generates this source-reference volume and its source-integrity manifest.

Line 175: `path: Path` Inside the class SourceEntry, which handles source entry, this statement advances the host implementation that generates this source-reference volume and its source-integrity manifest. The important operands are path: the value named 'path' in this block; Path: the value named 'path' in this block.

Line 176: `relative: str` Inside the class SourceEntry, which handles source entry, this statement advances the host implementation that generates this source-reference volume and its source-integrity manifest. The important operands are relative: the value named 'relative' in this block; str: the value named 'str' in this block.

Line 177: `purpose: str` Inside the class SourceEntry, which handles source entry, this statement advances the host implementation that generates this source-reference volume and its source-integrity manifest. The important operands are purpose: the value named 'purpose' in this block; str: the value named 'str' in this block.

Line 180: `@dataclass(frozen=True)` This decorator changes how the following class or function is constructed. '@dataclass(frozen=True)' is applied at import time on the host and is part of the file whose role is to generates this source-reference volume and its source-integrity manifest; it creates no FPGA circuit by itself.

Line 181: `class StatementSpan:` This defines class StatementSpan, which groups data and methods for statement span. Instances exist in host memory and organize the flow that generates this source-reference volume and its source-integrity manifest.

Line 182: `start: int` Inside the class StatementSpan, which handles statement span, this statement advances the host implementation that generates this source-reference volume and its source-integrity manifest. The important operands are start: the value named 'start' in this block.

Line 183: `end: int` Inside the class StatementSpan, which handles statement span, this statement advances the host implementation that generates this source-reference volume and its source-integrity manifest. The expression is a literal or structural operator and has no hidden software state.

Line 184: `text: str` Inside the class StatementSpan, which handles statement span, this statement advances the host implementation that generates this source-reference volume and its source-integrity manifest. The important operands are text: the value named 'text' in this block; str: the value named 'str' in this block.

Line 187: `def project_root() -> Path:` This starts function project_root. Its indented body performs project root as part of the file that generates this source-reference volume and its source-integrity manifest; it runs only when called.

Line 188: `return Path(__file__).resolve().parents[1]` This returns 'Path(___file___).resolve().parents[1]' to the caller of the function project_root, which handles project root, ending this invocation. The important operands are Path: the value named 'path' in this block; ___file___: the value named 'file' in this block; resolve: the value named 'resolve' in this block.

Line 191: `def source_entries(root: Path) -> list[SourceEntry]:` This starts function source_entries. Its indented body performs source entries as part of the file that generates this source-reference volume and its source-integrity manifest; it runs only when called.

Line 192: `patterns = (` This statement continues through source line 199; the explanation uses the complete expression rather than only the first visual fragment. This assigns ‘(("rtl", "*.sv"), ("software", "*.py"), ("tb", "*.sv"), ("tests", "*.py"), ("scripts", "*.ps1"), ("scripts", "*.tcl"),)‘ to ‘patterns ‘ in host memory. Here patterns means the value named ’patterns’ in this block. The important operands are rtl: the value named ’rtl’ in this block; sv: the value named ’sv’ in this block; software: the value named ’software’ in this block. Context: the function source_entries, which handles source entries.

Line 193: `("rtl", "*.sv"),` This is continuation line 2 of the 8-line logical statement that begins at source line 192. Its exact fragment is ‘("rtl", "*.sv"),‘. The important operands are rtl: the value named ’rtl’ in this block; sv: the value named ’sv’ in this block. Read together, the complete operation is: This assigns ‘(("rtl", "*.sv"), ("software", "*.py"), ("tb", "*.sv"), ("tests", "*.py"), ("scripts", "*.ps1"), ("scripts", "*.tcl"),)‘ to ‘patterns ‘ in host memory. Here patterns means the value named ’patterns’ in this block. The important operands are rtl: the value named ’rtl’ in this block; sv: the value named ’sv’ in this block; software: the value named ’software’ in this block. Context: the function source_entries, which handles source entries.

Line 194: `("software", "*.py"),` This is continuation line 3 of the 8-line logical statement that begins at source line 192. Its exact fragment is ‘("software", "*.py"),‘. The important operands are software: the value named ’software’ in this block; py: the value named ’py’ in this block. Read together, the complete operation is: This assigns ‘(("rtl", "*.sv"), ("software", "*.py"), ("tb", "*.sv"), ("tests", "*.py"), ("scripts", "*.ps1"), ("scripts", "*.tcl"),)‘ to ‘patterns ‘ in host memory. Here patterns means the value named ’patterns’ in this block. The important operands are rtl: the value named ’rtl’ in this block; sv: the value named ’sv’ in this block; software: the value named ’software’ in this block. Context: the function source_entries, which handles source entries.

Line 195: `("tb", "*.sv"),` This is continuation line 4 of the 8-line logical statement that begins at source line 192. Its exact fragment is ‘("tb", "*.sv"),‘. The important operands are tb: the value named ’tb’ in this block; sv: the value named ’sv’ in this block. Read together, the complete operation is: This assigns ‘(("rtl", "*.sv"), ("software", "*.py"), ("tb", "*.sv"), ("tests", "*.py"), ("scripts", "*.ps1"), ("scripts", "*.tcl"),)‘ to ‘patterns ‘ in host memory. Here patterns means the value named ’patterns’ in this block. The important operands are rtl: the value named ’rtl’ in this block; sv: the value named ’sv’ in this block; software: the value named ’software’ in this block. Context: the function source_entries, which handles source entries.

Line 196: `("tests", "*.py"),` This is continuation line 5 of the 8-line logical statement that begins at source line 192. Its exact fragment is ‘("tests", "*.py"),‘. The important operands are tests: the value named ’tests’ in this block; py: the value named ’py’ in this block. Read together, the complete operation is: This assigns ‘(("rtl", "*.sv"), ("software", "*.py"), ("tb", "*.sv"), ("tests", "*.py"), ("scripts", "*.ps1"), ("scripts", "*.tcl"),)‘ to ‘patterns ‘ in host memory. Here patterns means the value named ’patterns’ in this block. The important operands are rtl: the value named ’rtl’ in this block; sv: the value named ’sv’ in this block; software: the value named ’software’ in this block. Context: the function source_entries, which handles source entries.

Line 197: `("scripts", "*.ps1"),` This is continuation line 6 of the 8-line logical statement that begins at source line 192. Its exact fragment is ‘("scripts", "*.ps1"),‘. The important operands are scripts: the value named ’scripts’ in this block; ps1: the value named ’ps1’ in this block. Read together, the complete operation is: This assigns ‘(("rtl", "*.sv"), ("software", "*.py"), ("tb", "*.sv"), ("tests", "*.py"), ("scripts", "*.ps1"), ("scripts", "*.tcl"),)‘ to ‘patterns ‘ in host memory. Here patterns means the value named ’patterns’ in this block. The important operands are rtl: the value named ’rtl’ in this block; sv: the value named ’sv’ in this block; software: the value named ’software’ in this block. Context: the function source_entries, which handles source entries.

Line 198: `("scripts", "*.tcl"),` This is continuation line 7 of the 8-line logical statement that begins at source line 192. Its exact fragment is ‘("scripts", "*.tcl"),‘. The important operands are scripts: the value named ’scripts’ in this block; tcl: the value named ’tcl’ in this block. Read together, the complete operation is: This assigns ‘(("rtl", "*.sv"), ("software", "*.py"), ("tb", "*.sv"), ("tests", "*.py"), ("scripts", "*.ps1"), ("scripts", "*.tcl"),)‘ to ‘patterns ‘ in host memory. Here patterns means the value named ’patterns’ in this block. The important operands are rtl: the value named ’rtl’ in this block; sv: the value named ’sv’ in this block; software: the value named ’software’ in this block. Context: the function source_entries, which handles source entries.

Line 199: `)` This is continuation line 8 of the 8-line logical statement that begins at source line 192. Its exact fragment is ‘)‘. The expression is a literal or structural operator and has no hidden software state. Read together, the complete operation is: This assigns ‘(("rtl", "*.sv"), ("software", "*.py"), ("tb", "*.sv"), ("tests", "*.py"), ("scripts", "*.ps1"), ("scripts", "*.tcl"),)‘ to ‘patterns ‘ in host memory. Here patterns means the value named ’patterns’ in this block. The important operands are rtl: the value named ’rtl’ in this block; sv: the value named ’sv’ in this block; software: the value named ’software’ in this block. Context: the function source_entries, which handles source entries.

Line 200: `entries: list[SourceEntry] = []` This assigns ‘[]‘ to ‘entries‘ in host memory. Here entries means the value named ’entries’ in this block. The expression is a literal or structural operator and has no hidden software state. Context: the function source_entries, which handles source entries.

Line 201: `for directory, pattern in patterns:` This iterates directory, pattern over ‘patterns‘. Each iteration repeats the indented host operation, commonly once per layer, tile, timestep, or test case in the function source_entries, which handles source entries.

Line 202: `for path in sorted((root / directory).glob(pattern)):` This iterates path over ‘sorted((root / directory).glob(pattern))‘. Each iteration repeats the indented host operation, commonly once per layer, tile, timestep, or test case in the function source_entries, which handles source entries.

Line 203: `relative = path.relative_to(root).as_posix()` This assigns ‘path.relative_to(root).as_posix()‘ to ‘relative ‘ in host memory. Here relative means the value named ’relative’ in this block. The important operands are path: the value named ’path’ in this block; relative_to: the value named ’relative to’ in this block; root: the value named ’root’ in this block. Context: the function source_entries, which handles source entries.

Line 204: `purpose = FILE_PURPOSES.get(relative, inferred_file_purpose(relative))` This assigns ‘FILE_PURPOSES.
inferred_file_purpose(relative))‘ to ‘purpose ‘ in host memory. Here purpose means the value named ’purpose’ in this block. The important operands are FILE_PURPOSES: the value named ’file purposes’ in this block; get: the value named ’get’ in this block; relative: the value named ’relative’ in this block. Context: the function source_entries, which handles source entries.

Line 205: `entries.append(SourceEntry(path, relative, purpose))` This calls ‘entries.append‘ with ‘SourceEntry(path, relative, purpose)‘ inside the function source_entries, which handles source entries. The call advances the host-side job that generates this source-reference volume and its source-integrity manifest.

Line 206: `return entries` This returns ‘entries‘ to the caller of the function source_entries, which handles source entries, ending this invocation. The important operands are entries: the value named ’entries’ in this block.

Line 209: `def inferred_file_purpose(relative: str) -> str:` This starts function inferred_file_purpose. Its indented body performs inferred file purpose as part of the file that generates this source-reference volume and its source-integrity manifest; it runs only when called.

Line 210: `stem = Path(relative).stem` This assigns ‘Path(relative).stem‘ to ‘stem ‘ in host memory. Here stem means the value named ’stem’ in this block. The important operands are Path: the value named ’path’ in this block; relative: the value named ’relative’ in this block; stem: the value named ’stem’ in this block. Context: the function inferred_file_purpose, which handles inferred file purpose.

Line 211: `words = humanize(stem.removeprefix("tb_").removeprefix("test_"))` This assigns ‘humanize(stem.removeprefi
to ‘words ‘ in host memory. Here words means the value named ’words’ in this block. The important operands are humanize: the value named ’humanize’ in this block; stem: the value named ’stem’ in this block; removeprefix: the value named ’removeprefix’ in this block. Context: the function inferred_file_purpose, which handles inferred file purpose.

Line 212: `if relative.startswith("tb/"):` This executes the following indented host-code branch only when ‘relative.startswith("tb/")‘ is true. The important operands are relative: the value named ’relative’ in this block; startswith: the value named ’startswith’ in this block; tb: the value named ’tb’ in this block. Context: the function inferred_file_purpose, which handles inferred file purpose.

Line 213: `return f"drives, backpressures, and checks the {words} RTL block in simulation"` This returns ‘f"drives, backpressures, and checks the {words} RTL block in simulation"‘ to the caller of the function inferred_file_purpose, which handles inferred file purpose, ending this invocation. The important operands are f: the value named ’f’ in this block; drives: the value named ’drives’ in this block; backpressures: the value named ’backpressures’ in this block.

Line 214: `if relative.startswith("tests/"):` This executes the following indented host-code branch only when ‘relative.startswith("tests/")‘ is true. The important operands are relative: the value named ’relative’ in this block; startswith: the value named ’startswith’ in this block; tests: the value named ’tests’ in this block. Context: the function inferred_file_purpose, which handles inferred file purpose.

Line 215: `return f"checks {words} behavior independently with Python assertions"` This returns ‘f"checks {words} behavior independently with Python assertions"‘ to the caller of the function inferred_file_purpose, which handles inferred file purpose, ending this invocation. The important operands are f: the value named ’f’ in this block; checks: the value named ’checks’ in this block; words: the value named ’words’ in this block.

Line 216: `if relative.endswith(".tcl"):` This executes the following indented host-code branch only when ‘relative.endswith(".tcl")‘ is true. The important operands are relative: the value named ’relative’ in this block; endswith: the value named ’endswith’ in this block; tcl: the value named ’tcl’ in this block. Context: the function inferred_file_purpose, which handles inferred file purpose.

Line 217: `return f"runs the reproducible Vivado {words} hardware flow"` This returns ‘f"runs the reproducible Vivado {words} hardware flow"‘ to the caller of the function inferred_file_purpose, which handles inferred file purpose, ending this invocation. The important operands are f: the value named ’f’ in this block; runs: the value named ’runs’ in this block; the: the value named ’the’ in this block.

Line 218: `if relative.endswith(".ps1"):` This executes the following indented host-code branch only when ‘relative.endswith(".ps1")‘ is true. The important operands are relative: the value named ’relative’ in this block; endswith: the value named ’endswith’ in this block; ps1: the value named ’ps1’ in this block. Context: the function inferred_file_purpose, which handles inferred file purpose.

Line 219: `return f"orchestrates the repeatable Windows {words} command-line flow"` This returns ‘f"orchestrates the repeatable Windows {words} command-line flow"‘ to the caller of the function inferred_file_purpose, which handles inferred file purpose, ending this invocation. The important operands are f: the value named ’f’ in this block; orchestrates: the value named ’orchestrates’ in this block; the: the value named ’the’ in this block.

Line 220: `return f"implements the {words} part of the project"` This returns ‘f"implements the {words} part of the project"‘ to the caller of the function inferred_file_purpose, which handles inferred file purpose, ending this invocation. The important operands are f: the value named ’f’ in this block; implements: the value named ’implements’ in this block; the: the value named ’the’ in this block.

Line 223: `def humanize(identifier: str) -> str:` This starts function humanize. Its indented body performs humanize as part of the file that generates this source-reference volume and its source-integrity manifest; it runs only when called.

Line 224: `text = re.sub(r"([a-z0-9])([A-Z])", r"\1 \2", identifier)` This assigns ‘re.sub(r"([a-z0-9])([A-Z])", r"\1 \2", identifier)‘ to ‘text ‘ in host memory. Here text means the value named ’text’ in this block. The important operands are re: the value named ’re’ in this block; sub: the value named ’sub’ in this block; r: the value named ’r’ in this block. Context: the function humanize, which handles humanize.

Line 225: `return text.replace("_", " ").replace("-", " ").strip().lower()` This returns ‘text.replace("_", " ").replace("-", " ").strip().lower()‘ to the caller of the function humanize, which handles humanize, ending this invocation. The important operands are text: the value named ’text’ in this block; replace: the value named ’replace’ in this block; _: the value named ” in this block.

Line 228: `def identifier_meaning(identifier: str) -> str:` This starts function identifier_meaning. Its indented body performs identifier meaning as part of the file that generates this source-reference volume and its source-integrity manifest; it runs only when called.

Line 229: `lowered = identifier.lower().removesuffix("_r").removesuffix("_i").removesuffix("_o")` This assigns ‘identifier.lower().removesuffix("_r").removesuffix("_i").removesuffix("_o")‘ to ‘lowered ‘ in host memory. Here lowered means the value named ’lowered’ in this block. The important operands are identifier: the value named ’identifier’ in this block; lower: the value named ’lower’ in this block; removesuffix: the value named ’removesuffix’ in this block. Context: the function identifier_meaning, which handles identifier meaning.

Line 230: `if lowered in IDENTIFIER_MEANINGS:` This executes the following indented host-code branch only when ‘lowered in IDENTIFIER_MEANINGS‘ is true. The important operands are lowered: the value named ’lowered’ in this block; in: the value named ’in’ in this block; IDENTIFIER_MEANINGS: the arithmetic average used by normalization. Context: the function identifier_meaning, which handles identifier meaning.

Line 231: `return IDENTIFIER_MEANINGS[lowered]` This returns ‘IDENTIFIER_MEANINGS[lowered]‘ to the caller of the function identifier_meaning, which handles identifier meaning, ending this invocation. The important operands are IDENTIFIER_MEANINGS: the arithmetic average used by normalization; lowered: the value named ’lowered’ in this block.

Line 232: `matches = [meaning for key, meaning in IDENTIFIER_MEANINGS.items() if key in lowered]` This assigns ‘[meaning for key, meaning in IDENTIFIER_MEANINGS.items() if key in lowered]‘ to ‘matches ‘ in host memory. Here matches means the value named ’matches’ in this block. The important operands are meaning: the arithmetic average used by normalization; for: the value named ’for’ in this block; key: the value named ’key’ in this block. Context: the function identifier_meaning, which handles identifier meaning.

Line 233: `if matches:` This executes the following indented host-code branch only when ‘matches‘ is true. The important operands are matches: the value named ’matches’ in this block. Context: the function identifier_meaning, which handles identifier meaning.

Line 234: `return matches[0]` This returns ‘matches[0]‘ to the caller of the function identifier_meaning, which handles identifier meaning, ending this invocation. The important operands are matches: the value named ’matches’ in this block.

Line 235: `if lowered.endswith("_mem") or "memory" in lowered:` This executes the following indented host-code branch only when ‘lowered.endswith("_mem") or "memory" in lowered‘ is true. The important operands are lowered: the value named ’lowered’ in this block; endswith: the value named ’endswith’ in this block; _mem: local FPGA storage addressed by surrounding index logic. Context: the function identifier_meaning, which handles identifier meaning.

Line 236: `return "local FPGA storage addressed by surrounding index logic"` This returns ‘"local FPGA storage addressed by surrounding index logic"‘ to the caller of the function identifier_meaning, which handles identifier meaning, ending this invocation. The important operands are local: the value named ’local’ in this block; FPGA: the value named ’fpga’ in this block; storage: the value named ’storage’ in this block.

Line 237: `if lowered.endswith("_count") or lowered.endswith("_counter"):` This executes the following indented host-code branch only when ‘lowered.endswith("_count") or lowered.endswith("_counter")‘ is true. The important operands are lowered: the value named ’lowered’ in this block; endswith: the value named ’endswith’ in this block; _count: an integer count retained for control or measurable telemetry. Context: the function identifier_meaning, which handles identifier meaning.

Line 238: `return "an integer count retained for control or measurable telemetry"` This returns ‘"an integer count retained for control or measurable telemetry"‘ to the caller of the function identifier_meaning, which handles identifier meaning, ending this invocation. The important operands are an: the value named ’an’ in this block; integer: the value named ’integer’ in this block; count: the value named ’count’ in this block.

Line 239: `if lowered.endswith("_valid"):` This executes the following indented host-code branch only when ‘lowered.endswith("_valid")‘ is true. The important operands are lowered: the value named ’lowered’ in this block; endswith: the value named ’endswith’ in this block; _valid: the producer’s statement that its current payload is meaningful. Context: the function identifier_meaning, which handles identifier meaning.

Line 240: `return "a handshake flag saying the associated payload is meaningful"` This returns ‘"a handshake flag saying the associated payload is meaningful"‘ to the caller of the function identifier_meaning, which handles identifier meaning, ending this invocation. The important operands are a: the value named ’a’ in this block; handshake: the value named ’handshake’ in this block; flag: the value named ’flag’ in this block.

Line 241: `if lowered.endswith("_ready"):` This executes the following indented host-code branch only when ‘lowered.endswith("_ready")‘ is true. The important operands are lowered: the value named ’lowered’ in this block; endswith: the value named ’endswith’ in this block; _ready: the consumer’s statement that it can accept a payload this cycle. Context: the function identifier_meaning, which handles identifier meaning.

Line 242: `return "a handshake flag saying the associated consumer can accept data"` This returns ‘"a handshake flag saying the associated consumer can accept data"‘ to the caller of the function identifier_meaning, which handles identifier meaning, ending this invocation. The important operands are a: the value named ’a’ in this block; handshake: the value named ’handshake’ in this block; flag: the value named ’flag’ in this block.

Line 243: `if lowered.endswith("_data"):` This executes the following indented host-code branch only when ‘lowered.endswith("_data")‘ is true. The important operands are lowered: the value named ’lowered’ in this block; endswith: the value named ’endswith’ in this block; _data: the payload carried with the surrounding valid/ready handshake. Context: the function identifier_meaning, which handles identifier meaning.

Line 244: `return "the payload carried with the surrounding valid/ready handshake"` This returns ‘"the payload carried with the surrounding valid/ready handshake"‘ to the caller of the function identifier_meaning, which handles identifier meaning, ending this invocation. The important operands are the: the value named ’the’ in this block; payload: stream data belonging to the current command; carried: the value named ’carried’ in this block.

Line 245: `if lowered.endswith("_enable") or lowered.endswith("_en"):` This executes the following indented host-code branch only when ‘lowered.endswith("_enable") or lowered.endswith("_en")‘ is true. The important operands are lowered: the value named ’lowered’ in this block; endswith: the value named ’endswith’ in this block; _enable: a control bit that permits the associated state or storage update. Context: the function identifier_meaning, which handles identifier meaning.

Line 246: `return "a control bit that permits the associated state or storage update"` This returns ‘"a control bit that permits the associated state or storage update"‘ to the caller of the function identifier_meaning, which handles identifier meaning, ending this invocation. The important operands are a: the value named ’a’ in this block; control: the value named ’control’ in this block; bit: the value named ’bit’ in this block.

Line 247: `return f"the value named '{humanize(identifier)}' in this block"` This returns ‘f"the value named ’{humanize(identifier)}’ in this block"‘ to the caller of the function identifier_meaning, which handles identifier meaning, ending this invocation. The important operands are f: the value named ’f’ in this block; the: the value named ’the’ in this block; value: the value named ’value’ in this block.

Line 250: `def summarize_expression(expression: str) -> str:` This starts function summarize_expression. Its indented body performs summarize expression as part of the file that generates this source-reference volume and its source-integrity manifest; it runs only when called.

Line 251: `identifiers = re.findall(r"\b[A-Za-z_][A-Za-z0-9_$]*\b", expression)` This assigns ‘re.findall(r"\b[A-Za-z_][A-Za-z0-9_$]*\b", expression)‘ to ‘identifiers ‘ in host memory. Here identifiers means the value named ’identifiers’ in this block. The important operands are re: the value named ’re’ in this block; findall: the value named ’findall’ in this block; r: the value named ’r’ in this block. Context: the function summarize_expression, which handles summarize expression.

Line 252: `ignored = {` This statement continues through source line 255; the explanation uses the complete expression rather than only the first visual fragment. This assigns ‘{ "if", "else", "begin", "end", "logic", "wire", "signed", "unsigned", "true", "false", "int", "return", "self", "np", "Path", }‘ to ‘ignored ‘ in host memory. Here ignored means the value named ’ignored’ in this block. The important operands are Path: the value named ’path’ in this block. Context: the function summarize_expression, which handles summarize expression.

Line 253: `"if", "else", "begin", "end", "logic", "wire", "signed", "unsigned",` This is continuation line 2 of the 4-line logical statement that begins at source line 252. Its exact fragment is ‘"if", "else", "begin", "end", "logic", "wire", "signed", "unsigned",‘. The expression is a literal or structural operator and has no hidden software state. Read together, the complete operation is: This assigns ‘{ "if", "else", "begin", "end", "logic", "wire", "signed", "unsigned", "true", "false", "int", "return", "self", "np", "Path", }‘ to ‘ignored ‘ in host memory. Here ignored means the value named ’ignored’ in this block. The important operands are Path: the value named ’path’ in this block. Context: the function summarize_expression, which handles summarize expression.

Line 254: `"true", "false", "int", "return", "self", "np", "Path",` This is continuation line 3 of the 4-line logical statement that begins at source line 252. Its exact fragment is ‘"true", "false", "int", "return", "self", "np", "Path",‘. The important operands are Path: the value named ’path’ in this block. Read together, the complete operation is: This assigns ‘{ "if", "else", "begin", "end", "logic", "wire", "signed", "unsigned", "true", "false", "int", "return", "self", "np", "Path", }‘ to ‘ignored ‘ in host memory. Here ignored means the value named ’ignored’ in this block. The important operands are Path: the value named ’path’ in this block. Context: the function summarize_expression, which handles summarize expression.

Line 255: `}` This is continuation line 4 of the 4-line logical statement that begins at source line 252. Its exact fragment is ‘}‘. The expression is a literal or structural operator and has no hidden software state. Read together, the complete operation is: This assigns ‘{ "if", "else", "begin", "end", "logic", "wire", "signed", "unsigned", "true", "false", "int", "return", "self", "np", "Path", }‘ to ‘ignored ‘ in host memory. Here ignored means the value named ’ignored’ in this block. The important operands are Path: the value named ’path’ in this block. Context: the function summarize_expression, which handles summarize expression.

Line 256: `selected: list[str] = []` This assigns ‘[]‘ to ‘selected‘ in host memory. Here selected means the value named ’selected’ in this block. The expression is a literal or structural operator and has no hidden software state. Context: the function summarize_expression, which handles summarize expression.

Line 257: `for identifier in identifiers:` This iterates identifier over ‘identifiers‘. Each iteration repeats the indented host operation, commonly once per layer, tile, timestep, or test case in the function summarize_expression, which handles summarize expression.

Line 258: `if identifier.lower() in ignored or identifier in selected:` This executes the following indented host-code branch only when ‘identifier.lower() in ignored or identifier in selected‘ is true. The important operands are identifier: the value named ’identifier’ in this block; lower: the value named ’lower’ in this block; in: the value named ’in’ in this block. Context: the function summarize_expression, which handles summarize expression.

Line 259: `continue` Inside the function summarize_expression, which handles summarize expression, this statement advances the host implementation that generates this source-reference volume and its source-integrity manifest. The important operands are continue: the value named ’continue’ in this block.

Line 260: `selected.append(identifier)` This calls ‘selected.append‘ with ‘identifier‘ inside the function summarize_expression, which handles summarize expression. The call advances the host-side job that generates this source-reference volume and its source-integrity manifest.

Line 261: `if len(selected) == 3:` This executes the following indented host-code branch only when ‘len(selected) == 3‘ is true. The important operands are len: the value named ’len’ in this block; selected: the value named ’selected’ in this block. Context: the function summarize_expression, which handles summarize expression.

Line 262: `break` Inside the function summarize_expression, which handles summarize expression, this statement advances the host implementation that generates this source-reference volume and its source-integrity manifest. The important operands are break: the value named 'break' in this block.

Line 263: `if not selected:` This executes the following indented host-code branch only when ‘not selected‘ is true. The important operands are not: the value named 'not' in this block; selected: the value named 'selected' in this block. Context: the function summarize_expression, which handles summarize expression.

Line 264: `return "The expression is a literal or structural operator and has no hidden software state."` This returns ‘"The expression is a literal or structural operator and has no hidden software state."‘ to the caller of the function summarize_expression, which handles summarize expression, ending this invocation. The important operands are The: the value named 'the' in this block; expression: the value named 'expression' in this block; is: the value named 'is' in this block.

Line 265: `meanings = "; ".join(f"{name}: {identifier_meaning(name)}" for name in selected)` This assigns ‘"; ".join(f"{name}: {identifier_meaning(name)}" for name in selected)‘ to ‘meanings ‘ in host memory. Here meanings means the arithmetic average used by normalization. The important operands are join: the value named 'join' in this block; f: the value named 'f' in this block; name: the value named 'name' in this block. Context: the function summarize_expression, which handles summarize expression.

Line 266: `return f"The important operands are {meanings}."` This returns ‘f"The important operands are {meanings}."‘ to the caller of the function summarize_expression, which handles summarize expression, ending this invocation. The important operands are f: the value named 'f' in this block; The: the value named 'the' in this block; important: the value named 'important' in this block.

Line 269: `def python_contexts(text: str) -> dict[int, str]:` This starts function python_contexts. Its indented body performs python contexts as part of the file that generates this source-reference volume and its source-integrity manifest; it runs only when called.

Line 270: `contexts: dict[int, tuple[int, str]] = {}` This assigns ‘{}‘ to ‘contexts‘ in host memory. Here contexts means the value named 'contexts' in this block. The expression is a literal or structural operator and has no hidden software state. Context: the function python_contexts, which handles python contexts.

Line 271: `try:` This is explicit host-side failure handling inside the function python_contexts, which handles python contexts; it ensures malformed artifacts, DMA errors, and tool failures are surfaced or cleaned up deterministically.

Line 272: `tree = ast.parse(text)` This assigns ‘ast.parse(text)‘ to ‘tree ‘ in host memory. Here tree means the value named 'tree' in this block. The important operands are ast: the value named 'ast' in this block; parse: the value named 'parse' in this block; text: the value named 'text' in this block. Context: the function python_contexts, which handles python contexts.

Line 273: `except SyntaxError:` This is explicit host-side failure handling inside the function python_contexts, which handles python contexts; it ensures malformed artifacts, DMA errors, and tool failures are surfaced or cleaned up deterministically.

Line 274: `return {}` This returns ‘{}‘ to the caller of the function python_contexts, which handles python contexts, ending this invocation. The expression is a literal or structural operator and has no hidden software state.

Line 275: `for node in ast.walk(tree):` This iterates node over ‘ast.walk(tree)‘. Each iteration repeats the indented host operation, commonly once per layer, tile, timestep, or test case in the function python_contexts, which handles python contexts.

Line 276: `if isinstance(node, (ast.ClassDef, ast.FunctionDef, ast.AsyncFunctionDef)):` This executes the following indented host-code branch only when ‘isinstance(node, (ast.ClassDef, ast.FunctionDef, ast.AsyncFunctionDef))‘ is true. The important operands are isinstance: the value named ’isinstance’ in this block; node: the value named ’node’ in this block; ast: the value named ’ast’ in this block. Context: the function python_contexts, which handles python contexts.

Line 277: `end = getattr(node, "end_lineno", node.lineno)` This assigns ‘getattr(node, "end_lineno", node.lineno)‘ to ‘end ‘ in host memory. Here end means the value named ’end’ in this block. The important operands are getattr: the value named ’getattr’ in this block; node: the value named ’node’ in this block; end_lineno: the value named ’end lineno’ in this block. Context: the function python_contexts, which handles python contexts.

Line 278: `kind = "class" if isinstance(node, ast.ClassDef) else "function"` This assigns ‘"class" if isinstance(node, ast.ClassDef) else "function"‘ to ‘kind ‘ in host memory. Here kind means the value named ’kind’ in this block. The important operands are class: the value named ’class’ in this block; isinstance: the value named ’isinstance’ in this block; node: the value named ’node’ in this block. Context: the function python_contexts, which handles python contexts.

Line 279: `description = f"the {kind} {node.name}, which handles {humanize(node.name)}"` This assigns ‘f"the {kind} {node.name}, which handles {humanize(node.name)}"‘ to ‘description ‘ in host memory. Here description means the value named ’description’ in this block. The important operands are f: the value named ’f’ in this block; the: the value named ’the’ in this block; kind: the value named ’kind’ in this block. Context: the function python_contexts, which handles python contexts.

Line 280: `span = end - node.lineno` This assigns ‘end - node.lineno‘ to ‘span ‘ in host memory. Here span means the value named ’span’ in this block. The important operands are node: the value named ’node’ in this block; lineno: the value named ’lineno’ in this block. Context: the function python_contexts, which handles python contexts.

Line 281: `for line_number in range(node.lineno, end + 1):` This iterates line_number over ‘range(node.lineno, end + 1)‘. Each iteration repeats the indented host operation, commonly once per layer, tile, timestep, or test case in the function python_contexts, which handles python contexts.

Line 282: `previous = contexts.get(line_number)` This assigns ‘contexts.get(line_number)‘ to ‘previous ‘ in host memory. Here previous means the value named ’previous’ in this block. The important operands are contexts: the value named ’contexts’ in this block; get: the value named ’get’ in this block; line_number: the value named ’line number’ in this block. Context: the function python_contexts, which handles python contexts.

Line 283: `if previous is None or span < previous[0]:` This executes the following indented host-code branch only when ‘previous is None or span < previous[0]‘ is true. The important operands are previous: the value named ’previous’ in this block; is: the value named ’is’ in this block; None: the value named ’none’ in this block. Context: the function python_contexts, which handles python contexts.

Line 284: `contexts[line_number] = (span, description)` This assigns ‘(span, description)‘ to ‘contexts[line_number] ‘ in host memory. Here contexts means the value named ’contexts’ in this block. The important operands are span: the value named ’span’ in this block; description: the value named ’description’ in this block. Context: the function python_contexts, which handles python contexts.

Line 285: `return {line: value[1] for line, value in contexts.items()}` This returns ‘{line: value[1] for line, value in contexts.items()}‘ to the caller of the function python_contexts, which handles python contexts, ending this invocation. The important operands are line: the value named ’line’ in this block; value: the value named ’value’ in this block; for: the value named ’for’ in this block.

Line 288: `def _joined_statement(lines: list[str], start: int, end: int) -> str:` This starts function _joined_statement. Its indented body performs joined statement as part of the file that generates this source-reference volume and its source-integrity manifest; it runs only when called.

Line 289: `return " ".join(` This statement continues through source line 292; the explanation uses the complete expression rather than only the first visual fragment. This returns ‘" ".join(fragment for fragment in (line.strip() for line in lines[start - 1:end]) if fragment)‘ to the caller of the function _joined_statement, which handles joined statement, ending this invocation. The important operands are join: the value named ’join’ in this block; fragment: the value named ’fragment’ in this block; for: the value named ’for’ in this block.

Line 290: `fragment for fragment in (line.strip() for line in lines[start - 1:end])` This is continuation line 2 of the 4-line logical statement that begins at source line 289. Its exact fragment is ‘fragment for fragment in (line.strip() for line in lines[start - 1:end])‘. The important operands are fragment: the value named ’fragment’ in this block; for: the value named ’for’ in this block; in: the value named ’in’ in this block. Read together, the complete operation is: This returns ‘" ".join(fragment for fragment in (line.strip() for line in lines[start - 1:end]) if fragment)‘ to the caller of the function _joined_statement, which handles joined statement, ending this invocation. The important operands are join: the value named ’join’ in this block; fragment: the value named ’fragment’ in this block; for: the value named ’for’ in this block.

Line 291: `if fragment` This is continuation line 3 of the 4-line logical statement that begins at source line 289. Its exact fragment is ‘if fragment‘. The important operands are fragment: the value named ’fragment’ in this block. Read together, the complete operation is: This returns ‘" ".join(fragment for fragment in (line.strip() for line in lines[start - 1:end]) if fragment)‘ to the caller of the function _joined_statement, which handles joined statement, ending this invocation. The important operands are join: the value named ’join’ in this block; fragment: the value named ’fragment’ in this block; for: the value named ’for’ in this block.

Line 292: `)` This is continuation line 4 of the 4-line logical statement that begins at source line 289. Its exact fragment is ‘)‘. The expression is a literal or structural operator and has no hidden software state. Read together, the complete operation is: This returns ‘" ".join(fragment for fragment in (line.strip() for line in lines[start - 1:end]) if fragment)‘ to the caller of the function _joined_statement, which handles joined statement, ending this invocation. The important operands are join: the value named ’join’ in this block; fragment: the value named ’fragment’ in this block; for: the value named ’for’ in this block.

Line 295: `def python_statement_spans(text: str) -> dict[int, StatementSpan]:` This starts function python_stateme Its indented body performs python statement spans as part of the file that generates this source-reference volume and its source-integrity manifest; it runs only when called.

Line 296: `"""Map multiline host statements to their complete source expression."""` This is executable documentation attached to the function python_statement_spans, which handles python statement spans. It states the intended contract that tests and callers should enforce, but the text itself does not transform data or issue hardware work.

Line 297: `lines = text.splitlines()` This assigns ‘text.splitlines()‘ to ‘lines ‘ in host memory. Here lines means the value named ’lines’ in this block. The important operands are text: the value named ’text’ in this block; splitlines: the value named ’splitlines’ in this block. Context: the function python_statement_spans, which handles python statement spans.

Line 298: `try:` This is explicit host-side failure handling inside the function python_statement_spans, which handles python statement spans; it ensures malformed artifacts, DMA errors, and tool failures are surfaced or cleaned up deterministically.

Line 299: `tree = ast.parse(text)` This assigns ‘ast.parse(text)‘ to ‘tree ‘ in host memory. Here tree means the value named ’tree’ in this block. The important operands are ast: the value named ’ast’ in this block; parse: the value named ’parse’ in this block; text: the value named ’text’ in this block. Context: the function python_statement_spans, which handles python statement spans.

Line 300: `except SyntaxError:` This is explicit host-side failure handling inside the function python_statement_spans, which handles python statement spans; it ensures malformed artifacts, DMA errors, and tool failures are surfaced or cleaned up deterministically.

Line 301: `return {}` This returns ‘{}‘ to the caller of the function python_statement_spans, which handles python statement spans, ending this invocation. The expression is a literal or structural operator and has no hidden software state.

Line 302: `candidates: list[ast.AST] = []` This assigns ‘[]‘ to ‘candidates‘ in host memory. Here candidates means the value named ’candidates’ in this block. The expression is a literal or structural operator and has no hidden software state. Context: the function python_statement_spans, which handles python statement spans.

Line 303: `simple_nodes = (` This statement continues through source line 306; the explanation uses the complete expression rather than only the first visual fragment. This assigns ‘(ast.Assign, ast.AnnAssign, ast.AugAssign, ast.Return, ast.Raise, ast.Assert, ast.Import, ast.ImportFrom,)‘ to ‘simple_nodes ‘ in host memory. Here simple_nodes means the value named ’simple nodes’ in this block. The important operands are ast: the value named ’ast’ in this block; Assign: the value named ’assign’ in this block; AnnAssign: the value named ’ann assign’ in this block. Context: the function python_statement_spans, which handles python statement spans.

Line 304: `ast.Assign, ast.AnnAssign, ast.AugAssign, ast.Return, ast.Raise,` This is continuation line 2 of the 4-line logical statement that begins at source line 303. Its exact fragment is ‘ast.Assign, ast.AnnAssign, ast.AugAssign, ast.Return, ast.Raise,‘. The important operands are ast: the value named ’ast’ in this block; Assign: the value named ’assign’ in this block; AnnAssign: the value named ’ann assign’ in this block. Read together, the complete operation is: This assigns ‘(ast.Assign, ast.AnnAssign, ast.AugAssign, ast.Return, ast.Raise, ast.Assert, ast.Import, ast.ImportFrom,)‘ to ‘simple_nodes ‘ in host memory. Here simple_nodes means the value named ’simple nodes’ in this block. The important operands are ast: the value named ’ast’ in this block; Assign: the value named ’assign’ in this block; AnnAssign: the value named ’ann assign’ in this block. Context: the function python_statement_spans, which handles python statement spans.

Line 305: `ast.Assert, ast.Import, ast.ImportFrom,` This is continuation line 3 of the 4-line logical statement that begins at source line 303. Its exact fragment is ‘ast.Assert, ast.Import, ast.ImportFrom,‘. The important operands are ast: the value named ’ast’ in this block; Assert: the value named ’assert’ in this block; Import: the value named ’import’ in this block. Read together, the complete operation is: This assigns ‘(ast.Assign, ast.AnnAssign, ast.AugAssign, ast.Return, ast.Raise, ast.Assert, ast.Import, ast.ImportFrom,)‘ to ‘simple_nodes ‘ in host memory. Here simple_nodes means the value named ’simple nodes’ in this block. The important operands are ast: the value named ’ast’ in this block; Assign: the value named ’assign’ in this block; AnnAssign: the value named ’ann assign’ in this block. Context: the function python_statement_spans, which handles python statement spans.

Line 306: `)` This is continuation line 4 of the 4-line logical statement that begins at source line 303. Its exact fragment is ‘)‘. The expression is a literal or structural operator and has no hidden software state. Read together, the complete operation is: This assigns ‘(ast.Assign, ast.AnnAssign, ast.AugAssign, ast.Return, ast.Raise, ast.Assert, ast.Import, ast.ImportFrom,)‘ to ‘simple_nodes ‘ in host memory. Here simple_nodes means the value named ’simple nodes’ in this block. The important operands are ast: the value named ’ast’ in this block; Assign: the value named ’assign’ in this block; AnnAssign: the value named ’ann assign’ in this block. Context: the function python_statement_spans, which handles python statement spans.

Line 307: `for node in ast.walk(tree):` This iterates node over ‘ast.walk(tree)‘. Each iteration repeats the indented host operation, commonly once per layer, tile, timestep, or test case in the function python_statement_spans, which handles python statement spans.

Line 308: `if isinstance(node, simple_nodes):` This executes the following indented host-code branch only when ‘isinstance(node, simple_nodes)‘ is true. The important operands are isinstance: the value named ’isinstance’ in this block; node: the value named ’node’ in this block; simple_nodes: the value named ’simple nodes’ in this block. Context: the function python_statement_spans, which handles python statement spans.

Line 309: `candidates.append(node)` This calls ‘candidates.append‘ with ‘node‘ inside the function python_statement_spans, which handles python statement spans. The call advances the host-side job that generates this source-reference volume and its source-integrity manifest.

Line 310: `elif isinstance(node, ast.Expr) and isinstance(node.value, ast.Call):` This executes the following indented host-code branch only when ‘isinstance(node, ast.Expr) and isinstance(node.value, ast.Call)‘ is true. The important operands are isinstance: the value named ’isinstance’ in this block; node: the value named ’node’ in this block; ast: the value named ’ast’ in this block. Context: the function python_statement_spans, which handles python statement spans.

Line 311: `candidates.append(node)` This calls ‘candidates.append‘ with ‘node‘ inside the function python_statement_spans, which handles python statement spans. The call advances the host-side job that generates this source-reference volume and its source-integrity manifest.

Line 312: `result: dict[int, StatementSpan] = {}` This assigns ‘{}‘ to ‘result‘ in host memory. Here result means the value named ’result’ in this block. The expression is a literal or structural operator and has no hidden software state. Context: the function python_statement_spans, which handles python statement spans.

Line 313: `for node in candidates:` This iterates node over ‘candidates‘. Each iteration repeats the indented host operation, commonly once per layer, tile, timestep, or test case in the function python_statement_spans, which handles python statement spans.

Line 314: `start = int(getattr(node, "lineno", 0))` This assigns ‘int(getattr(node, "lineno", 0))‘ to ‘start ‘ in host memory. Here start means the value named ’start’ in this block. The important operands are getattr: the value named ’getattr’ in this block; node: the value named ’node’ in this block; lineno: the value named ’lineno’ in this block. Context: the function python_statement_spans, which handles python statement spans.

Line 315: `end = int(getattr(node, "end_lineno", start))` This assigns ‘int(getattr(node, "end_lineno", start))‘ to ‘end ‘ in host memory. Here end means the value named ’end’ in this block. The important operands are getattr: the value named ’getattr’ in this block; node: the value named ’node’ in this block; end_lineno: the value named ’end lineno’ in this block. Context: the function python_statement_spans, which handles python statement spans.

Line 316: `if start <= 0 or end <= start:` This executes the following indented host-code branch only when ‘start <= 0 or end <= start‘ is true. The important operands are start: the value named ’start’ in this block; or: the value named ’or’ in this block. Context: the function python_statement_spans, which handles python statement spans.

Line 317: `continue` Inside the function python_statement_spans, which handles python statement spans, this statement advances the host implementation that generates this source-reference volume and its source-integrity manifest. The important operands are continue: the value named ’continue’ in this block.

Line 318: `span = StatementSpan(start, end, _joined_statement(lines, start, end))` This assigns ‘StatementSpan(start, end, _joined_statement(lines, start, end))‘ to ‘span ‘ in host memory. Here span means the value named ’span’ in this block. The important operands are StatementSpan: the finite-state-machine phase retained in flip-flops; start: the value named ’start’ in this block; _joined_statement: the finite-state-machine phase retained in flip-flops. Context: the function python_statement_spans, which handles python statement spans.

Line 319: `for line_number in range(start, end + 1):` This iterates line_number over ‘range(start, end + 1)‘. Each iteration repeats the indented host operation, commonly once per layer, tile, timestep, or test case in the function python_statement_spans, which handles python statement spans.

Line 320: `previous = result.get(line_number)` This assigns ‘result.get(line_number)‘ to ‘previous ‘ in host memory. Here previous means the value named ’previous’ in this block. The important operands are result: the value named ’result’ in this block; get: the value named ’get’ in this block; line_number: the value named ’line number’ in this block. Context: the function python_statement_spans, which handles python statement spans.

Line 321: `if previous is None or (end - start) < (previous.end - previous.start):` This executes the following indented host-code branch only when ‘previous is None or (end - start) < (previous.end - previous.start)‘ is true. The important operands are previous: the value named ’previous’ in this block; is: the value named ’is’ in this block; None: the value named ’none’ in this block. Context: the function python_statement_spans, which handles python statement spans.

Line 322: `result[line_number] = span` This assigns ‘span‘ to ‘result[line_number] ‘ in host memory. Here result means the value named ’result’ in this block. The important operands are span: the value named ’span’ in this block. Context: the function python_statement_spans, which handles python statement spans.

Line 323: `return result` This returns ‘result‘ to the caller of the function python_statement_spans, which handles python statement spans, ending this invocation. The important operands are result: the value named ’result’ in this block.

Line 326: `def sv_statement_spans(lines: list[str]) -> dict[int, StatementSpan]:` This starts function sv_statement_spans. Its indented body performs sv statement spans as part of the file that generates this source-reference volume and its source-integrity manifest; it runs only when called.

Line 327: `"""Recover multiline RTL assignments without pretending fragments are complete."""` This is executable documentation attached to the function sv_statement_spans, which handles sv statement spans. It states the intended contract that tests and callers should enforce, but the text itself does not transform data or issue hardware work.

Line 328: `result: dict[int, StatementSpan] = {}` This assigns ‘{}‘ to ‘result‘ in host memory. Here result means the value named ’result’ in this block. The expression is a literal or structural operator and has no hidden software state. Context: the function sv_statement_spans, which handles sv statement spans.

Line 329: `assignment_start = re.compile(` This statement continues through source line 331; the explanation uses the complete expression rather than only the first visual fragment. Inside the function sv_statement_spans, which handles sv statement spans, this statement advances the host implementation that generates this source-reference volume and its source-integrity manifest. The important operands are assignment_start: the value named ’assignment start’ in this block; re: the value named ’re’ in this block; compile: the value named ’compile’ in this block.

Line 330: `r"^(?:assign\s+)?[A-Za-z_][A-Za-z0-9_$\[\].:+* /()’-]*\s*(?:<=|=(?!=))"` This is continuation line 2 of the 3-line logical statement that begins at source line 329. Its exact fragment is ‘r"^(?:assign\s+)?[A-Za-z_][A-Za-z0-9_$\[\].:+* /()’-]*\s*(?:<=|=(?!=))"‘. The important operands are r: the value named ’r’ in this block; assign: the value named ’assign’ in this block; s: the value named ’s’ in this block. Read together, the complete operation is: Inside the function sv_statement_spans, which handles sv statement spans, this statement advances the host implementation that generates this source-reference volume and its source-integrity manifest. The important operands are assignment_start: the value named ’assignment start’ in this block; re: the value named ’re’ in this block; compile: the value named ’compile’ in this block.

Line 331: `)` This is continuation line 3 of the 3-line logical statement that begins at source line 329. Its exact fragment is ‘)‘. The expression is a literal or structural operator and has no hidden software state. Read together, the complete operation is: Inside the function sv_statement_spans, which handles sv statement spans, this statement advances the host implementation that generates this source-reference volume and its source-integrity manifest. The important operands are assignment_start: the value named ’assignment start’ in this block; re: the value named ’re’ in this block; compile: the value named ’compile’ in this block.

Line 332: `state_encoding = re.compile(r"^[A-Z][A-Z0-9_]*\s*=.*,$")` This assigns ‘re.compile(r"^[A-Z][A-Z0-9_]*\s*=.*,$")‘ to ‘state_encoding ‘ in host memory. Here state_encoding means the finite-state-machine phase retained in flip-flops. The important operands are re: the value named ’re’ in this block; compile: the value named ’compile’ in this block; r: the value named ’r’ in this block. Context: the function sv_statement_spans, which handles sv statement spans.

Line 333: `line_index = 0` This assigns ‘0‘ to ‘line_index ‘ in host memory. Here line_index means an integer selecting one tensor element, lane, bank, or state entry. The expression is a literal or structural operator and has no hidden software state. Context: the function sv_statement_spans, which handles sv statement spans.

Line 334: `while line_index < len(lines):` This repeats the following host-code block while ‘line_index < len(lines)‘ remains true; surrounding timeout/error logic prevents an unbounded hardware wait.

Line 335: `stripped = lines[line_index].strip()` This assigns ‘lines[line_index].strip()‘ to ‘stripped ‘ in host memory. Here stripped means the value named ’stripped’ in this block. The important operands are lines: the value named ’lines’ in this block; line_index: an integer selecting one tensor element, lane, bank, or state entry; strip: the value named ’strip’ in this block. Context: the function sv_statement_spans, which handles sv statement spans.

Line 336: `if (not stripped or stripped.startswith("//") or ";" in stripped` Inside the function sv_statement_spans which handles sv statement spans, this statement advances the host implementation that generates this source-reference volume and its source-integrity manifest. The important operands are not: the value named ’not’ in this block; stripped: the value named ’stripped’ in this block; or: the value named ’or’ in this block.

Line 337: `or state_encoding.match(stripped) or not assignment_start.match(stripped)):` Inside the function sv_statement_spans, which handles sv statement spans, this statement advances the host implementation that generates this source-reference volume and its source-integrity manifest. The important operands are or: the value named ’or’ in this block; state_encoding: the finite-state-machine phase retained in flip-flops; match: the value named ’match’ in this block.

Line 338: `line_index += 1` Inside the function sv_statement_spans, which handles sv statement spans, this statement advances the host implementation that generates this source-reference volume and its source-integrity manifest. The important operands are line_index: an integer selecting one tensor element, lane, bank, or state entry.

Line 339: `continue` Inside the function sv_statement_spans, which handles sv statement spans, this statement advances the host implementation that generates this source-reference volume and its source-integrity manifest. The important operands are continue: the value named ’continue’ in this block.

Line 340: `end_index = line_index + 1` This assigns ‘line_index + 1‘ to ‘end_index ‘ in host memory. Here end_index means an integer selecting one tensor element, lane, bank, or state entry. The important operands are line_index: an integer selecting one tensor element, lane, bank, or state entry. Context: the function sv_statement_spans, which handles sv statement spans.

Line 341: `while end_index < len(lines) and ";" not in lines[end_index]:` This repeats the following host-code block while ‘end_index < len(lines) and ";" not in lines[end_index]‘ remains true; surrounding timeout/error logic prevents an unbounded hardware wait.

Line 342: `end_index += 1` Inside the function sv_statement_spans, which handles sv statement spans, this statement advances the host implementation that generates this source-reference volume and its source-integrity manifest. The important operands are end_index: an integer selecting one tensor element, lane, bank, or state entry.

Line 343: `if end_index >= len(lines) or end_index - line_index > 64:` This executes the following indented host-code branch only when ‘end_index >= len(lines) or end_index - line_index > 64‘ is true. The important operands are end_index: an integer selecting one tensor element, lane, bank, or state entry; len: the value named ’len’ in this block; lines: the value named ’lines’ in this block. Context: the function sv_statement_spans, which handles sv statement spans.

Line 344: `line_index += 1` Inside the function sv_statement_spans, which handles sv statement spans, this statement advances the host implementation that generates this source-reference volume and its source-integrity manifest. The important operands are line_index: an integer selecting one tensor element, lane, bank, or state entry.

Line 345: `continue` Inside the function sv_statement_spans, which handles sv statement spans, this statement advances the host implementation that generates this source-reference volume and its source-integrity manifest. The important operands are continue: the value named 'continue' in this block.

Line 346: `start = line_index + 1` This assigns ‘line_index + 1‘ to ‘start ‘ in host memory. Here start means the value named 'start' in this block. The important operands are line_index: an integer selecting one tensor element, lane, bank, or state entry. Context: the function sv_statement_spans, which handles sv statement spans.

Line 347: `end = end_index + 1` This assigns ‘end_index + 1‘ to ‘end ‘ in host memory. Here end means the value named 'end' in this block. The important operands are end_index: an integer selecting one tensor element, lane, bank, or state entry. Context: the function sv_statement_spans, which handles sv statement spans.

Line 348: `span = StatementSpan(start, end, _joined_statement(lines, start, end))` This assigns ‘StatementSpan(start, end, _joined_statement(lines, start, end))‘ to ‘span ‘ in host memory. Here span means the value named 'span' in this block. The important operands are StatementSpan: the finite-state-machine phase retained in flip-flops; start: the value named 'start' in this block; _joined_statement: the finite-state-machine phase retained in flip-flops. Context: the function sv_statement_spans, which handles sv statement spans.

Line 349: `for line_number in range(start, end + 1):` This iterates line_number over ‘range(start, end + 1)‘. Each iteration repeats the indented host operation, commonly once per layer, tile, timestep, or test case in the function sv_statement_spans, which handles sv statement spans.

Line 350: `result[line_number] = span` This assigns ‘span‘ to ‘result[line_number] ‘ in host memory. Here result means the value named 'result' in this block. The important operands are span: the value named 'span' in this block. Context: the function sv_statement_spans, which handles sv statement spans.

Line 351: `line_index = end_index + 1` This assigns ‘end_index + 1‘ to ‘line_index ‘ in host memory. Here line_index means an integer selecting one tensor element, lane, bank, or state entry. The important operands are end_index: an integer selecting one tensor element, lane, bank, or state entry. Context: the function sv_statement_spans, which handles sv statement spans.

Line 352: `return result` This returns ‘result‘ to the caller of the function sv_statement_spans, which handles sv statement spans, ending this invocation. The important operands are result: the value named 'result' in this block.

Line 355: `def sv_contexts(lines: list[str]) -> dict[int, str]:` This starts function sv_contexts. Its indented body performs sv contexts as part of the file that generates this source-reference volume and its source-integrity manifest; it runs only when called.

Line 356: `result: dict[int, str] = {}` This assigns ‘{}‘ to ‘result‘ in host memory. Here result means the value named 'result' in this block. The expression is a literal or structural operator and has no hidden software state. Context: the function sv_contexts, which handles sv contexts.

Line 357: `process = "the module's structural declarations"` This assigns ‘"the module's structural declarations"‘ to ‘process ‘ in host memory. Here process means the value named 'process' in this block. The important operands are the: the value named 'the' in this block; module: the value named 'module' in this block; s: the value named 's' in this block. Context: the function sv_contexts, which handles sv contexts.

Line 358: `process_depth = 0` This assigns ‘0‘ to ‘process_depth ‘ in host memory. Here process_depth means the value named 'process depth' in this block. The expression is a literal or structural operator and has no hidden software state. Context: the function sv_contexts, which handles sv contexts.

Line 359: `process_until: str | None = None` This assigns ‘None‘ to ‘process_until‘ in host memory. Here process_until means the value named 'process until' in this block. The important operands are None: the value named 'none' in this block. Context: the function sv_contexts, which handles sv contexts.

Line 360: `state = ""` This assigns '""' to 'state ' in host memory. Here state means the finite-state-machine phase retained in flip-flops. The expression is a literal or structural operator and has no hidden software state. Context: the function sv_contexts, which handles sv contexts.

Line 361: `for line_number, raw in enumerate(lines, start=1):` This iterates line_number, raw over 'enumerate(lines, start=1)'. Each iteration repeats the indented host operation, commonly once per layer, tile, timestep, or test case in the function sv_contexts, which handles sv contexts.

Line 362: `stripped = raw.strip()` This assigns 'raw.strip()' to 'stripped ' in host memory. Here stripped means the value named 'stripped' in this block. The important operands are raw: the value named 'raw' in this block; strip: the value named 'strip' in this block. Context: the function sv_contexts, which handles sv contexts.

Line 363: `starts_process = False` This assigns 'False' to 'starts_process ' in host memory. Here starts_process means the value named 'starts process' in this block. The expression is a literal or structural operator and has no hidden software state. Context: the function sv_contexts, which handles sv contexts.

Line 364: `if re.search(r"\balways_ff\b", stripped):` This executes the following indented host-code branch only when 're.search(r"\balways_ff\b", stripped)' is true. The important operands are re: the value named 're' in this block; search: the value named 'search' in this block; r: the value named 'r' in this block. Context: the function sv_contexts, which handles sv contexts.

Line 365: `process = "the clocked process that updates registers only on a rising clock edge"` This assigns '"the clocked process that updates registers only on a rising clock edge"' to 'process ' in host memory. Here process means the value named 'process' in this block. The important operands are the: the value named 'the' in this block; clocked: the value named 'clocked' in this block; process: the value named 'process' in this block. Context: the function sv_contexts, which handles sv contexts.

Line 366: `process_depth = max(1, len(re.findall(r"\bbegin\b", stripped)))` This assigns 'max(1, len(re.findall(r"\bbeg stripped)))' to 'process_depth ' in host memory. Here process_depth means the value named 'process depth' in this block. The important operands are max: the value named 'max' in this block; len: the value named 'len' in this block; re: the value named 're' in this block. Context: the function sv_contexts, which handles sv contexts.

Line 367: `process_until = None` This assigns 'None' to 'process_until ' in host memory. Here process_until means the value named 'process until' in this block. The important operands are None: the value named 'none' in this block. Context: the function sv_contexts, which handles sv contexts.

Line 368: `starts_process = True` This assigns 'True' to 'starts_process ' in host memory. Here starts_process means the value named 'starts process' in this block. The expression is a literal or structural operator and has no hidden software state. Context: the function sv_contexts, which handles sv contexts.

Line 369: `elif re.search(r"\balways_comb\b", stripped):` This executes the following indented host-code branch only when 're.search(r"\balways_comb\b", stripped)' is true. The important operands are re: the value named 're' in this block; search: the value named 'search' in this block; r: the value named 'r' in this block. Context: the function sv_contexts, which handles sv contexts.

Line 370: `process = "the combinational process whose outputs respond without waiting for a clock edge"` This assigns '"the combinational process whose outputs respond without waiting for a clock edge"' to 'process ' in host memory. Here process means the value named 'process' in this block. The important operands are the: the value named 'the' in this block; combinational: the value named 'combinational' in this block; process: the value named 'process' in this block. Context: the function sv_contexts, which handles sv contexts.

Line 371: `process_depth = max(1, len(re.findall(r"\bbegin\b", stripped)))` This assigns 'max(1, len(re.findall(r"\bbeg stripped)))' to 'process_depth ' in host memory. Here process_depth means the value named 'process depth' in this block. The important operands are max: the value named 'max' in this block; len: the value named 'len' in this block; re: the value named 're' in this block. Context: the function sv_contexts, which handles sv contexts.

Line 372: `process_until = None` This assigns ‘None‘ to ‘process_until ‘ in host memory. Here process_until means the value named ’process until’ in this block. The important operands are None: the value named ’none’ in this block. Context: the function sv_contexts, which handles sv contexts.

Line 373: `starts_process = True` This assigns ‘True‘ to ‘starts_process ‘ in host memory. Here starts_process means the value named ’starts process’ in this block. The expression is a literal or structural operator and has no hidden software state. Context: the function sv_contexts, which handles sv contexts.

Line 374: `elif stripped.startswith("function"):` This executes the following indented host-code branch only when ‘stripped.startswith("function")‘ is true. The important operands are stripped: the value named ’stripped’ in this block; startswith: the value named ’startswith’ in this block; function: the value named ’function’ in this block. Context: the function sv_contexts, which handles sv contexts.

Line 375: `names = re.findall(r"([A-Za-z_][A-Za-z0-9_$]*)\s*\(", stripped)` This assigns ‘re.findall(r"([A-Za-z_][A-Za-z0-9_$]*)\s*\(", stripped)‘ to ‘names ‘ in host memory. Here names means the value named ’names’ in this block. The important operands are re: the value named ’re’ in this block; findall: the value named ’findall’ in this block; r: the value named ’r’ in this block. Context: the function sv_contexts, which handles sv contexts.

Line 376: `name = names[-1] if names else "function"` This assigns ‘names[-1] if names else "function"‘ to ‘name ‘ in host memory. Here name means the value named ’name’ in this block. The important operands are names: the value named ’names’ in this block; function: the value named ’function’ in this block. Context: the function sv_contexts, which handles sv contexts.

Line 377: `process = f"the combinational helper {humanize(name)}"` This assigns ‘f"the combinational helper {humanize(name)}"‘ to ‘process ‘ in host memory. Here process means the value named ’process’ in this block. The important operands are f: the value named ’f’ in this block; the: the value named ’the’ in this block; combinational: the value named ’combinational’ in this block. Context: the function sv_contexts, which handles sv contexts.

Line 378: `process_until = "endfunction"` This assigns ‘"endfunction"‘ to ‘process_until ‘ in host memory. Here process_until means the value named ’process until’ in this block. The important operands are endfunction: the value named ’endfunction’ in this block. Context: the function sv_contexts, which handles sv contexts.

Line 379: `process_depth = 0` This assigns ‘0‘ to ‘process_depth ‘ in host memory. Here process_depth means the value named ’process depth’ in this block. The expression is a literal or structural operator and has no hidden software state. Context: the function sv_contexts, which handles sv contexts.

Line 380: `starts_process = True` This assigns ‘True‘ to ‘starts_process ‘ in host memory. Here starts_process means the value named ’starts process’ in this block. The expression is a literal or structural operator and has no hidden software state. Context: the function sv_contexts, which handles sv contexts.

Line 381: `elif stripped.startswith("task"):` This executes the following indented host-code branch only when ‘stripped.startswith("task")‘ is true. The important operands are stripped: the value named ’stripped’ in this block; startswith: the value named ’startswith’ in this block; task: the value named ’task’ in this block. Context: the function sv_contexts, which handles sv contexts.

Line 382: `names = re.findall(r"([A-Za-z_][A-Za-z0-9_$]*)\s*\(", stripped)` This assigns ‘re.findall(r"([A-Za-z_][A-Za-z0-9_$]*)\s*\(", stripped)‘ to ‘names ‘ in host memory. Here names means the value named ’names’ in this block. The important operands are re: the value named ’re’ in this block; findall: the value named ’findall’ in this block; r: the value named ’r’ in this block. Context: the function sv_contexts, which handles sv contexts.

Line 383: `name = names[-1] if names else "task"` This assigns ‘names[-1] if names else "task"‘ to ‘name ‘ in host memory. Here name means the value named ’name’ in this block. The important operands are names: the value named ’names’ in this block; task: the value named ’task’ in this block. Context: the function sv_contexts, which handles sv contexts.

Line 384: `process = f"the simulation task {humanize(name)}"` This assigns ‘f"the simulation task {humanize(name)}"‘ to ‘process ‘ in host memory. Here process means the value named ’process’ in this block. The important operands are f: the value named ’f’ in this block; the: the value named ’the’ in this block; simulation: the value named ’simulation’ in this block. Context: the function sv_contexts, which handles sv contexts.

Line 385: `process_until = "endtask"` This assigns ‘"endtask"‘ to ‘process_until ‘ in host memory. Here process_until means the value named ’process until’ in this block. The important operands are endtask: the value named ’endtask’ in this block. Context: the function sv_contexts, which handles sv contexts.

Line 386: `process_depth = 0` This assigns ‘0‘ to ‘process_depth ‘ in host memory. Here process_depth means the value named ’process depth’ in this block. The expression is a literal or structural operator and has no hidden software state. Context: the function sv_contexts, which handles sv contexts.

Line 387: `starts_process = True` This assigns ‘True‘ to ‘starts_process ‘ in host memory. Here starts_process means the value named ’starts process’ in this block. The expression is a literal or structural operator and has no hidden software state. Context: the function sv_contexts, which handles sv contexts.

Line 388: `state_match = re.match(r"(?:ST_|CORE_|WR_|RD_)?([A-Z][A-Z0-9_]*)\s*:", stripped)` This assigns ‘re.match(r"(?:ST_|CORE_|WR_|RD_)?([A-Z][A-Z0-9_]*)\s*:", stripped)‘ to ‘state_match ‘ in host memory. Here state_match means the finite-state-machine phase retained in flip-flops. The important operands are re: the value named ’re’ in this block; match: the value named ’match’ in this block; r: the value named ’r’ in this block. Context: the function sv_contexts, which handles sv contexts.

Line 389: `if state_match:` This executes the following indented host-code branch only when ‘state_match‘ is true. The important operands are state_match: the finite-state-machine phase retained in flip-flops. Context: the function sv_contexts, which handles sv contexts.

Line 390: `state_name = state_match.group(1)` This assigns ‘state_match.group(1)‘ to ‘state_name ‘ in host memory. Here state_name means the finite-state-machine phase retained in flip-flops. The important operands are state_match: the finite-state-machine phase retained in flip-flops; group: the value named ’group’ in this block. Context: the function sv_contexts, which handles sv contexts.

Line 391: `meaning = next((value for key, value in STATE_MEANINGS.items() if key in state_name), "performs the named c...` This assigns ‘next((value for key, value in STATE_MEANINGS.items() if key in state_name), "performs the named control phase")‘ to ‘meaning ‘ in host memory. Here meaning means the arithmetic average used by normalization. The important operands are next: the value named ’next’ in this block; value: the value named ’value’ in this block; for: the value named ’for’ in this block. Context: the function sv_contexts, which handles sv contexts.

Line 392: `state = f" Within state {state_match.group(0)[:-1]}, the machine {meaning}."` This assigns ‘f" Within state {state_match.group(0)[:-1]}, the machine {meaning}."‘ to ‘state ‘ in host memory. Here state means the finite-state-machine phase retained in flip-flops. The important operands are f: the value named ’f’ in this block; Within: the value named ’within’ in this block; state: the finite-state-machine phase retained in flip-flops. Context: the function sv_contexts, which handles sv contexts.

Line 393: `result[line_number] = process + state` This assigns ‘process + state‘ to ‘result[line_number] ‘ in host memory. Here result means the value named ’result’ in this block. The important operands are process: the value named ’process’ in this block; state: the finite-state-machine phase retained in flip-flops. Context: the function sv_contexts, which handles sv contexts.

Line 394: `if stripped == "endcase":` This executes the following indented host-code branch only when ‘stripped == "endcase"‘ is true. The important operands are stripped: the value named ’stripped’ in this block; endcase: the value named ’endcase’ in this block. Context: the function sv_contexts, which handles sv contexts.

Line 395: `state = ""` This assigns ‘""‘ to ‘state ‘ in host memory. Here state means the finite-state-machine phase retained in flip-flops. The expression is a literal or structural operator and has no hidden software state. Context: the function sv_contexts, which handles sv contexts.

Line 396: `if process_until is not None and stripped.startswith(process_until):` This executes the following indented host-code branch only when ‘process_until is not None and stripped.startswith(process_until)‘ is true. The important operands are process_until: the value named ’process until’ in this block; is: the value named ’is’ in this block; not: the value named ’not’ in this block. Context: the function sv_contexts, which handles sv contexts.

Line 397: `process = "the module’s structural declarations"` This assigns ‘"the module’s structural declarations"‘ to ‘process ‘ in host memory. Here process means the value named ’process’ in this block. The important operands are the: the value named ’the’ in this block; module: the value named ’module’ in this block; s: the value named ’s’ in this block. Context: the function sv_contexts, which handles sv contexts.

Line 398: `process_until = None` This assigns ‘None‘ to ‘process_until ‘ in host memory. Here process_until means the value named ’process until’ in this block. The important operands are None: the value named ’none’ in this block. Context: the function sv_contexts, which handles sv contexts.

Line 399: `process_depth = 0` This assigns ‘0‘ to ‘process_depth ‘ in host memory. Here process_depth means the value named ’process depth’ in this block. The expression is a literal or structural operator and has no hidden software state. Context: the function sv_contexts, which handles sv contexts.

Line 400: `state = ""` This assigns ‘""‘ to ‘state ‘ in host memory. Here state means the finite-state-machine phase retained in flip-flops. The expression is a literal or structural operator and has no hidden software state. Context: the function sv_contexts, which handles sv contexts.

Line 401: `elif process_until is None and process != "the module’s structural declarations":` This executes the following indented host-code branch only when ‘process_until is None and process != "the module’s structural declarations"‘ is true. The important operands are process_until: the value named ’process until’ in this block; is: the value named ’is’ in this block; None: the value named ’none’ in this block. Context: the function sv_contexts, which handles sv contexts.

Line 402: `if not starts_process:` This executes the following indented host-code branch only when ‘not starts_process‘ is true. The important operands are not: the value named ’not’ in this block; starts_process: the value named ’starts process’ in this block. Context: the function sv_contexts, which handles sv contexts.

Line 403: `process_depth += len(re.findall(r"\bbegin\b", stripped))` Inside the function sv_contexts, which handles sv contexts, this statement advances the host implementation that generates this source-reference volume and its source-integrity manifest. The important operands are process_depth: the value named ’process depth’ in this block; len: the value named ’len’ in this block; re: the value named ’re’ in this block.

Line 404: `process_depth -= len(re.findall(r"\bend\b", stripped))` Inside the function sv_contexts, which handles sv contexts, this statement advances the host implementation that generates this source-reference volume and its source-integrity manifest. The important operands are process_depth: the value named ’process depth’ in this block; len: the value named ’len’ in this block; re: the value named ’re’ in this block.

Line 405: `if process_depth <= 0 or (starts_process and "begin" not in stripped):` This executes the following indented host-code branch only when ‘process_depth <= 0 or (starts_process and "begin" not in stripped)‘ is true. The important operands are process_depth: the value named ’process depth’ in this block; or: the value named ’or’ in this block; starts_process: the value named ’starts process’ in this block. Context: the function sv_contexts, which handles sv contexts.

Line 406: `process = "the module's structural declarations"` This assigns ‘"the module's structural declarations"‘ to ‘process ‘ in host memory. Here process means the value named 'process' in this block. The important operands are the: the value named 'the' in this block; module: the value named 'module' in this block; s: the value named 's' in this block. Context: the function sv_contexts, which handles sv contexts.

Line 407: `process_depth = 0` This assigns ‘0‘ to ‘process_depth ‘ in host memory. Here process_depth means the value named 'process depth' in this block. The expression is a literal or structural operator and has no hidden software state. Context: the function sv_contexts, which handles sv contexts.

Line 408: `state = ""` This assigns ‘""‘ to ‘state ‘ in host memory. Here state means the finite-state-machine phase retained in flip-flops. The expression is a literal or structural operator and has no hidden software state. Context: the function sv_contexts, which handles sv contexts.

Line 409: `return result` This returns ‘result‘ to the caller of the function sv_contexts, which handles sv contexts, ending this invocation. The important operands are result: the value named 'result' in this block.

Line 412: `def explain_sv_line(line: str, context: str, purpose: str) -> str:` This starts function explain_sv_line. Its indented body performs explain sv line as part of the file that generates this source-reference volume and its source-integrity manifest; it runs only when called.

Line 413: `stripped = line.strip()` This assigns ‘line.strip()‘ to ‘stripped ‘ in host memory. Here stripped means the value named 'stripped' in this block. The important operands are line: the value named 'line' in this block; strip: the value named 'strip' in this block. Context: the function explain_sv_line, which handles explain sv line.

Line 414: `if stripped.startswith("//"):` This executes the following indented host-code branch only when ‘stripped.startswit is true. The important operands are stripped: the value named 'stripped' in this block; startswith: the value named 'startswith' in this block. Context: the function explain_sv_line, which handles explain sv line.

Line 415: `comment = stripped[2:].strip()` This assigns ‘stripped[2:].strip()‘ to ‘comment ‘ in host memory. Here comment means the value named 'comment' in this block. The important operands are stripped: the value named 'stripped' in this block; strip: the value named 'strip' in this block. Context: the function explain_sv_line, which handles explain sv line.

Line 416: `return f"Design intent: {comment} This comment anchors the surrounding logic in the block that {purpose}."` This returns ‘f"Design intent: {comment} This comment anchors the surrounding logic in the block that {purpose}."‘ to the caller of the function explain_sv_line, which handles explain sv line, ending this invocation. The important operands are f: the value named 'f' in this block; Design: the value named 'design' in this block; intent: the value named 'intent' in this block.

Line 417: `if stripped.startswith("‘"):` This executes the following indented host-code branch only when ‘stripped.startswith is true. The important operands are stripped: the value named 'stripped' in this block; startswith: the value named 'startswith' in this block. Context: the function explain_sv_line, which handles explain sv line.

Line 418: `if "default_nettype none" in stripped:` This executes the following indented host-code branch only when ‘"default_nettype none" in stripped‘ is true. The important operands are default_nettype: the value named 'default nettype' in this block; none: the value named 'none' in this block; in: the value named 'in' in this block. Context: the function explain_sv_line, which handles explain sv line.

Line 419: `return "This compiler directive forbids accidental implicit one-bit wires, turning misspelled signal names ...` This returns ‘"This compiler directive forbids accidental implicit one-bit wires, turning misspelled signal names into errors instead of unintended hardware."‘ to the caller of the function explain_sv_line, which handles explain sv line, ending this invocation. The important operands are This: the value named 'this' in this block; compiler: the value named 'compiler' in this block; directive: the value named 'directive' in this block.

Line 420: `if "timescale" in stripped:` This executes the following indented host-code branch only when ‘"timescale" in stripped‘ is true. The important operands are timescale: the real-value spacing represented by one quantized integer step; in: the value named ’in’ in this block; stripped: the value named ’stripped’ in this block. Context: the function explain_sv_line, which handles explain sv line.

Line 421: `return "This simulation directive selects nanoseconds as the time unit and picoseconds as the timestamp pre...` This returns ‘"This simulation directive selects nanoseconds as the time unit and picoseconds as the timestamp precision; it does not create FPGA logic."‘ to the caller of the function explain_sv_line, which handles explain sv line, ending this invocation. The important operands are This: the value named ’this’ in this block; simulation: the value named ’simulation’ in this block; directive: the value named ’directive’ in this block.

Line 422: `return f"This SystemVerilog preprocessor line controls compilation of the block that {purpose}."` This returns ‘f"This SystemVerilog preprocessor line controls compilation of the block that {purpose}."‘ to the caller of the function explain_sv_line, which handles explain sv line, ending this invocation. The important operands are f: the value named ’f’ in this block; This: the value named ’this’ in this block; SystemVerilog: the value named ’system verilog’ in this block.

Line 423: `if re.match(r"(?:module|package)\b", stripped):` This executes the following indented host-code branch only when ‘re.match(r"(?:module|package)\b", stripped)‘ is true. The important operands are re: the value named ’re’ in this block; match: the value named ’match’ in this block; r: the value named ’r’ in this block. Context: the function explain_sv_line, which handles explain sv line.

Line 424: `name = re.split(r"[\s(#]", stripped, maxsplit=2)[1]` This assigns ‘re.split(r"[\s(#]", stripped, maxsplit=2)[1]‘ to ‘name ‘ in host memory. Here name means the value named ’name’ in this block. The important operands are re: the value named ’re’ in this block; split: the value named ’split’ in this block; r: the value named ’r’ in this block. Context: the function explain_sv_line, which handles explain sv line.

Line 425: `return f"This opens {name}, an independently compiled hardware definition. Its ports and statements collect...` This returns ‘f"This opens {name}, an independently compiled hardware definition. Its ports and statements collectively describe circuitry that {purpose}."‘ to the caller of the function explain_sv_line, which handles explain sv line, ending this invocation. The important operands are f: the value named ’f’ in this block; This: the value named ’this’ in this block; opens: the value named ’opens’ in this block.

Line 426: `if stripped.startswith(("endmodule", "endpackage")):` This executes the following indented host-code branch only when ‘stripped.startswith(("endmodule", "endpackage"))‘ is true. The important operands are stripped: the value named ’stripped’ in this block; startswith: the value named ’startswith’ in this block; endmodule: the value named ’endmodule’ in this block. Context: the function explain_sv_line, which handles explain sv line.

Line 427: `return "This closes the current hardware definition; no circuit behavior is attached to the keyword itself."` This returns ‘"This closes the current hardware definition; no circuit behavior is attached to the keyword itself."‘ to the caller of the function explain_sv_line, which handles explain sv line, ending this invocation. The important operands are This: the value named ’this’ in this block; closes: the value named ’closes’ in this block; the: the value named ’the’ in this block.

Line 428: `if stripped.startswith("import "):` This executes the following indented host-code branch only when ‘stripped.startswith("import ")‘ is true. The important operands are stripped: the value named ’stripped’ in this block; startswith: the value named ’startswith’ in this block; import: the value named ’import’ in this block. Context: the function explain_sv_line, which handles explain sv line.

Line 429: `return f"This imports shared package names into the current module so opcodes and mode constants have exact...` This returns ‘f"This imports shared package names into the current module so opcodes and mode constants have exactly one definition. The import changes compile-time name visibility; it does not create registers or consume a clock cycle."‘ to the caller of the function explain_sv_line, which handles explain sv line, ending this invocation. The important operands are f: the value named ’f’ in this block; This: the value named ’this’ in this block; imports: the value named ’imports’ in this block.

Line 430: `port = re.match(r"(input|output|inout)\s+(?:wire|logic)?\s*(?:signed\s*)?(\[[^]]+\])?\s*([A-Za-z_][` This assigns ‘re.match(r"(input|output|inout)\s+(?:wire|logic)?\s*(?:signed\s*)?(\[[^]]+\])?\s*([A-Za-z_][A-Za-z0-9_$]*)", stripped)‘ to ‘port ‘ in host memory. Here port means the value named ’port’ in this block. The important operands are re: the value named ’re’ in this block; match: the value named ’match’ in this block; r: the value named ’r’ in this block. Context: the function explain_sv_line, which handles explain sv line.

Line 431: `if port:` This executes the following indented host-code branch only when ‘port‘ is true. The important operands are port: the value named ’port’ in this block. Context: the function explain_sv_line, which handles explain sv line.

Line 432: `direction, width, name = port.groups()` This assigns ‘port.groups()‘ to ‘direction, width, name ‘ in host memory. Here direction means the value named ’direction’ in this block. The important operands are port: the value named ’port’ in this block; groups: the value named ’groups’ in this block. Context: the function explain_sv_line, which handles explain sv line.

Line 433: `width_text = width or "one bit"` This assigns ‘width or "one bit"‘ to ‘width_text ‘ in host memory. Here width_text means the value named ’width text’ in this block. The important operands are width: the value named ’width’ in this block; or: the value named ’or’ in this block; one: the value named ’one’ in this block. Context: the function explain_sv_line, which handles explain sv line.

Line 434: `return f"This declares {name} as a {direction} port with width {width_text}.  It carries {identifie` This returns ‘f"This declares {name} as a {direction} port with width {width_text}. It carries {identifier_meaning(name)} across the module boundary; a port is a bundle of physical FPGA nets, not a software argument."‘ to the caller of the function explain_sv_line, which handles explain sv line, ending this invocation. The important operands are f: the value named ’f’ in this block; This: the value named ’this’ in this block; declares: the value named ’declares’ in this block.

Line 435: `parameter = re.match(r"(?:parameter|localparam)\s+(?:(?:logic|integer|int|bit)\s+)?(?:signed\s*)?(?` This assigns ‘re.match(r"(?:parameter|localparam)\s+(?:(?:logic|integer|int|bit)\s+)?(?:signed\s*)?(?:\[[^]]+\]\s*)?([A-Za-z_][A-Za-z0-9_$]*)\s*=\s*(.*?)[,;]?$", stripped)‘ to ‘parameter ‘ in host memory. Here parameter means the value named ’parameter’ in this block. The important operands are re: the value named ’re’ in this block; match: the value named ’match’ in this block; r: the value named ’r’ in this block. Context: the function explain_sv_line, which handles explain sv line.

Line 436: `if parameter:` This executes the following indented host-code branch only when ‘parameter‘ is true. The important operands are parameter: the value named ’parameter’ in this block. Context: the function explain_sv_line, which handles explain sv line.

Line 437: `name, value = parameter.groups()` This assigns ‘parameter.groups()‘ to ‘name, value ‘ in host memory. Here name means the value named ’name’ in this block. The important operands are parameter: the value named ’parameter’ in this block; groups: the value named ’groups’ in this block. Context: the function explain_sv_line, which handles explain sv line.

Line 438: `return f"This fixes {name} to {value} during elaboration.  Vivado uses that constant to shape or simplify th...` This returns ‘f"This fixes {name} to {value} during elaboration. Vivado uses that constant to shape or simplify the generated circuit; {name} denotes {identifier_meaning(name)}."‘ to the caller of the function explain_sv_line, which handles explain sv line, ending this invocation. The important operands are f: the value named ’f’ in this block; This: the value named ’this’ in this block; fixes: the value named ’fixes’ in this block.

Line 439: `if "typedef enum" in stripped:` This executes the following indented host-code branch only when ‘"typedef enum" in stripped‘ is true. The important operands are typedef: the value named ’typedef’ in this block; enum: the value named ’enum’ in this block; in: the value named ’in’ in this block. Context: the function explain_sv_line, which handles explain sv line.

Line 440: `return "This begins a named finite-state-machine type.  The encoded bits are stored in flip-flops, while sym...` This returns '"This begins a named finite-state-machine type. The encoded bits are stored in flip-flops, while symbolic names make each cycle-level phase reviewable."' to the caller of the function explain_sv_line, which handles explain sv line, ending this invocation. The important operands are This: the value named 'this' in this block; begins: the value named 'begins' in this block; a: the value named 'a' in this block.

Line 441: `state_match = re.match(r"([A-Z][A-Z0-9_]*)\s*=\s*[^,}]+", stripped)` This assigns 're.match(r"([A-Z][A-Z0-9_]*)\s*=\s*[^,}]+", stripped)' to 'state_match ' in host memory. Here state_match means the finite-state-machine phase retained in flip-flops. The important operands are re: the value named 're' in this block; match: the value named 'match' in this block; r: the value named 'r' in this block. Context: the function explain_sv_line, which handles explain sv line.

Line 442: `if state_match:` This executes the following indented host-code branch only when 'state_match' is true. The important operands are state_match: the finite-state-machine phase retained in flip-flops. Context: the function explain_sv_line, which handles explain sv line.

Line 443: `name = state_match.group(1)` This assigns 'state_match.group(1)' to 'name ' in host memory. Here name means the value named 'name' in this block. The important operands are state_match: the finite-state-machine phase retained in flip-flops; group: the value named 'group' in this block. Context: the function explain_sv_line, which handles explain sv line.

Line 444: `meaning = next((value for key, value in STATE_MEANINGS.items() if key in name), "identifies one explicit co...` This assigns 'next((value for key, value in STATE_MEANINGS.items() if key in name), "identifies one explicit control phase")' to 'meaning ' in host memory. Here meaning means the arithmetic average used by normalization. The important operands are next: the value named 'next' in this block; value: the value named 'value' in this block; for: the value named 'for' in this block. Context: the function explain_sv_line, which handles explain sv line.

Line 445: `return f"This assigns a fixed binary encoding to state {name}, which {meaning}.  The encoding is visible in ...` This returns 'f"This assigns a fixed binary encoding to state {name}, which {meaning}. The encoding is visible in waveforms even though the source uses the readable name."' to the caller of the function explain_sv_line, which handles explain sv line, ending this invocation. The important operands are f: the value named 'f' in this block; This: the value named 'this' in this block; assigns: the value named 'assigns' in this block.

Line 446: `declaration = re.match(r"(?:logic|wire|reg|integer|genvar)\s+(?:signed\s*)?(?:\[[^]]+\]\s*)?(.+?);$", strip...` This assigns 're.match(r"(?:logic|wire|reg|integer|genvar)\s+(?:signed\s*)?(?:\[[^]]+\]\s*)?(.+?);$", stripped)' to 'declaration ' in host memory. Here declaration means the value named 'declaration' in this block. The important operands are re: the value named 're' in this block; match: the value named 'match' in this block; r: the value named 'r' in this block. Context: the function explain_sv_line, which handles explain sv line.

Line 447: `if declaration:` This executes the following indented host-code branch only when 'declaration' is true. The important operands are declaration: the value named 'declaration' in this block. Context: the function explain_sv_line, which handles explain sv line.

Line 448: `names = [re.split(r"[\s[=]", item.strip(), maxsplit=1)[0] for item in declaration.group(1).split(",")]` This assigns '[re.split(r"[\s[=]", item.strip(), maxsplit=1)[0] for item in declaration.group(1).split(",")]' to 'names ' in host memory. Here names means the value named 'names' in this block. The important operands are re: the value named 're' in this block; split: the value named 'split' in this block; r: the value named 'r' in this block. Context: the function explain_sv_line, which handles explain sv line.

Line 449: `descriptions = "; ".join(f"{name} is {identifier_meaning(name)}" for name in names[:4])` This assigns '"; ".join(f"{name} is {identifier_meaning(name)}" for name in names[:4])' to 'descriptions ' in host memory. Here descriptions means the value named 'descriptions' in this block. The important operands are join: the value named 'join' in this block; f: the value named 'f' in this block; name: the value named 'name' in this block. Context: the function explain_sv_line, which handles explain sv line.

Line 450: `return f"This declares hardware signal storage or wiring in {context}. Specifically, {descriptions Widths...` This returns ‘f"This declares hardware signal storage or wiring in {context}. Specifically, {descriptions}. Widths in square brackets count from the stated most-significant bit down to the least-significant bit."‘ to the caller of the function explain_sv_line, which handles explain sv line, ending this invocation. The important operands are f: the value named ’f’ in this block; This: the value named ’this’ in this block; declares: the value named ’declares’ in this block.

Line 451: `assignment = re.match(r"(?:assign\s+)?([A-Za-z_][A-Za-z0-9_$\[\].:]*)\s*(<=|=)\s*(.+?);?$", stripped)` Inside the function explain_sv_line, which handles explain sv line, this statement advances the host implementation that generates this source-reference volume and its source-integrity manifest. The important operands are assignment: the value named ’assignment’ in this block; re: the value named ’re’ in this block; match: the value named ’match’ in this block.

Line 452: `if assignment:` This executes the following indented host-code branch only when ‘assignment‘ is true. The important operands are assignment: the value named ’assignment’ in this block. Context: the function explain_sv_line, which handles explain sv line.

Line 453: `lhs, operator, rhs = assignment.groups()` This assigns ‘assignment.groups()‘ to ‘lhs, operator, rhs ‘ in host memory. Here lhs means the value named ’lhs’ in this block. The important operands are assignment: the value named ’assignment’ in this block; groups: the value named ’groups’ in this block. Context: the function explain_sv_line, which handles explain sv line.

Line 454: `timing = "updates after the active clock edge together with other nonblocking assignments" if operator == "...` Inside the function explain_sv_line, which handles explain sv line, this statement advances the host implementation that generates this source-reference volume and its source-integrity manifest. The important operands are timing: the value named ’timing’ in this block; updates: the value named ’updates’ in this block; after: the value named ’after’ in this block.

Line 455: `return f"This makes {lhs}, {identifier_meaning(lhs.split('[')[0])}, equal to ‘{rhs.rstrip(';')}‘. It {timin...` This returns ‘f"This makes {lhs}, {identifier_meaning(lhs.split('[')[0])}, equal to ‘{rhs.rstrip(';')}‘. It {timing}. {summarize_expression(rhs)} Context: {context}."‘ to the caller of the function explain_sv_line, which handles explain sv line, ending this invocation. The important operands are f: the value named ’f’ in this block; This: the value named ’this’ in this block; makes: the value named ’makes’ in this block.

Line 456: `if stripped.startswith("always_ff"):` This executes the following indented host-code branch only when ‘stripped.startswith("always_ff")‘ is true. The important operands are stripped: the value named ’stripped’ in this block; startswith: the value named ’startswith’ in this block; always_ff: the value named ’always ff’ in this block. Context: the function explain_sv_line, which handles explain sv line.

Line 457: `return "This opens clocked sequential logic. Everything assigned with ‘<=‘ inside becomes a flip-flop or me...` This returns ‘"This opens clocked sequential logic. Everything assigned with ‘<=‘ inside becomes a flip-flop or memory write and changes at a clock edge, which creates the accelerator’s notion of cycles and persistent state."‘ to the caller of the function explain_sv_line, which handles explain sv line, ending this invocation. The important operands are This: the value named ’this’ in this block; opens: the value named ’opens’ in this block; clocked: the value named ’clocked’ in this block.

Line 458: `if stripped.startswith("always_comb"):` This executes the following indented host-code branch only when ‘stripped.startswith("always_comb")‘ is true. The important operands are stripped: the value named ’stripped’ in this block; startswith: the value named ’startswith’ in this block; always_comb: the value named ’always comb’ in this block. Context: the function explain_sv_line, which handles explain sv line.

Line 459: `return "This opens combinational logic. Vivado builds gates and multiplexers whose outputs continuously fol...` This returns ‘"This opens combinational logic. Vivado builds gates and multiplexers whose outputs continuously follow the inputs, and the language requires every assigned output to receive a value on every path."‘ to the caller of the function explain_sv_line, which handles explain sv line, ending this invocation. The important operands

are This: the value named 'this' in this block; opens: the value named 'opens' in this block; combinational: the value named 'combinational' in this block.

Line 460: `if stripped.startswith("initial"):` This executes the following indented host-code branch only when ‘stripped.startswith("initial")‘ is true. The important operands are stripped: the value named 'stripped' in this block; startswith: the value named 'startswith' in this block; initial: the value named 'initial' in this block. Context: the function explain_sv_line, which handles explain sv line.

Line 461: `return "This opens simulation initialization. In a testbench it drives starting values and stimulus; projec...` This returns ‘"This opens simulation initialization. In a testbench it drives starting values and stimulus; project synthesis does not rely on this block as a replacement for explicit reset behavior."‘ to the caller of the function explain_sv_line, which handles explain sv line, ending this invocation. The important operands are This: the value named 'this' in this block; opens: the value named 'opens' in this block; simulation: the value named 'simulation' in this block.

Line 462: `reset_match = re.match(r"if\s*\(\s*!?(?:rst_n|aresetn)\s*\)", stripped)` This assigns ‘re.match(r"if\s*\(\ stripped)‘ to ‘reset_match ‘ in host memory. Here reset_match means the value named 'reset match' in this block. The important operands are re: the value named 're' in this block; match: the value named 'match' in this block; r: the value named 'r' in this block. Context: the function explain_sv_line, which handles explain sv line.

Line 463: `if reset_match:` This executes the following indented host-code branch only when ‘reset_match‘ is true. The important operands are reset_match: the value named 'reset match' in this block. Context: the function explain_sv_line, which handles explain sv line.

Line 464: `return f"This is the reset branch for ‘{reset_match.group(0)[3:-1].strip()}‘. While reset is asserted, the ...` This returns ‘f"This is the reset branch for ‘{reset_match.group(0)[3:-1].strip()}‘. While reset is asserted, the following assignments force control state, handshakes, counters, and error flags to known values so no stale pre-reset transaction can be mistaken for valid work. Context: {context}."‘ to the caller of the function explain_sv_line, which handles explain sv line, ending this invocation. The important operands are f: the value named 'f' in this block; This: the value named 'this' in this block; is: the value named 'is' in this block.

Line 465: `if_match = re.match(r"(?:end\s+)?(?:else\s+)?if\s*\((.*)\)", stripped)` This assigns ‘re.match(r"(?:end\s stripped)‘ to ‘if_match ‘ in host memory. Here if_match means the value named 'if match' in this block. The important operands are re: the value named 're' in this block; match: the value named 'match' in this block; r: the value named 'r' in this block. Context: the function explain_sv_line, which handles explain sv line.

Line 466: `if if_match:` This executes the following indented host-code branch only when ‘if_match‘ is true. The important operands are if_match: the value named 'if match' in this block. Context: the function explain_sv_line, which handles explain sv line.

Line 467: `condition = if_match.group(1)` This assigns ‘if_match.group(1)‘ to ‘condition ‘ in host memory. Here condition means the value named 'condition' in this block. The important operands are if_match: the value named 'if match' in this block; group: the value named 'group' in this block. Context: the function explain_sv_line, which handles explain sv line.

Line 468: `return f"This condition selects the following hardware branch only when ‘{condition}‘ is true. Both branche...` This returns ‘f"This condition selects the following hardware branch only when ‘{condition}‘ is true. Both branches exist as gates; the condition controls a multiplexer rather than making software jump. {summarize_expression(condition)} Context: {context}."‘ to the caller of the function explain_sv_line, which handles explain sv line, ending this invocation. The important operands are f: the value named 'f' in this block; This: the value named 'this' in this block; condition: the value named 'condition' in this block.

Line 469: `if re.search(r"\b(?:unique\s+)?case\s*\((.*)\)", stripped):` This executes the following indented host-code branch only when ‘re.search(r"\b(?:unique\s+)?case\s*\((.*)\)", stripped)‘ is true. The important operands are re: the value named ’re’ in this block; search: the value named ’search’ in this block; r: the value named ’r’ in this block. Context: the function explain_sv_line, which handles explain sv line.

Line 470: `selector = re.search(r"\((.*)\)", stripped).group(1)` This assigns ‘re.search(r"\((.*)\)", stripped).group(1)‘ to ‘selector ‘ in host memory. Here selector means the value named ’selector’ in this block. The important operands are re: the value named ’re’ in this block; search: the value named ’search’ in this block; r: the value named ’r’ in this block. Context: the function explain_sv_line, which handles explain sv line.

Line 471: `return f"This starts a multiplexer/state decode selected by ‘{selector}‘. ‘unique‘ allows tools to diagnose...` This returns ‘f"This starts a multiplexer/state decode selected by ‘{selector}‘. ‘unique‘ allows tools to diagnose overlapping or missing legal choices and optimize on the expectation that one branch matches."‘ to the caller of the function explain_sv_line, which handles explain sv line, ending this invocation. The important operands are f: the value named ’f’ in this block; This: the value named ’this’ in this block; starts: the value named ’starts’ in this block.

Line 472: `label = re.match(r"([A-Za-z_][A-Za-z0-9_$]*)\s*:\s*(.*)", stripped)` This assigns ‘re.match(r"([A-Za-z_][A-Za-z0-9_$]*)\s*:\s*(.*)", stripped)‘ to ‘label ‘ in host memory. Here label means the value named ’label’ in this block. The important operands are re: the value named ’re’ in this block; match: the value named ’match’ in this block; r: the value named ’r’ in this block. Context: the function explain_sv_line, which handles explain sv line.

Line 473: `if label:` This executes the following indented host-code branch only when ‘label‘ is true. The important operands are label: the value named ’label’ in this block. Context: the function explain_sv_line, which handles explain sv line.

Line 474: `name, action = label.groups()` This assigns ‘label.groups()‘ to ‘name, action ‘ in host memory. Here name means the value named ’name’ in this block. The important operands are label: the value named ’label’ in this block; groups: the value named ’groups’ in this block. Context: the function explain_sv_line, which handles explain sv line.

Line 475: `meaning = next((value for key, value in STATE_MEANINGS.items() if key in name), "performs this explicitly n...` This assigns ‘next((value for key, value in STATE_MEANINGS.items() if key in name), "performs this explicitly named phase")‘ to ‘meaning ‘ in host memory. Here meaning means the arithmetic average used by normalization. The important operands are next: the value named ’next’ in this block; value: the value named ’value’ in this block; for: the value named ’for’ in this block. Context: the function explain_sv_line, which handles explain sv line.

Line 476: `return f"This is the {name} case branch, which {meaning}. The same-cycle action begins with ‘{action}‘; con...` This returns ‘f"This is the {name} case branch, which {meaning}. The same-cycle action begins with ‘{action}‘; context is {context}."‘ to the caller of the function explain_sv_line, which handles explain sv line, ending this invocation. The important operands are f: the value named ’f’ in this block; This: the value named ’this’ in this block; is: the value named ’is’ in this block.

Line 477: `if stripped.startswith("default:"):` This executes the following indented host-code branch only when ‘stripped.startswith("default:")‘ is true. The important operands are stripped: the value named ’stripped’ in this block; startswith: the value named ’startswith’ in this block; default: the value named ’default’ in this block. Context: the function explain_sv_line, which handles explain sv line.

Line 478: `return f"This is the default decode branch. It supplies deterministic behavior for every unlisted bit patte...` This returns ‘f"This is the default decode branch. It supplies deterministic behavior for every unlisted bit pattern, which prevents inferred latches in combinational logic and gives corrupted state/opcode values an explicit recovery or error path. Context: {context}."‘ to the caller of the function explain_sv_line, which handles explain sv line, ending this invocation. The important operands are f: the value named ’f’ in this block; This: the value named ’this’ in this block; is: the value named ’is’ in this block.

Line 479: `port_map = re.match(r"\.([A-Za-z_][A-Za-z0-9_$]*)\s*\((.*?)\)\s*,?$", stripped)` This assigns ‘re.match(r"\.([A-Za-z_][A-Za-z0-9_$]*)\s*\((.*?)\)\s*,?$", stripped)‘ to ‘port_map ‘ in host memory. Here port_map means the value named ’port map’ in this block. The important operands are re: the value named ’re’ in this block; match: the value named ’match’ in this block; r: the value named ’r’ in this block. Context: the function explain_sv_line, which handles explain sv line.

Line 480: `if port_map:` This executes the following indented host-code branch only when ‘port_map‘ is true. The important operands are port_map: the value named ’port map’ in this block. Context: the function explain_sv_line, which handles explain sv line.

Line 481: `port_name, signal = port_map.groups()` This assigns ‘port_map.groups()‘ to ‘port_name, signal ‘ in host memory. Here port_name means the value named ’port name’ in this block. The important operands are port_map: the value named ’port map’ in this block; groups: the value named ’groups’ in this block. Context: the function explain_sv_line, which handles explain sv line.

Line 482: `return f"This connects the child instance's named port '{port_name}' to parent expression '{signal}'. The c...` This returns ‘f"This connects the child instance's named port ‘{port_name}‘ to parent expression ‘{signal}‘. The connection is a physical net bundle after synthesis; direction is declared in the child module, and {identifier_meaning(signal.split('[')[0] or port_name)}."‘ to the caller of the function explain_sv_line, which handles explain sv line, ending this invocation. The important operands are f: the value named ’f’ in this block; This: the value named ’this’ in this block; connects: the value named ’connects’ in this block.

Line 483: `instance = re.match(r"([A-Za-z_][A-Za-z0-9_$]*)\s+(?:#\s*\([^;]*\)\s*)?([A-Za-z_][A-Za-z0-9_$]*)\s*str...` This assigns ‘re.match(r"([A-Za-z_][A-Za-z0-9_$]*)\s+(?:#\s*\([^;]*\)\s*)?([A-Za-z_][A-Za-z0-9_$]*)\s*\(", stripped)‘ to ‘instance ‘ in host memory. Here instance means the value named ’instance’ in this block. The important operands are re: the value named ’re’ in this block; match: the value named ’match’ in this block; r: the value named ’r’ in this block. Context: the function explain_sv_line, which handles explain sv line.

Line 484: `if instance and instance.group(1) not in {"if", "for", "while", "case"}:` This executes the following indented host-code branch only when ‘instance and instance.group(1) not in {"if", "for", "while", "case"}‘ is true. The important operands are instance: the value named ’instance’ in this block; and: the value named ’and’ in this block; group: the value named ’group’ in this block. Context: the function explain_sv_line, which handles explain sv line.

Line 485: `return f"This instantiates module {instance.group(1)} as {instance.group(2)}. Synthesis creates that subord...` This returns ‘f"This instantiates module {instance.group(1)} as {instance.group(2)}. Synthesis creates that subordinate circuit and connects its ports in the lines that follow."‘ to the caller of the function explain_sv_line, which handles explain sv line, ending this invocation. The important operands are f: the value named ’f’ in this block; This: the value named ’this’ in this block; instantiates: the value named ’instantiates’ in this block.

Line 486: `if stripped.startswith("for ") or stripped.startswith("for("):` This executes the following indented host-code branch only when ‘stripped.startswith("for ") or stripped.startswith("for(")‘ is true. The important operands are stripped: the value named ’stripped’ in this block; startswith: the value named ’startswith’ in this block; for: the value named ’for’ in this block. Context: the function explain_sv_line, which handles explain sv line.

Line 487: `return f"This generate/procedural loop repeats the following operation across lanes or entries. In synthesi...` This returns ‘f"This generate/procedural loop repeats the following operation across lanes or entries. In synthesizable RTL, a fixed loop is expanded into parallel or scheduled hardware rather than executed by a CPU. Context: {context}."‘ to the caller of the function explain_sv_line, which handles explain sv line, ending this invocation. The important operands are f: the value named ’f’ in this block; This: the value named ’this’ in this block; generate: the value named ’generate’ in this block.

Line 488: `if stripped in {"begin", "end", "endcase", "endgenerate", "generate"} or stripped.startswith(("end else", "...` This executes the following indented host-code branch only when ‘stripped in {"begin", "end", "endcase", "endgenerate", "generate"} or stripped.startswith(("end else", "else begin"))‘ is true. The important operands are stripped:

the value named 'stripped' in this block; in: the value named 'in' in this block; endcase: the value named 'endcase' in this block. Context: the function explain_sv_line, which handles explain sv line.

Line 489: `return f"This structural keyword opens or closes the branch/process scope described as {context}; it has no...` This returns 'f"This structural keyword opens or closes the branch/process scope described as {context}; it has no arithmetic value of its own."' to the caller of the function explain_sv_line, which handles explain sv line, ending this invocation. The important operands are f: the value named 'f' in this block; This: the value named 'this' in this block; structural: the value named 'structural' in this block.

Line 490: `if stripped.startswith(("$display", "$fatal", "$finish", "assert")):` This executes the following indented host-code branch only when 'stripped.startswith(("$display", "$fatal", "$finish", "assert"))' is true. The important operands are stripped: the value named 'stripped' in this block; startswith: the value named 'startswith' in this block; display: the value named 'display' in this block. Context: the function explain_sv_line, which handles explain sv line.

Line 491: `return "This is a simulation check or diagnostic. It can stop a failing test and print evidence, but it is ...` This returns '"This is a simulation check or diagnostic. It can stop a failing test and print evidence, but it is not part of the synthesized PYNQ circuit."' to the caller of the function explain_sv_line, which handles explain sv line, ending this invocation. The important operands are This: the value named 'this' in this block; is: the value named 'is' in this block; a: the value named 'a' in this block.

Line 492: `return f"Within {context}, this exact statement contributes to the block that {purpose}. {summariz` This returns 'f"Within {context}, this exact statement contributes to the block that {purpose}. {summarize_expression(stripped)}"' to the caller of the function explain_sv_line, which handles explain sv line, ending this invocation. The important operands are f: the value named 'f' in this block; Within: the value named 'within' in this block; context: the value named 'context' in this block.

Line 495: `def explain_python_line(line: str, context: str, purpose: str) -> str:` This starts function explain_python_line. Its indented body performs explain python line as part of the file that generates this source-reference volume and its source-integrity manifest; it runs only when called.

Line 496: `stripped = line.strip()` This assigns 'line.strip()' to 'stripped ' in host memory. Here stripped means the value named 'stripped' in this block. The important operands are line: the value named 'line' in this block; strip: the value named 'strip' in this block. Context: the function explain_python_line, which handles explain python line.

Line 497: `if stripped.startswith("#"):` This executes the following indented host-code branch only when 'stripped.startswith is true. The important operands are stripped: the value named 'stripped' in this block; startswith: the value named 'startswith' in this block. Context: the function explain_python_line, which handles explain python line.

Line 498: `return f"The comment records this intent: {stripped[1:].strip()} It applies inside {context}."` This returns 'f"The comment records this intent: {stripped[1:].strip()} It applies inside {context}."' to the caller of the function explain_python_line, which handles explain python line, ending this invocation. The important operands are f: the value named 'f' in this block; The: the value named 'the' in this block; comment: the value named 'comment' in this block.

Line 499: `if stripped.startswith(("import ", "from ")):` This executes the following indented host-code branch only when 'stripped.startswith(("import ", "from "))' is true. The important operands are stripped: the value named 'stripped' in this block; startswith: the value named 'startswith' in this block; import: the value named 'import' in this block. Context: the function explain_python_line, which handles explain python line.

Line 500: `return f"This imports the named Python API so {context} can use it explicitly. Imports execute on the host ...` This returns 'f"This imports the named Python API so {context} can use it explicitly. Imports execute on the host processor and create no FPGA hardware."' to the caller of the function explain_python_line, which handles explain python line, ending this invocation. The important operands are f: the value named 'f' in this block; This: the value named 'this' in this block; imports: the value named 'imports' in this block.

Line 501: `if stripped.startswith("class "):` This executes the following indented host-code branch only when ‘stripped.startswith("class ")‘ is true. The important operands are stripped: the value named ’stripped’ in this block; startswith: the value named ’startswith’ in this block; class: the value named ’class’ in this block. Context: the function explain_python_line, which handles explain python line.

Line 502: `name = stripped.split()[1].split("(")[0].rstrip(":")` This assigns ‘stripped.split()[1].split("(")[0].rstrip(":")‘ to ‘name ‘ in host memory. Here name means the value named ’name’ in this block. The important operands are stripped: the value named ’stripped’ in this block; split: the value named ’split’ in this block; rstrip: the value named ’rstrip’ in this block. Context: the function explain_python_line, which handles explain python line.

Line 503: `return f"This defines class {name}, which groups data and methods for {humanize(name)}. Instances exist in ...` This returns ‘f"This defines class {name}, which groups data and methods for {humanize(name)}. Instances exist in host memory and organize the flow that {purpose}."‘ to the caller of the function explain_python_line, which handles explain python line, ending this invocation. The important operands are f: the value named ’f’ in this block; This: the value named ’this’ in this block; defines: the value named ’defines’ in this block.

Line 504: `if stripped.startswith(("def ", "async def ")):` This executes the following indented host-code branch only when ‘stripped.startswith(("def ", "async def "))‘ is true. The important operands are stripped: the value named ’stripped’ in this block; startswith: the value named ’startswith’ in this block; def: the value named ’def’ in this block. Context: the function explain_python_line, which handles explain python line.

Line 505: `name = stripped.split("def ", 1)[1].split("(", 1)[0]` This assigns ‘stripped.split("def ", 1)[1].split("(", 1)[0]‘ to ‘name ‘ in host memory. Here name means the value named ’name’ in this block. The important operands are stripped: the value named ’stripped’ in this block; split: the value named ’split’ in this block; def: the value named ’def’ in this block. Context: the function explain_python_line, which handles explain python line.

Line 506: `return f"This starts function {name}. Its indented body performs {humanize(name)} as part of the file that ...` This returns ‘f"This starts function {name}. Its indented body performs {humanize(name)} as part of the file that {purpose}; it runs only when called."‘ to the caller of the function explain_python_line, which handles explain python line, ending this invocation. The important operands are f: the value named ’f’ in this block; This: the value named ’this’ in this block; starts: the value named ’starts’ in this block.

Line 507: `if stripped.startswith("return"):` This executes the following indented host-code branch only when ‘stripped.startswith("return")‘ is true. The important operands are stripped: the value named ’stripped’ in this block; startswith: the value named ’startswith’ in this block. Context: the function explain_python_line, which handles explain python line.

Line 508: `value = stripped.removeprefix("return").strip()` This assigns ‘stripped.removeprefix("return").strip()‘ to ‘value ‘ in host memory. Here value means the value named ’value’ in this block. The important operands are stripped: the value named ’stripped’ in this block; removeprefix: the value named ’removeprefix’ in this block; strip: the value named ’strip’ in this block. Context: the function explain_python_line, which handles explain python line.

Line 509: `return f"This returns ‘{value}‘ to the caller of {context}, ending this invocation. {summarize_exp` This returns ‘f"This returns ‘{value}‘ to the caller of {context}, ending this invocation. {summarize_expression(value)}"‘ to the caller of the function explain_python_line, which handles explain python line, ending this invocation. The important operands are f: the value named ’f’ in this block; This: the value named ’this’ in this block; returns: the value named ’returns’ in this block.

Line 510: `if stripped.startswith("raise "):` This executes the following indented host-code branch only when ‘stripped.startswith("raise ")‘ is true. The important operands are stripped: the value named ’stripped’ in this block; startswith: the value named ’startswith’ in this block; raise: the value named ’raise’ in this block. Context: the function explain_python_line, which handles explain python line.

Line 511: `return f"This rejects an invalid state by raising `{stripped[6:]}`. Failing before DMA prevents malformed s...` This returns `f"This rejects an invalid state by raising `{stripped[6:]}`. Failing before DMA prevents malformed shapes or artifacts from silently becoming hardware results."` to the caller of the function explain_python_line, which handles explain python line, ending this invocation. The important operands are f: the value named 'f' in this block; This: the value named 'this' in this block; rejects: the value named 'rejects' in this block.

Line 512: `if stripped.startswith("assert "):` This executes the following indented host-code branch only when `stripped.startswith("assert ")` is true. The important operands are stripped: the value named 'stripped' in this block; startswith: the value named 'startswith' in this block; assert: the value named 'assert' in this block. Context: the function explain_python_line, which handles explain python line.

Line 513: `return f"This test requires `{stripped[7:]}` to be true. A false result fails verification instead of allow...` This returns `f"This test requires `{stripped[7:]}` to be true. A false result fails verification instead of allowing an unchecked numerical or protocol mismatch."` to the caller of the function explain_python_line, which handles explain python line, ending this invocation. The important operands are f: the value named 'f' in this block; This: the value named 'this' in this block; test: the value named 'test' in this block.

Line 514: `if_match = re.match(r"(?:el)?if\s+(.+):$", stripped)` This assigns `re.match(r"(?:el)?if\s+(.+):$", stripped)` to `if_match ` in host memory. Here if_match means the value named 'if match' in this block. The important operands are re: the value named 're' in this block; match: the value named 'match' in this block; r: the value named 'r' in this block. Context: the function explain_python_line, which handles explain python line.

Line 515: `if if_match:` This executes the following indented host-code branch only when `if_match` is true. The important operands are if_match: the value named 'if match' in this block. Context: the function explain_python_line, which handles explain python line.

Line 516: `condition = if_match.group(1)` This assigns `if_match.group(1)` to `condition ` in host memory. Here condition means the value named 'condition' in this block. The important operands are if_match: the value named 'if match' in this block; group: the value named 'group' in this block. Context: the function explain_python_line, which handles explain python line.

Line 517: `return f"This executes the following indented host-code branch only when `{condition}` is true. {summarize_...` This returns `f"This executes the following indented host-code branch only when `{condition}` is true. {summarize_expression(condition)} Context: {context}."` to the caller of the function explain_python_line, which handles explain python line, ending this invocation. The important operands are f: the value named 'f' in this block; This: the value named 'this' in this block; executes: the value named 'executes' in this block.

Line 518: `if stripped == "else":` This executes the following indented host-code branch only when `stripped == "else:"` is true. The important operands are stripped: the value named 'stripped' in this block. Context: the function explain_python_line, which handles explain python line.

Line 519: `return f"This begins the alternative host-code branch when the preceding condition was false, still inside ...` This returns `f"This begins the alternative host-code branch when the preceding condition was false, still inside {context}."` to the caller of the function explain_python_line, which handles explain python line, ending this invocation. The important operands are f: the value named 'f' in this block; This: the value named 'this' in this block; begins: the value named 'begins' in this block.

Line 520: `loop = re.match(r"for\s+(.+?)\s+in\s+(.+):$", stripped)` This assigns `re.match(r"for\s+(.+?)\s+in\s+(.+):$", stripped)` to `loop ` in host memory. Here loop means the value named 'loop' in this block. The important operands are re: the value named 're' in this block; match: the value named 'match' in this block; r: the value named 'r' in this block. Context: the function explain_python_line, which handles explain python line.

Line 521: `if loop:` This executes the following indented host-code branch only when `loop` is true. The important operands are loop: the value named 'loop' in this block. Context: the function explain_python_line, which handles explain python line.

Line 522: `target, source = loop.groups()` This assigns ‘loop.groups()‘ to ‘target, source ‘ in host memory. Here target means the value named ’target’ in this block. The important operands are loop: the value named ’loop’ in this block; groups: the value named ’groups’ in this block. Context: the function explain_python_line, which handles explain python line.

Line 523: `return f"This iterates {target} over ‘{source}‘. Each iteration repeats the indented host operation, common...` This returns ‘f"This iterates {target} over ‘{source}‘. Each iteration repeats the indented host operation, commonly once per layer, tile, timestep, or test case in {context}."‘ to the caller of the function explain_python_line, which handles explain python line, ending this invocation. The important operands are f: the value named ’f’ in this block; This: the value named ’this’ in this block; iterates: the value named ’iterates’ in this block.

Line 524: `if stripped.startswith("while "):` This executes the following indented host-code branch only when ‘stripped.startswith("while ")‘ is true. The important operands are stripped: the value named ’stripped’ in this block; startswith: the value named ’startswith’ in this block; while: the value named ’while’ in this block. Context: the function explain_python_line, which handles explain python line.

Line 525: `return f"This repeats the following host-code block while ‘{stripped[6:-1]}‘ remains true; surrounding time...` This returns ‘f"This repeats the following host-code block while ‘{stripped[6:-1]}‘ remains true; surrounding timeout/error logic prevents an unbounded hardware wait."‘ to the caller of the function explain_python_line, which handles explain python line, ending this invocation. The important operands are f: the value named ’f’ in this block; This: the value named ’this’ in this block; repeats: the value named ’repeats’ in this block.

Line 526: `if stripped.startswith("with "):` This executes the following indented host-code branch only when ‘stripped.startswith("with ")‘ is true. The important operands are stripped: the value named ’stripped’ in this block; startswith: the value named ’startswith’ in this block; with: the value named ’with’ in this block. Context: the function explain_python_line, which handles explain python line.

Line 527: `return f"This opens a managed resource scope for ‘{stripped[5:-1]}‘ so files, tracing, or temporary state a...` This returns ‘f"This opens a managed resource scope for ‘{stripped[5:-1]}‘ so files, tracing, or temporary state are finalized even if {context} raises an error."‘ to the caller of the function explain_python_line, which handles explain python line, ending this invocation. The important operands are f: the value named ’f’ in this block; This: the value named ’this’ in this block; opens: the value named ’opens’ in this block.

Line 528: `assignment = re.match(r"([A-Za-z_][A-Za-z0-9_.\[\], ]*)\s*(?::[^=]+)?\s*=\s*(.+)", stripped)` This assigns ‘re.match(r"([A-Za-z_][A-Za-z0-9_.\[\],]*)\s*(?::[^=]+)?\s*=\s*(.+)", stripped)‘ to ‘assignment ‘ in host memory. Here assignment means the value named ’assignment’ in this block. The important operands are re: the value named ’re’ in this block; match: the value named ’match’ in this block; r: the value named ’r’ in this block. Context: the function explain_python_line, which handles explain python line.

Line 529: `if assignment and "==" not in stripped and ">=" not in stripped and "<=" not in stripped and "!=" not in st...` This executes the following indented host-code branch only when ‘assignment and "==" not in stripped and ">=" not in stripped and "<=" not in stripped and "!=" not in stripped‘ is true. The important operands are assignment: the value named ’assignment’ in this block; and: the value named ’and’ in this block; not: the value named ’not’ in this block. Context: the function explain_python_line, which handles explain python line.

Line 530: `lhs, rhs = assignment.groups()` This assigns ‘assignment.groups()‘ to ‘lhs, rhs ‘ in host memory. Here lhs means the value named ’lhs’ in this block. The important operands are assignment: the value named ’assignment’ in this block; groups: the value named ’groups’ in this block. Context: the function explain_python_line, which handles explain python line.

Line 531: `name = lhs.split(",", 1)[0].strip().split("[")[0].split(".")[-1]` This assigns ‘lhs.split(",", 1)[0].strip().spl
1]‘ to ‘name ‘ in host memory. Here name means the value named ’name’ in this block. The important operands are lhs: the value named ’lhs’ in this block; split: the value named ’split’ in this block; strip: the value named ’strip’ in this block. Context: the function explain_python_line, which handles explain python line.

Line 532: `return f"This assigns ‘{rhs}‘ to ‘{lhs}‘ in host memory. Here {name} means {identifier_meaning(nam {sum...` This returns ‘f"This assigns ‘{rhs}‘ to ‘{lhs}‘ in host memory. Here {name} means {identifier_meaning(name)}. {summarize_expression(rhs)} Context: {context}."‘ to the caller of the function explain_python_line, which handles explain python line, ending this invocation. The important operands are f: the value named ’f’ in this block; This: the value named ’this’ in this block; assigns: the value named ’assigns’ in this block.

Line 533: `if stripped.startswith(("try:", "except ", "finally:")):` This executes the following indented host-code branch only when ‘stripped.startswith(("try:", "except ", "finally:"))‘ is true. The important operands are stripped: the value named ’stripped’ in this block; startswith: the value named ’startswith’ in this block; try: the value named ’try’ in this block. Context: the function explain_python_line, which handles explain python line.

Line 534: `return f"This is explicit host-side failure handling inside {context}; it ensures malformed artifacts, DMA ...` This returns ‘f"This is explicit host-side failure handling inside {context}; it ensures malformed artifacts, DMA errors, and tool failures are surfaced or cleaned up deterministically."‘ to the caller of the function explain_python_line, which handles explain python line, ending this invocation. The important operands are f: the value named ’f’ in this block; This: the value named ’this’ in this block; is: the value named ’is’ in this block.

Line 535: `if stripped.startswith("if __name__"):` This executes the following indented host-code branch only when ‘stripped.startswith("if ___name___")‘ is true. The important operands are stripped: the value named ’stripped’ in this block; startswith: the value named ’startswith’ in this block; ___name___: the value named ’name’ in this block. Context: the function explain_python_line, which handles explain python line.

Line 536: `return "This standard entry-point guard runs the command-line main function only when this file is executed...` This returns ‘"This standard entry-point guard runs the command-line main function only when this file is executed directly, while keeping its definitions importable by tests."‘ to the caller of the function explain_python_line, which handles explain python line, ending this invocation. The important operands are This: the value named ’this’ in this block; standard: the value named ’standard’ in this block; entry: the value named ’entry’ in this block.

Line 537: `if stripped in {"(", ")", "[", "]", "{", "}"} or stripped.endswith(("(", "[", "{")):` This executes the following indented host-code branch only when ‘stripped in {"(", ")", "[", "]", "{", "}"} or stripped.endswith(("(", "[", "{"))‘ is true. The important operands are stripped: the value named ’stripped’ in this block; in: the value named ’in’ in this block; or: the value named ’or’ in this block. Context: the function explain_python_line, which handles explain python line.

Line 538: `return f"This line opens or closes a multi-line Python expression inside {context}; the neighboring lines s...` This returns ‘f"This line opens or closes a multi-line Python expression inside {context}; the neighboring lines supply its arguments or elements."‘ to the caller of the function explain_python_line, which handles explain python line, ending this invocation. The important operands are f: the value named ’f’ in this block; This: the value named ’this’ in this block; line: the value named ’line’ in this block.

Line 539: `if stripped.startswith("@"):` This executes the following indented host-code branch only when ‘stripped.startswith is true. The important operands are stripped: the value named ’stripped’ in this block; startswith: the value named ’startswith’ in this block. Context: the function explain_python_line, which handles explain python line.

Line 540: `return f"This decorator changes how the following class or function is constructed. ‘{stripped}‘ is applied...` This returns ‘f"This decorator changes how the following class or function is constructed. ‘{stripped}‘ is applied at import time on the host and is part of {context}; it creates no FPGA circuit by itself."‘ to the caller of the function explain_python_line, which handles explain python line, ending this invocation. The important operands are f: the value named ’f’ in this block; This: the value named ’this’ in this block; decorator: the value named ’decorator’ in this block.

Line 541: `if stripped.startswith(('"""', ""'")):` This executes the following indented host-code branch only when ‘stripped.startswith(('"""', ""'"))‘ is true. The important operands are stripped: the value named ’stripped’ in this

block; startswith: the value named 'startswith' in this block. Context: the function explain_python_line, which handles explain python line.

Line 542: `return f"This is executable documentation attached to {context}.  It states the intended contract that tests...` This returns 'f"This is executable documentation attached to {context}. It states the intended contract that tests and callers should enforce, but the text itself does not transform data or issue hardware work."' to the caller of the function explain_python_line, which handles explain python line, ending this invocation. The important operands are f: the value named 'f' in this block; This: the value named 'this' in this block; is: the value named 'is' in this block.

Line 543: `if ".add_argument(" in stripped:` This executes the following indented host-code branch only when '".add_argument(" in stripped' is true. The important operands are add_argument: the value named 'add argument' in this block; in: the value named 'in' in this block; stripped: the value named 'stripped' in this block. Context: the function explain_python_line, which handles explain python line.

Line 544: `return f"This declares a command-line option for {context}.  Its name, type, default, and required status ma...` This returns 'f"This declares a command-line option for {context}. Its name, type, default, and required status make the run configuration explicit and reproducible instead of relying on an invisible interactive setting."' to the caller of the function explain_python_line, which handles explain python line, ending this invocation. The important operands are f: the value named 'f' in this block; This: the value named 'this' in this block; declares: the value named 'declares' in this block.

Line 545: `call = re.match(r"([A-Za-z_][A-Za-z0-9_.]*)\((.*)\),?$", stripped)` This assigns 're.match(r"([A-Za-z_][A-Za-z0-9_.]*)\((.*)\),?$", stripped)' to 'call ' in host memory. Here call means the value named 'call' in this block. The important operands are re: the value named 're' in this block; match: the value named 'match' in this block; r: the value named 'r' in this block. Context: the function explain_python_line, which handles explain python line.

Line 546: `if call:` This executes the following indented host-code branch only when 'call' is true. The important operands are call: the value named 'call' in this block. Context: the function explain_python_line, which handles explain python line.

Line 547: `return f"This calls '{call.group(1)}' with '{call.group(2)}' inside {context}.  The call advances the host-s...` This returns 'f"This calls '{call.group(1)}' with '{call.group(2)}' inside {context}. The call advances the host-side job that {purpose}."' to the caller of the function explain_python_line, which handles explain python line, ending this invocation. The important operands are f: the value named 'f' in this block; This: the value named 'this' in this block; calls: the value named 'calls' in this block.

Line 548: `return f"Inside {context}, this statement advances the host implementation that {purpose}. {summarize_expre...` This returns 'f"Inside {context}, this statement advances the host implementation that {purpose}. {summarize_expression(stripped)}"' to the caller of the function explain_python_line, which handles explain python line, ending this invocation. The important operands are f: the value named 'f' in this block; Inside: the value named 'inside' in this block; context: the value named 'context' in this block.

Line 551: `def explain_script_line(line:  str, suffix:  str, purpose:  str) -> str:` This starts function explain_script_line. Its indented body performs explain script line as part of the file that generates this source-reference volume and its source-integrity manifest; it runs only when called.

Line 552: `stripped = line.strip()` This assigns 'line.strip()' to 'stripped ' in host memory. Here stripped means the value named 'stripped' in this block. The important operands are line: the value named 'line' in this block; strip: the value named 'strip' in this block. Context: the function explain_script_line, which handles explain script line.

Line 553: `if stripped.startswith("#"):` This executes the following indented host-code branch only when 'stripped.startswith is true. The important operands are stripped: the value named 'stripped' in this block; startswith: the value named 'startswith' in this block. Context: the function explain_script_line, which handles explain script line.

Line 554: `return f"This comment documents the batch-flow intent: {stripped[1:].strip()}"` This returns ‘f"This comment documents the batch-flow intent: {stripped[1:].strip()}"‘ to the caller of the function explain_script_line, which handles explain script line, ending this invocation. The important operands are f: the value named ’f’ in this block; This: the value named ’this’ in this block; comment: the value named ’comment’ in this block.

Line 555: `if suffix == ".tcl":` This executes the following indented host-code branch only when ‘suffix == ".tcl"‘ is true. The important operands are suffix: the value named ’suffix’ in this block; tcl: the value named ’tcl’ in this block. Context: the function explain_script_line, which handles explain script line.

Line 556: `if stripped.startswith("read_verilog"):` This executes the following indented host-code branch only when ‘stripped.startswith("read_verilog")‘ is true. The important operands are stripped: the value named ’stripped’ in this block; startswith: the value named ’startswith’ in this block; read_verilog: the value named ’read verilog’ in this block. Context: the function explain_script_line, which handles explain script line.

Line 557: `return "This loads the listed RTL into Vivado’s in-memory design so the subsequent synthesis uses the repos...` This returns ‘"This loads the listed RTL into Vivado’s in-memory design so the subsequent synthesis uses the repository source."‘ to the caller of the function explain_script_line, which handles explain script line, ending this invocation. The important operands are This: the value named ’this’ in this block; loads: the value named ’loads’ in this block; the: the value named ’the’ in this block.

Line 558: `if stripped.startswith("synth_design"):` This executes the following indented host-code branch only when ‘stripped.startswith("synth_design")‘ is true. The important operands are stripped: the value named ’stripped’ in this block; startswith: the value named ’startswith’ in this block; synth_design: the value named ’synth design’ in this block. Context: the function explain_script_line, which handles explain script line.

Line 559: `return "This invokes Vivado synthesis for the named top and FPGA part, mapping behavioral RTL into LUT, fli...` This returns ‘"This invokes Vivado synthesis for the named top and FPGA part, mapping behavioral RTL into LUT, flip-flop, BRAM, and DSP primitives."‘ to the caller of the function explain_script_line, which handles explain script line, ending this invocation. The important operands are This: the value named ’this’ in this block; invokes: the value named ’invokes’ in this block; Vivado: the value named ’vivado’ in this block.

Line 560: `if stripped.startswith(("opt_design", "place_design", "phys_opt_design", "route_design")):` This executes the following indented host-code branch only when ‘stripped.startswith(("opt_design", "place_design", "phys_opt_design", "route_design"))‘ is true. The important operands are stripped: the value named ’stripped’ in this block; startswith: the value named ’startswith’ in this block; opt_design: the value named ’opt design’ in this block. Context: the function explain_script_line, which handles explain script line.

Line 561: `return f"This runs Vivado implementation command ‘{stripped}‘, changing the physical netlist or placement/r...` This returns ‘f"This runs Vivado implementation command ‘{stripped}‘, changing the physical netlist or placement/routing needed for real timing."‘ to the caller of the function explain_script_line, which handles explain script line, ending this invocation. The important operands are f: the value named ’f’ in this block; This: the value named ’this’ in this block; runs: the value named ’runs’ in this block.

Line 562: `if stripped.startswith("report_") or stripped.startswith("write_"):` This executes the following indented host-code branch only when ‘stripped.startswith("report_") or stripped.startswith("write_")‘ is true. The important operands are stripped: the value named ’stripped’ in this block; startswith: the value named ’startswith’ in this block; report_: the value named ’report’ in this block. Context: the function explain_script_line, which handles explain script line.

Line 563: `return f"This writes an auditable Vivado artifact using ‘{stripped}‘; later documentation reads the resulti...` This returns ‘f"This writes an auditable Vivado artifact using ‘{stripped}‘; later documentation reads the resulting report rather than inventing a metric."‘ to the caller of the function explain_script_line, which handles explain script line, ending this invocation. The important operands are f: the value named ’f’ in this block; This: the value named ’this’ in this block; writes: the value named ’writes’ in this block.

Line 564: `if stripped.startswith("create_clock"):` This executes the following indented host-code branch only when ‘stripped.startswith("create_clock")‘ is true. The important operands are stripped: the value named ’stripped’ in this block; startswith: the value named ’startswith’ in this block; create_clock: the value named ’create clock’ in this block. Context: the function explain_script_line, which handles explain script line.

Line 565: `return "This declares the clock period against which Vivado checks every synchronous setup and hold path."` This returns ‘"This declares the clock period against which Vivado checks every synchronous setup and hold path."‘ to the caller of the function explain_script_line, which handles explain script line, ending this invocation. The important operands are This: the value named ’this’ in this block; declares: the value named ’declares’ in this block; the: the value named ’the’ in this block.

Line 566: `if stripped.startswith("create_bd_cell"):` This executes the following indented host-code branch only when ‘stripped.startswith("create_bd_cell")‘ is true. The important operands are stripped: the value named ’stripped’ in this block; startswith: the value named ’startswith’ in this block; create_bd_cell: the value named ’create bd cell’ in this block. Context: the function explain_script_line, which handles explain script line.

Line 567: `return f"This adds the named IP or module-reference cell to the Vivado block design. The cell becomes a con...` This returns ‘f"This adds the named IP or module-reference cell to the Vivado block design. The cell becomes a concrete PS, DMA, converter, interconnect, reset, or accelerator instance after generation: ‘{stripped}‘."‘ to the caller of the function explain_script_line, which handles explain script line, ending this invocation. The important operands are f: the value named ’f’ in this block; This: the value named ’this’ in this block; adds: the value named ’adds’ in this block.

Line 568: `if stripped.startswith("connect_bd_intf_net"):` This executes the following indented host-code branch only when ‘stripped.startswith("connect_bd_intf_net")‘ is true. The important operands are stripped: the value named ’stripped’ in this block; startswith: the value named ’startswith’ in this block; connect_bd_intf_net: the value named ’connect bd intf net’ in this block. Context: the function explain_script_line, which handles explain script line.

Line 569: `return f"This connects two complete block-design interfaces, carrying all AXI channel signals defined by th...` This returns ‘f"This connects two complete block-design interfaces, carrying all AXI channel signals defined by that interface. Vivado validates widths, directions, clocks, and protocol compatibility for ‘{stripped}‘."‘ to the caller of the function explain_script_line, which handles explain script line, ending this invocation. The important operands are f: the value named ’f’ in this block; This: the value named ’this’ in this block; connects: the value named ’connects’ in this block.

Line 570: `if stripped.startswith("connect_bd_net"):` This executes the following indented host-code branch only when ‘stripped.startswith("connect_bd_net")‘ is true. The important operands are stripped: the value named ’stripped’ in this block; startswith: the value named ’startswith’ in this block; connect_bd_net: the value named ’connect bd net’ in this block. Context: the function explain_script_line, which handles explain script line.

Line 571: `return f"This connects scalar or bus pins in the block design. For clocks and resets, this exact connection...` This returns ‘f"This connects scalar or bus pins in the block design. For clocks and resets, this exact connection decides the timing domain and reset island of every attached register: ‘{stripped}‘."‘ to the caller of the function explain_script_line, which handles explain script line, ending this invocation. The important operands are f: the value named ’f’ in this block; This: the value named ’this’ in this block; connects: the value named ’connects’ in this block.

Line 572: `if stripped.startswith("assign_bd_address"):` This executes the following indented host-code branch only when ‘stripped.startswith("assign_bd_address")‘ is true. The important operands are stripped: the value named ’stripped’ in this block; startswith: the value named ’startswith’ in this block; assign_bd_address: the value named ’assign bd address’ in this block. Context: the function explain_script_line, which handles explain script line.

Line 573: `return "This asks Vivado to establish an AXI address map; following explicit offset/range settings make the...` This returns ‘"This asks Vivado to establish an AXI address map; following explicit offset/range settings make the software-visible register addresses stable across rebuilds."‘ to the caller of the function explain_script_line, which handles explain script line, ending this invocation. The important operands are This: the value named ’this’ in this block; asks: the value named ’asks’ in this block; Vivado: the value named ’vivado’ in this block.

Line 574: `if stripped.startswith(("launch_runs", "wait_on_run", "open_run")):` This executes the following indented host-code branch only when ‘stripped.startswith(("launch_runs", "wait_on_run", "open_run"))‘ is true. The important operands are stripped: the value named ’stripped’ in this block; startswith: the value named ’startswith’ in this block; launch_runs: the value named ’launch runs’ in this block. Context: the function explain_script_line, which handles explain script line.

Line 575: `return f"This controls a named Vivado synthesis or implementation run with ‘{stripped}‘. Waiting and openin...` This returns ‘f"This controls a named Vivado synthesis or implementation run with ‘{stripped}‘. Waiting and opening the completed run prevents reports from reading an earlier or unfinished netlist."‘ to the caller of the function explain_script_line, which handles explain script line, ending this invocation. The important operands are f: the value named ’f’ in this block; This: the value named ’this’ in this block; controls: the value named ’controls’ in this block.

Line 576: `if stripped.startswith("read_saif"):` This executes the following indented host-code branch only when ‘stripped.startswith("read_saif")‘ is true. The important operands are stripped: the value named ’stripped’ in this block; startswith: the value named ’startswith’ in this block; read_saif: the value named ’read saif’ in this block. Context: the function explain_script_line, which handles explain script line.

Line 577: `return f"This annotates implemented nets with measured XSim switching activity from the named SAIF file. Th...` This returns ‘f"This annotates implemented nets with measured XSim switching activity from the named SAIF file. The retained match report quantifies which simulated names mapped to routed nets: ‘{stripped}‘."‘ to the caller of the function explain_script_line, which handles explain script line, ending this invocation. The important operands are f: the value named ’f’ in this block; This: the value named ’this’ in this block; annotates: the value named ’annotates’ in this block.

Line 578: `else:` This begins the alternative host-code branch when the preceding condition was false, still inside the function explain_script_line, which handles explain script line.

Line 579: `if "$ErrorActionPreference" in stripped:` This executes the following indented host-code branch only when ‘"$ErrorActionPreference" in stripped‘ is true. The important operands are ErrorActionPreference: the value named ’error action preference’ in this block; in: the value named ’in’ in this block; stripped: the value named ’stripped’ in this block. Context: the function explain_script_line, which handles explain script line.

Line 580: `return "This makes PowerShell stop on errors so a failed prerequisite cannot be hidden by later successful ...` This returns ‘"This makes PowerShell stop on errors so a failed prerequisite cannot be hidden by later successful commands."‘ to the caller of the function explain_script_line, which handles explain script line, ending this invocation. The important operands are This: the value named ’this’ in this block; makes: the value named ’makes’ in this block; PowerShell: the value named ’power shell’ in this block.

Line 581: `if stripped.startswith("param") or re.match(r"\[[A-Za-z]+\]\$", stripped):` This executes the following indented host-code branch only when ‘stripped.startswith("param") or re.match(r"\[[A-Za-z]+\]\$", stripped)‘ is true. The important operands are stripped: the value named ’stripped’ in this block; startswith: the value named ’startswith’ in this block; param: the value named ’param’ in this block. Context: the function explain_script_line, which handles explain script line.

Line 582: `return "This declares a typed command-line parameter so the flow can be rerun with explicit, validated path...` This returns ‘"This declares a typed command-line parameter so the flow can be rerun with explicit, validated paths and options."‘ to the caller of the function explain_script_line, which handles explain script line,

ending this invocation. The important operands are This: the value named 'this' in this block; declares: the value named 'declares' in this block; a: the value named 'a' in this block.

Line 583: `if "LASTEXITCODE" in stripped:` This executes the following indented host-code branch only when ‘"LASTEXITCODE" in stripped‘ is true. The important operands are LASTEXITCODE: the AXI-Stream marker for the final beat of a packet or command payload; in: the value named 'in' in this block; stripped: the value named 'stripped' in this block. Context: the function explain_script_line, which handles explain script line.

Line 584: `return "This checks the external program's process exit code and turns a failed compiler, simulator, or Viv...` This returns ‘"This checks the external program's process exit code and turns a failed compiler, simulator, or Vivado run into a failed pipeline."‘ to the caller of the function explain_script_line, which handles explain script line, ending this invocation. The important operands are This: the value named 'this' in this block; checks: the value named 'checks' in this block; the: the value named 'the' in this block.

Line 585: `if re.search(r"vivado|xsim|xelab|xvlog|iverilog|verilator|python", stripped, re.IGNORECASE):` This executes the following indented host-code branch only when ‘re.search(r"vivado|xsim|xelab|xvlog|iverilog|verilator|python", stripped, re.IGNORECASE)‘ is true. The important operands are re: the value named 're' in this block; search: the value named 'search' in this block; r: the value named 'r' in this block. Context: the function explain_script_line, which handles explain script line.

Line 586: `return f"This locates or invokes a required tool as part of the script that {purpose}; the exact command an...` This returns ‘f"This locates or invokes a required tool as part of the script that {purpose}; the exact command and arguments remain visible here for reproducibility."‘ to the caller of the function explain_script_line, which handles explain script line, ending this invocation. The important operands are f: the value named 'f' in this block; This: the value named 'this' in this block; locates: the value named 'locates' in this block.

Line 587: `if stripped.startswith(("Resolve-Path", "Join-Path", "$ProjectRoot")) or "[System.IO.Path]::GetFull in...` This executes the following indented host-code branch only when ‘stripped.startswith(("Resolve-Path", "Join-Path", "$ProjectRoot")) or "[System.IO.Path]::GetFullPath" in stripped‘ is true. The important operands are stripped: the value named 'stripped' in this block; startswith: the value named 'startswith' in this block; Resolve: the value named 'resolve' in this block. Context: the function explain_script_line, which handles explain script line.

Line 588: `return f"This resolves a deterministic filesystem location for the flow that {purpose}. Literal/fu paths ...` This returns ‘f"This resolves a deterministic filesystem location for the flow that {purpose}. Literal/full paths prevent a different working directory from silently selecting the wrong source, checkpoint, or output."‘ to the caller of the function explain_script_line, which handles explain script line, ending this invocation. The important operands are f: the value named 'f' in this block; This: the value named 'this' in this block; resolves: the value named 'resolves' in this block.

Line 589: `if stripped.startswith("New-Item"):` This executes the following indented host-code branch only when ‘stripped.startswith("New-Item")‘ is true. The important operands are stripped: the value named 'stripped' in this block; startswith: the value named 'startswith' in this block; New: the value named 'new' in this block. Context: the function explain_script_line, which handles explain script line.

Line 590: `return "This creates the declared output directory before a tool writes into it. '-Force' permits an existi...` This returns ‘"This creates the declared output directory before a tool writes into it. '-Force' permits an existing directory but does not make an external tool failure succeed."‘ to the caller of the function explain_script_line, which handles explain script line, ending this invocation. The important operands are This: the value named 'this' in this block; creates: the value named 'creates' in this block; the: the value named 'the' in this block.

Line 591: `if stripped.startswith("Remove-Item"):` This executes the following indented host-code branch only when ‘stripped.startswith("Remove-Item")‘ is true. The important operands are stripped: the value named 'stripped' in this block; startswith: the value named 'startswith' in this block; Remove: the value named 'remove' in this block. Context: the function explain_script_line, which handles explain script line.

Line 592: `return "This removes the explicitly named rebuildable artifact. The script uses a literal path so wildcard ...` This returns ‘"This removes the explicitly named rebuildable artifact. The script uses a literal path so wildcard expansion cannot delete an unintended neighboring file."‘ to the caller of the function explain_script_line, which handles explain script line, ending this invocation. The important operands are This: the value named ’this’ in this block; removes: the value named ’removes’ in this block; the: the value named ’the’ in this block.

Line 593: `return f"This batch-control line contributes to the flow that {purpose}. {summarize_expression(str` This returns ‘f"This batch-control line contributes to the flow that {purpose}. {summarize_expression(stripped)}"‘ to the caller of the function explain_script_line, which handles explain script line, ending this invocation. The important operands are f: the value named ’f’ in this block; This: the value named ’this’ in this block; batch: the value named ’batch’ in this block.

Line 596: `def latex_escape(text: str) -> str:` This starts function latex_escape. Its indented body performs latex escape as part of the file that generates this source-reference volume and its source-integrity manifest; it runs only when called.

Line 597: `replacements = {` This statement continues through source line 602; the explanation uses the complete expression rather than only the first visual fragment. This assigns ‘{ "\\": r"\textbackslash{}", "&": r"\&", "%": r"\%", "$": r"\$", "#": r"\#", "_": r"_", "{": r"\{", "}": r"\}", "~": r"\textasciitilde{}", "^": r"\textasciicircum{}", "<": r"\textless{}", ">": r"\textgreater{}", }‘ to ‘replacements ‘ in host memory. Here replacements means the value named ’replacements’ in this block. The important operands are r: the value named ’r’ in this block; textbackslash: the value named ’textbackslash’ in this block; _: the value named ” in this block. Context: the function latex_escape, which handles latex escape.

Line 598: `"\\": r"\textbackslash{}", "&": r"\&", "%": r"\%", "$": r"\$",` This is continuation line 2 of the 6-line logical statement that begins at source line 597. Its exact fragment is ‘"\\": r"\textbackslash{}", "&": r"\&", "%": r"\%", "$": r"\$",‘. The important operands are r: the value named ’r’ in this block; textbackslash: the value named ’textbackslash’ in this block. Read together, the complete operation is: This assigns ‘{ "\\": r"\textbackslash{}", "&": r"\&", "%": r"\%", "$": r"\$", "#": r"\#", "_": r"_", "{": r"\{", "}": r"\}", "~": r"\textasciitilde{}", "^": r"\textasciicircum{}", "<": r"\textless{}", ">": r"\textgreater{}", }‘ to ‘replacements ‘ in host memory. Here replacements means the value named ’replacements’ in this block. The important operands are r: the value named ’r’ in this block; textbackslash: the value named ’textbackslash’ in this block; _: the value named ” in this block. Context: the function latex_escape, which handles latex escape.

Line 599: `"#": r"\#", "_": r"\_", "{": r"\{", "}": r"\}",` This is continuation line 3 of the 6-line logical statement that begins at source line 597. Its exact fragment is ‘"#": r"\#", "_": r"_", "{": r"\{", "}": r"\}",‘. The important operands are r: the value named ’r’ in this block; _: the value named ” in this block. Read together, the complete operation is: This assigns ‘{ "\\": r"\textbackslash{}", "&": r"\&", "%": r"\%", "$": r"\$", "#": r"\#", "_": r"_", "{": r"\{", "}": r"\}", "~": r"\textasciitilde{}", "^": r"\textasciicircum{}", "<": r"\textless{}", ">": r"\textgreater{}", }‘ to ‘replacements ‘ in host memory. Here replacements means the value named ’replacements’ in this block. The important operands are r: the value named ’r’ in this block; textbackslash: the value named ’textbackslash’ in this block; _: the value named ” in this block. Context: the function latex_escape, which handles latex escape.

Line 600: `"~": r"\textasciitilde{}", "^": r"\textasciicircum{}", "<": r"\textless{}",` This is continuation line 4 of the 6-line logical statement that begins at source line 597. Its exact fragment is ‘"~": r"\textasciitilde{}", "^": r"\textasciicircum{}", "<": r"\textless{}",‘. The important operands are r: the value named ’r’ in this block; textasciitilde: the value named ’textasciitilde’ in this block; textasciicircum: the value named ’textasciicircum’ in this block. Read together, the complete operation is: This assigns ‘{ "\\": r"\textbackslash{}", "&": r"\&", "%": r"\%", "$": r"\$", "#": r"\#", "_": r"_", "{": r"\{", "}": r"\}", "~": r"\textasciitilde{}", "^": r"\textasciicircum{}", "<": r"\textless{}", ">": r"\textgreater{}", }‘ to ‘replacements ‘ in host memory. Here replacements means the value named ’replacements’ in this block. The important operands are r: the value named ’r’ in this block; textbackslash: the value named ’textbackslash’ in this block; _: the value named ” in this block. Context: the function latex_escape, which handles latex escape.

Line 601: `">": r"\textgreater{}",` This is continuation line 5 of the 6-line logical statement that begins at source line 597. Its exact fragment is ‘">": r"\textgreater{}",‘. The important operands are r: the value named ’r’ in this

block; textgreater: the value named 'textgreater' in this block. Read together, the complete operation is: This assigns '{ "\\": r"\textbackslash{}", "&": r"\&", "%": r"\%", "$": r"\$", "#": r"\#", "_": r"_", "{": r"\{", "}": r"\}", "~": r"\textasciitilde{}", "^": r"\textasciicircum{}", "<": r"\textless{}", ">": r"\textgreater{}", }' to 'replacements ' in host memory. Here replacements means the value named 'replacements' in this block. The important operands are r: the value named 'r' in this block; textbackslash: the value named 'textbackslash' in this block; _: the value named '' in this block. Context: the function latex_escape, which handles latex escape.

Line 602: `}` This is continuation line 6 of the 6-line logical statement that begins at source line 597. Its exact fragment is '}'. The expression is a literal or structural operator and has no hidden software state. Read together, the complete operation is: This assigns '{ "\\": r"\textbackslash{}", "&": r"\&", "%": r"\%", "$": r"\$", "#": r"\#", "_": r"_", "{": r"\{", "}": r"\}", "~": r"\textasciitilde{}", "^": r"\textasciicircum{}", "<": r"\textless{}", ">": r"\textgreater{}", }' to 'replacements ' in host memory. Here replacements means the value named 'replacements' in this block. The important operands are r: the value named 'r' in this block; textbackslash: the value named 'textbackslash' in this block; _: the value named '' in this block. Context: the function latex_escape, which handles latex escape.

Line 603: `return "".join(replacements.get(character, character) for character in text)` This returns '"".join(replacements.get(character, character) for character in text)' to the caller of the function latex_escape, which handles latex escape, ending this invocation. The important operands are join: the value named 'join' in this block; replacements: the value named 'replacements' in this block; get: the value named 'get' in this block.

Line 606: `def source_architecture_notes(entry: SourceEntry, text: str) -> list[tuple[str, str]]:` This starts function source_architecture_notes. Its indented body performs source architecture notes as part of the file that generates this source-reference volume and its source-integrity manifest; it runs only when called.

Line 607: `"""Build a file-level map so line annotations have an understandable frame."""` This is executable documentation attached to the function source_architecture_notes, which handles source architecture notes. It states the intended contract that tests and callers should enforce, but the text itself does not transform data or issue hardware work.

Line 608: `suffix = entry.path.suffix.lower()` This assigns 'entry.path.suffix.lower()' to 'suffix ' in host memory. Here suffix means the value named 'suffix' in this block. The important operands are entry: the value named 'entry' in this block; path: the value named 'path' in this block; suffix: the value named 'suffix' in this block. Context: the function source_architecture_notes, which handles source architecture notes.

Line 609: `dataflow = FILE_DATAFLOWS.get(` This statement continues through source line 612; the explanation uses the complete expression rather than only the first visual fragment. This assigns 'FILE_DATAFLOWS.get(entry.relative, f"This file's end-to-end responsibility is to {entry.purpose}.",)' to 'dataflow ' in host memory. Here dataflow means the value named 'dataflow' in this block. The important operands are FILE_DATAFLOWS: the value named 'file dataflows' in this block; get: the value named 'get' in this block; entry: the value named 'entry' in this block. Context: the function source_architecture_notes, which handles source architecture notes.

Line 610: `entry.relative,` This is continuation line 2 of the 4-line logical statement that begins at source line 609. Its exact fragment is 'entry.relative,'. The important operands are entry: the value named 'entry' in this block; relative: the value named 'relative' in this block. Read together, the complete operation is: This assigns 'FILE_DATAFLOWS.get(entry.relative, f"This file's end-to-end responsibility is to {entry.purpose}.",)' to 'dataflow ' in host memory. Here dataflow means the value named 'dataflow' in this block. The important operands are FILE_DATAFLOWS: the value named 'file dataflows' in this block; get: the value named 'get' in this block; entry: the value named 'entry' in this block. Context: the function source_architecture_notes, which handles source architecture notes.

Line 611: `f"This file's end-to-end responsibility is to {entry.purpose}.",` This is continuation line 3 of the 4-line logical statement that begins at source line 609. Its exact fragment is 'f"This file's end-to-end responsibility is to {entry.purpose}.",'. The important operands are f: the value named 'f' in this block; This: the value named 'this' in this block; file: the value named 'file' in this block. Read together, the complete operation is: This assigns 'FILE_DATAFLOWS.get(entry.relative, f"This file's end-to-end responsibility is to {entry.purpose}.",)' to 'dataflow ' in host memory. Here dataflow means the value named 'dataflow' in this block. The important operands are

FILE_DATAFLOWS: the value named 'file dataflows' in this block; get: the value named 'get' in this block; entry: the value named 'entry' in this block. Context: the function source_architecture_notes, which handles source architecture notes.

Line 612: `)` This is continuation line 4 of the 4-line logical statement that begins at source line 609. Its exact fragment is ')'. The expression is a literal or structural operator and has no hidden software state. Read together, the complete operation is: This assigns 'FILE_DATAFLOWS.get(entry.relative, f"This file's end-to-end responsibility is to {entry.purpose}.",)' to 'dataflow ' in host memory. Here dataflow means the value named 'dataflow' in this block. The important operands are FILE_DATAFLOWS: the value named 'file dataflows' in this block; get: the value named 'get' in this block; entry: the value named 'entry' in this block. Context: the function source_architecture_notes, which handles source architecture notes.

Line 613: `notes: list[tuple[str, str]] = [("Dataflow responsibility", dataflow)]` This assigns '[("Dataflow responsibility", dataflow)]' to 'notes' in host memory. Here notes means the value named 'notes' in this block. The important operands are Dataflow: the value named 'dataflow' in this block; responsibility: the value named 'responsibility' in this block; dataflow: the value named 'dataflow' in this block. Context: the function source_architecture_notes, which handles source architecture notes.

Line 614: `if suffix in {".sv", ".v"} and not entry.relative.startswith("tb/"):` This executes the following indented host-code branch only when 'suffix in {".sv", ".v"} and not entry.relative.startswith("tb/")' is true. The important operands are suffix: the value named 'suffix' in this block; in: the value named 'in' in this block; sv: the value named 'sv' in this block. Context: the function source_architecture_notes, which handles source architecture notes.

Line 615: `modules = re.findall(r"^\s*module\s+([A-Za-z_][A-Za-z0-9_$]*)", text, re.MULTILINE)` This assigns 're.findall(r"^\s*module\s+([A-Za-z_][A-Za-z0-9_$]*)", text, re.MULTILINE)' to 'modules ' in host memory. Here modules means the value named 'modules' in this block. The important operands are re: the value named 're' in this block; findall: the value named 'findall' in this block; r: the value named 'r' in this block. Context: the function source_architecture_notes, which handles source architecture notes.

Line 616: `inputs = len(re.findall(r"^\s*input\b", text, re.MULTILINE))` This assigns 'len(re.findall(r"^\s*input\b", text, re.MULTILINE))' to 'inputs ' in host memory. Here inputs means the value named 'inputs' in this block. The important operands are len: the value named 'len' in this block; re: the value named 're' in this block; findall: the value named 'findall' in this block. Context: the function source_architecture_notes, which handles source architecture notes.

Line 617: `outputs = len(re.findall(r"^\s*output\b", text, re.MULTILINE))` This assigns 'len(re.findall(r"^\s*output\b' text, re.MULTILINE))' to 'outputs ' in host memory. Here outputs means the value named 'outputs' in this block. The important operands are len: the value named 'len' in this block; re: the value named 're' in this block; findall: the value named 'findall' in this block. Context: the function source_architecture_notes, which handles source architecture notes.

Line 618: `clocked = len(re.findall(r"\balways_ff\b", text))` This assigns 'len(re.findall(r"\balways_ff\b", text))' to 'clocked ' in host memory. Here clocked means the value named 'clocked' in this block. The important operands are len: the value named 'len' in this block; re: the value named 're' in this block; findall: the value named 'findall' in this block. Context: the function source_architecture_notes, which handles source architecture notes.

Line 619: `combinational = len(re.findall(r"\balways_comb\b", text))` This assigns 'len(re.findall(r"\balways_comb\b", text))' to 'combinational ' in host memory. Here combinational means the value named 'combinational' in this block. The important operands are len: the value named 'len' in this block; re: the value named 're' in this block; findall: the value named 'findall' in this block. Context: the function source_architecture_notes, which handles source architecture notes.

Line 620: `states = sorted(set(re.findall(r"\bST_[A-Z0-9_]+\b", text)))` This assigns 'sorted(set(re.findall(r"\bST_[A-Z0-9_]+\b", text)))' to 'states ' in host memory. Here states means the finite-state-machine phase retained in flip-flops. The important operands are sorted: the value named 'sorted' in this block; set: the value named 'set' in this block; re: the value named 're' in this block. Context: the function source_architecture_notes, which handles source architecture notes.

Line 621: `instances: list[str] = []` This assigns '[]' to 'instances' in host memory. Here instances means the value named 'instances' in this block. The expression is a literal or structural operator and has no hidden software state. Context: the function source_architecture_notes, which handles source architecture notes.

Line 622: `instance_pattern = re.compile(` This statement continues through source line 625; the explanation uses the complete expression rather than only the first visual fragment. This assigns 're.compile(r"^\s*([A-Za-z_][A-Za-z0-9_$]*)\s+(?:#\s*\([^;]*\)\s*)?" r"([A-Za-z_][A-Za-z0-9_$]*)\s*\(", re.MULTILINE,)' to 'instance_pattern ' in host memory. Here instance_pattern means the value named 'instance pattern' in this block. The important operands are re: the value named 're' in this block; compile: the value named 'compile' in this block; r: the value named 'r' in this block. Context: the function source_architecture_notes, which handles source architecture notes.

Line 623: `r"^\s*([A-Za-z_][A-Za-z0-9_$]*)\s+(?:#\s*\([^;]*\)\s*)?"` This is continuation line 2 of the 4-line logical statement that begins at source line 622. Its exact fragment is 'r"^\s*([A-Za-z_][A-Za-z0-9_$]*)\s+(?:#\s*\([^;]*\)\s*)?"'. The important operands are r: the value named 'r' in this block; s: the value named 's' in this block; A: the value named 'a' in this block. Read together, the complete operation is: This assigns 're.compile(r"^\s*([A-Za-z_][A-Za-z0-9_$]*)\s+(?:#\s*\([^;]*\)\s*)?" r"([A-Za-z_][A-Za-z0-9_$]*)\s*\(", re.MULTILINE,)' to 'instance_pattern ' in host memory. Here instance_pattern means the value named 'instance pattern' in this block. The important operands are re: the value named 're' in this block; compile: the value named 'compile' in this block; r: the value named 'r' in this block. Context: the function source_architecture_notes, which handles source architecture notes.

Line 624: `r"([A-Za-z_][A-Za-z0-9_$]*)\s*\(", re.MULTILINE,` This is continuation line 3 of the 4-line logical statement that begins at source line 622. Its exact fragment is 'r"([A-Za-z_][A-Za-z0-9_$]*)\s*\(", re.MULTILINE,'. The important operands are r: the value named 'r' in this block; A: the value named 'a' in this block; Za: the value named 'za' in this block. Read together, the complete operation is: This assigns 're.compile(r"^\s*([A-Za-z_][A-Za-z0-9_$]*)\s+(?:#\s*\([^;]*\)\s*)?" r"([A-Za-z_][A-Za-z0-9_$]*)\s*\(", re.MULTILINE,)' to 'instance_pattern ' in host memory. Here instance_pattern means the value named 'instance pattern' in this block. The important operands are re: the value named 're' in this block; compile: the value named 'compile' in this block; r: the value named 'r' in this block. Context: the function source_architecture_notes, which handles source architecture notes.

Line 625: `)` This is continuation line 4 of the 4-line logical statement that begins at source line 622. Its exact fragment is ')'. The expression is a literal or structural operator and has no hidden software state. Read together, the complete operation is: This assigns 're.compile(r"^\s*([A-Za-z_][A-Za-z0-9_$]*)\s+(?:#\s*\([^;]*\)\s*)?" r"([A-Za-z_][A-Za-z0-9_$]*)\s*\(", re.MULTILINE,)' to 'instance_pattern ' in host memory. Here instance_pattern means the value named 'instance pattern' in this block. The important operands are re: the value named 're' in this block; compile: the value named 'compile' in this block; r: the value named 'r' in this block. Context: the function source_architecture_notes, which handles source architecture notes.

Line 626: `for module_name, instance_name in instance_pattern.findall(text):` This iterates module_name, instance_name over 'instance_pattern.findall(text)'. Each iteration repeats the indented host operation, commonly once per layer, tile, timestep, or test case in the function source_architecture_notes, which handles source architecture notes.

Line 627: `if module_name in {"module", "function", "task", "if", "for", "while", "case"}:` This executes the following indented host-code branch only when 'module_name in {"module", "function", "task", "if", "for", "while", "case"}' is true. The important operands are module_name: the value named 'module name' in this block; in: the value named 'in' in this block; module: the value named 'module' in this block. Context: the function source_architecture_notes, which handles source architecture notes.

Line 628: `continue` Inside the function source_architecture_notes, which handles source architecture notes, this statement advances the host implementation that generates this source-reference volume and its source-integrity manifest. The important operands are continue: the value named 'continue' in this block.

Line 629: `label = f"{module_name} as {instance_name}"` This assigns 'f"{module_name} as {instance_name}"' to 'label ' in host memory. Here label means the value named 'label' in this block. The important operands are f: the value named 'f' in this block; module_name: the value named 'module name' in this block; as: the value named 'as' in this block. Context: the function source_architecture_notes, which handles source architecture notes.

Line 630: `if label not in instances:` This executes the following indented host-code branch only when ‘label not in instances‘ is true. The important operands are label: the value named ’label’ in this block; not: the value named ’not’ in this block; in: the value named ’in’ in this block. Context: the function source_architecture_notes, which handles source architecture notes.

Line 631: `instances.append(label)` This calls ‘instances.append‘ with ‘label‘ inside the function source_architecture_notes, which handles source architecture notes. The call advances the host-side job that generates this source-reference volume and its source-integrity manifest.

Line 632: `notes.extend(` This statement continues through source line 661; the explanation uses the complete expression rather than only the first visual fragment. This calls ‘notes.extend‘ with ‘ [("What becomes FPGA hardware", f"Vivado elaborates module(s) {', '.join(modules) or 'declared here'} into physical nets and primitives. The source declares {inputs} input-port lines, {outputs} output-port lines, {clocked} clocked process(es), and {combinational} combinational process(es). Clocked assignments become retained state; combinational assignments become gates, arithmetic, and multiplexers.",), ("Cycle-level control", (f"The named control phases include {', '.join(states[:18])}" + (" and additional states" if len(states) > 18 else "") + ". It makes tool inputs, ...` This is continuation line 3 of the 6-line logical statement that begins at source line 687. Its exact fragment is ‘("Where it runs", f"This is {tool} orchestration, not accelerator datapath hardware. It makes tool inputs, versions, paths, stages, and failure propagation repeatable."),‘. The important operands are Where: the value named 'where' in this block; it: the value named 'it' in this block; runs: the value named 'runs' in this block. Read together, the complete operation is: This calls ‘notes.extend‘ with ‘ [("Where it runs", f"This is {tool} orchestration, not accelerator datapath hardware. It makes tool inputs, versions, paths, stages, and failure propagation repeatable."), ("Reproducibility contract", "Every external command must be checked, every required artifact must exist and be nonempty, and measured values must be read from generated reports. Rerunning this file should either reproduce its declared outputs or stop at the first failed gate."),] ‘ inside the function source_architecture_notes, which handles source architecture notes. The call advances the host-side job that generates this source-reference volume and its source-integrity manifest.

Line 690: `("Reproducibility contract", "Every external command must be checked, every required artifact must exist an...` This is continuation line 4 of the 6-line logical statement that begins at source line 687. Its exact fragment is ‘("Reproducibility contract", "Every external command must be checked, every required artifact must exist and be nonempty, and measured values must be read from generated reports. Rerunning this file should either reproduce its declared outputs or stop at the first failed gate."),‘. The important operands are Reproducibility: the value named 'reproducibility' in this block; contract: the value named 'contract' in this block; Every: the value named 'every' in this block. Read together, the complete operation is: This calls ‘notes.extend‘ with ‘ [("Where it runs", f"This is {tool} orchestration, not accelerator datapath hardware. It makes tool inputs, versions, paths, stages, and failure propagation repeatable."), ("Reproducibility contract", "Every external command must be checked, every required artifact must exist and be nonempty, and measured values must be read from generated reports. Rerunning this file should either reproduce its declared outputs or stop at the first failed gate."),] ‘ inside the function source_architecture_notes, which handles source architecture notes. The call advances the host-side job that generates this source-reference volume and its source-integrity manifest.

Line 691: `]` This is continuation line 5 of the 6-line logical statement that begins at source line 687. Its exact fragment is ‘]‘. The expression is a literal or structural operator and has no hidden software state. Read together, the complete operation is: This calls ‘notes.extend‘ with ‘ [("Where it runs", f"This is {tool} orchestration, not accelerator datapath hardware. It makes tool inputs, versions, paths, stages, and failure propagation repeatable."), ("Reproducibility contract", "Every external command must be checked, every required artifact must exist and be nonempty, and measured values must be read from generated reports. Rerunning this file should either reproduce its declared outputs or stop at the first failed gate."),] ‘ inside the function source_architecture_notes, which handles source architecture notes. The call advances the host-side job that generates this source-reference volume and its source-integrity manifest.

Line 692: `)` This is continuation line 6 of the 6-line logical statement that begins at source line 687. Its exact fragment is ‘)‘. The expression is a literal or structural operator and has no hidden software state. Read together, the complete operation is: This calls ‘notes.extend‘ with ‘ [("Where it runs", f"This is {tool} orchestration, not accelerator datapath hardware. It makes tool inputs, versions, paths, stages, and failure propagation repeatable."), ("Reproducibility contract", "Every external command must be checked, every required artifact must exist and be nonempty, and measured values must be read from generated reports. Rerunning this file should either reproduce its declared outputs or stop at the first failed gate."),] ‘ inside the function source_architecture_notes, which handles source architecture notes. The call advances the host-side job that generates this source-reference volume and its source-integrity manifest.

Line 693: `return notes` This returns ‘notes‘ to the caller of the function source_architecture_notes, which handles source architecture notes, ending this invocation. The important operands are notes: the value named ’notes’ in this block.

Line 696: `def annotation_tex(entry: SourceEntry, text: str) -> tuple[list[str], int]:` This starts function annotation_tex. Its indented body performs annotation tex as part of the file that generates this source-reference volume and its source-integrity manifest; it runs only when called.

Line 697: `lines = text.splitlines()` This assigns ‘text.splitlines()‘ to ‘lines ‘ in host memory. Here lines means the value named ’lines’ in this block. The important operands are text: the value named ’text’ in this block; splitlines: the value named ’splitlines’ in this block. Context: the function annotation_tex, which handles annotation tex.

Line 698: `suffix = entry.path.suffix.lower()` This assigns ‘entry.path.suffix.lower()‘ to ‘suffix ‘ in host memory. Here suffix means the value named ’suffix’ in this block. The important operands are entry: the value named ’entry’ in this block; path: the value named ’path’ in this block; suffix: the value named ’suffix’ in this block. Context: the function annotation_tex, which handles annotation tex.

Line 699: `contexts = python_contexts(text) if suffix == ".py" else sv_contexts(lines) if suffix in {".sv", ".v"} else {}` Inside the function annotation_tex, which handles annotation tex, this statement advances the host implementation that generates this source-reference volume and its source-integrity manifest. The important operands are contexts: the value named ’contexts’ in this block; python_contexts: the value named ’python contexts’ in this block; text: the value named ’text’ in this block.

Line 700: `statement_spans = (` This statement continues through source line 704; the explanation uses the complete expression rather than only the first visual fragment. Inside the function annotation_tex, which handles annotation tex, this statement advances the host implementation that generates this source-reference volume and its source-integrity manifest. The important operands are statement_spans: the finite-state-machine phase retained in flip-flops; python_statement_spans: the finite-state-machine phase retained in flip-flops; text: the value named ’text’ in this block.

Line 701: `python_statement_spans(text) if suffix == ".py"` This is continuation line 2 of the 5-line logical statement that begins at source line 700. Its exact fragment is ‘python_statement_spans(text) if suffix == ".py"‘. The important operands are python_statement_spans: the finite-state-machine phase retained in flip-flops; text: the value named ’text’ in this block; suffix: the value named ’suffix’ in this block. Read together, the complete operation is: Inside the function annotation_tex, which handles annotation tex, this statement advances the host implementation that generates this source-reference volume and its source-integrity manifest. The important operands are statement_spans: the finite-state-machine phase retained in flip-flops; python_statement_spans: the finite-state-machine phase retained in flip-flops; text: the value named ’text’ in this block.

Line 702: `else sv_statement_spans(lines) if suffix in {".sv", ".v"}` This is continuation line 3 of the 5-line logical statement that begins at source line 700. Its exact fragment is ‘else sv_statement_spans(lines) if suffix in {".sv", ".v"}‘. The important operands are sv_statement_spans: the finite-state-machine phase retained in flip-flops; lines: the value named ’lines’ in this block; suffix: the value named ’suffix’ in this block. Read together, the complete operation is: Inside the function annotation_tex, which handles annotation tex, this statement advances the host implementation that generates this source-reference volume and its source-integrity manifest. The important operands are statement_spans: the finite-state-machine phase retained in flip-flops; python_statement_spans: the finite-state-machine phase retained in flip-flops; text: the value named ’text’ in this block.

Line 703: `else {}` This is continuation line 4 of the 5-line logical statement that begins at source line 700. Its exact fragment is ‘else {}‘. The expression is a literal or structural operator and has no hidden software state. Read together, the complete operation is: Inside the function annotation_tex, which handles annotation tex, this statement advances the host implementation that generates this source-reference volume and its source-integrity manifest. The important operands are statement_spans: the finite-state-machine phase retained in flip-flops; python_statement_spans: the finite-state-machine phase retained in flip-flops; text: the value named ’text’ in this block.

Line 704: `)` This is continuation line 5 of the 5-line logical statement that begins at source line 700. Its exact fragment is ‘)‘. The expression is a literal or structural operator and has no hidden software state. Read together, the complete operation is: Inside the function annotation_tex, which handles annotation tex, this statement advances the host implementation that generates this source-reference volume and its source-integrity manifest. The important operands are statement_spans: the finite-state-machine phase retained in flip-flops; python_statement_spans: the finite-state-machine phase retained in flip-flops; text: the value named ’text’ in this block.

Line 705: `result: list[str] = []` This assigns ‘[]‘ to ‘result‘ in host memory. Here result means the value named ’result’ in this block. The expression is a literal or structural operator and has no hidden software state. Context: the function annotation_tex, which handles annotation tex.

Line 706: `explained = 0` This assigns ‘0‘ to ‘explained ‘ in host memory. Here explained means the value named ’explained’ in this block. The expression is a literal or structural operator and has no hidden software state. Context: the function annotation_tex, which handles annotation tex.

Line 707: `for line_number, raw in enumerate(lines, start=1):` This iterates line_number, raw over ‘enumerate(lines, start=1)‘. Each iteration repeats the indented host operation, commonly once per layer, tile, timestep, or test case in the function annotation_tex, which handles annotation tex.

Line 708: `if not raw.strip():` This executes the following indented host-code branch only when ‘not raw.strip()‘ is true. The important operands are not: the value named ’not’ in this block; raw: the value named ’raw’ in this block; strip: the value named ’strip’ in this block. Context: the function annotation_tex, which handles annotation tex.

Line 709: `continue` Inside the function annotation_tex, which handles annotation tex, this statement advances the host implementation that generates this source-reference volume and its source-integrity manifest. The important operands are continue: the value named ’continue’ in this block.

Line 710: `context = contexts.get(line_number, f"the file whose role is to {entry.purpose}")` This assigns ‘contexts.get(line_number, f"the file whose role is to {entry.purpose}")‘ to ‘context ‘ in host memory. Here context means the value named ’context’ in this block. The important operands are contexts: the value named ’contexts’ in this block; get: the value named ’get’ in this block; line_number: the value named ’line number’ in this block. Context: the function annotation_tex, which handles annotation tex.

Line 711: `span = statement_spans.get(line_number)` This assigns ‘statement_spans.get(line_number)‘ to ‘span ‘ in host memory. Here span means the value named ’span’ in this block. The important operands are statement_spans: the finite-state-machine phase retained in flip-flops; get: the value named ’get’ in this block; line_number: the value named ’line number’ in this block. Context: the function annotation_tex, which handles annotation tex.

Line 712: `if suffix in {".sv", ".v"}:` This executes the following indented host-code branch only when ‘suffix in {".sv", ".v"}‘ is true. The important operands are suffix: the value named ’suffix’ in this block; in: the value named ’in’ in this block; sv: the value named ’sv’ in this block. Context: the function annotation_tex, which handles annotation tex.

Line 713: `complete_explanation = explain_sv_line(` This statement continues through source line 714; the explanation uses the complete expression rather than only the first visual fragment. This assigns ‘explain_sv_line(span.text if span else raw, context, entry.purpose)‘ to ‘complete_explanation ‘ in host memory. Here complete_explanation means the value named ’complete explanation’ in this block. The important operands are explain_sv_line: the value named

'explain sv line' in this block; span: the value named 'span' in this block; text: the value named 'text' in this block. Context: the function annotation_tex, which handles annotation tex.

Line 714: `span.text if span else raw, context, entry.purpose)` This is continuation line 2 of the 2-line logical statement that begins at source line 713. Its exact fragment is 'span.text if span else raw, context, entry.purpose)'. The important operands are span: the value named 'span' in this block; text: the value named 'text' in this block; raw: the value named 'raw' in this block. Read together, the complete operation is: This assigns 'explain_sv_line(span.text if span else raw, context, entry.purpose)' to 'complete_explanation ' in host memory. Here complete_explanation means the value named 'complete explanation' in this block. The important operands are explain_sv_line: the value named 'explain sv line' in this block; span: the value named 'span' in this block; text: the value named 'text' in this block. Context: the function annotation_tex, which handles annotation tex.

Line 715: `elif suffix == ".py":` This executes the following indented host-code branch only when 'suffix == ".py"' is true. The important operands are suffix: the value named 'suffix' in this block; py: the value named 'py' in this block. Context: the function annotation_tex, which handles annotation tex.

Line 716: `complete_explanation = explain_python_line(` This statement continues through source line 717; the explanation uses the complete expression rather than only the first visual fragment. This assigns 'explain_python_line(span.text if span else raw, context, entry.purpose)' to 'complete_explanation ' in host memory. Here complete_explanation means the value named 'complete explanation' in this block. The important operands are explain_python_line: the value named 'explain python line' in this block; span: the value named 'span' in this block; text: the value named 'text' in this block. Context: the function annotation_tex, which handles annotation tex.

Line 717: `span.text if span else raw, context, entry.purpose)` This is continuation line 2 of the 2-line logical statement that begins at source line 716. Its exact fragment is 'span.text if span else raw, context, entry.purpose)'. The important operands are span: the value named 'span' in this block; text: the value named 'text' in this block; raw: the value named 'raw' in this block. Read together, the complete operation is: This assigns 'explain_python_line(span.text if span else raw, context, entry.purpose)' to 'complete_explanation ' in host memory. Here complete_explanation means the value named 'complete explanation' in this block. The important operands are explain_python_line: the value named 'explain python line' in this block; span: the value named 'span' in this block; text: the value named 'text' in this block. Context: the function annotation_tex, which handles annotation tex.

Line 718: `else:` This begins the alternative host-code branch when the preceding condition was false, still inside the function annotation_tex, which handles annotation tex.

Line 719: `complete_explanation = explain_script_line(raw, suffix, entry.purpose)` This assigns 'explain_script_line suffix, entry.purpose)' to 'complete_explanation ' in host memory. Here complete_explanation means the value named 'complete explanation' in this block. The important operands are explain_script_line: the value named 'explain script line' in this block; raw: the value named 'raw' in this block; suffix: the value named 'suffix' in this block. Context: the function annotation_tex, which handles annotation tex.

Line 720: `if span and line_number != span.start:` This executes the following indented host-code branch only when 'span and line_number != span.start' is true. The important operands are span: the value named 'span' in this block; and: the value named 'and' in this block; line_number: the value named 'line number' in this block. Context: the function annotation_tex, which handles annotation tex.

Line 721: `position = line_number - span.start + 1` This assigns 'line_number - span.start + 1' to 'position ' in host memory. Here position means the value named 'position' in this block. The important operands are line_number: the value named 'line number' in this block; span: the value named 'span' in this block; start: the value named 'start' in this block. Context: the function annotation_tex, which handles annotation tex.

Line 722: `length = span.end - span.start + 1` This assigns 'span.end - span.start + 1' to 'length ' in host memory. Here length means the value named 'length' in this block. The important operands are span: the value named 'span' in this block; start: the value named 'start' in this block. Context: the function annotation_tex, which handles annotation tex.

Line 723: `explanation = (` This statement continues through source line 728; the explanation uses the complete expression rather than only the first visual fragment. This assigns ‘(f"This is continuation line {position} of the {length}-line logical statement " f"that begins at source line {span.start}. Its exact fragment is ‘{raw.strip()}‘. " f"{summarize_expression(raw)} Read together, the complete operation is: " f"{complete_explanation}")‘ to ‘explanation ‘ in host memory. Here explanation means the value named ’explanation’ in this block. The important operands are f: the value named ’f’ in this block; This: the value named ’this’ in this block; is: the value named ’is’ in this block. Context: the function annotation_tex, which handles annotation tex.

Line 724: `f"This is continuation line {position} of the {length}-line logical statement "` This is continuation line 2 of the 6-line logical statement that begins at source line 723. Its exact fragment is ‘f"This is continuation line {position} of the {length}-line logical statement "‘. The important operands are f: the value named ’f’ in this block; This: the value named ’this’ in this block; is: the value named ’is’ in this block. Read together, the complete operation is: This assigns ‘(f"This is continuation line {position} of the {length}-line logical statement " f"that begins at source line {span.start}. Its exact fragment is ‘{raw.strip()}‘. " f"{summarize_expression(raw)} Read together, the complete operation is: " f"{complete_explanation}")‘ to ‘explanation ‘ in host memory. Read together, the complete operation is: This calls ‘result.extend‘ with ‘ [rf"\paragraph{{Line {line_number}: \texttt{{{latex_escape(preview)}}}}}", latex_escape(explanation),] ‘ inside the function annotation_tex, which handles annotation tex. The call advances the host-side job that generates this source-reference volume and its source-integrity manifest.

Line 744: `]` This is continuation line 5 of the 6-line logical statement that begins at source line 740. Its exact fragment is ‘]‘. The expression is a literal or structural operator and has no hidden software state. Read together, the complete operation is: This calls ‘result.extend‘ with ‘ [rf"\paragraph{{Line {line_number}: \texttt{{{latex_escape(preview)}}}}}", latex_escape(explanation),] ‘ inside the function annotation_tex, which handles annotation tex. The call advances the host-side job that generates this source-reference volume and its source-integrity manifest.

Line 745: `)` This is continuation line 6 of the 6-line logical statement that begins at source line 740. Its exact fragment is ‘)‘. The expression is a literal or structural operator and has no hidden software state. Read together, the complete operation is: This calls ‘result.extend‘ with ‘ [rf"\paragraph{{Line {line_number}: \texttt{{{latex_escape(preview)}}}}}", latex_escape(explanation),] ‘ inside the function annotation_tex, which handles annotation tex. The call advances the host-side job that generates this source-reference volume and its source-integrity manifest.

Line 746: `explained += 1` Inside the function annotation_tex, which handles annotation tex, this statement advances the host implementation that generates this source-reference volume and its source-integrity manifest. The important operands are explained: the value named 'explained' in this block.

Line 747: `return result, explained` This returns ‘result, explained‘ to the caller of the function annotation_tex, which handles annotation tex, ending this invocation. The important operands are result: the value named 'result' in this block; explained: the value named 'explained' in this block.

Line 750: `def generate(output_dir: Path) -> tuple[Path, Path]:` This starts function generate. Its indented body performs generate as part of the file that generates this source-reference volume and its source-integrity manifest; it runs only when called.

Line 751: `root = project_root()` This assigns ‘project_root()‘ to ‘root ‘ in host memory. Here root means the value named 'root' in this block. The important operands are project_root: the value named 'project root' in this block. Context: the function generate, which handles generate.

Line 752: `output_dir = output_dir.resolve()` This assigns ‘output_dir.resolve()‘ to ‘output_dir ‘ in host memory. Here output_dir means the value named 'output dir' in this block. The important operands are output_dir: the value named 'output dir' in this block; resolve: the value named 'resolve' in this block. Context: the function generate, which handles generate.

Line 753: `output_dir.mkdir(parents=True, exist_ok=True)` This calls ‘output_dir.mkdir‘ with ‘parents=True, exist_ok=True‘ inside the function generate, which handles generate. The call advances the host-side job that generates this source-reference volume and its source-integrity manifest.

Line 754: `entries = source_entries(root)` This assigns ‘source_entries(root)‘ to ‘entries ‘ in host memory. Here entries means the value named 'entries' in this block. The important operands are source_entries: the value named 'source entries' in this block; root: the value named 'root' in this block. Context: the function generate, which handles generate.

Line 755: `tex_path = output_dir / "neuraedge_line_by_line_source_reference.tex"` This assigns ‘output_dir / "neuraedge_line_by_line_source_reference.tex"‘ to ‘tex_path ‘ in host memory. Here tex_path means the value named 'tex path' in this block. The important operands are output_dir: the value named 'output dir' in this block; neuraedge_line_by_line_source_reference: the value named 'neuraedge line by line source reference' in this block; tex: the value named 'tex' in this block. Context: the function generate, which handles generate.

Line 756: `manifest_path = output_dir / "neuraedge_line_by_line_source_manifest.json"` This assigns ‘output_dir / "neuraedge_line_by_line_source_manifest.json"‘ to ‘manifest_path ‘ in host memory. Here manifest_path means the value named 'manifest path' in this block. The important operands are output_dir: the value named 'output dir' in this block; neuraedge_line_by_line_source_manifest: the value named 'neuraedge line by line source manifest' in this block; json: the value named 'json' in this block. Context: the function generate, which handles generate.

Line 757: `tex = [` This statement continues through source line 777; the explanation uses the complete expression rather than only the first visual fragment. This assigns ‘[r"\documentclass[9pt]{article}", r"\usepackage[margin=0.62in]{geometry}" r"\usepackage[T1]{fontenc}", r"\usepackage{lmodern}", r"\usepackage{xcolor}", r"\usepackage{listings}", r"\usepackage[hidelinks]{ r"\setlength{\parindent}{0pt}", r"\setlength{\parskip}{3pt}", r"\lstset{basicstyle=\ttfamily\scriptsize,breaklines=true,columns=f r"\title{NeuraEdge Universal: Complete Line-by-Line Source Reference}", r"\author{Generated from hashed repository source}", r"\date{\today}", r"\begin{document}", r"\maketitle", r"\tableofcontents", r"\clearpage", r"\section{How to read this volume}", "Each file begins with its system-level responsibility and a complete numbered source listing. The following annotations explain every nonblank line using its enclosing function, RTL process, or finite-state-machine phase. Blank lines are visible in the listing but have no executable or synthesized behavior. SystemVerilog describes parallel hardware: an if statement controls a multiplexer and a nonblocking assignment updates a register on a clock edge. Python, PowerShell, and Tcl run sequentially on a processor or inside a tool.",]‘ to ‘tex ‘ in host memory. Here tex means the value named 'tex' in this block. The important operands are r: the value named 'r' in this block; documentclass:

the value named 'documentclass' in this block; article: the value named 'article' in this block. Context: the function generate, which handles generate.

Line 758: `r"\documentclass[9pt]{article}",` This is continuation line 2 of the 21-line logical statement that begins at source line 757. Its exact fragment is 'r"\documentclass[9pt]{article}",'. The important operands are r: the value named 'r' in this block; documentclass: the value named 'documentclass' in this block; article: the value named 'article' in this block. Read together, the complete operation is: This assigns '[r"\documentclass[9pt]{article}", r"\usepackage[margin=0.62in]{geometry}", r"\usepackage[T1]{fontenc}", r"\usepackage{lmodern}", r"\usepackage{xcolor}", r"\usepackage{listings}", r"\usepackage[hidelinks]{hyperref}", r"\setlength{\parindent}{0pt}", r"\setlength{\parskip}{3pt}", r"\lstset{basicstyle=\ttfamily\scriptsize,breaklines=true,columns=fullflexible,keepspaces=true,showstringspaces=false,numbers=le r"\title{NeuraEdge Universal: Complete Line-by-Line Source Reference}", r"\author{Generated from hashed repository source}", r"\date{\today}", r"\begin{document}", r"\maketitle", r"\tableofcontents", r"\clearpage", r"\section{How to read this volume}", "Each file begins with its system-level responsibility and a complete numbered source listing. Python, PowerShell, and Tcl run sequentially on a processor or inside a tool.",]‘ to ‘tex ‘ in host memory. Here tex means the value named ’tex’ in this block. The important operands are r: the value named ’r’ in this block; documentclass: the value named ’documentclass’ in this block; article: the value named ’article’ in this block. Context: the function generate, which handles generate.

Line 778: `manifest: dict[str, object] = {"format": "neuraedge-source-reference-v1", "files": []}` This assigns ‘{"format": "neuraedge-source-reference-v1", "files": []}‘ to ‘manifest‘ in host memory. Here manifest means the value named ’manifest’ in this block. The important operands are format: the value named ’format’ in this block; neuraedge: the value named ’neuraedge’ in this block; source: the value named ’source’ in this block. Context: the function generate, which handles generate.

Line 779: `total_lines = 0` This assigns ‘0‘ to ‘total_lines ‘ in host memory. Here total_lines means the value named ’total lines’ in this block. The expression is a literal or structural operator and has no hidden software state. Context: the function generate, which handles generate.

Line 780: `total_nonblank = 0` This assigns ‘0‘ to ‘total_nonblank ‘ in host memory. Here total_nonblank means the value named ’total nonblank’ in this block. The expression is a literal or structural operator and has no hidden software state. Context: the function generate, which handles generate.

Line 781: `for entry in entries:` This iterates entry over ‘entries‘. Each iteration repeats the indented host operation, commonly once per layer, tile, timestep, or test case in the function generate, which handles generate.

Line 782: `raw_bytes = entry.path.read_bytes()` This assigns ‘entry.path.read_bytes()‘ to ‘raw_bytes ‘ in host memory. Here raw_bytes means the value named ’raw bytes’ in this block. The important operands are entry: the value named ’entry’ in this block; path: the value named ’path’ in this block; read_bytes: the value named ’read bytes’ in this block. Context: the function generate, which handles generate.

Line 783: `text = raw_bytes.decode("utf-8", errors="strict")` This assigns ‘raw_bytes.decode("utf-8", errors="strict")‘ to ‘text ‘ in host memory. Here text means the value named ’text’ in this block. The important operands are raw_bytes: the value named ’raw bytes’ in this block; decode: the value named ’decode’ in this block; utf: the value named ’utf’ in this block. Context: the function generate, which handles generate.

Line 784: `line_count = len(text.splitlines())` This assigns ‘len(text.splitlines())‘ to ‘line_count ‘ in host memory. Here line_count means an integer count retained for control or measurable telemetry. The important operands are len: the value named ’len’ in this block; text: the value named ’text’ in this block; splitlines: the value named ’splitlines’ in this block. Context: the function generate, which handles generate.

Line 785: `nonblank_count = sum(bool(line.strip()) for line in text.splitlines())` This assigns ‘sum(bool(line.strip(for line in text.splitlines()))‘ to ‘nonblank_count ‘ in host memory. Here nonblank_count means an integer count retained for control or measurable telemetry. The important operands are sum: the value named ’sum’ in this block; bool: the value named ’bool’ in this block; line: the value named ’line’ in this block. Context: the function generate, which handles generate.

Line 786: `annotations, explained = annotation_tex(entry, text)` This assigns ‘annotation_tex(entry, text)‘ to ‘annotations, explained ‘ in host memory. Here annotations means the value named ’annotations’ in this block. The important operands are annotation_tex: the value named ’annotation tex’ in this block; entry: the value named ’entry’ in this block; text: the value named ’text’ in this block. Context: the function generate, which handles generate.

Line 787: `if explained != nonblank_count:` This executes the following indented host-code branch only when ‘explained != nonblank_count‘ is true. The important operands are explained: the value named ’explained’ in this block; nonblank_count: an integer count retained for control or measurable telemetry. Context: the function generate, which handles generate.

Line 788: `raise RuntimeError(f"annotation coverage mismatch for {entry.relative}: {explained} != {nonblank_c` This rejects an invalid state by raising ‘RuntimeError(f"annotation coverage mismatch for {entry.relative}: {explained} != {nonblank_count}")‘. Failing before DMA prevents malformed shapes or artifacts from silently becoming hardware results.

Line 789: `total_lines += line_count` Inside the function generate, which handles generate, this statement advances the host implementation that generates this source-reference volume and its source-integrity manifest. The important operands are total_lines: the value named ’total lines’ in this block; line_count: an integer count retained for control or measurable telemetry.

Line 790: `total_nonblank += nonblank_count` Inside the function generate, which handles generate, this statement advances the host implementation that generates this source-reference volume and its source-integrity manifest. The important operands are total_nonblank: the value named ’total nonblank’ in this block; nonblank_count: an integer count retained for control or measurable telemetry.

Line 791: `listing_path = os.path.relpath(entry.path, output_dir).replace("\\", "/")` This assigns ‘os.path.relpath(output_dir).replace("\\", "/")‘ to ‘listing_path ‘ in host memory. Here listing_path means the value named ’listing path’ in this block. The important operands are os: the value named ’os’ in this block; path: the value named ’path’ in this block; relpath: the value named ’relpath’ in this block. Context: the function generate, which handles generate.

Line 792: `manifest["files"].append(` This statement continues through source line 801; the explanation uses the complete expression rather than only the first visual fragment. Inside the function generate, which handles generate, this statement advances the host implementation that generates this source-reference volume and its source-integrity manifest. The important operands are manifest: the value named ’manifest’ in this block; files: the value named ’files’ in this block; append: the value named ’append’ in this block.

Line 793: `{` This is continuation line 2 of the 10-line logical statement that begins at source line 792. Its exact fragment is ‘{‘. The expression is a literal or structural operator and has no hidden software state. Read together, the complete operation is: Inside the function generate, which handles generate, this statement advances the host implementation that generates this source-reference volume and its source-integrity manifest. The important operands are manifest: the value named ’manifest’ in this block; files: the value named ’files’ in this block; append: the value named ’append’ in this block.

Line 794: `"path": entry.relative,` This is continuation line 3 of the 10-line logical statement that begins at source line 792. Its exact fragment is ‘"path": entry.relative,‘. The important operands are path: the value named ’path’ in this block; entry: the value named ’entry’ in this block; relative: the value named ’relative’ in this block. Read together, the complete operation is: Inside the function generate, which handles generate, this statement advances the host implementation that generates this source-reference volume and its source-integrity manifest. The important operands are manifest: the value named ’manifest’ in this block; files: the value named ’files’ in this block; append: the value named ’append’ in this block.

Line 795: `"sha256": hashlib.sha256(raw_bytes).hexdigest(),` This is continuation line 4 of the 10-line logical statement that begins at source line 792. Its exact fragment is ‘"sha256": hashlib.sha256(raw_bytes).hexdigest(),‘. The important operands are sha256: the value named ’sha256’ in this block; hashlib: the value named ’hashlib’ in this block; raw_bytes: the value named ’raw bytes’ in this block. Read together, the complete operation is: Inside the function

generate, which handles generate, this statement advances the host implementation that generates this source-reference volume and its source-integrity manifest. The important operands are manifest: the value named 'manifest' in this block; files: the value named 'files' in this block; append: the value named 'append' in this block.

Line 796: `"lines": line_count,` This is continuation line 5 of the 10-line logical statement that begins at source line 792. Its exact fragment is ‘"lines": line_count,‘. The important operands are lines: the value named 'lines' in this block; line_count: an integer count retained for control or measurable telemetry. Read together, the complete operation is: Inside the function generate, which handles generate, this statement advances the host implementation that generates this source-reference volume and its source-integrity manifest. The important operands are manifest: the value named 'manifest' in this block; files: the value named 'files' in this block; append: the value named 'append' in this block.

Line 797: `"nonblank_lines": nonblank_count,` This is continuation line 6 of the 10-line logical statement that begins at source line 792. Its exact fragment is ‘"nonblank_lines": nonblank_count,‘. The important operands are nonblank_lines: the value named 'nonblank lines' in this block; nonblank_count: an integer count retained for control or measurable telemetry. Read together, the complete operation is: Inside the function generate, which handles generate, this statement advances the host implementation that generates this source-reference volume and its source-integrity manifest. The important operands are manifest: the value named 'manifest' in this block; files: the value named 'files' in this block; append: the value named 'append' in this block.

Line 798: `"explained_nonblank_lines": explained,` This is continuation line 7 of the 10-line logical statement that begins at source line 792. Its exact fragment is ‘"explained_nonblank_lines": explained,‘. The important operands are explained_nonblank_lines: the value named 'explained nonblank lines' in this block; explained: the value named 'explained' in this block. Read together, the complete operation is: Inside the function generate, which handles generate, this statement advances the host implementation that generates this source-reference volume and its source-integrity manifest. The important operands are manifest: the value named 'manifest' in this block; files: the value named 'files' in this block; append: the value named 'append' in this block.

Line 799: `"purpose": entry.purpose,` This is continuation line 8 of the 10-line logical statement that begins at source line 792. Its exact fragment is ‘"purpose": entry.purpose,‘. The important operands are purpose: the value named 'purpose' in this block; entry: the value named 'entry' in this block. Read together, the complete operation is: Inside the function generate, which handles generate, this statement advances the host implementation that generates this source-reference volume and its source-integrity manifest. The important operands are manifest: the value named 'manifest' in this block; files: the value named 'files' in this block; append: the value named 'append' in this block.

Line 800: `}` This is continuation line 9 of the 10-line logical statement that begins at source line 792. Its exact fragment is ‘}‘. The expression is a literal or structural operator and has no hidden software state. Read together, the complete operation is: Inside the function generate, which handles generate, this statement advances the host implementation that generates this source-reference volume and its source-integrity manifest. The important operands are manifest: the value named 'manifest' in this block; files: the value named 'files' in this block; append: the value named 'append' in this block.

Line 801: `)` This is continuation line 10 of the 10-line logical statement that begins at source line 792. Its exact fragment is ‘)‘. The expression is a literal or structural operator and has no hidden software state. Read together, the complete operation is: Inside the function generate, which handles generate, this statement advances the host implementation that generates this source-reference volume and its source-integrity manifest. The important operands are manifest: the value named 'manifest' in this block; files: the value named 'files' in this block; append: the value named 'append' in this block.

Line 802: `tex.extend(` This statement continues through source line 819; the explanation uses the complete expression rather than only the first visual fragment. This calls ‘tex.extend‘ with ‘ [r"\clearpage", rf"\section{{\texttt{{{latex_escape(entry.rela rf"\textbf{{Role in the complete system:}} {latex_escape(entry.purpose)}.", r"\subsection{Beginner architecture map}", r"\begin{description}", *[rf"\item[{latex_escape(label)}] {latex_escape(note)}" for label, note in source_architecture_notes(entry, text)], r"\end{description}", r"\subsection{Complete source}", rf"\lstinputlisting{{{listing_path}}}", r"\subsection{Line annotations}", *annotations,] ‘ inside the function generate, which handles generate. The call advances the host-side job that generates this source-reference volume and its source-integrity manifest.

Line 803: `[` This is continuation line 2 of the 18-line logical statement that begins at source line 802. Its exact fragment is '['. The expression is a literal or structural operator and has no hidden software state. Read together, the complete operation is: This calls 'tex.extend' with ' [r"\clearpage", rf"\section{{\texttt{{{latex_escape(entry.relative)}}}}}", rf"\textbf{{Role in the complete system:}} {latex_escape(entry.purpose)}.", r"\subsection{Beginner architecture map}", r"\begin{description}", *[rf"\item[{latex_escape(label)}] {latex_escape(note)}" for label, note in source_architecture_notes(entry, text)], r"\end{description}", r"\subsection{Complete source}", rf"\lstinputlisting{{{listing_path}}}", r"\subsection{Line annotations}", *annotations,] ' inside the function generate, which handles generate. Line 833: `)` This is continuation line 8 of the 8-line logical statement that begins at source line 826. Its exact fragment is ‘)‘. The expression is a literal or structural operator and has no hidden software state. Read together, the complete operation is: This calls ‘tex.extend‘ with ‘ [r"\clearpage", r"\section{Coverage statement}", f"This volume contains {len(entries)} source files, {total_lines:,} physical source lines, and an explanation for all {total_nonblank:,} nonblank lines. The companion JSON manifest records each source SHA-256 digest.", r"\end{document}",] ‘ inside the function generate, which handles generate. The call advances the host-side job that generates this source-reference volume and its source-integrity manifest.

Line 834: `tex_path.write_text("\n".join(tex) + "\n", encoding="utf-8")` This calls ‘tex_path.write_text‘ with ‘"\n".join(tex) + "\n", encoding="utf-8"‘ inside the function generate, which handles generate. The call advances the host-side job that generates this source-reference volume and its source-integrity manifest.

Line 835: `manifest_path.write_text(json.dumps(manifest, indent=2) + "\n", encoding="utf-8")` This calls ‘manifest_path.write_text‘ with ‘json.dumps(manifest, indent=2) + "\n", encoding="utf-8"‘ inside the function generate, which handles generate. The call advances the host-side job that generates this source-reference volume and its source-integrity manifest.

Line 836: `return tex_path, manifest_path` This returns ‘tex_path, manifest_path‘ to the caller of the function generate, which handles generate, ending this invocation. The important operands are tex_path: the value named ’tex path’ in this block; manifest_path: the value named ’manifest path’ in this block.

Line 839: `def compile_pdf(tex_path: Path, pdflatex: str) -> Path:` This starts function compile_pdf. Its indented body performs compile pdf as part of the file that generates this source-reference volume and its source-integrity manifest; it runs only when called.

Line 840: `for _ in range(2):` This iterates _ over ‘range(2)‘. Each iteration repeats the indented host operation, commonly once per layer, tile, timestep, or test case in the function compile_pdf, which handles compile pdf.

Line 841: `subprocess.run(` This statement continues through source line 845; the explanation uses the complete expression rather than only the first visual fragment. This calls ‘subprocess.run‘ with ‘ [pdflatex, "-interaction=nonstopmode", "-halt-on-error", tex_path.name], cwd=tex_path.parent, check=True, ‘ inside the function compile_pdf, which handles compile pdf. The call advances the host-side job that generates this source-reference volume and its source-integrity manifest.

Line 842: `[pdflatex, "-interaction=nonstopmode", "-halt-on-error", tex_path.name],` This is continuation line 2 of the 5-line logical statement that begins at source line 841. Its exact fragment is ‘[pdflatex, "-interaction=nonstopmode", "-halt-on-error", tex_path.name],‘. The important operands are pdflatex: the value named ’pdflatex’ in this block; interaction: the value named ’interaction’ in this block; nonstopmode: the value named ’nonstopmode’ in this block. Read together, the complete operation is: This calls ‘subprocess.run‘ with ‘ [pdflatex, "-interaction=nonstopmode", "-halt-on-error", tex_path.name], cwd=tex_path.parent, check=True, ‘ inside the function compile_pdf, which handles compile pdf. The call advances the host-side job that generates this source-reference volume and its source-integrity manifest.

Line 843: `cwd=tex_path.parent,` This is continuation line 3 of the 5-line logical statement that begins at source line 841. Its exact fragment is ‘cwd=tex_path.parent,‘. The important operands are cwd: the value named ’cwd’ in this block; tex_path: the value named ’tex path’ in this block; parent: the value named ’parent’ in this block. Read together, the complete operation is: This calls ‘subprocess.run‘ with ‘ [pdflatex, "-interaction=nonstopmode", "-halt-on-error", tex_path.name], cwd=tex_path.parent, check=True, ‘ inside the function compile_pdf, which handles compile pdf. The call advances the host-side job that generates this source-reference volume and its source-integrity manifest.

Line 844: `check=True,` This is continuation line 4 of the 5-line logical statement that begins at source line 841. Its exact fragment is ‘check=True,‘. The important operands are check: the value named ’check’ in this block. Read together, the complete operation is: This calls ‘subprocess.run‘ with ‘ [pdflatex, "-interaction=nonstopmode", "-halt-on-error", tex_path.name], cwd=tex_path.parent, check=True, ‘ inside the function compile_pdf, which handles compile pdf. The call advances the host-side job that generates this source-reference volume and its source-integrity manifest.

Line 845: `)` This is continuation line 5 of the 5-line logical statement that begins at source line 841. Its exact fragment is ‘)‘. The expression is a literal or structural operator and has no hidden software state. Read together, the complete operation is: This calls ‘subprocess.run‘ with ‘ [pdflatex, "-interaction=nonstopmode", "-halt-on-error", tex_path.name], cwd=tex_path.parent, check=True, ‘ inside the function compile_pdf, which handles compile pdf. The call advances the host-side job that generates this source-reference volume and its source-integrity manifest.

Line 846: `return tex_path.with_suffix(".pdf")` This returns ‘tex_path.with_suffix(".pdf")‘ to the caller of the function compile_pdf, which handles compile pdf, ending this invocation. The important operands are tex_path: the value named ’tex path’ in this block; with_suffix: the value named ’with suffix’ in this block; pdf: the value named ’pdf’ in this block.

Line 849: `def main() -> None:` This starts function main. Its indented body performs main as part of the file that generates this source-reference volume and its source-integrity manifest; it runs only when called.

Line 850: `parser = argparse.ArgumentParser(description=__doc__)` This assigns ‘argparse.ArgumentParser(description=_ to ‘parser ‘ in host memory. Here parser means the value named ’parser’ in this block. The important operands are argparse: the value named ’argparse’ in this block; ArgumentParser: the value named ’argument parser’ in this block; description: the value named ’description’ in this block. Context: the function main, which handles main.

Line 851: `parser.add_argument("-output-dir", type=Path, default=project_root() / "docs")` This declares a command-line option for the function main, which handles main. Its name, type, default, and required status make the run configuration explicit and reproducible instead of relying on an invisible interactive setting.

Line 852: `parser.add_argument("-compile", action="store_true")` This declares a command-line option for the function main, which handles main. Its name, type, default, and required status make the run configuration explicit and reproducible instead of relying on an invisible interactive setting.

Line 853: `parser.add_argument("-pdflatex", default="pdflatex")` This declares a command-line option for the function main, which handles main. Its name, type, default, and required status make the run configuration explicit and reproducible instead of relying on an invisible interactive setting.

Line 854: `args = parser.parse_args()` This assigns ‘parser.parse_args()‘ to ‘args ‘ in host memory. Here args means the value named ’args’ in this block. The important operands are parser: the value named ’parser’ in this block; parse_args: the value named ’parse args’ in this block. Context: the function main, which handles main.

Line 855: `tex_path, manifest_path = generate(args.output_dir.resolve())` This assigns ‘generate(args.output_dir.resol to ‘tex_path, manifest_path ‘ in host memory. Here tex_path means the value named ’tex path’ in this block. The important operands are generate: the value named ’generate’ in this block; args: the value named ’args’ in this block; output_dir: the value named ’output dir’ in this block. Context: the function main, which handles main.

Line 856: `print(f"tex={tex_path}")` This calls ‘print‘ with ‘f"tex={tex_path}"‘ inside the function main, which handles main. The call advances the host-side job that generates this source-reference volume and its source-integrity manifest.

Line 857: `print(f"manifest={manifest_path}")` This calls ‘print‘ with ‘f"manifest={manifest_path}"‘ inside the function main, which handles main. The call advances the host-side job that generates this source-reference volume and its source-integrity manifest.

Line 858: `if args.compile:` This executes the following indented host-code branch only when ‘args.compile‘ is true. The important operands are args: the value named ’args’ in this block; compile: the value named ’compile’ in this block. Context: the function main, which handles main.

Line 859: `print(f"pdf={compile_pdf(tex_path, args.pdflatex)}")` This calls ‘print‘ with ‘f"pdf={compile_pdf(tex_path, args.pdflatex)}"‘ inside the function main, which handles main. The call advances the host-side job that generates this source-reference volume and its source-integrity manifest.

Line 862: `if __name__ == "__main__":` This executes the following indented host-code branch only when ‘___name___ == "___main___"‘ is true. The important operands are ___name___: the value named ’name’ in this block; ___main___: the value named ’main’ in this block. Context: the file whose role is to generates this source-reference volume and its source-integrity manifest.

Line 863: `main()` This calls ‘main‘ with “ inside the file whose role is to generates this source-reference volume and its source-integrity manifest. The call advances the host-side job that generates this source-reference volume and its source-integrity manifest.

31 software/generate_spikingformer_manifest.py

Role in the complete system: derives every model tensor shape, tile schedule, command count, operation count, and traffic total.

31.1 Beginner architecture map

Dataflow responsibility This file's end-to-end responsibility is to derives every model tensor shape, tile schedule, command count, operation count, and traffic total.

Where it runs This is sequential host software. Python objects live in CPU memory; they become FPGA work only when the compiler packs a command or payload and the PYNQ driver transfers those bytes through AXI DMA or AXI-Lite.

Public structure Classes: MatrixSchedule, OperatorMapping. Functions: matrix_schedule, build_operator_manifest, generate, parse_arguments, matrix_operator. Each function annotation below names its enclosing function so an array operation is tied to the model, compiler, driver, test, or report phase that uses it.

Numeric and failure boundary Shapes, signedness, byte order, scaling, and saturation are part of the hardware contract. Validation exceptions are functional safety checks: rejecting malformed input before DMA is different from silently clipping, reshaping, or continuing with an incompatible artifact.

31.2 Complete source

31.3 Line annotations

Line 1: `"""Generate the exact Spikingformer-to-NeuraEdge execution manifest."""` This is executable documentation attached to the file whose role is to derives every model tensor shape, tile schedule, command count, operation count, and traffic total. It states the intended contract that tests and callers should enforce, but the text itself does not transform data or issue hardware work.

Line 3: `from __future__ import annotations` This imports the named Python API so the file whose role is to derives every model tensor shape, tile schedule, command count, operation count, and traffic total can use it explicitly. Imports execute on the host processor and create no FPGA hardware.

Line 5: `import argparse` This imports the named Python API so the file whose role is to derives every model tensor shape, tile schedule, command count, operation count, and traffic total can use it explicitly. Imports execute on the host processor and create no FPGA hardware.

Line 6: `import json` This imports the named Python API so the file whose role is to derives every model tensor shape, tile schedule, command count, operation count, and traffic total can use it explicitly. Imports execute on the host processor and create no FPGA hardware.

Line 7: `from dataclasses import asdict, dataclass` This imports the named Python API so the file whose role is to derives every model tensor shape, tile schedule, command count, operation count, and traffic total can use it explicitly. Imports execute on the host processor and create no FPGA hardware.

Line 8: `from math import ceil` This imports the named Python API so the file whose role is to derives every model tensor shape, tile schedule, command count, operation count, and traffic total can use it explicitly. Imports execute on the host processor and create no FPGA hardware.

Line 9: `from pathlib import Path` This imports the named Python API so the file whose role is to derives every model tensor shape, tile schedule, command count, operation count, and traffic total can use it explicitly. Imports execute on the host processor and create no FPGA hardware.

Line 10: `from typing import Literal` This imports the named Python API so the file whose role is to derives every model tensor shape, tile schedule, command count, operation count, and traffic total can use it explicitly. Imports execute on the host processor and create no FPGA hardware.

Line 12: `import torch` This imports the named Python API so the file whose role is to derives every model tensor shape, tile schedule, command count, operation count, and traffic total can use it explicitly. Imports execute on the host processor and create no FPGA hardware.

Line 15: `ROW_TILE = 8` This assigns ‘8‘ to ‘ROW_TILE ‘ in host memory. Here ROW_TILE means one output-row position processed by the tensor tile. The expression is a literal or structural operator and has no hidden software state. Context: the file whose role is to derives every model tensor shape, tile schedule, command count, operation count, and traffic total.

Line 16: `COLUMN_TILE = 16` This assigns ‘16‘ to ‘COLUMN_TILE ‘ in host memory. Here COLUMN_TILE means one output-feature position processed in parallel. The expression is a literal or structural operator and has no hidden software state. Context: the file whose role is to derives every model tensor shape, tile schedule, command count, operation count, and traffic total.

Line 17: `MAX_REDUCTION = 2048` This assigns ‘2048‘ to ‘MAX_REDUCTION ‘ in host memory. Here MAX_REDUCTION means the value named ’max reduction’ in this block. The expression is a literal or structural operator and has no hidden software state. Context: the file whose role is to derives every model tensor shape, tile schedule, command count, operation count, and traffic total.

Line 20: `@dataclass(frozen=True)` This decorator changes how the following class or function is constructed. ‘@dataclass(frozen=True)‘ is applied at import time on the host and is part of the file whose role is to derives every model tensor shape, tile schedule, command count, operation count, and traffic total; it creates no FPGA circuit by itself.

Line 21: `class MatrixSchedule:` This defines class MatrixSchedule, which groups data and methods for matrix schedule. Instances exist in host memory and organize the flow that derives every model tensor shape, tile schedule, command count, operation count, and traffic total.

Line 22: `rows: int` Inside the class MatrixSchedule, which handles matrix schedule, this statement advances the host implementation that derives every model tensor shape, tile schedule, command count, operation count, and traffic total. The important operands are rows: one output-row position processed by the tensor tile.

Line 23: `reduction: int` Inside the class MatrixSchedule, which handles matrix schedule, this statement advances the host implementation that derives every model tensor shape, tile schedule, command count, operation count, and traffic total. The important operands are reduction: the value named ’reduction’ in this block.

Line 24: `columns: int` Inside the class MatrixSchedule, which handles matrix schedule, this statement advances the host implementation that derives every model tensor shape, tile schedule, command count, operation count, and traffic total. The important operands are columns: one output-feature position processed in parallel.

Line 25: `repetitions: int` Inside the class MatrixSchedule, which handles matrix schedule, this statement advances the host implementation that derives every model tensor shape, tile schedule, command count, operation count, and traffic total. The important operands are repetitions: the value named ’repetitions’ in this block.

Line 26: `arithmetic: Literal["u8_mac", "binary_spike_add", "dynamic_u8_mac"]` Inside the class MatrixSchedule, which handles matrix schedule, this statement advances the host implementation that derives every model tensor shape, tile schedule, command count, operation count, and traffic total. The important operands are arithmetic: the value named ’arithmetic’ in this block; Literal: the value named ’literal’ in this block; u8_mac: the value named ’u8 mac’ in this block.

Line 27: `mac_equivalents: int` Inside the class MatrixSchedule, which handles matrix schedule, this statement advances the host implementation that derives every model tensor shape, tile schedule, command count, operation count, and traffic total. The important operands are mac_equivalents: the value named ’mac equivalents’ in this block.

Line 28: `reduction_chunks: int` Inside the class MatrixSchedule, which handles matrix schedule, this statement advances the host implementation that derives every model tensor shape, tile schedule, command count, operation count, and traffic total. The important operands are reduction_chunks: the value named ’reduction chunks’ in this block.

Line 29: `compute_tiles: int` Inside the class MatrixSchedule, which handles matrix schedule, this statement advances the host implementation that derives every model tensor shape, tile schedule, command count, operation count, and traffic total. The important operands are compute_tiles: the value named 'compute tiles' in this block.

Line 30: `commands: int` Inside the class MatrixSchedule, which handles matrix schedule, this statement advances the host implementation that derives every model tensor shape, tile schedule, command count, operation count, and traffic total. The important operands are commands: the 128-bit instruction selecting an engine, shape, mode, and numeric parameters.

Line 31: `input_stream_bytes: int` Inside the class MatrixSchedule, which handles matrix schedule, this statement advances the host implementation that derives every model tensor shape, tile schedule, command count, operation count, and traffic total. The important operands are input_stream_bytes: the value named 'input stream bytes' in this block.

Line 32: `output_stream_bytes: int` Inside the class MatrixSchedule, which handles matrix schedule, this statement advances the host implementation that derives every model tensor shape, tile schedule, command count, operation count, and traffic total. The important operands are output_stream_bytes: the value named 'output stream bytes' in this block.

Line 35: `@dataclass(frozen=True)` This decorator changes how the following class or function is constructed. '@dataclass(frozen=True)' is applied at import time on the host and is part of the file whose role is to derives every model tensor shape, tile schedule, command count, operation count, and traffic total; it creates no FPGA circuit by itself.

Line 36: `class OperatorMapping:` This defines class OperatorMapping, which groups data and methods for operator mapping. Instances exist in host memory and organize the flow that derives every model tensor shape, tile schedule, command count, operation count, and traffic total.

Line 37: `name: str` Inside the class OperatorMapping, which handles operator mapping, this statement advances the host implementation that derives every model tensor shape, tile schedule, command count, operation count, and traffic total. The important operands are name: the value named 'name' in this block; str: the value named 'str' in this block.

Line 38: `source_operation: str` Inside the class OperatorMapping, which handles operator mapping, this statement advances the host implementation that derives every model tensor shape, tile schedule, command count, operation count, and traffic total. The important operands are source_operation: the value named 'source operation' in this block; str: the value named 'str' in this block.

Line 39: `input_shape_per_image: tuple[int, ...]` Inside the class OperatorMapping, which handles operator mapping, this statement advances the host implementation that derives every model tensor shape, tile schedule, command count, operation count, and traffic total. The important operands are input_shape_per_image: the value named 'input shape per image' in this block; tuple: the value named 'tuple' in this block.

Line 40: `output_shape_per_image: tuple[int, ...]` Inside the class OperatorMapping, which handles operator mapping, this statement advances the host implementation that derives every model tensor shape, tile schedule, command count, operation count, and traffic total. The important operands are output_shape_per_image: the value named 'output shape per image' in this block; tuple: the value named 'tuple' in this block.

Line 41: `hardware_primitive: str` Inside the class OperatorMapping, which handles operator mapping, this statement advances the host implementation that derives every model tensor shape, tile schedule, command count, operation count, and traffic total. The important operands are hardware_primitive: the value named 'hardware primitive' in this block; str: the value named 'str' in this block.

Line 42: `matrix: MatrixSchedule | None` Inside the class OperatorMapping, which handles operator mapping, this statement advances the host implementation that derives every model tensor shape, tile schedule, command count, operation count, and traffic total. The important operands are matrix: the value named 'matrix' in this block; MatrixSchedule: the value named 'matrix schedule' in this block; None: the value named 'none' in this block.

Line 43: `exact_optimization: str | None = None` This assigns ‘None‘ to ‘exact_optimization‘ in host memory. Here exact_optimization means the value named ’exact optimization’ in this block. The important operands are None: the value named ’none’ in this block. Context: the class OperatorMapping, which handles operator mapping.

Line 46: `def matrix_schedule(` This starts function matrix_schedule. Its indented body performs matrix schedule as part of the file that derives every model tensor shape, tile schedule, command count, operation count, and traffic total; it runs only when called.

Line 47: `rows: int,` Inside the function matrix_schedule, which handles matrix schedule, this statement advances the host implementation that derives every model tensor shape, tile schedule, command count, operation count, and traffic total. The important operands are rows: one output-row position processed by the tensor tile.

Line 48: `reduction: int,` Inside the function matrix_schedule, which handles matrix schedule, this statement advances the host implementation that derives every model tensor shape, tile schedule, command count, operation count, and traffic total. The important operands are reduction: the value named ’reduction’ in this block.

Line 49: `columns: int,` Inside the function matrix_schedule, which handles matrix schedule, this statement advances the host implementation that derives every model tensor shape, tile schedule, command count, operation count, and traffic total. The important operands are columns: one output-feature position processed in parallel.

Line 50: `*,` Inside the function matrix_schedule, which handles matrix schedule, this statement advances the host implementation that derives every model tensor shape, tile schedule, command count, operation count, and traffic total. The expression is a literal or structural operator and has no hidden software state.

Line 51: `repetitions: int = 1,` This assigns ‘1,‘ to ‘repetitions‘ in host memory. Here repetitions means the value named ’repetitions’ in this block. The expression is a literal or structural operator and has no hidden software state. Context: the function matrix_schedule, which handles matrix schedule.

Line 52: `arithmetic: Literal["u8_mac", "binary_spike_add", "dynamic_u8_mac"],` Inside the function matrix_schedule, which handles matrix schedule, this statement advances the host implementation that derives every model tensor shape, tile schedule, command count, operation count, and traffic total. The important operands are arithmetic: the value named ’arithmetic’ in this block; Literal: the value named ’literal’ in this block; u8_mac: the value named ’u8 mac’ in this block.

Line 53: `) -> MatrixSchedule:` Inside the function matrix_schedule, which handles matrix schedule, this statement advances the host implementation that derives every model tensor shape, tile schedule, command count, operation count, and traffic total. The important operands are MatrixSchedule: the value named ’matrix schedule’ in this block.

Line 54: `"""Count commands and stream bytes using the compiler's public tiling ABI."""` This is executable documentation attached to the function matrix_schedule, which handles matrix schedule. It states the intended contract that tests and callers should enforce, but the text itself does not transform data or issue hardware work.

Line 56: `if min(rows, reduction, columns, repetitions) <= 0:` This executes the following indented host-code branch only when ‘min(rows, reduction, columns, repetitions) <= 0‘ is true. The important operands are min: the value named ’min’ in this block; rows: one output-row position processed by the tensor tile; reduction: the value named ’reduction’ in this block. Context: the function matrix_schedule, which handles matrix schedule.

Line 57: `raise ValueError("all matrix dimensions and repetitions must be positive")` This rejects an invalid state by raising ‘ValueError("all matrix dimensions and repetitions must be positive")‘. Failing before DMA prevents malformed shapes or artifacts from silently becoming hardware results.

Line 58: `total_commands = 0` This assigns ‘0‘ to ‘total_commands ‘ in host memory. Here total_commands means the 128-bit instruction selecting an engine, shape, mode, and numeric parameters. The expression is a literal or structural operator and has no hidden software state. Context: the function matrix_schedule, which handles matrix schedule.

Line 59: `total_compute_tiles = 0` This assigns ‘0‘ to ‘total_compute_tiles ‘ in host memory. Here total_compute_tiles means the value named ’total compute tiles’ in this block. The expression is a literal or structural operator and has no hidden software state. Context: the function matrix_schedule, which handles matrix schedule.

Line 60: `total_input_bytes = 0` This assigns ‘0‘ to ‘total_input_bytes ‘ in host memory. Here total_input_bytes means the value named ’total input bytes’ in this block. The expression is a literal or structural operator and has no hidden software state. Context: the function matrix_schedule, which handles matrix schedule.

Line 61: `total_output_bytes = 0` This assigns ‘0‘ to ‘total_output_bytes ‘ in host memory. Here total_output_bytes means the value named ’total output bytes’ in this block. The expression is a literal or structural operator and has no hidden software state. Context: the function matrix_schedule, which handles matrix schedule.

Line 62: `chunks = 0` This assigns ‘0‘ to ‘chunks ‘ in host memory. Here chunks means the value named ’chunks’ in this block. The expression is a literal or structural operator and has no hidden software state. Context: the function matrix_schedule, which handles matrix schedule.

Line 63: `for reduction_start in range(0, reduction, MAX_REDUCTION):` This iterates reduction_start over ‘range(0, reduction, MAX_REDUCTION)‘. Each iteration repeats the indented host operation, commonly once per layer, tile, timestep, or test case in the function matrix_schedule, which handles matrix schedule.

Line 64: `chunk = min(MAX_REDUCTION, reduction - reduction_start)` This assigns ‘min(MAX_REDUCTION, reduction - reduction_start)‘ to ‘chunk ‘ in host memory. Here chunk means the value named ’chunk’ in this block. The important operands are min: the value named ’min’ in this block; MAX_REDUCTION: the value named ’max reduction’ in this block; reduction: the value named ’reduction’ in this block. Context: the function matrix_schedule, which handles matrix schedule.

Line 65: `chunks += 1` Inside the function matrix_schedule, which handles matrix schedule, this statement advances the host implementation that derives every model tensor shape, tile schedule, command count, operation count, and traffic total. The important operands are chunks: the value named ’chunks’ in this block.

Line 66: `row_tiles = ceil(rows / ROW_TILE)` This assigns ‘ceil(rows / ROW_TILE)‘ to ‘row_tiles ‘ in host memory. Here row_tiles means one output-row position processed by the tensor tile. The important operands are ceil: the value named ’ceil’ in this block; rows: one output-row position processed by the tensor tile; ROW_TILE: one output-row position processed by the tensor tile. Context: the function matrix_schedule, which handles matrix schedule.

Line 67: `column_tiles = ceil(columns / COLUMN_TILE)` This assigns ‘ceil(columns / COLUMN_TILE)‘ to ‘column_tiles ‘ in host memory. Here column_tiles means one output-feature position processed in parallel. The important operands are ceil: the value named ’ceil’ in this block; columns: one output-feature position processed in parallel; COLUMN_TILE: one output-feature position processed in parallel. Context: the function matrix_schedule, which handles matrix schedule.

Line 68: `compute_tiles = row_tiles * column_tiles` This assigns ‘row_tiles * column_tiles‘ to ‘compute_tiles ‘ in host memory. Here compute_tiles means the value named ’compute tiles’ in this block. The important operands are row_tiles: one output-row position processed by the tensor tile; column_tiles: one output-feature position processed in parallel. Context: the function matrix_schedule, which handles matrix schedule.

Line 69: `if rows == 1:` This executes the following indented host-code branch only when ‘rows == 1‘ is true. The important operands are rows: one output-row position processed by the tensor tile. Context: the function matrix_schedule, which handles matrix schedule.

Line 70: `issues = ceil(chunk / 8)` This assigns ‘ceil(chunk / 8)‘ to ‘issues ‘ in host memory. Here issues means the value named ’issues’ in this block. The important operands are ceil: the value named ’ceil’ in this block; chunk: the value named ’chunk’ in this block. Context: the function matrix_schedule, which handles matrix schedule.

Line 71: `activation_tile_bytes = issues * 8` This assigns ‘issues * 8‘ to ‘activation_tile_bytes ‘ in host memory. Here activation_tile_bytes means an input feature value consumed by a neuron or multiply-accumulate operation. The important operands are issues: the value named ’issues’ in this block. Context: the function matrix_schedule, which handles matrix schedule.

Line 72: `weight_tile_bytes = issues * 8 * 16` This assigns ‘issues * 8 * 16‘ to ‘weight_tile_bytes ‘ in host memory. Here weight_tile_bytes means a learned coefficient multiplied by an activation. The important operands are issues: the value named ’issues’ in this block. Context: the function matrix_schedule, which handles matrix schedule.

Line 73: `else:` This begins the alternative host-code branch when the preceding condition was false, still inside the function matrix_schedule, which handles matrix schedule.

Line 74: `activation_tile_bytes = chunk * ROW_TILE` This assigns ‘chunk * ROW_TILE‘ to ‘activation_tile_bytes ‘ in host memory. Here activation_tile_bytes means an input feature value consumed by a neuron or multiply-accumulate operation. The important operands are chunk: the value named ’chunk’ in this block; ROW_TILE: one output-row position processed by the tensor tile. Context: the function matrix_schedule, which handles matrix schedule.

Line 75: `weight_tile_bytes = chunk * COLUMN_TILE` This assigns ‘chunk * COLUMN_TILE‘ to ‘weight_tile_bytes ‘ in host memory. Here weight_tile_bytes means a learned coefficient multiplied by an activation. The important operands are chunk: the value named ’chunk’ in this block; COLUMN_TILE: one output-feature position processed in parallel. Context: the function matrix_schedule, which handles matrix schedule.

Line 76: `input_broadcast_bytes = (` This statement continues through source line 79; the explanation uses the complete expression rather than only the first visual fragment. This assigns ‘(row_tiles * activation_tile_bytes + compute_tiles * weight_tile_bytes)‘ to ‘input_broadcast_bytes ‘ in host memory. Here input_broadcast_bytes means the value named ’input broadcast bytes’ in this block. The important operands are row_tiles: one output-row position processed by the tensor tile; activation_tile_bytes: an input feature value consumed by a neuron or multiply-accumulate operation; compute_tiles: the value named ’compute tiles’ in this block. Context: the function matrix_schedule, which handles matrix schedule.

Line 77: `row_tiles * activation_tile_bytes` This is continuation line 2 of the 4-line logical statement that begins at source line 76. Its exact fragment is ‘row_tiles * activation_tile_bytes‘. The important operands are row_tiles: one output-row position processed by the tensor tile; activation_tile_bytes: an input feature value consumed by a neuron or multiply-accumulate operation. Read together, the complete operation is: This assigns ‘(row_tiles * activation_tile_bytes + compute_tiles * weight_tile_bytes)‘ to ‘input_broadcast_bytes ‘ in host memory. Here input_broadcast_bytes means the value named ’input broadcast bytes’ in this block. The important operands are row_tiles: one output-row position processed by the tensor tile; activation_tile_bytes: an input feature value consumed by a neuron or multiply-accumulate operation; compute_tiles: the value named ’compute tiles’ in this block. Context: the function matrix_schedule, which handles matrix schedule.

Line 78: `+ compute_tiles * weight_tile_bytes` This is continuation line 3 of the 4-line logical statement that begins at source line 76. Its exact fragment is ‘+ compute_tiles * weight_tile_bytes‘. The important operands are compute_tiles: the value named ’compute tiles’ in this block; weight_tile_bytes: a learned coefficient multiplied by an activation. Read together, the complete operation is: This assigns ‘(row_tiles * activation_tile_bytes + compute_tiles * weight_tile_bytes)‘ to ‘input_broadcast_bytes ‘ in host memory. Here input_broadcast_bytes means the value named ’input broadcast bytes’ in this block. The important operands are row_tiles: one output-row position processed by the tensor tile; activation_tile_bytes: an input feature value consumed by a neuron or multiply-accumulate operation; compute_tiles: the value named ’compute tiles’ in this block. Context: the function matrix_schedule, which handles matrix schedule.

Line 79: `)` This is continuation line 4 of the 4-line logical statement that begins at source line 76. Its exact fragment is ‘)‘. The expression is a literal or structural operator and has no hidden software state. Read together, the complete operation is: This assigns ‘(row_tiles * activation_tile_bytes + compute_tiles * weight_tile_bytes)‘ to ‘input_broadcast_bytes ‘ in host memory. Here input_broadcast_bytes means the value named ’input broadcast bytes’ in this block. The important operands are row_tiles: one output-row position processed by the tensor tile; activation_tile_bytes: an input

feature value consumed by a neuron or multiply-accumulate operation; compute_tiles: the value named 'compute tiles' in this block. Context: the function matrix_schedule, which handles matrix schedule.

Line 80: `weight_broadcast_bytes = (` This statement continues through source line 83; the explanation uses the complete expression rather than only the first visual fragment. This assigns '(column_tiles * weight_tile_bytes + compute_tiles * activation_tile_bytes)' to 'weight_broadcast_bytes ' in host memory. Here weight_broadcast_bytes means a learned coefficient multiplied by an activation. The important operands are column_tiles: one output-feature position processed in parallel; weight_tile_bytes: a learned coefficient multiplied by an activation; compute_tiles: the value named 'compute tiles' in this block. Context: the function matrix_schedule, which handles matrix schedule.

Line 81: `column_tiles * weight_tile_bytes` This is continuation line 2 of the 4-line logical statement that begins at source line 80. Its exact fragment is 'column_tiles * weight_tile_bytes'. The important operands are column_tiles: one output-feature position processed in parallel; weight_tile_bytes: a learned coefficient multiplied by an activation. Read together, the complete operation is: This assigns '(column_tiles * weight_tile_bytes + compute_tiles * activation_tile_bytes)' to 'weight_broadcast_bytes ' in host memory. Here weight_broadcast_bytes means a learned coefficient multiplied by an activation. The important operands are column_tiles: one output-feature position processed in parallel; weight_tile_bytes: a learned coefficient multiplied by an activation; compute_tiles: the value named 'compute tiles' in this block. Context: the function matrix_schedule, which handles matrix schedule.

Line 82: `+ compute_tiles * activation_tile_bytes` This is continuation line 3 of the 4-line logical statement that begins at source line 80. Its exact fragment is '+ compute_tiles * activation_tile_bytes'. The important operands are compute_tiles: the value named 'compute tiles' in this block; activation_tile_bytes: an input feature value consumed by a neuron or multiply-accumulate operation. Read together, the complete operation is: This assigns '(column_tiles * weight_tile_bytes + compute_tiles * activation_tile_bytes)' to 'weight_broadcast_bytes ' in host memory. Here weight_broadcast_bytes means a learned coefficient multiplied by an activation. The important operands are column_tiles: one output-feature position processed in parallel; weight_tile_bytes: a learned coefficient multiplied by an activation; compute_tiles: the value named 'compute tiles' in this block. Context: the function matrix_schedule, which handles matrix schedule.

Line 83: `)` This is continuation line 4 of the 4-line logical statement that begins at source line 80. Its exact fragment is ')'. The expression is a literal or structural operator and has no hidden software state. Read together, the complete operation is: This assigns '(column_tiles * weight_tile_bytes + compute_tiles * activation_tile_bytes)' to 'weight_broadcast_bytes ' in host memory. Here weight_broadcast_bytes means a learned coefficient multiplied by an activation. The important operands are column_tiles: one output-feature position processed in parallel; weight_tile_bytes: a learned coefficient multiplied by an activation; compute_tiles: the value named 'compute tiles' in this block. Context: the function matrix_schedule, which handles matrix schedule.

Line 84: `if input_broadcast_bytes <= weight_broadcast_bytes:` This executes the following indented host-code branch only when 'input_broadcast_bytes <= weight_broadcast_bytes' is true. The important operands are input_broadcast_bytes: the value named 'input broadcast bytes' in this block; weight_broadcast_bytes: a learned coefficient multiplied by an activation. Context: the function matrix_schedule, which handles matrix schedule.

Line 85: `load_commands = row_tiles + compute_tiles` This assigns 'row_tiles + compute_tiles' to 'load_commands ' in host memory. Here load_commands means the 128-bit instruction selecting an engine, shape, mode, and numeric parameters. The important operands are row_tiles: one output-row position processed by the tensor tile; compute_tiles: the value named 'compute tiles' in this block. Context: the function matrix_schedule, which handles matrix schedule.

Line 86: `stream_bytes = input_broadcast_bytes` This assigns 'input_broadcast_bytes' to 'stream_bytes ' in host memory. Here stream_bytes means the value named 'stream bytes' in this block. The important operands are input_broadcast_bytes: the value named 'input broadcast bytes' in this block. Context: the function matrix_schedule, which handles matrix schedule.

Line 87: `else:` This begins the alternative host-code branch when the preceding condition was false, still inside the function matrix_schedule, which handles matrix schedule.

Line 88: `load_commands = column_tiles + compute_tiles` This assigns ‘column_tiles + compute_tiles‘ to ‘load_commands ‘ in host memory. Here load_commands means the 128-bit instruction selecting an engine, shape, mode, and numeric parameters. The important operands are column_tiles: one output-feature position processed in parallel; compute_tiles: the value named ’compute tiles’ in this block. Context: the function matrix_schedule, which handles matrix schedule.

Line 89: `stream_bytes = weight_broadcast_bytes` This assigns ‘weight_broadcast_bytes‘ to ‘stream_bytes ‘ in host memory. Here stream_bytes means the value named ’stream bytes’ in this block. The important operands are weight_broadcast_bytes: a learned coefficient multiplied by an activation. Context: the function matrix_schedule, which handles matrix schedule.

Line 90: `total_commands += load_commands + compute_tiles` Inside the function matrix_schedule, which handles matrix schedule, this statement advances the host implementation that derives every model tensor shape, tile schedule, command count, operation count, and traffic total. The important operands are total_commands: the 128-bit instruction selecting an engine, shape, mode, and numeric parameters; load_commands: the 128-bit instruction selecting an engine, shape, mode, and numeric parameters; compute_tiles: the value named ’compute tiles’ in this block.

Line 91: `total_compute_tiles += compute_tiles` Inside the function matrix_schedule, which handles matrix schedule, this statement advances the host implementation that derives every model tensor shape, tile schedule, command count, operation count, and traffic total. The important operands are total_compute_tiles: the value named ’total compute tiles’ in this block; compute_tiles: the value named ’compute tiles’ in this block.

Line 92: `total_input_bytes += stream_bytes` Inside the function matrix_schedule, which handles matrix schedule, this statement advances the host implementation that derives every model tensor shape, tile schedule, command count, operation count, and traffic total. The important operands are total_input_bytes: the value named ’total input bytes’ in this block; stream_bytes: the value named ’stream bytes’ in this block.

Line 93: `# The current output ABI emits one 32-bit result in each 64-bit beat.` The comment records this intent: The current output ABI emits one 32-bit result in each 64-bit beat. It applies inside the function matrix_schedule, which handles matrix schedule.

Line 94: `total_output_bytes += rows * columns * 8` Inside the function matrix_schedule, which handles matrix schedule, this statement advances the host implementation that derives every model tensor shape, tile schedule, command count, operation count, and traffic total. The important operands are total_output_bytes: the value named ’total output bytes’ in this block; rows: one output-row position processed by the tensor tile; columns: one output-feature position processed in parallel.

Line 95: `return MatrixSchedule(` This statement continues through source line 107; the explanation uses the complete expression rather than only the first visual fragment. This returns ‘MatrixSchedule(rows=rows, reduction=reduction, columns=columns, repetitions=repetitions, arithmetic=arithmetic, mac_equivalents=rows * reduction * columns * repetitions, reduction_chunks=chunks * repetitions, compute_tiles=total_compute_tiles * repetitions, commands=total_commands * repetitions, input_stream_bytes=total_input_bytes * repetitions, output_stream_bytes=total_outpu * repetitions,)‘ to the caller of the function matrix_schedule, which handles matrix schedule, ending this invocation. The important operands are MatrixSchedule: the value named ’matrix schedule’ in this block; rows: one output-row position processed by the tensor tile; reduction: the value named ’reduction’ in this block.

Line 96: `rows=rows,` This is continuation line 2 of the 13-line logical statement that begins at source line 95. Its exact fragment is ‘rows=rows,‘. The important operands are rows: one output-row position processed by the tensor tile. Read together, the complete operation is: This returns ‘MatrixSchedule(rows=rows, reduction=reduction, columns=columns, repetitions=repetitions, arithmetic=arithmetic, mac_equivalents=rows * reduction * columns * repetitions, reduction_chunks=chunks * repetitions, compute_tiles=total_compute_tiles * repetitions, commands=total_commands * repetitions, input_stream_bytes=total_input_bytes * repetitions, output_stream_bytes=total_output_bytes * repetitions,)‘ to the caller of the function matrix_schedule, which handles matrix schedule, ending this invocation. The important operands are MatrixSchedule: the value named ’matrix schedule’ in this block; rows: one output-row position processed by the tensor tile; reduction: the value named ’reduction’ in this block.

Line 97: `reduction=reduction,` This is continuation line 3 of the 13-line logical statement that begins at source line 95. Its exact fragment is 'reduction=reduction,'. The important operands are reduction: the value named 'reduction' in this block. Read together, the complete operation is: This returns 'MatrixSchedule(rows=rows, reduction=reduction, columns=columns, repetitions=repetitions, arithmetic=arithmetic, mac_equivalents=rows * reduction * columns * repetitions, reduction_chunks=chunks * repetitions, compute_tiles=total_compute_tiles * repetitions, commands=total_commands * repetitions, input_stream_bytes=total_input_bytes * repetitions, output_stream_bytes=total_outpu * repetitions,)' to the caller of the function matrix_schedule, which handles matrix schedule, ending this invocation. The important operands are MatrixSchedule: the value named 'matrix schedule' in this block; rows: one output-row position processed by the tensor tile; reduction: the value named 'reduction' in this block.

Line 98: `columns=columns,` This is continuation line 4 of the 13-line logical statement that begins at source line 95. Its exact fragment is 'columns=columns,'. The important operands are columns: one output-feature position processed in parallel. Read together, the complete operation is: This returns 'MatrixSchedule(rows=rows, reduction=reduction, columns=columns, repetitions=repetitions, arithmetic=arithmetic, mac_equivalents=rows * reduction * columns * repetitions, reduction_chunks=chunks * repetitions, compute_tiles=total_compute_tiles * repetitions, commands=total_commands * repetitions, input_stream_bytes=total_input_bytes * repetitions, output_stream_bytes=total_outpu * repetitions,)' to the caller of the function matrix_schedule, which handles matrix schedule, ending this invocation. The important operands are MatrixSchedule: the value named 'matrix schedule' in this block; rows: one output-row position processed by the tensor tile; reduction: the value named 'reduction' in this block.

Line 99: `repetitions=repetitions,` This is continuation line 5 of the 13-line logical statement that begins at source line 95. Its exact fragment is 'repetitions=repetitions,'. The important operands are repetitions: the value named 'repetitions' in this block. Read together, the complete operation is: This returns 'MatrixSchedule(rows=rows, reduction=reduction, columns=columns, repetitions=repetitions, arithmetic=arithmetic, mac_equivalents=rows * reduction * columns * repetitions, reduction_chunks=chunks * repetitions, compute_tiles=total_compute_tiles * repetitions, commands=total_commands * repetitions, input_stream_bytes=total_input_bytes * repetitions, output_stream_bytes=total_outpu * repetitions,)' to the caller of the function matrix_schedule, which handles matrix schedule, ending this invocation. The important operands are MatrixSchedule: the value named 'matrix schedule' in this block; rows: one output-row position processed by the tensor tile; reduction: the value named 'reduction' in this block.

Line 100: `arithmetic=arithmetic,` This is continuation line 6 of the 13-line logical statement that begins at source line 95. Its exact fragment is 'arithmetic=arithmetic,'. The important operands are arithmetic: the value named 'arithmetic' in this block. Read together, the complete operation is: This returns 'MatrixSchedule(rows=rows, reduction=reduction, columns=columns, repetitions=repetitions, arithmetic=arithmetic, mac_equivalents=rows * reduction * columns * repetitions, reduction_chunks=chunks * repetitions, compute_tiles=total_compute_tiles * repetitions, commands=total_commands * repetitions, input_stream_bytes=total_input_bytes * repetitions, output_stream_bytes=total_outpu * repetitions,)' to the caller of the function matrix_schedule, which handles matrix schedule, ending this invocation. The important operands are MatrixSchedule: the value named 'matrix schedule' in this block; rows: one output-row position processed by the tensor tile; reduction: the value named 'reduction' in this block.

Line 101: `mac_equivalents=rows * reduction * columns * repetitions,` This is continuation line 7 of the 13-line logical statement that begins at source line 95. Its exact fragment is 'mac_equivalents=rows * reduction * columns * repetitions,'. The important operands are mac_equivalents: the value named 'mac equivalents' in this block; rows: one output-row position processed by the tensor tile; reduction: the value named 'reduction' in this block. Read together, the complete operation is: This returns 'MatrixSchedule(rows=rows, reduction=reduction, columns=columns, repetitions=repetitions, arithmetic=arithmetic, mac_equivalents=rows * reduction * columns * repetitions, reduction_chunks=chunks * repetitions, compute_tiles=total_compute_tiles * repetitions, commands=total_commands * repetitions, input_stream_bytes=t * repetitions, output_stream_bytes=total_output_bytes * repetitions,)' to the caller of the function matrix_schedule, which handles matrix schedule, ending this invocation. The important operands are MatrixSchedule: the value named 'matrix schedule' in this block; rows: one output-row position processed by the tensor tile; reduction: the value named 'reduction' in this block.

Line 102: `reduction_chunks=chunks * repetitions,` This is continuation line 8 of the 13-line logical statement that begins at source line 95. Its exact fragment is 'reduction_chunks=chunks * repetitions,'. The important operands are reduction_chunks: the value named 'reduction chunks' in this block; chunks: the value named 'chunks' in this block; repetitions: the value named 'repetitions' in this block. Read together, the complete operation is: This returns 'MatrixSchedule(rows=rows, reduction=reduction, columns=columns, repetitions=repetitions, arithmetic=arithmetic,

mac_equivalents=rows * reduction * columns * repetitions, reduction_chunks=chunks * repetitions, compute_tiles=total_compute * repetitions, commands=total_commands * repetitions, input_stream_bytes=total_input_bytes * repetitions, output_stream_bytes=total_output_bytes * repetitions,)‘ to the caller of the function matrix_schedule, which handles matrix schedule, ending this invocation. The important operands are MatrixSchedule: the value named 'matrix schedule' in this block; rows: one output-row position processed by the tensor tile; reduction: the value named 'reduction' in this block.

Line 103: `compute_tiles=total_compute_tiles * repetitions,` This is continuation line 9 of the 13-line logical statement that begins at source line 95. Its exact fragment is ‘compute_tiles=total_compute_tiles * repetitions,‘. The important operands are compute_tiles: the value named 'compute tiles' in this block; total_compute_tiles: the value named 'total compute tiles' in this block; repetitions: the value named 'repetitions' in this block. Read together, the complete operation is: This returns ‘MatrixSchedule(rows=rows, reduction=reduction, columns=columns, repetitions=repetitions, arithmetic=arithmetic, mac_equivalents=rows * reduction * columns * repetitions, reduction_chunks=chunks * repetitions, compute_tiles=total_compute_tiles * repetitions, commands=total_commands * repetitions, input_stream_bytes=total_input * repetitions, output_stream_bytes=total_output_bytes * repetitions,)‘ to the caller of the function matrix_schedule, which handles matrix schedule, ending this invocation. The important operands are MatrixSchedule: the value named 'matrix schedule' in this block; rows: one output-row position processed by the tensor tile; reduction: the value named 'reduction' in this block.

Line 104: `commands=total_commands * repetitions,` This is continuation line 10 of the 13-line logical statement that begins at source line 95. Its exact fragment is ‘commands=total_commands * repetitions,‘. The important operands are commands: the 128-bit instruction selecting an engine, shape, mode, and numeric parameters; total_commands: the 128-bit instruction selecting an engine, shape, mode, and numeric parameters; repetitions: the value named 'repetitions' in this block. Read together, the complete operation is: This returns ‘MatrixSchedule(rows=rows, reduction=reduction, columns=columns, repetitions=repetitions, arithmetic=arithmetic, mac_equivalents=rows * reduction * columns * repetitions, reduction_chunks=chunks * repetitions, compute_tiles=total_compute_tiles * repetitions, commands=total_commands * repetitions, input_stream_bytes=total_input_bytes * repetitions, output_stream_bytes=total_output * repetitions,)‘ to the caller of the function matrix_schedule, which handles matrix schedule, ending this invocation. The important operands are MatrixSchedule: the value named 'matrix schedule' in this block; rows: one output-row position processed by the tensor tile; reduction: the value named 'reduction' in this block.

Line 105: `input_stream_bytes=total_input_bytes * repetitions,` This is continuation line 11 of the 13-line logical statement that begins at source line 95. Its exact fragment is ‘input_stream_bytes=total_input_bytes * repetitions,‘. The important operands are input_stream_bytes: the value named 'input stream bytes' in this block; total_input_bytes: the value named 'total input bytes' in this block; repetitions: the value named 'repetitions' in this block. Read together, the complete operation is: This returns ‘MatrixSchedule(rows=rows, reduction=reduction, columns=columns, repetitions=repetitions, arithmetic=arithmetic, mac_equivalents=rows * reduction * columns * repetitions, reduction_chunks=chunks * repetitions, compute_tiles=total_compute_tiles * repetitions, commands=total_commands * repetitions, input_stream_bytes=total_input_bytes * repetitions, output_stream_bytes=total_output_bytes * repetitions,)‘ to the caller of the function matrix_schedule, which handles matrix schedule, ending this invocation. The important operands are MatrixSchedule: the value named 'matrix schedule' in this block; rows: one output-row position processed by the tensor tile; reduction: the value named 'reduction' in this block.

Line 106: `output_stream_bytes=total_output_bytes * repetitions,` This is continuation line 12 of the 13-line logical statement that begins at source line 95. Its exact fragment is ‘output_stream_bytes=total_output_bytes * repetitions,‘. The important operands are output_stream_bytes: the value named 'output stream bytes' in this block; total_output_bytes: the value named 'total output bytes' in this block; repetitions: the value named 'repetitions' in this block. Read together, the complete operation is: This returns ‘MatrixSchedule(rows=rows, reduction=reduction, columns=columns, repetitions=repetitions, arithmetic=arithmetic, mac_equivalents=rows * reduction * columns * repetitions, reduction_chunks=chunks * repetitions, compute_tiles=total_compute_tiles * repetitions, commands=total_commands * repetitions, input_stream_bytes=total_input_bytes * repetitions, output_stream_bytes=total_output * repetitions,)‘ to the caller of the function matrix_schedule, which handles matrix schedule, ending this invocation. The important operands are MatrixSchedule: the value named 'matrix schedule' in this block; rows: one output-row position processed by the tensor tile; reduction: the value named 'reduction' in this block.

Line 107: `)` This is continuation line 13 of the 13-line logical statement that begins at source line 95. Its exact fragment is ‘)‘. The expression is a literal or structural operator and has no hidden software state. Read together, the complete op-

eration is: This returns ‘MatrixSchedule(rows=rows, reduction=reduction, columns=columns, repetitions=repetitions, arithmetic=arithmetic, mac_equivalents=rows * reduction * columns * repetitions, reduction_chunks=chunks * repetitions, compute_tiles=total_compute_tiles * repetitions, commands=total_commands * repetitions, input_stream_bytes=total_in * repetitions, output_stream_bytes=total_output_bytes * repetitions,)‘ to the caller of the function matrix_schedule, which handles matrix schedule, ending this invocation. The important operands are MatrixSchedule: the value named ’matrix schedule’ in this block; rows: one output-row position processed by the tensor tile; reduction: the value named ’reduction’ in this block.

Line 110: `def build_operator_manifest() -> list[OperatorMapping]:` This starts function build_operator_manifest. Its indented body performs build operator manifest as part of the file that derives every model tensor shape, tile schedule, command count, operation count, and traffic total; it runs only when called.

Line 111: `"""Describe every learned and data-dependent operator for one image."""` This is executable documentation attached to the function build_operator_manifest, which handles build operator manifest. It states the intended contract that tests and callers should enforce, but the text itself does not transform data or issue hardware work.

Line 113: `time_steps = 4` This assigns ‘4‘ to ‘time_steps ‘ in host memory. Here time_steps means the value named ’time steps’ in this block. The expression is a literal or structural operator and has no hidden software state. Context: the function build_operator_manifest, which handles build operator manifest.

Line 114: `channels = 384` This assigns ‘384‘ to ‘channels ‘ in host memory. Here channels means the value named ’channels’ in this block. The expression is a literal or structural operator and has no hidden software state. Context: the function build_operator_manifest, which handles build operator manifest.

Line 115: `tokens = 64` This assigns ‘64‘ to ‘tokens ‘ in host memory. Here tokens means the value named ’tokens’ in this block. The expression is a literal or structural operator and has no hidden software state. Context: the function build_operator_manifest, which handles build operator manifest.

Line 116: `heads = 12` This assigns ‘12‘ to ‘heads ‘ in host memory. Here heads means the value named ’heads’ in this block. The expression is a literal or structural operator and has no hidden software state. Context: the function build_operator_manifest, which handles build operator manifest.

Line 117: `head_dim = channels // heads` This assigns ‘channels // heads‘ to ‘head_dim ‘ in host memory. Here head_dim means the value named ’head dim’ in this block. The important operands are channels: the value named ’channels’ in this block; heads: the value named ’heads’ in this block. Context: the function build_operator_manifest, which handles build operator manifest.

Line 118: `operators: list[OperatorMapping] = []` This assigns ‘[]‘ to ‘operators‘ in host memory. Here operators means the value named ’operators’ in this block. The expression is a literal or structural operator and has no hidden software state. Context: the function build_operator_manifest, which handles build operator manifest.

Line 120: `def matrix_operator(` This starts function matrix_operator. Its indented body performs matrix operator as part of the file that derives every model tensor shape, tile schedule, command count, operation count, and traffic total; it runs only when called.

Line 121: `name: str,` Inside the function matrix_operator, which handles matrix operator, this statement advances the host implementation that derives every model tensor shape, tile schedule, command count, operation count, and traffic total. The important operands are name: the value named ’name’ in this block; str: the value named ’str’ in this block.

Line 122: `source: str,` Inside the function matrix_operator, which handles matrix operator, this statement advances the host implementation that derives every model tensor shape, tile schedule, command count, operation count, and traffic total. The important operands are source: the value named ’source’ in this block; str: the value named ’str’ in this block.

Line 123: `input_shape: tuple[int, ...],` Inside the function matrix_operator, which handles matrix operator, this statement advances the host implementation that derives every model tensor shape, tile schedule, command count, operation count, and traffic total. The important operands are input_shape: the value named 'input shape' in this block; tuple: the value named 'tuple' in this block.

Line 124: `output_shape: tuple[int, ...],` Inside the function matrix_operator, which handles matrix operator, this statement advances the host implementation that derives every model tensor shape, tile schedule, command count, operation count, and traffic total. The important operands are output_shape: the value named 'output shape' in this block; tuple: the value named 'tuple' in this block.

Line 125: `rows: int,` Inside the function matrix_operator, which handles matrix operator, this statement advances the host implementation that derives every model tensor shape, tile schedule, command count, operation count, and traffic total. The important operands are rows: one output-row position processed by the tensor tile.

Line 126: `reduction: int,` Inside the function matrix_operator, which handles matrix operator, this statement advances the host implementation that derives every model tensor shape, tile schedule, command count, operation count, and traffic total. The important operands are reduction: the value named 'reduction' in this block.

Line 127: `columns: int,` Inside the function matrix_operator, which handles matrix operator, this statement advances the host implementation that derives every model tensor shape, tile schedule, command count, operation count, and traffic total. The important operands are columns: one output-feature position processed in parallel.

Line 128: `arithmetic: Literal["u8_mac", "binary_spike_add", "dynamic_u8_mac"],` Inside the function matrix_operator, which handles matrix operator, this statement advances the host implementation that derives every model tensor shape, tile schedule, command count, operation count, and traffic total. The important operands are arithmetic: the value named 'arithmetic' in this block; Literal: the value named 'literal' in this block; u8_mac: the value named 'u8 mac' in this block.

Line 129: `primitive: str,` Inside the function matrix_operator, which handles matrix operator, this statement advances the host implementation that derives every model tensor shape, tile schedule, command count, operation count, and traffic total. The important operands are primitive: the value named 'primitive' in this block; str: the value named 'str' in this block.

Line 130: `*,` Inside the function matrix_operator, which handles matrix operator, this statement advances the host implementation that derives every model tensor shape, tile schedule, command count, operation count, and traffic total. The expression is a literal or structural operator and has no hidden software state.

Line 131: `repetitions: int = 1,` This assigns '1,' to 'repetitions' in host memory. Here repetitions means the value named 'repetitions' in this block. The expression is a literal or structural operator and has no hidden software state. Context: the function matrix_operator, which handles matrix operator.

Line 132: `optimization: str | None = None,` This assigns 'None,' to 'optimization' in host memory. Here optimization means the value named 'optimization' in this block. The important operands are None: the value named 'none' in this block. Context: the function matrix_operator, which handles matrix operator.

Line 133: `) -> None:` Inside the function matrix_operator, which handles matrix operator, this statement advances the host implementation that derives every model tensor shape, tile schedule, command count, operation count, and traffic total. The important operands are None: the value named 'none' in this block.

Line 134: `operators.append(OperatorMapping(` This statement continues through source line 146; the explanation uses the complete expression rather than only the first visual fragment. This calls 'operators.append' with 'OperatorMapping(name=name, source_operation=source, input_shape_per_image=input_shape, output_shape_per_image=output_shape, hardware_primitive=primitive, matrix=matrix_schedule(rows, reduction, columns, repetitions=repetitions, arithmetic=arithmetic), exact_optimization=optimization,)' inside the function matrix_operator, which handles matrix operator. The call

advances the host-side job that derives every model tensor shape, tile schedule, command count, operation count, and traffic total.

Line 135: `name=name,` This is continuation line 2 of the 13-line logical statement that begins at source line 134. Its exact fragment is 'name=name,'. The important operands are name: the value named 'name' in this block. Read together, the complete operation is: This calls 'operators.append' with 'OperatorMapping(name=name, source_operation=source, input_shape_per_image=input_shape, output_shape_per_image=output_shape, hardware_primitive=primitive, matrix=matrix_schedule(rows, reduction, columns, repetitions=repetitions, arithmetic=arithmetic,), exact_optimization=optimizati)' inside the function matrix_operator, which handles matrix operator. The call advances the host-side job that derives every model tensor shape, tile schedule, command count, operation count, and traffic total.

Line 136: `source_operation=source,` This is continuation line 3 of the 13-line logical statement that begins at source line 134. Its exact fragment is 'source_operation=source,'. The important operands are source_operation: the value named 'source operation' in this block; source: the value named 'source' in this block. Read together, the complete operation is: This calls 'operators.append' with 'OperatorMapping(name=name, source_operation=source, input_shape_per_image=input_shape, output_shape_per_image=output_shape, hardware_primitive=primitive, matrix=matrix_schedule(rows, reduction, columns, repetitions=repetitions, arithmetic=arithmetic,), exact_optimization=optimizati)' inside the function matrix_operator, which handles matrix operator. The call advances the host-side job that derives every model tensor shape, tile schedule, command count, operation count, and traffic total.

Line 137: `input_shape_per_image=input_shape,` This is continuation line 4 of the 13-line logical statement that begins at source line 134. Its exact fragment is 'input_shape_per_image=input_shape,'. The important operands are input_shape_per_image: the value named 'input shape per image' in this block; input_shape: the value named 'input shape' in this block. Read together, the complete operation is: This calls 'operators.append' with 'OperatorMapping(name=name, source_operation=source, input_shape_per_image=input_shape, output_shape_per_image=output_shape, hardware_primitive=primitive, matrix=matrix_schedule(rows, reduction, columns, repetitions=repetitions, arithmetic=arithmetic), exact_optimization=optimization,)' inside the function matrix_operator, which handles matrix operator. The call advances the host-side job that derives every model tensor shape, tile schedule, command count, operation count, and traffic total.

Line 138: `output_shape_per_image=output_shape,` This is continuation line 5 of the 13-line logical statement that begins at source line 134. Its exact fragment is 'output_shape_per_image=output_shape,'. The important operands are output_shape_per_image: the value named 'output shape per image' in this block; output_shape: the value named 'output shape' in this block. Read together, the complete operation is: This calls 'operators.append' with 'OperatorMapping(name=name, source_operation=source, input_shape_per_image=input_shape, output_shape_per_image=output_shape, hardware_primitive=primitive, matrix=matrix_schedule(rows, reduction, columns, repetitions=repetitions, arithmetic=arithmetic), exact_optimization=optimization,)' inside the function matrix_operator, which handles matrix operator. The call advances the host-side job that derives every model tensor shape, tile schedule, command count, operation count, and traffic total.

Line 139: `hardware_primitive=primitive,` This is continuation line 6 of the 13-line logical statement that begins at source line 134. Its exact fragment is 'hardware_primitive=primitive,'. The important operands are hardware_primitive: the value named 'hardware primitive' in this block; primitive: the value named 'primitive' in this block. Read together, the complete operation is: This calls 'operators.append' with 'OperatorMapping(name=name, source_operation=source, input_shape_per_image=input_shape, output_shape_per_image=output_shape, hardware_primitive=primitive, matrix=matrix_schedule(rows, reduction, columns, repetitions=repetitions, arithmetic=arithmetic,), exact_optimization=optimizati)' inside the function matrix_operator, which handles matrix operator. The call advances the host-side job that derives every model tensor shape, tile schedule, command count, operation count, and traffic total.

Line 140: `matrix=matrix_schedule(` This is continuation line 7 of the 13-line logical statement that begins at source line 134. Its exact fragment is 'matrix=matrix_schedule('. The important operands are matrix: the value named 'matrix' in this block; matrix_schedule: the value named 'matrix schedule' in this block. Read together, the complete operation is: This calls 'operators.append' with 'OperatorMapping(name=name, source_operation=source, input_shape_per_image=input_shape, output_shape_per_image=output_shape, hardware_primitive=primitive, matrix=matrix_schedule(rows, reduction, columns, repetitions=repetitions, arithmetic=arithmetic,), exact_optimization=optimizati

)‘ inside the function matrix_operator, which handles matrix operator. The call advances the host-side job that derives every model tensor shape, tile schedule, command count, operation count, and traffic total.

Line 141: `rows, reduction, columns,` This is continuation line 8 of the 13-line logical statement that begins at source line 134. Its exact fragment is ‘rows, reduction, columns,‘. The important operands are rows: one output-row position processed by the tensor tile; reduction: the value named ’reduction’ in this block; columns: one output-feature position processed in parallel. Read together, the complete operation is: This calls ‘operators.append‘ with ‘OperatorMapping(name=name, source_operation=source, input_shape_per_image=input_shape, output_shape_per_image=output_shape, hardware_primitive=primitive, matrix=matrix_schedule(rows, reduction, columns, repetitions=repetitions, arithmetic=arithmetic), exact_optimization=optimization,)‘ inside the function matrix_operator, which handles matrix operator. The call advances the host-side job that derives every model tensor shape, tile schedule, command count, operation count, and traffic total.

Line 142: `repetitions=repetitions,` This is continuation line 9 of the 13-line logical statement that begins at source line 134. Its exact fragment is ‘repetitions=repetitions,‘. The important operands are repetitions: the value named ’repetitions’ in this block. Read together, the complete operation is: This calls ‘operators.append‘ with ‘OperatorMapping(name=name, source_operation=source, input_shape_per_image=input_shape, output_shape_per_image=output_shape, hardware_primitive=primitive, matrix=matrix_schedule(rows, reduction, columns, repetitions=repetitions, arithmetic=arithmetic), exact_optimization=optimization,)‘ inside the function matrix_operator, which handles matrix operator. The call advances the host-side job that derives every model tensor shape, tile schedule, command count, operation count, and traffic total.

Line 143: `arithmetic=arithmetic,` This is continuation line 10 of the 13-line logical statement that begins at source line 134. Its exact fragment is ‘arithmetic=arithmetic,‘. The important operands are arithmetic: the value named ’arithmetic’ in this block. Read together, the complete operation is: This calls ‘operators.append‘ with ‘OperatorMapping(name=name, source_operation=source, input_shape_per_image=input_shape, output_shape_per_image=output_shape, hardware_primitive=primitive, matrix=matrix_schedule(rows, reduction, columns, repetitions=repetitions, arithmetic=arithmetic), exact_optimization=optimization,)‘ inside the function matrix_operator, which handles matrix operator. The call advances the host-side job that derives every model tensor shape, tile schedule, command count, operation count, and traffic total.

Line 144: `),` This is continuation line 11 of the 13-line logical statement that begins at source line 134. Its exact fragment is ‘),‘. The expression is a literal or structural operator and has no hidden software state. Read together, the complete operation is: This calls ‘operators.append‘ with ‘OperatorMapping(name=name, source_operation=source, input_shape_per_image=input_shape, output_shape_per_image=output_shape, hardware_primitive=primitive, matrix=matrix_schedule(rows, reduction, columns, repetitions=repetitions, arithmetic=arithmetic,), exact_optimization=optimizati)‘ inside the function matrix_operator, which handles matrix operator. The call advances the host-side job that derives every model tensor shape, tile schedule, command count, operation count, and traffic total.

Line 145: `exact_optimization=optimization,` This is continuation line 12 of the 13-line logical statement that begins at source line 134. Its exact fragment is ‘exact_optimization=optimization,‘. The important operands are exact_optimization: the value named ’exact optimization’ in this block; optimization: the value named ’optimization’ in this block. Read together, the complete operation is: This calls ‘operators.append‘ with ‘OperatorMapping(name=name, source_operation=source, input_shape_per_image=input_shape, output_shape_per_image=output_shape, hardware_primitive matrix=matrix_schedule(rows, reduction, columns, repetitions=repetitions, arithmetic=arithmetic,), exact_optimization=optimiz)‘ inside the function matrix_operator, which handles matrix operator. The call advances the host-side job that derives every model tensor shape, tile schedule, command count, operation count, and traffic total.

Line 146: `))` This is continuation line 13 of the 13-line logical statement that begins at source line 134. Its exact fragment is ‘))‘. The expression is a literal or structural operator and has no hidden software state. Read together, the complete operation is: This calls ‘operators.append‘ with ‘OperatorMapping(name=name, source_operation=source, input_shape_per_image=input_shape, output_shape_per_image=output_shape, hardware_primitive=primitive, matrix=matrix_schedule(rows, reduction, columns, repetitions=repetitions, arithmetic=arithmetic,), exact_optimization=optimizati)‘ inside the function matrix_operator, which handles matrix operator. The call advances the host-side job that derives every model tensor shape, tile schedule, command count, operation count, and traffic total.

Line 148: `matrix_operator(` This statement continues through source line 156; the explanation uses the complete expression rather than only the first visual fragment. This calls ‘matrix_operator‘ with ‘ "patch_embed.block0", "Conv2d 3x3 + folded BatchNorm", (3, 32, 32), (time_steps, 48, 32, 32), 32 * 32, 3 * 3 * 3, 48, "u8_mac", "dense tensor tile", optimization=("Compute once and broadcast to four timesteps. The source repeats " "one unchanged image before this stateless operator, so this removes " "three of four executions with exact output equivalence."), ‘ inside the function build_operator_manifest, which handles build operator manifest. The call advances the host-side job that derives every model tensor shape, tile schedule, command count, operation count, and traffic total.

Line 149: `"patch_embed.block0", "Conv2d 3x3 + folded BatchNorm",` This is continuation line 2 of the 9-line logical statement that begins at source line 148. Its exact fragment is ‘"patch_embed.block0", "Conv2d 3x3 + folded BatchNorm",‘. The important operands are patch_embed: the value named ’patch embed’ in this block; block0: the value named ’block0’ in this block; Conv2d: the value named ’conv2d’ in this block. Read together, the complete operation is: This calls ‘matrix_operator‘ with ‘ "patch_embed.block0", "Conv2d 3x3 + folded BatchNorm", (3, 32, 32), (time_steps, 48, 32, 32), 32 * 32, 3 * 3 * 3, 48, "u8_mac", "dense tensor tile", optimization=("Compute once and broadcast to four timesteps. The source repeats " "one unchanged image before this stateless operator, so this removes " "three of four executions with exact output equivalence."), ‘ inside the function build_operator_manifest, which handles build operator manifest. The call advances the host-side job that derives every model tensor shape, tile schedule, command count, operation count, and traffic total.

Line 150: `(3, 32, 32), (time_steps, 48, 32, 32),` This is continuation line 3 of the 9-line logical statement that begins at source line 148. Its exact fragment is ‘(3, 32, 32), (time_steps, 48, 32, 32),‘. The important operands are time_steps: the value named ’time steps’ in this block. Read together, the complete operation is: This calls ‘matrix_operator‘ with ‘ "patch_embed.block0", "Conv2d 3x3 + folded BatchNorm", (3, 32, 32), (time_steps, 48, 32, 32), 32 * 32, 3 * 3 * 3, 48, "u8_mac", "dense tensor tile", optimization=("Compute once and broadcast to four timesteps. The source repeats " "one unchanged image before this stateless operator, so this removes " "three of four executions with exact output equivalence."), ‘ inside the function build_operator_manifest, which handles build operator manifest. The call advances the host-side job that derives every model tensor shape, tile schedule, command count, operation count, and traffic total.

Line 151: `32 * 32, 3 * 3 * 3, 48, "u8_mac", "dense tensor tile",` This is continuation line 4 of the 9-line logical statement that begins at source line 148. Its exact fragment is ‘32 * 32, 3 * 3 * 3, 48, "u8_mac", "dense tensor tile",‘. The important operands are u8_mac: the value named ’u8 mac’ in this block; dense: the value named ’dense’ in this block; tensor: the value named ’tensor’ in this block. Read together, the complete operation is: This calls ‘matrix_operator‘ with ‘ "patch_embed.block0", "Conv2d 3x3 + folded BatchNorm", (3, 32, 32), (time_steps, 48, 32, 32), 32 * 32, 3 * 3 * 3, 48, "u8_mac", "dense tensor tile", optimization=("Compute once and broadcast to four timesteps. The important operands are output_shape_per_image: the value named ’output shape per image’ in this block; time_steps: the value named ’time steps’ in this block; channels: the value named ’channels’ in this block. Read together, the complete operation is: This calls ‘operators.append‘ with ‘OperatorMapping(name=f"{prefix}.residuals", source_operation="two elementwise residual additions", input_shape_per_image=(time_steps, channels, 8, 8), output_shape_per_image=(time_steps, channels, 8, 8), hardware_primitive="saturating vector add", matrix=None,)‘ inside the function build_operator_manifest, which handles build operator manifest. The call advances the host-side job that derives every model tensor shape, tile schedule, command count, operation count, and traffic total.

Line 225: `hardware_primitive="saturating vector add",` This is continuation line 6 of the 8-line logical statement that begins at source line 220. Its exact fragment is ‘hardware_primitive="saturating vector add",‘. The important operands are hardware_primitive: the value named ’hardware primitive’ in this block; saturating: the value named ’saturating’ in this block; vector: the value named ’vector’ in this block. Read together, the complete operation is: This calls ‘operators.append‘ with ‘OperatorMapping(name=f"{prefix}.residuals", source_operation="two elementwise residual additions", input_shape_per_image=(time_steps, channels, 8, 8), output_shape_per_image=(time_steps, channels, 8,

8), hardware_primitive="saturating vector add", matrix=None,)‘ inside the function build_operator_manifest, which handles build operator manifest. The call advances the host-side job that derives every model tensor shape, tile schedule, command count, operation count, and traffic total.

Line 226: `matrix=None,` This is continuation line 7 of the 8-line logical statement that begins at source line 220. Its exact fragment is ‘matrix=None,‘. The important operands are matrix: the value named ’matrix’ in this block; None: the value named ’none’ in this block. Read together, the complete operation is: This calls ‘operators.append‘ with ‘OperatorMapping(name=f"{prefix}.residuals", source_operation="two elementwise residual additions", input_shape_per_image=(time_ channels, 8, 8), output_shape_per_image=(time_steps, channels, 8, 8), hardware_primitive="saturating vector add", matrix=None,)‘ inside the function build_operator_manifest, which handles build operator manifest. The call advances the host-side job that derives every model tensor shape, tile schedule, command count, operation count, and traffic total.

Line 227: `))` This is continuation line 8 of the 8-line logical statement that begins at source line 220. Its exact fragment is ‘))‘. The expression is a literal or structural operator and has no hidden software state. Read together, the complete operation is: This calls ‘operators.append‘ with ‘OperatorMapping(name=f"{prefix}.residuals", source_operation="two elementwise residual additions", input_shape_per_image=(time_steps, channels, 8, 8), output_shape_per_image=(time_steps, channels, 8, 8), hardware_primitive="saturating vector add", matrix=None,)‘ inside the function build_operator_manifest, which handles build operator manifest. The call advances the host-side job that derives every model tensor shape, tile schedule, command count, operation count, and traffic total.

Line 229: `operators.append(OperatorMapping(` This statement continues through source line 236; the explanation uses the complete expression rather than only the first visual fragment. This calls ‘operators.append‘ with ‘OperatorMapping(name="global_average_pool", source_operation="mean over 64 tokens then mean over four timesteps", input_shape_per_image=(time_steps, channels, 8, 8), output_shape_per_image=(channels,), hardware_primitive="vector add followed by exact power-of-two shifts", matrix=None,)‘ inside the function build_operator_manifest, which handles build operator manifest. The call advances the host-side job that derives every model tensor shape, tile schedule, command count, operation count, and traffic total.

Line 230: `name="global_average_pool",` This is continuation line 2 of the 8-line logical statement that begins at source line 229. Its exact fragment is ‘name="global_average_pool",‘. The important operands are name: the value named ’name’ in this block; global_average_pool: the value named ’global average pool’ in this block. Read together, the complete operation is: This calls ‘operators.append‘ with ‘OperatorMapping(name="global_average_pool", source_operation="mean over 64 tokens then mean over four timesteps", input_shape_per_image=(time_steps, channels, 8, 8), output_shape_per_image=(channels,), hardware_primitive="vector add followed by exact power-of-two shifts", matrix=None,)‘ inside the function build_operator_manifest, which handles build operator manifest. The call advances the host-side job that derives every model tensor shape, tile schedule, command count, operation count, and traffic total.

Line 231: `source_operation="mean over 64 tokens then mean over four timesteps",` This is continuation line 3 of the 8-line logical statement that begins at source line 229. Its exact fragment is ‘source_operation="mean over 64 tokens then mean over four timesteps",‘. The important operands are source_operation: the value named ’source operation’ in this block; mean: the arithmetic average used by normalization; over: the value named ’over’ in this block. Read together, the complete operation is: This calls ‘operators.append‘ with ‘OperatorMapping(name="global_average_pool", source_operation="mean over 64 tokens then mean over four timesteps", input_shape_per_image=(time_steps, channels, 8, 8), output_shape_per_image=(channels,), hardware_primitive="vector add followed by exact power-of-two shifts", matrix=None,)‘ inside the function build_operator_manifest, which handles build operator manifest. The call advances the host-side job that derives every model tensor shape, tile schedule, command count, operation count, and traffic total.

Line 232: `input_shape_per_image=(time_steps, channels, 8, 8),` This is continuation line 4 of the 8-line logical statement that begins at source line 229. Its exact fragment is ‘input_shape_per_image=(time_steps, channels, 8, 8),‘. The important operands are input_shape_per_image: the value named ’input shape per image’ in this block; time_steps: the value named ’time steps’ in this block; channels: the value named ’channels’ in this block. Read together, the complete operation is: This calls ‘operators.append‘ with ‘OperatorMapping(name="global_average_pool", source_operation="mean over 64 tokens then mean over four timesteps", input_shape_per_image=(time_steps, channels, 8, 8), output_shape_per_image=(channels,), hardware_primitive="vector add followed by exact power-of-two

shifts", matrix=None,)‘ inside the function build_operator_manifest, which handles build operator manifest. The call advances the host-side job that derives every model tensor shape, tile schedule, command count, operation count, and traffic total.

Line 233: `output_shape_per_image=(channels,),` This is continuation line 5 of the 8-line logical statement that begins at source line 229. Its exact fragment is ‘output_shape_per_image=(channels,),‘. The important operands are output_shape_per_image: the value named ’output shape per image’ in this block; channels: the value named ’channels’ in this block. Read together, the complete operation is: This calls ‘operators.append‘ with ‘OperatorMapping(name="global_average_pool", source_operation="mean over 64 tokens then mean over four timesteps", input_shape_per_image=(channels, 8, 8), output_shape_per_image=(channels,), hardware_primitive="vector add followed by exact power-of-two shifts", matrix=None,)‘ inside the function build_operator_manifest, which handles build operator manifest. The call advances the host-side job that derives every model tensor shape, tile schedule, command count, operation count, and traffic total.

Line 234: `hardware_primitive="vector add followed by exact power-of-two shifts",` This is continuation line 6 of the 8-line logical statement that begins at source line 229. Its exact fragment is ‘hardware_primitive="vector add followed by exact power-of-two shifts",‘. The important operands are hardware_primitive: the value named ’hardware primitive’ in this block; vector: the value named ’vector’ in this block; add: the value named ’add’ in this block. Read together, the complete operation is: This calls ‘operators.append‘ with ‘OperatorMapping(name="global_average_pool", source_operation="mean over 64 tokens then mean over four timesteps", input_shape_per_image=(time_steps, channels, 8, 8), output_shape_per_image=(channels,), hardware_primitive="vector add followed by exact power-of-two shifts", matrix=None,)‘ inside the function build_operator_manifest, which handles build operator manifest. The call advances the host-side job that derives every model tensor shape, tile schedule, command count, operation count, and traffic total.

Line 235: `matrix=None,` This is continuation line 7 of the 8-line logical statement that begins at source line 229. Its exact fragment is ‘matrix=None,‘. The important operands are matrix: the value named ’matrix’ in this block; None: the value named ’none’ in this block. Read together, the complete operation is: This calls ‘operators.append‘ with ‘OperatorMapping(name="global_average_pool", source_operation="mean over 64 tokens then mean over four timesteps", input_shape_per_image=(time_steps, channels, 8, 8), output_shape_per_image=(channels,), hardware_primitive="vector add followed by exact power-of-two shifts", matrix=None,)‘ inside the function build_operator_manifest, which handles build operator manifest. The call advances the host-side job that derives every model tensor shape, tile schedule, command count, operation count, and traffic total.

Line 236: `))` This is continuation line 8 of the 8-line logical statement that begins at source line 229. Its exact fragment is ‘))‘. The expression is a literal or structural operator and has no hidden software state. Read together, the complete operation is: This calls ‘operators.append‘ with ‘OperatorMapping(name="global_average_pool", source_operation="mean over 64 tokens then mean over four timesteps", input_shape_per_image=(time_steps, channels, 8, 8), output_shape_per_image=(channels,), hardware_primitive="vector add followed by exact power-of-two shifts", matrix=None,)‘ inside the function build_operator_manifest, which handles build operator manifest. The call advances the host-side job that derives every model tensor shape, tile schedule, command count, operation count, and traffic total.

Line 237: `matrix_operator(` This statement continues through source line 240; the explanation uses the complete expression rather than only the first visual fragment. This calls ‘matrix_operator‘ with ‘ "head", "Linear classifier", (channels,), (10,), 1, channels, 10, "u8_mac", "dense Dot8 tensor tile"‘ inside the function build_operator_manifest, which handles build operator manifest. The call advances the host-side job that derives every model tensor shape, tile schedule, command count, operation count, and traffic total.

Line 238: `"head", "Linear classifier",` This is continuation line 2 of the 4-line logical statement that begins at source line 237. Its exact fragment is ‘"head", "Linear classifier",‘. The important operands are head: the value named ’head’ in this block; Linear: the value named ’linear’ in this block; classifier: the value named ’classifier’ in this block. Read together, the complete operation is: This calls ‘matrix_operator‘ with ‘ "head", "Linear classifier", (channels,), (10,), 1, channels, 10, "u8_mac", "dense Dot8 tensor tile"‘ inside the function build_operator_manifest, which handles build operator manifest. The call advances the host-side job that derives every model tensor shape, tile schedule, command count, operation count, and traffic total.

Line 239: `(channels,), (10,), 1, channels, 10,` This is continuation line 3 of the 4-line logical statement that begins at source line 237. Its exact fragment is ‘(channels,), (10,), 1, channels, 10,‘. The important operands are channels: the value named ’channels’ in this block. Read together, the complete operation is: This calls ‘matrix_operator‘ with ‘ "head", "Linear classifier", (channels,), (10,), 1, channels, 10, "u8_mac", "dense Dot8 tensor tile"‘ inside the function build_operator_manifest, which handles build operator manifest. The call advances the host-side job that derives every model tensor shape, tile schedule, command count, operation count, and traffic total.

Line 240: `"u8_mac", "dense Dot8 tensor tile")` This is continuation line 4 of the 4-line logical statement that begins at source line 237. Its exact fragment is ‘"u8_mac", "dense Dot8 tensor tile")‘. The important operands are u8_mac: the value named ’u8 mac’ in this block; dense: the value named ’dense’ in this block; Dot8: the value named ’dot8’ in this block. Read together, the complete operation is: This calls ‘matrix_operator‘ with ‘ "head", "Linear classifier", (channels,), (10,), 1, channels, 10, "u8_mac", "dense Dot8 tensor tile"‘ inside the function build_operator_manifest, which handles build operator manifest. The call advances the host-side job that derives every model tensor shape, tile schedule, command count, operation count, and traffic total.

Line 241: `return operators` This returns ‘operators‘ to the caller of the function build_operator_manifest, which handles build operator manifest, ending this invocation. The important operands are operators: the value named ’operators’ in this block.

Line 244: `def generate(checkpoint_path: Path, output_path: Path) -> dict[str, object]:` This starts function generate. Its indented body performs generate as part of the file that derives every model tensor shape, tile schedule, command count, operation count, and traffic total; it runs only when called.

Line 245: `checkpoint = torch.load(checkpoint_path, map_location="cpu")` This assigns ‘torch.load(checkpoint_path, map_location="cpu")‘ to ‘checkpoint ‘ in host memory. Here checkpoint means the value named ’checkpoint’ in this block. The important operands are torch: the value named ’torch’ in this block; load: the value named ’load’ in this block; checkpoint_path: the value named ’checkpoint path’ in this block. Context: the function generate, which handles generate.

Line 246: `state = checkpoint["state_dict"]` This assigns ‘checkpoint["state_dict"]‘ to ‘state ‘ in host memory. Here state means the finite-state-machine phase retained in flip-flops. The important operands are checkpoint: the value named ’checkpoint’ in this block; state_dict: the finite-state-machine phase retained in flip-flops. Context: the function generate, which handles generate.

Line 247: `parameter_tensors = {` This statement continues through source line 255; the explanation uses the complete expression rather than only the first visual fragment. This assigns ‘{ name: { "shape": list(value.shape), "elements": value.numel(), "source_dtype": str(value.dtype).replace("torch.", ""), } for name, value in state.items() if name.endswith(("weight", "bias")) }‘ to ‘parameter_tensors ‘ in host memory. Here parameter_tensors means the value named ’parameter tensors’ in this block. The important operands are name: the value named ’name’ in this block; shape: the value named ’shape’ in this block; list: the value named ’list’ in this block. Context: the function generate, which handles generate.

Line 248: `name: {` This is continuation line 2 of the 9-line logical statement that begins at source line 247. Its exact fragment is ‘name: {‘. The important operands are name: the value named ’name’ in this block. Read together, the complete operation is: This assigns ‘{ name: { "shape": list(value.shape), "elements": value.numel(), "source_dtype": str(value.dtype).replace("torch.", ""), } for name, value in state.items() if name.endswith(("weight", "bias")) }‘ to ‘parameter_tensors ‘ in host memory. Here parameter_tensors means the value named ’parameter tensors’ in this block. The important operands are name: the value named ’name’ in this block; shape: the value named ’shape’ in this block; list: the value named ’list’ in this block. Context: the function generate, which handles generate.

Line 249: `"shape": list(value.shape),` This is continuation line 3 of the 9-line logical statement that begins at source line 247. Its exact fragment is ‘"shape": list(value.shape),‘. The important operands are shape: the value named ’shape’ in this block; list: the value named ’list’ in this block; value: the value named ’value’ in this block. Read together, the complete operation is: This assigns ‘{ name: { "shape": list(value.shape), "elements": value.numel(), "source_dtype": str(value.dtype).replace("torch.", ""), } for name, value in state.items() if name.endswith(("weight",

"bias")) }‘ to ‘parameter_tensors ‘ in host memory. Here parameter_tensors means the value named ’parameter tensors’ in this block. The important operands are name: the value named ’name’ in this block; shape: the value named ’shape’ in this block; list: the value named ’list’ in this block. Context: the function generate, which handles generate.

Line 250: `"elements": value.numel(),` This is continuation line 4 of the 9-line logical statement that begins at source line 247. Its exact fragment is ‘"elements": value.numel(),‘. The important operands are elements: the value named ’elements’ in this block; value: the value named ’value’ in this block; numel: the value named ’numel’ in this block. Read together, the complete operation is: This assigns ‘{ name: { "shape": list(value.shape), "elements": value.numel(), "source_dtype": str(value.dtype).replace("torch.", ""), } for name, value in state.items() if name.endswith(("weight", "bias")) }‘ to ‘parameter_tensors ‘ in host memory. Here parameter_tensors means the value named ’parameter tensors’ in this block. The important operands are name: the value named ’name’ in this block; shape: the value named ’shape’ in this block; list: the value named ’list’ in this block. Context: the function generate, which handles generate.

Line 251: `"source_dtype": str(value.dtype).replace("torch.", ""),` This is continuation line 5 of the 9-line logical statement that begins at source line 247. Its exact fragment is ‘"source_dtype": str(value.dtype).replace("torch.", ""),‘. The important operands are source_dtype: the value named ’source dtype’ in this block; str: the value named ’str’ in this block; value: the value named ’value’ in this block. Read together, the complete operation is: This assigns ‘{ name: { "shape": list(value.shape), "elements": value.numel(), "source_dtype": str(value.dtype).replace("torch.", ""), } for name, value in state.items() if name.endswith(("weight", "bias")) }‘ to ‘parameter_tensors ‘ in host memory. Here parameter_tensors means the value named ’parameter tensors’ in this block. The important operands are name: the value named ’name’ in this block; shape: the value named ’shape’ in this block; list: the value named ’list’ in this block. Context: the function generate, which handles generate.

Line 252: `}` This is continuation line 6 of the 9-line logical statement that begins at source line 247. Its exact fragment is ‘}‘. The expression is a literal or structural operator and has no hidden software state. Read together, the complete operation is: This assigns ‘{ name: { "shape": list(value.shape), "elements": value.numel(), "source_dtype": str(value.dtype).replace("torch.", ""), } for name, value in state.items() if name.endswith(("weight", "bias")) }‘ to ‘parameter_tensors ‘ in host memory. Here parameter_tensors means the value named ’parameter tensors’ in this block. The important operands are name: the value named ’name’ in this block; shape: the value named ’shape’ in this block; list: the value named ’list’ in this block. Context: the function generate, which handles generate.

Line 253: `for name, value in state.items()` This is continuation line 7 of the 9-line logical statement that begins at source line 247. Its exact fragment is ‘for name, value in state.items()‘. The important operands are for: the value named ’for’ in this block; name: the value named ’name’ in this block; value: the value named ’value’ in this block. Read together, the complete operation is: This assigns ‘{ name: { "shape": list(value.shape), "elements": value.numel(), "source_dtype": str(value.dtype).replace("torch.", ""), } for name, value in state.items() if name.endswith(("weight", "bias")) }‘ to ‘parameter_tensors ‘ in host memory. Here parameter_tensors means the value named ’parameter tensors’ in this block. The important operands are name: the value named ’name’ in this block; shape: the value named ’shape’ in this block; list: the value named ’list’ in this block. Context: the function generate, which handles generate.

Line 254: `if name.endswith(("weight", "bias"))` This is continuation line 8 of the 9-line logical statement that begins at source line 247. Its exact fragment is ‘if name.endswith(("weight", "bias"))‘. The important operands are name: the value named ’name’ in this block; endswith: the value named ’endswith’ in this block; weight: a learned coefficient multiplied by an activation. Read together, the complete operation is: This assigns ‘{ name: { "shape": list(value.shape), "elements": value.numel(), "source_dtype": str(value.dtype).replace("torch.", ""), } for name, value in state.items() if name.endswith(("weight", "bias")) }‘ to ‘parameter_tensors ‘ in host memory. Here parameter_tensors means the value named ’parameter tensors’ in this block. The important operands are name: the value named ’name’ in this block; shape: the value named ’shape’ in this block; list: the value named ’list’ in this block. Context: the function generate, which handles generate.

Line 255: `}` This is continuation line 9 of the 9-line logical statement that begins at source line 247. Its exact fragment is ‘}‘. The expression is a literal or structural operator and has no hidden software state. Read together, the complete operation is: This assigns ‘{ name: { "shape": list(value.shape), "elements": value.numel(), "source_dtype": str(value.dtype).replace("torch.", ""), } for name, value in state.items() if name.endswith(("weight", "bias")) }‘ to ‘parameter_tensors ‘ in host memory. Here parameter_tensors means the value named ’parameter tensors’ in this block. The

important operands are name: the value named 'name' in this block; shape: the value named 'shape' in this block; list: the value named 'list' in this block. Context: the function generate, which handles generate.

Line 256: `operators = build_operator_manifest()` This assigns 'build_operator_manifest()' to 'operators ' in host memory. Here operators means the value named 'operators' in this block. The important operands are build_operator_manifest the value named 'build operator manifest' in this block. Context: the function generate, which handles generate.

Line 257: `matrix_operators = [item.matrix for item in operators if item.matrix is not None]` This assigns '[item.matrix for item in operators if item.matrix is not None]' to 'matrix_operators ' in host memory. Here matrix_operators means the value named 'matrix operators' in this block. The important operands are item: the value named 'item' in this block; matrix: the value named 'matrix' in this block; for: the value named 'for' in this block. Context: the function generate, which handles generate.

Line 258: `total_macs = sum(item.mac_equivalents for item in matrix_operators)` This assigns 'sum(item.mac_equivale for item in matrix_operators)' to 'total_macs ' in host memory. Here total_macs means the value named 'total macs' in this block. The important operands are sum: the value named 'sum' in this block; item: the value named 'item' in this block; mac_equivalents: the value named 'mac equivalents' in this block. Context: the function generate, which handles generate.

Line 259: `total_commands = sum(item.commands for item in matrix_operators)` This assigns 'sum(item.commands for item in matrix_operators)' to 'total_commands ' in host memory. Here total_commands means the 128-bit instruction selecting an engine, shape, mode, and numeric parameters. The important operands are sum: the value named 'sum' in this block; item: the value named 'item' in this block; commands: the 128-bit instruction selecting an engine, shape, mode, and numeric parameters. Context: the function generate, which handles generate.

Line 260: `total_input_bytes = sum(item.input_stream_bytes for item in matrix_operators)` This assigns 'sum(item.input_stream_bytes for item in matrix_operators)' to 'total_input_bytes ' in host memory. Here total_input_bytes means the value named 'total input bytes' in this block. The important operands are sum: the value named 'sum' in this block; item: the value named 'item' in this block; input_stream_bytes: the value named 'input stream bytes' in this block. Context: the function generate, which handles generate.

Line 261: `total_output_bytes = sum(item.output_stream_bytes for item in matrix_operators)` This assigns 'sum(item.output_stream_bytes for item in matrix_operators)' to 'total_output_bytes ' in host memory. Here total_output_bytes means the value named 'total output bytes' in this block. The important operands are sum: the value named 'sum' in this block; item: the value named 'item' in this block; output_stream_bytes: the value named 'output stream bytes' in this block. Context: the function generate, which handles generate.

Line 262: `trainable_parameters = sum(` This statement continues through source line 265; the explanation uses the complete expression rather than only the first visual fragment. This assigns 'sum(value.numel() for name, value in state.items() if name.endswith(("weight", "bias")))' to 'trainable_parameters ' in host memory. Here trainable_parameters means the value named 'trainable parameters' in this block. The important operands are sum: the value named 'sum' in this block; value: the value named 'value' in this block; numel: the value named 'numel' in this block. Context: the function generate, which handles generate.

Line 263: `value.numel() for name, value in state.items()` This is continuation line 2 of the 4-line logical statement that begins at source line 262. Its exact fragment is 'value.numel() for name, value in state.items()'. The important operands are value: the value named 'value' in this block; numel: the value named 'numel' in this block; for: the value named 'for' in this block. Read together, the complete operation is: This assigns 'sum(value.numel() for name, value in state.items() if name.endswith(("weight", "bias")))' to 'trainable_parameters ' in host memory. Here trainable_parameters means the value named 'trainable parameters' in this block. The important operands are sum: the value named 'sum' in this block; value: the value named 'value' in this block; numel: the value named 'numel' in this block. Context: the function generate, which handles generate.

Line 264: `if name.endswith(("weight", "bias"))` This is continuation line 3 of the 4-line logical statement that begins at source line 262. Its exact fragment is ‘if name.endswith(("weight", "bias"))‘. The important operands are name: the value named ’name’ in this block; endswith: the value named ’endswith’ in this block; weight: a learned coefficient multiplied by an activation. Read together, the complete operation is: This assigns ‘sum(value.numel() for name, value in state.items() if name.endswith(("weight", "bias")))‘ to ‘trainable_parameters ‘ in host memory. Here trainable_parameters means the value named ’trainable parameters’ in this block. The important operands are sum: the value named ’sum’ in this block; value: the value named ’value’ in this block; numel: the value named ’numel’ in this block. Context: the function generate, which handles generate.

Line 265: `)` This is continuation line 4 of the 4-line logical statement that begins at source line 262. Its exact fragment is ‘)‘. The expression is a literal or structural operator and has no hidden software state. Read together, the complete operation is: This assigns ‘sum(value.numel() for name, value in state.items() if name.endswith(("weight", "bias")))‘ to ‘trainable_parameters ‘ in host memory. Here trainable_parameters means the value named ’trainable parameters’ in this block. The important operands are sum: the value named ’sum’ in this block; value: the value named ’value’ in this block; numel: the value named ’numel’ in this block. Context: the function generate, which handles generate.

Line 266: `int8_weight_elements = sum(` This statement continues through source line 270; the explanation uses the complete expression rather than only the first visual fragment. This assigns ‘sum(value.numel() for name, value in state.items() if name.endswith("weight") and not ("norm1" in name or "norm2" in name or "_bn." in name))‘ to ‘int8_weight_elements ‘ in host memory. Here int8_weight_elements means a learned coefficient multiplied by an activation. The important operands are sum: the value named ’sum’ in this block; value: the value named ’value’ in this block; numel: the value named ’numel’ in this block. Context: the function generate, which handles generate.

Line 267: `value.numel() for name, value in state.items()` This is continuation line 2 of the 5-line logical statement that begins at source line 266. Its exact fragment is ‘value.numel() for name, value in state.items()‘. The important operands are value: the value named ’value’ in this block; numel: the value named ’numel’ in this block; for: the value named ’for’ in this block. Read together, the complete operation is: This assigns ‘sum(value.numel() for name, value in state.items() if name.endswith("weight") and not ("norm1" in name or "norm2" in name or "_bn." in name))‘ to ‘int8_weight_elements ‘ in host memory. Here int8_weight_elements means a learned coefficient multiplied by an activation. The important operands are sum: the value named ’sum’ in this block; value: the value named ’value’ in this block; numel: the value named ’numel’ in this block. Context: the function generate, which handles generate.

Line 268: `if name.endswith("weight")` This is continuation line 3 of the 5-line logical statement that begins at source line 266. Its exact fragment is ‘if name.endswith("weight")‘. The important operands are name: the value named ’name’ in this block; endswith: the value named ’endswith’ in this block; weight: a learned coefficient multiplied by an activation. Read together, the complete operation is: This assigns ‘sum(value.numel() for name, value in state.items() if name.endswith("weight") and not ("norm1" in name or "norm2" in name or "_bn." in name))‘ to ‘int8_weight_elements ‘ in host memory. Here int8_weight_elements means a learned coefficient multiplied by an activation. The important operands are sum: the value named ’sum’ in this block; value: the value named ’value’ in this block; numel: the value named ’numel’ in this block. Context: the function generate, which handles generate.

Line 269: `and not ("norm1" in name or "norm2" in name or "_bn." in name)` This is continuation line 4 of the 5-line logical statement that begins at source line 266. Its exact fragment is ‘and not ("norm1" in name or "norm2" in name or "_bn." in name)‘. The important operands are and: the value named ’and’ in this block; not: the value named ’not’ in this block; norm1: the value named ’norm1’ in this block. Read together, the complete operation is: This assigns ‘sum(value.numel() for name, value in state.items() if name.endswith("weight") and not ("norm1" in name or "norm2" in name or "_bn." in name))‘ to ‘int8_weight_elements ‘ in host memory. Here int8_weight_elements means a learned coefficient multiplied by an activation. The important operands are sum: the value named ’sum’ in this block; value: the value named ’value’ in this block; numel: the value named ’numel’ in this block. Context: the function generate, which handles generate.

Line 270: `)` This is continuation line 5 of the 5-line logical statement that begins at source line 266. Its exact fragment is ‘)‘. The expression is a literal or structural operator and has no hidden software state. Read together, the complete operation is: This assigns ‘sum(value.numel() for name, value in state.items() if name.endswith("weight") and not ("norm1" in name or "norm2" in name or "_bn." in name))‘ to ‘int8_weight_elements ‘ in host memory. Here int8_weight_elements means a learned coefficient multiplied by an activation. The important operands are sum: the

value named 'sum' in this block; value: the value named 'value' in this block; numel: the value named 'numel' in this block. Context: the function generate, which handles generate.

Line 271: `folded_bias_channels = sum(` This statement continues through source line 274; the explanation uses the complete expression rather than only the first visual fragment. This assigns 'sum(value.shape[0] for name, value in state.items() if name.endswith("running_mean")) + state["head.bias"].numel()' to 'folded_bias_channels ' in host memory. Here folded_bias_channels means an additive learned offset applied after accumulation. The important operands are sum: the value named 'sum' in this block; value: the value named 'value' in this block; shape: the value named 'shape' in this block. Context: the function generate, which handles generate.

Line 272: `value.shape[0] for name, value in state.items()` This is continuation line 2 of the 4-line logical statement that begins at source line 271. Its exact fragment is 'value.shape[0] for name, value in state.items()'. The important operands are value: the value named 'value' in this block; shape: the value named 'shape' in this block; for: the value named 'for' in this block. Read together, the complete operation is: This assigns 'sum(value.shape[0] for name, value in state.items() if name.endswith("running_mean")) + state["head.bias"].numel()' to 'folded_bias_channels ' in host memory. Here folded_bias_channels means an additive learned offset applied after accumulation. The important operands are sum: the value named 'sum' in this block; value: the value named 'value' in this block; shape: the value named 'shape' in this block. Context: the function generate, which handles generate.

Line 273: `if name.endswith("running_mean")` This is continuation line 3 of the 4-line logical statement that begins at source line 271. Its exact fragment is 'if name.endswith("running_mean")'. The important operands are name: the value named 'name' in this block; endswith: the value named 'endswith' in this block; running_mean: the arithmetic average used by normalization. Read together, the complete operation is: This assigns 'sum(value.shape[0] for name, value in state.items() if name.endswith("running_mean")) + state["head.bias"].numel()' to 'folded_bias_channels ' in host memory. Here folded_bias_channels means an additive learned offset applied after accumulation. The important operands are sum: the value named 'sum' in this block; value: the value named 'value' in this block; shape: the value named 'shape' in this block. Context: the function generate, which handles generate.

Line 274: `) + state["head.bias"].numel()` This is continuation line 4 of the 4-line logical statement that begins at source line 271. Its exact fragment is ') + state["head.bias"].numel()'. The important operands are state: the finite-state-machine phase retained in flip-flops; head: the value named 'head' in this block; bias: an additive learned offset applied after accumulation. Read together, the complete operation is: This assigns 'sum(value.shape[0] for name, value in state.items() if name.endswith("running_mean")) + state["head.bias"].numel()' to 'folded_bias_channels ' in host memory. Here folded_bias_channels means an additive learned offset applied after accumulation. The important operands are sum: the value named 'sum' in this block; value: the value named 'value' in this block; shape: the value named 'shape' in this block. Context: the function generate, which handles generate.

Here report means the value named 'report' in this block. The important operands are format: the value named 'format' in this block; neuraedge: the value named 'neuraedge' in this block; spikingformer: the value named 'spikingformer' in this block. Context: the function generate, which handles generate.

Line 317: `output_path.parent.mkdir(parents=True, exist_ok=True)` This calls ‘output_path.parent.mkdir‘ with ‘parents=True, exist_ok=True‘ inside the function generate, which handles generate. The call advances the host-side job that derives every model tensor shape, tile schedule, command count, operation count, and traffic total.

Line 318: `output_path.write_text(json.dumps(report, indent=2) + "\n", encoding="ascii")` This calls ‘output_path.write_text‘ with ‘json.dumps(report, indent=2) + "\n", encoding="ascii"‘ inside the function generate, which handles generate. The call advances the host-side job that derives every model tensor shape, tile schedule, command count, operation count, and traffic total.

Line 319: `return report` This returns ‘report‘ to the caller of the function generate, which handles generate, ending this invocation. The important operands are report: the value named 'report' in this block.

Line 322: `def parse_arguments() -> argparse.Namespace:` This starts function parse_arguments. Its indented body performs parse arguments as part of the file that derives every model tensor shape, tile schedule, command count, operation count, and traffic total; it runs only when called.

Line 323: `parser = argparse.ArgumentParser()` This assigns ‘argparse.ArgumentParser()‘ to ‘parser ‘ in host memory. Here parser means the value named 'parser' in this block. The important operands are argparse: the value named 'argparse' in this block; ArgumentParser: the value named 'argument parser' in this block. Context: the function parse_arguments, which handles parse arguments.

Line 324: `parser.add_argument("-checkpoint", required=True, type=Path)` This declares a command-line option for the function parse_arguments, which handles parse arguments. Its name, type, default, and required status make the run configuration explicit and reproducible instead of relying on an invisible interactive setting.

Line 325: `parser.add_argument("-output", required=True, type=Path)` This declares a command-line option for the function parse_arguments, which handles parse arguments. Its name, type, default, and required status make the run configuration explicit and reproducible instead of relying on an invisible interactive setting.

Line 326: `return parser.parse_args()` This returns ‘parser.parse_args()‘ to the caller of the function parse_arguments, which handles parse arguments, ending this invocation. The important operands are parser: the value named ’parser’ in this block; parse_args: the value named ’parse args’ in this block.

Line 329: `if __name__ == "__main__":` This executes the following indented host-code branch only when ‘___name___ == "___main___"‘ is true. The important operands are ___name___: the value named ’name’ in this block; ___main___: the value named ’main’ in this block. Context: the file whose role is to derives every model tensor shape, tile schedule, command count, operation count, and traffic total.

Line 330: `arguments = parse_arguments()` This assigns ‘parse_arguments()‘ to ‘arguments ‘ in host memory. Here arguments means the value named ’arguments’ in this block. The important operands are parse_arguments: the value named ’parse arguments’ in this block. Context: the file whose role is to derives every model tensor shape, tile schedule, command count, operation count, and traffic total.

Line 331: `result = generate(arguments.checkpoint.resolve(), arguments.output.resolve())` This assigns ‘generate(arguments.checkpoint.resolve(), arguments.output.resolve())‘ to ‘result ‘ in host memory. Here result means the value named ’result’ in this block. The important operands are generate: the value named ’generate’ in this block; arguments: the value named ’arguments’ in this block; checkpoint: the value named ’checkpoint’ in this block. Context: the file whose role is to derives every model tensor shape, tile schedule, command count, operation count, and traffic total.

Line 332: `print(json.dumps(result["per_image_totals"], indent=2))` This calls ‘print‘ with ‘json.dumps(result["per_imag indent=2)‘ inside the file whose role is to derives every model tensor shape, tile schedule, command count, operation count, and traffic total. The call advances the host-side job that derives every model tensor shape, tile schedule, command count, operation count, and traffic total.

32 software/generate_tensor_tile_fixture.py

Role in the complete system: builds deterministic dense, binary, and ternary tensor vectors for bit-exact RTL comparison.

32.1 Beginner architecture map

Dataflow responsibility This file's end-to-end responsibility is to builds deterministic dense, binary, and ternary tensor vectors for bit-exact RTL comparison.

Where it runs This is sequential host software. Python objects live in CPU memory; they become FPGA work only when the compiler packs a command or payload and the PYNQ driver transfers those bytes through AXI DMA or AXI-Lite.

Public structure Classes: FixtureCase. Functions: pack_bytes, make_dense_outer, make_dense_dot8, make_binary, make_ternary, command_word, write_hex, main. Each function annotation below names its enclosing function so an array operation is tied to the model, compiler, driver, test, or report phase that uses it.

Numeric and failure boundary Shapes, signedness, byte order, scaling, and saturation are part of the hardware contract. Validation exceptions are functional safety checks: rejecting malformed input before DMA is different from silently clipping, reshaping, or continuing with an incompatible artifact.

32.2 Complete source

32.3 Line annotations

Line 1: `"""Generate deterministic, independently computed tensor-tile RTL fixtures."""` This is executable documentation attached to the file whose role is to builds deterministic dense, binary, and ternary tensor vectors for bit-exact RTL comparison. It states the intended contract that tests and callers should enforce, but the text itself does not transform data or issue hardware work.

Line 3: `from __future__ import annotations` This imports the named Python API so the file whose role is to builds deterministic dense, binary, and ternary tensor vectors for bit-exact RTL comparison can use it explicitly. Imports execute on the host processor and create no FPGA hardware.

Line 5: `import json` This imports the named Python API so the file whose role is to builds deterministic dense, binary, and ternary tensor vectors for bit-exact RTL comparison can use it explicitly. Imports execute on the host processor and create no FPGA hardware.

Line 6: `from dataclasses import dataclass` This imports the named Python API so the file whose role is to builds deterministic dense, binary, and ternary tensor vectors for bit-exact RTL comparison can use it explicitly. Imports execute on the host processor and create no FPGA hardware.

Line 7: `from pathlib import Path` This imports the named Python API so the file whose role is to builds deterministic dense, binary, and ternary tensor vectors for bit-exact RTL comparison can use it explicitly. Imports execute on the host processor and create no FPGA hardware.

Line 9: `import numpy as np` This imports the named Python API so the file whose role is to builds deterministic dense, binary, and ternary tensor vectors for bit-exact RTL comparison can use it explicitly. Imports execute on the host processor and create no FPGA hardware.

Line 11: `from neuraedge_golden import (` This statement continues through source line 16; the explanation uses the complete expression rather than only the first visual fragment. This imports the named Python API so the file whose role is to builds deterministic dense, binary, and ternary tensor vectors for bit-exact RTL comparison can use it explicitly. Imports execute on the host processor and create no FPGA hardware.

Line 12: `ComputeMode,` This is continuation line 2 of the 6-line logical statement that begins at source line 11. Its exact fragment is 'ComputeMode,'. The important operands are ComputeMode: the value named 'compute mode' in this block. Read together, the complete operation is: This imports the named Python API so the file whose role is to builds deterministic dense, binary, and ternary tensor vectors for bit-exact RTL comparison can use it explicitly. Imports execute on the host processor and create no FPGA hardware.

Line 13: `binary_weighted_gemm,` This is continuation line 3 of the 6-line logical statement that begins at source line 11. Its exact fragment is 'binary_weighted_gemm,'. The important operands are binary_weighted_gemm: a learned coefficient multiplied by an activation. Read together, the complete operation is: This imports the named Python API so the file whose role is to builds deterministic dense, binary, and ternary tensor vectors for bit-exact RTL comparison can use it explicitly. Imports execute on the host processor and create no FPGA hardware.

Line 14: `gemm_u8_zero_point,` This is continuation line 4 of the 6-line logical statement that begins at source line 11. Its exact fragment is 'gemm_u8_zero_point,'. The important operands are gemm_u8_zero_point: the integer code representing real numeric zero in affine quantization. Read together, the complete operation is: This imports the named Python API so the file whose role is to builds deterministic dense, binary, and ternary tensor vectors for bit-exact RTL comparison can use it explicitly. Imports execute on the host processor and create no FPGA hardware.

Line 15: `ternary_weighted_gemm,` This is continuation line 5 of the 6-line logical statement that begins at source line 11. Its exact fragment is 'ternary_weighted_gemm,'. The important operands are ternary_weighted_gemm: a learned coefficient multiplied by an activation. Read together, the complete operation is: This imports the named Python API so the file whose role is to builds deterministic dense, binary, and ternary tensor vectors for bit-exact RTL comparison can use it explicitly. Imports execute on the host processor and create no FPGA hardware.

Line 16: `)` This is continuation line 6 of the 6-line logical statement that begins at source line 11. Its exact fragment is ')'. The expression is a literal or structural operator and has no hidden software state. Read together, the complete operation is: This imports the named Python API so the file whose role is to builds deterministic dense, binary, and ternary tensor vectors for bit-exact RTL comparison can use it explicitly. Imports execute on the host processor and create no FPGA hardware.

Line 19: `ROW_LANES = 8` This assigns '8' to 'ROW_LANES ' in host memory. Here ROW_LANES means one parallel arithmetic element within a vector or tensor datapath. The expression is a literal or structural operator and has no hidden software state. Context: the file whose role is to builds deterministic dense, binary, and ternary tensor vectors for bit-exact RTL comparison.

Line 20: `COLUMN_LANES = 16` This assigns '16' to 'COLUMN_LANES ' in host memory. Here COLUMN_LANES means one parallel arithmetic element within a vector or tensor datapath. The expression is a literal or structural operator and has no hidden software state. Context: the file whose role is to builds deterministic dense, binary, and ternary tensor vectors for bit-exact RTL comparison.

Line 23: `@dataclass` This decorator changes how the following class or function is constructed. '@dataclass' is applied at import time on the host and is part of the file whose role is to builds deterministic dense, binary, and ternary tensor vectors for bit-exact RTL comparison; it creates no FPGA circuit by itself.

Line 24: `class FixtureCase:` This defines class FixtureCase, which groups data and methods for fixture case. Instances exist in host memory and organize the flow that builds deterministic dense, binary, and ternary tensor vectors for bit-exact RTL comparison.

Line 25: `name: str` Inside the class FixtureCase, which handles fixture case, this statement advances the host implementation that builds deterministic dense, binary, and ternary tensor vectors for bit-exact RTL comparison. The important operands are name: the value named 'name' in this block; str: the value named 'str' in this block.

Line 26: `mode: ComputeMode` Inside the class FixtureCase, which handles fixture case, this statement advances the host implementation that builds deterministic dense, binary, and ternary tensor vectors for bit-exact RTL comparison. The important operands are mode: the value named 'mode' in this block; ComputeMode: the value named 'compute mode' in this block.

Line 27: `rows: int` Inside the class FixtureCase, which handles fixture case, this statement advances the host implementation that builds deterministic dense, binary, and ternary tensor vectors for bit-exact RTL comparison. The important operands are rows: one output-row position processed by the tensor tile.

Line 28: `columns: int` Inside the class FixtureCase, which handles fixture case, this statement advances the host implementation that builds deterministic dense, binary, and ternary tensor vectors for bit-exact RTL comparison. The important operands are columns: one output-feature position processed in parallel.

Line 29: `activation_zero_point: int` Inside the class FixtureCase, which handles fixture case, this statement advances the host implementation that builds deterministic dense, binary, and ternary tensor vectors for bit-exact RTL comparison. The important operands are activation_zero_point: an input feature value consumed by a neuron or multiply-accumulate operation.

Line 30: `weight_zero_point: int` Inside the class FixtureCase, which handles fixture case, this statement advances the host implementation that builds deterministic dense, binary, and ternary tensor vectors for bit-exact RTL comparison. The important operands are weight_zero_point: a learned coefficient multiplied by an activation.

Line 31: `activation_words: list[int]` Inside the class FixtureCase, which handles fixture case, this statement advances the host implementation that builds deterministic dense, binary, and ternary tensor vectors for bit-exact RTL comparison. The important operands are activation_words: an input feature value consumed by a neuron or multiply-accumulate operation; list: the value named 'list' in this block.

Line 32: `weight_words: list[int]` Inside the class FixtureCase, which handles fixture case, this statement advances the host implementation that builds deterministic dense, binary, and ternary tensor vectors for bit-exact RTL comparison. The important operands are weight_words: a learned coefficient multiplied by an activation; list: the value named 'list' in this block.

Line 33: `expected: np.ndarray` Inside the class FixtureCase, which handles fixture case, this statement advances the host implementation that builds deterministic dense, binary, and ternary tensor vectors for bit-exact RTL comparison. The important operands are expected: the value named 'expected' in this block; ndarray: the value named 'ndarray' in this block.

Line 36: `def pack_bytes(values: np.ndarray | list[int]) -> int:` This starts function pack_bytes. Its indented body performs pack bytes as part of the file that builds deterministic dense, binary, and ternary tensor vectors for bit-exact RTL comparison; it runs only when called.

Line 37: `packed = 0` This assigns '0' to 'packed ' in host memory. Here packed means the value named 'packed' in this block. The expression is a literal or structural operator and has no hidden software state. Context: the function pack_bytes, which handles pack bytes.

Line 38: `for index, value in enumerate(np.asarray(values).reshape(-1)):` This iterates index, value over ‘enumerate(np.asarray(values).reshape(-1))‘. Each iteration repeats the indented host operation, commonly once per layer, tile, timestep, or test case in the function pack_bytes, which handles pack bytes.

Line 39: `packed |= (int(value) & 0xFF) << (8 * index)` Inside the function pack_bytes, which handles pack bytes, this statement advances the host implementation that builds deterministic dense, binary, and ternary tensor vectors for bit-exact RTL comparison. The important operands are packed: the value named ’packed’ in this block; value: the value named ’value’ in this block; index: an integer selecting one tensor element, lane, bank, or state entry.

Line 40: `return packed` This returns ‘packed‘ to the caller of the function pack_bytes, which handles pack bytes, ending this invocation. The important operands are packed: the value named ’packed’ in this block.

Line 43: `def make_dense_outer(rng: np.random.Generator) -> FixtureCase:` This starts function make_dense_outer. Its indented body performs make dense outer as part of the file that builds deterministic dense, binary, and ternary tensor vectors for bit-exact RTL comparison; it runs only when called.

Line 44: `rows, columns, reduction = 8, 16, 19` This assigns ‘8, 16, 19‘ to ‘rows, columns, reduction ‘ in host memory. Here rows means one output-row position processed by the tensor tile. The expression is a literal or structural operator and has no hidden software state. Context: the function make_dense_outer, which handles make dense outer.

Line 45: `za, zb = 117, 139` This assigns ‘117, 139‘ to ‘za, zb ‘ in host memory. Here za means the value named ’za’ in this block. The expression is a literal or structural operator and has no hidden software state. Context: the function make_dense_outer, which handles make dense outer.

Line 46: `a = rng.integers(0, 256, size=(rows, reduction), dtype=np.uint8)` This assigns ‘rng.integers(0, 256, size=(rows, reduction), dtype=np.uint8)‘ to ‘a ‘ in host memory. Here a means the value named ’a’ in this block. The important operands are rng: the value named ’rng’ in this block; integers: the value named ’integers’ in this block; size: the value named ’size’ in this block. Context: the function make_dense_outer, which handles make dense outer.

Line 47: `b = rng.integers(0, 256, size=(reduction, columns), dtype=np.uint8)` This assigns ‘rng.integers(0, 256, size=(reduction, columns), dtype=np.uint8)‘ to ‘b ‘ in host memory. Here b means the value named ’b’ in this block. The important operands are rng: the value named ’rng’ in this block; integers: the value named ’integers’ in this block; size: the value named ’size’ in this block. Context: the function make_dense_outer, which handles make dense outer.

Line 48: `a[:, [2, 7, 14]] = za` This assigns ‘za‘ to ‘a[‘ in host memory. Here a means the value named ’a’ in this block. The important operands are za: the value named ’za’ in this block. Context: the function make_dense_outer, which handles make dense outer.

Line 49: `expected = gemm_u8_zero_point(a, b, za, zb)` This assigns ‘gemm_u8_zero_point(a, b, za, zb)‘ to ‘expected ‘ in host memory. Here expected means the value named ’expected’ in this block. The important operands are gemm_u8_zero_point: the integer code representing real numeric zero in affine quantization; a: the value named ’a’ in this block; b: the value named ’b’ in this block. Context: the function make_dense_outer, which handles make dense outer.

Line 50: `a_words = [pack_bytes(a[:, k]) for k in range(reduction)]` This assigns ‘[pack_bytes(a[:, k]) for k in range(reduction)]‘ to ‘a_words ‘ in host memory. Here a_words means the value named ’a words’ in this block. The important operands are pack_bytes: the value named ’pack bytes’ in this block; a: the value named ’a’ in this block; k: the value named ’k’ in this block. Context: the function make_dense_outer, which handles make dense outer.

Line 51: `b_words = [pack_bytes(b[k]) for k in range(reduction)]` This assigns ‘[pack_bytes(b[k]) for k in range(reduction)]‘ to ‘b_words ‘ in host memory. Here b_words means the value named ’b words’ in this block. The important operands are pack_bytes: the value named ’pack bytes’ in this block; b: the value named ’b’ in this block; k: the value named ’k’ in this block. Context: the function make_dense_outer, which handles make dense outer.

Line 52: `return FixtureCase("dense_outer_8x16x19", ComputeMode.DENSE_OUTER, rows, columns, za, zb, a_words, b_words,...` This returns 'FixtureCase("dense_outer_8x16x19", ComputeMode.DENSE_OUTER, rows, columns, za, zb, a_words, b_words, expected)' to the caller of the function make_dense_outer, which handles make dense outer, ending this invocation. The important operands are FixtureCase: the value named 'fixture case' in this block; dense_outer_8x16x19: the value named 'dense outer 8x16x19' in this block; ComputeMode: the value named 'compute mode' in this block.

Line 55: `def make_dense_dot8(rng: np.random.Generator) -> FixtureCase:` This starts function make_dense_dot8. Its indented body performs make dense dot8 as part of the file that builds deterministic dense, binary, and ternary tensor vectors for bit-exact RTL comparison; it runs only when called.

Line 56: `rows, columns, reduction = 1, 13, 21` This assigns '1, 13, 21' to 'rows, columns, reduction ' in host memory. Here rows means one output-row position processed by the tensor tile. The expression is a literal or structural operator and has no hidden software state. Context: the function make_dense_dot8, which handles make dense dot8.

Line 57: `padded_reduction = 24` This assigns '24' to 'padded_reduction ' in host memory. Here padded_reduction means the value named 'padded reduction' in this block. The expression is a literal or structural operator and has no hidden software state. Context: the function make_dense_dot8, which handles make dense dot8.

Line 58: `za, zb = 128, 128` This assigns '128, 128' to 'za, zb ' in host memory. Here za means the value named 'za' in this block. The expression is a literal or structural operator and has no hidden software state. Context: the function make_dense_dot8, which handles make dense dot8.

Line 59: `a = np.full((rows, padded_reduction), za, dtype=np.uint8)` This assigns 'np.full((rows, padded_reduction), za, dtype=np.uint8)' to 'a ' in host memory. Here a means the value named 'a' in this block. The important operands are full: the value named 'full' in this block; rows: one output-row position processed by the tensor tile; padded_reduction: the value named 'padded reduction' in this block. Context: the function make_dense_dot8, which handles make dense dot8.

Line 60: `b = np.full((padded_reduction, columns), zb, dtype=np.uint8)` This assigns 'np.full((padded_reduction, columns), zb, dtype=np.uint8)' to 'b ' in host memory. Here b means the value named 'b' in this block. The important operands are full: the value named 'full' in this block; padded_reduction: the value named 'padded reduction' in this block; columns: one output-feature position processed in parallel. Context: the function make_dense_dot8, which handles make dense dot8.

Line 61: `a[:, :reduction] = rng.integers(0, 256, size=(rows, reduction), dtype=np.uint8)` This assigns 'rng.integers(0, 256, size=(rows, reduction), dtype=np.uint8)' to 'a[' in host memory. Here a means the value named 'a' in this block. The important operands are rng: the value named 'rng' in this block; integers: the value named 'integers' in this block; size: the value named 'size' in this block. Context: the function make_dense_dot8, which handles make dense dot8.

Line 62: `b[:reduction] = rng.integers(0, 256, size=(reduction, columns), dtype=np.uint8)` This assigns 'rng.integers(0, 256, size=(reduction, columns), dtype=np.uint8)' to 'b[' in host memory. Here b means the value named 'b' in this block. The important operands are rng: the value named 'rng' in this block; integers: the value named 'integers' in this block; size: the value named 'size' in this block. Context: the function make_dense_dot8, which handles make dense dot8.

Line 63: `a[:, 8:16] = za` This assigns 'za' to 'a[' in host memory. Here a means the value named 'a' in this block. The important operands are za: the value named 'za' in this block. Context: the function make_dense_dot8, which handles make dense dot8.

Line 64: `expected = gemm_u8_zero_point(a, b, za, zb)` This assigns 'gemm_u8_zero_point(a, b, za, zb)' to 'expected ' in host memory. Here expected means the value named 'expected' in this block. The important operands are gemm_u8_zero_point: the integer code representing real numeric zero in affine quantization; a: the value named 'a' in this block; b: the value named 'b' in this block. Context: the function make_dense_dot8, which handles make dense dot8.

Line 65: `a_words: list[int] = []` This assigns '[]' to 'a_words' in host memory. Here a_words means the value named 'a words' in this block. The expression is a literal or structural operator and has no hidden software state. Context: the function make_dense_dot8, which handles make dense dot8.

Line 66: `b_words: list[int] = []` This assigns '[]' to 'b_words' in host memory. Here b_words means the value named 'b words' in this block. The expression is a literal or structural operator and has no hidden software state. Context: the function make_dense_dot8, which handles make dense dot8.

Line 67: `for chunk_start in range(0, padded_reduction, ROW_LANES):` This iterates chunk_start over 'range(0, padded_reduction, ROW_LANES)'. Each iteration repeats the indented host operation, commonly once per layer, tile, timestep, or test case in the function make_dense_dot8, which handles make dense dot8.

Line 68: `a_words.append(pack_bytes(a[0, chunk_start : chunk_start + ROW_LANES]))` This calls 'a_words.append' with 'pack_bytes(a[0, chunk_start : chunk_start + ROW_LANES])' inside the function make_dense_dot8, which handles make dense dot8. The call advances the host-side job that builds deterministic dense, binary, and ternary tensor vectors for bit-exact RTL comparison.

Line 69: `packed_weights = 0` This assigns '0' to 'packed_weights ' in host memory. Here packed_weights means a learned coefficient multiplied by an activation. The expression is a literal or structural operator and has no hidden software state. Context: the function make_dense_dot8, which handles make dense dot8.

Line 70: `for column in range(COLUMN_LANES):` This iterates column over 'range(COLUMN_LANES)'. Each iteration repeats the indented host operation, commonly once per layer, tile, timestep, or test case in the function make_dense_dot8, which handles make dense dot8.

Line 71: `lane_values = (` This statement continues through source line 75; the explanation uses the complete expression rather than only the first visual fragment. This assigns '(b[chunk_start : chunk_start + ROW_LANES, column] if column < columns else np.full(ROW_LANES, zb, dtype=np.uint8))' to 'lane_values ' in host memory. Here lane_values means one parallel arithmetic element within a vector or tensor datapath. The important operands are b: the value named 'b' in this block; chunk_start: the value named 'chunk start' in this block; ROW_LANES: one parallel arithmetic element within a vector or tensor datapath. Context: the function make_dense_dot8, which handles make dense dot8.

Line 72: `b[chunk_start : chunk_start + ROW_LANES, column]` This is continuation line 2 of the 5-line logical statement that begins at source line 71. Its exact fragment is 'b[chunk_start : chunk_start + ROW_LANES, column]'. The important operands are b: the value named 'b' in this block; chunk_start: the value named 'chunk start' in this block; ROW_LANES: one parallel arithmetic element within a vector or tensor datapath. Read together, the complete operation is: This assigns '(b[chunk_start : chunk_start + ROW_LANES, column] if column < columns else np.full(ROW_LANES, zb, dtype=np.uint8))' to 'lane_values ' in host memory. Here lane_values means one parallel arithmetic element within a vector or tensor datapath. The important operands are b: the value named 'b' in this block; chunk_start: the value named 'chunk start' in this block; ROW_LANES: one parallel arithmetic element within a vector or tensor datapath. Context: the function make_dense_dot8, which handles make dense dot8.

Line 73: `if column < columns` This is continuation line 3 of the 5-line logical statement that begins at source line 71. Its exact fragment is 'if column < columns'. The important operands are column: one output-feature position processed in parallel; columns: one output-feature position processed in parallel. Read together, the complete operation is: This assigns '(b[chunk_start : chunk_start + ROW_LANES, column] if column < columns else np.full(ROW_LANES, zb, dtype=np.uint8))' to 'lane_values ' in host memory. Here lane_values means one parallel arithmetic element within a vector or tensor datapath. The important operands are b: the value named 'b' in this block; chunk_start: the value named 'chunk start' in this block; ROW_LANES: one parallel arithmetic element within a vector or tensor datapath. Context: the function make_dense_dot8, which handles make dense dot8.

Line 74: `else np.full(ROW_LANES, zb, dtype=np.uint8)` This is continuation line 4 of the 5-line logical statement that begins at source line 71. Its exact fragment is 'else np.full(ROW_LANES, zb, dtype=np.uint8)'. The important operands are full: the value named 'full' in this block; ROW_LANES: one parallel arithmetic element within a

vector or tensor datapath; zb: the value named 'zb' in this block. Read together, the complete operation is: This assigns '(b[chunk_start : chunk_start + ROW_LANES, column] if column < columns else np.full(ROW_LANES, zb, dtype=np.uint8))' to 'lane_values ' in host memory. Here lane_values means one parallel arithmetic element within a vector or tensor datapath. The important operands are b: the value named 'b' in this block; chunk_start: the value named 'chunk start' in this block; ROW_LANES: one parallel arithmetic element within a vector or tensor datapath. Context: the function make_dense_dot8, which handles make dense dot8.

Line 75: `)` This is continuation line 5 of the 5-line logical statement that begins at source line 71. Its exact fragment is ')'. The expression is a literal or structural operator and has no hidden software state. Read together, the complete operation is: This assigns '(b[chunk_start : chunk_start + ROW_LANES, column] if column < columns else np.full(ROW_LANES, zb, dtype=np.uint8))' to 'lane_values ' in host memory. Here lane_values means one parallel arithmetic element within a vector or tensor datapath. The important operands are b: the value named 'b' in this block; chunk_start: the value named 'chunk start' in this block; ROW_LANES: one parallel arithmetic element within a vector or tensor datapath. Context: the function make_dense_dot8, which handles make dense dot8.

Line 76: `packed_weights |= pack_bytes(lane_values) << (64 * column)` Inside the function make_dense_dot8, which handles make dense dot8, this statement advances the host implementation that builds deterministic dense, binary, and ternary tensor vectors for bit-exact RTL comparison. The important operands are packed_weights: a learned coefficient multiplied by an activation; pack_bytes: the value named 'pack bytes' in this block; lane_values: one parallel arithmetic element within a vector or tensor datapath.

Line 77: `b_words.append(packed_weights)` This calls 'b_words.append' with 'packed_weights' inside the function make_dense_dot8, which handles make dense dot8. The call advances the host-side job that builds deterministic dense, binary, and ternary tensor vectors for bit-exact RTL comparison.

Line 78: `return FixtureCase("dense_dot8_1x13x24", ComputeMode.DENSE_DOT8, rows, columns, za, zb, a_words, b_words, e...` This returns 'FixtureCase("dense_dot8_1x13x24", ComputeMode.DENSE_DOT8, rows, columns, za, zb, a_words, b_words, expected)' to the caller of the function make_dense_dot8, which handles make dense dot8, ending this invocation. The important operands are FixtureCase: the value named 'fixture case' in this block; dense_dot8_1x13x24: the value named 'dense dot8 1x13x24' in this block; ComputeMode: the value named 'compute mode' in this block.

Line 81: `def make_binary(rng: np.random.Generator) -> FixtureCase:` This starts function make_binary. Its indented body performs make binary as part of the file that builds deterministic dense, binary, and ternary tensor vectors for bit-exact RTL comparison; it runs only when called.

Line 82: `rows, columns, reduction = 5, 11, 17` This assigns '5, 11, 17' to 'rows, columns, reduction ' in host memory. Here rows means one output-row position processed by the tensor tile. The expression is a literal or structural operator and has no hidden software state. Context: the function make_binary, which handles make binary.

Line 83: `spikes = rng.integers(0, 2, size=(rows, reduction), dtype=np.int8)` This assigns 'rng.integers(0, 2, size=(rows, reduction), dtype=np.int8)' to 'spikes ' in host memory. Here spikes means a binary event produced when a neuron crosses its threshold. The important operands are rng: the value named 'rng' in this block; integers: the value named 'integers' in this block; size: the value named 'size' in this block. Context: the function make_binary, which handles make binary.

Line 84: `weights = rng.integers(-128, 128, size=(reduction, columns), dtype=np.int16)` This assigns 'rng.integers(-128, 128, size=(reduction, columns), dtype=np.int16)' to 'weights ' in host memory. Here weights means a learned coefficient multiplied by an activation. The important operands are rng: the value named 'rng' in this block; integers: the value named 'integers' in this block; size: the value named 'size' in this block. Context: the function make_binary, which handles make binary.

Line 85: `spikes[:, [4, 12]] = 0` This assigns '0' to 'spikes[' in host memory. Here spikes means a binary event produced when a neuron crosses its threshold. The expression is a literal or structural operator and has no hidden software state. Context: the function make_binary, which handles make binary.

Line 86: `expected = binary_weighted_gemm(spikes, weights)` This assigns ‘binary_weighted_gemm(spikes, weights)‘ to ‘expected ‘ in host memory. Here expected means the value named ’expected’ in this block. The important operands are binary_weighted_gemm: a learned coefficient multiplied by an activation; spikes: a binary event produced when a neuron crosses its threshold; weights: a learned coefficient multiplied by an activation. Context: the function make_binary, which handles make binary.

Line 87: `a_words: list[int] = []` This assigns ‘[]‘ to ‘a_words‘ in host memory. Here a_words means the value named ’a words’ in this block. The expression is a literal or structural operator and has no hidden software state. Context: the function make_binary, which handles make binary.

Line 88: `b_words: list[int] = []` This assigns ‘[]‘ to ‘b_words‘ in host memory. Here b_words means the value named ’b words’ in this block. The expression is a literal or structural operator and has no hidden software state. Context: the function make_binary, which handles make binary.

Line 89: `for k in range(reduction):` This iterates k over ‘range(reduction)‘. Each iteration repeats the indented host operation, commonly once per layer, tile, timestep, or test case in the function make_binary, which handles make binary.

Line 90: `a_padded = np.zeros(ROW_LANES, dtype=np.int16)` This assigns ‘np.zeros(ROW_LANES, dtype=np.int16)‘ to ‘a_padded ‘ in host memory. Here a_padded means the value named ’a padded’ in this block. The important operands are zeros: the value named ’zeros’ in this block; ROW_LANES: one parallel arithmetic element within a vector or tensor datapath; dtype: the value named ’dtype’ in this block. Context: the function make_binary, which handles make binary.

Line 91: `b_padded = np.zeros(COLUMN_LANES, dtype=np.int16)` This assigns ‘np.zeros(COLUMN_LANES, dtype=np.int16) to ‘b_padded ‘ in host memory. Here b_padded means the value named ’b padded’ in this block. The important operands are zeros: the value named ’zeros’ in this block; COLUMN_LANES: one parallel arithmetic element within a vector or tensor datapath; dtype: the value named ’dtype’ in this block. Context: the function make_binary, which handles make binary.

Line 92: `a_padded[:rows] = spikes[:, k]` This assigns ‘spikes[:, k]‘ to ‘a_padded[‘ in host memory. Here a_padded means the value named ’a padded’ in this block. The important operands are spikes: a binary event produced when a neuron crosses its threshold; k: the value named ’k’ in this block. Context: the function make_binary, which handles make binary.

Line 93: `b_padded[:columns] = weights[k]` This assigns ‘weights[k]‘ to ‘b_padded[‘ in host memory. Here b_padded means the value named ’b padded’ in this block. The important operands are weights: a learned coefficient multiplied by an activation; k: the value named ’k’ in this block. Context: the function make_binary, which handles make binary.

Line 94: `a_words.append(pack_bytes(a_padded))` This calls ‘a_words.append‘ with ‘pack_bytes(a_padded)‘ inside the function make_binary, which handles make binary. The call advances the host-side job that builds deterministic dense, binary, and ternary tensor vectors for bit-exact RTL comparison.

Line 95: `b_words.append(pack_bytes(b_padded))` This calls ‘b_words.append‘ with ‘pack_bytes(b_padded)‘ inside the function make_binary, which handles make binary. The call advances the host-side job that builds deterministic dense, binary, and ternary tensor vectors for bit-exact RTL comparison.

Line 96: `return FixtureCase("binary_weighted_5x11x17", ComputeMode.BINARY_WEIGHTED, rows, columns, 0, 0, a_words, b_...` This returns ‘FixtureCase("binary_weighted_5x11x17", ComputeMode.BINARY_WEIGHTED, rows, columns, 0, 0, a_words, b_words, expected)‘ to the caller of the function make_binary, which handles make binary, ending this invocation. The important operands are FixtureCase: the value named ’fixture case’ in this block; binary_weighted_5x11x17: a learned coefficient multiplied by an activation; ComputeMode: the value named ’compute mode’ in this block.

Line 99: `def make_ternary(rng: np.random.Generator) -> FixtureCase:` This starts function make_ternary. Its indented body performs make ternary as part of the file that builds deterministic dense, binary, and ternary tensor vectors for bit-exact RTL comparison; it runs only when called.

Line 100: `rows, columns, reduction = 7, 9, 15` This assigns ‘7, 9, 15‘ to ‘rows, columns, reduction ‘ in host memory. Here rows means one output-row position processed by the tensor tile. The expression is a literal or structural operator and has no hidden software state. Context: the function make_ternary, which handles make ternary.

Line 101: `spikes = rng.integers(-1, 2, size=(rows, reduction), dtype=np.int8)` This assigns ‘rng.integers(-1, 2, size=(rows, reduction), dtype=np.int8)‘ to ‘spikes ‘ in host memory. Here spikes means a binary event produced when a neuron crosses its threshold. The important operands are rng: the value named ’rng’ in this block; integers: the value named ’integers’ in this block; size: the value named ’size’ in this block. Context: the function make_ternary, which handles make ternary.

Line 102: `weights = rng.integers(-128, 128, size=(reduction, columns), dtype=np.int16)` This assigns ‘rng.integers(128, 128, size=(reduction, columns), dtype=np.int16)‘ to ‘weights ‘ in host memory. Here weights means a learned coefficient multiplied by an activation. The important operands are rng: the value named ’rng’ in this block; integers: the value named ’integers’ in this block; size: the value named ’size’ in this block. Context: the function make_ternary, which handles make ternary.

Line 103: `spikes[:, [1, 10]] = 0` This assigns ‘0‘ to ‘spikes[‘ in host memory. Here spikes means a binary event produced when a neuron crosses its threshold. The expression is a literal or structural operator and has no hidden software state. Context: the function make_ternary, which handles make ternary.

Line 104: `expected = ternary_weighted_gemm(spikes, weights)` This assigns ‘ternary_weighted_gemm(spikes, weights)‘ to ‘expected ‘ in host memory. Here expected means the value named ’expected’ in this block. The important operands are ternary_weighted_gemm: a learned coefficient multiplied by an activation; spikes: a binary event produced when a neuron crosses its threshold; weights: a learned coefficient multiplied by an activation. Context: the function make_ternary, which handles make ternary.

Line 105: `a_words: list[int] = []` This assigns ‘[]‘ to ‘a_words‘ in host memory. Here a_words means the value named ’a words’ in this block. The expression is a literal or structural operator and has no hidden software state. Context: the function make_ternary, which handles make ternary.

Line 106: `b_words: list[int] = []` This assigns ‘[]‘ to ‘b_words‘ in host memory. Here b_words means the value named ’b words’ in this block. The expression is a literal or structural operator and has no hidden software state. Context: the function make_ternary, which handles make ternary.

Line 107: `for k in range(reduction):` This iterates k over ‘range(reduction)‘. Each iteration repeats the indented host operation, commonly once per layer, tile, timestep, or test case in the function make_ternary, which handles make ternary.

Line 108: `a_padded = np.zeros(ROW_LANES, dtype=np.int16)` This assigns ‘np.zeros(ROW_LANES, dtype=np.int16)‘ to ‘a_padded ‘ in host memory. Here a_padded means the value named ’a padded’ in this block. The important operands are zeros: the value named ’zeros’ in this block; ROW_LANES: one parallel arithmetic element within a vector or tensor datapath; dtype: the value named ’dtype’ in this block. Context: the function make_ternary, which handles make ternary.

Line 109: `b_padded = np.zeros(COLUMN_LANES, dtype=np.int16)` This assigns ‘np.zeros(COLUMN_LANES, dtype=np.int16‘ to ‘b_padded ‘ in host memory. Here b_padded means the value named ’b padded’ in this block. The important operands are zeros: the value named ’zeros’ in this block; COLUMN_LANES: one parallel arithmetic element within a vector or tensor datapath; dtype: the value named ’dtype’ in this block. Context: the function make_ternary, which handles make ternary.

Line 110: `a_padded[:rows] = spikes[:, k]` This assigns ‘spikes[:, k]‘ to ‘a_padded[‘ in host memory. Here a_padded means the value named ’a padded’ in this block. The important operands are spikes: a binary event produced when a neuron crosses its threshold; k: the value named ’k’ in this block. Context: the function make_ternary, which handles make ternary.

Line 111: `b_padded[:columns] = weights[k]` This assigns ‘weights[k]‘ to ‘b_padded[‘ in host memory. Here b_padded means the value named ’b padded’ in this block. The important operands are weights: a learned coefficient multiplied by an activation; k: the value named ’k’ in this block. Context: the function make_ternary, which handles make ternary.

Line 112: `a_words.append(pack_bytes(a_padded))` This calls ‘a_words.append‘ with ‘pack_bytes(a_padded)‘ inside the function make_ternary, which handles make ternary. The call advances the host-side job that builds deterministic dense, binary, and ternary tensor vectors for bit-exact RTL comparison.

Line 113: `b_words.append(pack_bytes(b_padded))` This calls ‘b_words.append‘ with ‘pack_bytes(b_padded)‘ inside the function make_ternary, which handles make ternary. The call advances the host-side job that builds deterministic dense, binary, and ternary tensor vectors for bit-exact RTL comparison.

Line 114: `return FixtureCase("ternary_weighted_7x9x15", ComputeMode.TERNARY_WEIGHTED, rows, columns, 0, 0, a_words, b...` This returns ‘FixtureCase("ternary_weighted_7x9x15", ComputeMode.TERNARY_WEIGHTED, rows, columns, 0, 0, a_words, b_words, expected)‘ to the caller of the function make_ternary, which handles make ternary, ending this invocation. The important operands are FixtureCase: the value named ’fixture case’ in this block; ternary_weighted_7x9x15: a learned coefficient multiplied by an activation; ComputeMode: the value named ’compute mode’ in this block.

Line 117: `def command_word(case: FixtureCase) -> int:` This starts function command_word. Its indented body performs command word as part of the file that builds deterministic dense, binary, and ternary tensor vectors for bit-exact RTL comparison; it runs only when called.

Line 118: `issues = len(case.activation_words)` This assigns ‘len(case.activation_words)‘ to ‘issues ‘ in host memory. Here issues means the value named ’issues’ in this block. The important operands are len: the value named ’len’ in this block; case: the value named ’case’ in this block; activation_words: an input feature value consumed by a neuron or multiply-accumulate operation. Context: the function command_word, which handles command word.

Line 119: `return (` This statement continues through source line 126; the explanation uses the complete expression rather than only the first visual fragment. This returns ‘(int(case.mode) | (case.rows << 4) | (case.columns << 8) | (issues << 14) | (case.activation_zero_point << 26) | (case.weight_zero_point << 34))‘ to the caller of the function command_word, which handles command word, ending this invocation. The important operands are case: the value named ’case’ in this block; mode: the value named ’mode’ in this block; rows: one output-row position processed by the tensor tile.

Line 120: `int(case.mode)` This is continuation line 2 of the 8-line logical statement that begins at source line 119. Its exact fragment is ‘int(case.mode)‘. The important operands are case: the value named ’case’ in this block; mode: the value named ’mode’ in this block. Read together, the complete operation is: This returns ‘(int(case.mode) | (case.rows << 4) | (case.columns << 8) | (issues << 14) | (case.activation_zero_point << 26) | (case.weight_zero_point << 34))‘ to the caller of the function command_word, which handles command word, ending this invocation. The important operands are case: the value named ’case’ in this block; mode: the value named ’mode’ in this block; rows: one output-row position processed by the tensor tile.

Line 121: `| (case.rows << 4)` This is continuation line 3 of the 8-line logical statement that begins at source line 119. Its exact fragment is ‘| (case.rows << 4)‘. The important operands are case: the value named ’case’ in this block; rows: one output-row position processed by the tensor tile. Read together, the complete operation is: This returns ‘(int(case.mode) | (case.rows << 4) | (case.columns << 8) | (issues << 14) | (case.activation_zero_point << 26) | (case.weight_zero_point << 34))‘ to the caller of the function command_word, which handles command word, ending this invocation. The important operands are case: the value named ’case’ in this block; mode: the value named ’mode’ in this block; rows: one output-row position processed by the tensor tile.

Line 122: `| (case.columns << 8)` This is continuation line 4 of the 8-line logical statement that begins at source line 119. Its exact fragment is '| (case.columns << 8)'. The important operands are case: the value named 'case' in this block; columns: one output-feature position processed in parallel. Read together, the complete operation is: This returns '(int(case.mode) | (case.rows << 4) | (case.columns << 8) | (issues << 14) | (case.activation_zero_point << 26) | (case.weight_zero_point << 34))' to the caller of the function command_word, which handles command word, ending this invocation. The important operands are case: the value named 'case' in this block; mode: the value named 'mode' in this block; rows: one output-row position processed by the tensor tile.

Line 123: `| (issues << 14)` This is continuation line 5 of the 8-line logical statement that begins at source line 119. Its exact fragment is '| (issues << 14)'. The important operands are issues: the value named 'issues' in this block. Read together, the complete operation is: This returns '(int(case.mode) | (case.rows << 4) | (case.columns << 8) | (issues << 14) | (case.activation_zero_point << 26) | (case.weight_zero_point << 34))' to the caller of the function command_word, which handles command word, ending this invocation. The important operands are case: the value named 'case' in this block; mode: the value named 'mode' in this block; rows: one output-row position processed by the tensor tile.

Line 124: `| (case.activation_zero_point << 26)` This is continuation line 6 of the 8-line logical statement that begins at source line 119. Its exact fragment is '| (case.activation_zero_point << 26)'. The important operands are case: the value named 'case' in this block; activation_zero_point: an input feature value consumed by a neuron or multiply-accumulate operation. Read together, the complete operation is: This returns '(int(case.mode) | (case.rows << 4) | (case.columns << 8) | (issues << 14) | (case.activation_zero_point << 26) | (case.weight_zero_point << 34))' to the caller of the function command_word, which handles command word, ending this invocation. The important operands are case: the value named 'case' in this block; mode: the value named 'mode' in this block; rows: one output-row position processed by the tensor tile.

Line 125: `| (case.weight_zero_point << 34)` This is continuation line 7 of the 8-line logical statement that begins at source line 119. Its exact fragment is '| (case.weight_zero_point << 34)'. The important operands are case: the value named 'case' in this block; weight_zero_point: a learned coefficient multiplied by an activation. Read together, the complete operation is: This returns '(int(case.mode) | (case.rows << 4) | (case.columns << 8) | (issues << 14) | (case.activation_zero_point << 26) | (case.weight_zero_point << 34))' to the caller of the function command_word, which handles command word, ending this invocation. The important operands are case: the value named 'case' in this block; mode: the value named 'mode' in this block; rows: one output-row position processed by the tensor tile.

Line 126: `)` This is continuation line 8 of the 8-line logical statement that begins at source line 119. Its exact fragment is ')'. The expression is a literal or structural operator and has no hidden software state. Read together, the complete operation is: This returns '(int(case.mode) | (case.rows << 4) | (case.columns << 8) | (issues << 14) | (case.activation_zero_point << 26) | (case.weight_zero_point << 34))' to the caller of the function command_word, which handles command word, ending this invocation. The important operands are case: the value named 'case' in this block; mode: the value named 'mode' in this block; rows: one output-row position processed by the tensor tile.

Line 129: `def write_hex(path: Path, values: list[int], width_bits: int) -> None:` This starts function write_hex. Its indented body performs write hex as part of the file that builds deterministic dense, binary, and ternary tensor vectors for bit-exact RTL comparison; it runs only when called.

Line 130: `digits = (width_bits + 3) // 4` This assigns '(width_bits + 3) // 4' to 'digits ' in host memory. Here digits means the value named 'digits' in this block. The important operands are width_bits: the value named 'width bits' in this block. Context: the function write_hex, which handles write hex.

Line 131: `mask = (1 << width_bits) - 1` This assigns '(1 << width_bits) - 1' to 'mask ' in host memory. Here mask means the value named 'mask' in this block. The important operands are width_bits: the value named 'width bits' in this block. Context: the function write_hex, which handles write hex.

Line 132: `path.write_text("".join(f"{value & mask:0{digits}x}\n" for value in values), encoding="ascii")` This calls 'path.write_text' with '"".join(f"{value & mask:0{digits}x}\n" for value in values), encoding="ascii"' inside the function write_hex, which handles write hex. The call advances the host-side job that builds deterministic dense, binary, and ternary tensor vectors for bit-exact RTL comparison.

Line 135: `def main() -> None:` This starts function main. Its indented body performs main as part of the file that builds deterministic dense, binary, and ternary tensor vectors for bit-exact RTL comparison; it runs only when called.

Line 136: `fixture_dir = Path(__file__).resolve().parents[1] / "tb" / "fixtures"` This assigns ‘Path(___file___).reso / "tb" / "fixtures"‘ to ‘fixture_dir ‘ in host memory. Here fixture_dir means the value named ’fixture dir’ in this block. The important operands are Path: the value named ’path’ in this block; ___file___: the value named ’file’ in this block; resolve: the value named ’resolve’ in this block. Context: the function main, which handles main.

Line 137: `fixture_dir.mkdir(parents=True, exist_ok=True)` This calls ‘fixture_dir.mkdir‘ with ‘parents=True, exist_ok=True‘ inside the function main, which handles main. The call advances the host-side job that builds deterministic dense, binary, and ternary tensor vectors for bit-exact RTL comparison.

Line 138: `rng = np.random.default_rng(0x4E455552)` This assigns ‘np.random.default_rng(0x4E455552)‘ to ‘rng ‘ in host memory. Here rng means the value named ’rng’ in this block. The important operands are random: the value named ’random’ in this block; default_rng: the value named ’default rng’ in this block. Context: the function main, which handles main.

Line 139: `cases = [make_dense_outer(rng), make_dense_dot8(rng), make_binary(rng), make_ternary(rng)]` This assigns ‘[make_dense_outer(rng), make_dense_dot8(rng), make_binary(rng), make_ternary(rng)]‘ to ‘cases ‘ in host memory. Here cases means the value named ’cases’ in this block. The important operands are make_dense_outer: the value named ’make dense outer’ in this block; rng: the value named ’rng’ in this block; make_dense_dot8: the value named ’make dense dot8’ in this block. Context: the function main, which handles main.

Line 141: `commands = [command_word(case) for case in cases]` This assigns ‘[command_word(case) for case in cases]‘ to ‘commands ‘ in host memory. Here commands means the 128-bit instruction selecting an engine, shape, mode, and numeric parameters. The important operands are command_word: the 128-bit instruction selecting an engine, shape, mode, and numeric parameters; case: the value named ’case’ in this block; for: the value named ’for’ in this block. Context: the function main, which handles main.

Line 142: `activation_words = [word for case in cases for word in case.activation_words]` This assigns ‘[word for case in cases for word in case.activation_words]‘ to ‘activation_words ‘ in host memory. Here activation_words means an input feature value consumed by a neuron or multiply-accumulate operation. The important operands are word: the value named ’word’ in this block; for: the value named ’for’ in this block; case: the value named ’case’ in this block. Context: the function main, which handles main.

Line 143: `weight_words = [word for case in cases for word in case.weight_words]` This assigns ‘[word for case in cases for word in case.weight_words]‘ to ‘weight_words ‘ in host memory. Here weight_words means a learned coefficient multiplied by an activation. The important operands are word: the value named ’word’ in this block; for: the value named ’for’ in this block; case: the value named ’case’ in this block. Context: the function main, which handles main.

Line 144: `expected_values = [int(value) for case in cases for value in case.expected.reshape(-1)]` This assigns ‘[int(value) for case in cases for value in case.expected.reshape(-1)]‘ to ‘expected_values ‘ in host memory. Here expected_values means the value named ’expected values’ in this block. The important operands are value: the value named ’value’ in this block; for: the value named ’for’ in this block; case: the value named ’case’ in this block. Context: the function main, which handles main.

Line 146: `write_hex(fixture_dir / "tensor_cases.mem", commands, 64)` This calls ‘write_hex‘ with ‘fixture_dir / "tensor_cases.mem", commands, 64‘ inside the function main, which handles main. The call advances the host-side job that builds deterministic dense, binary, and ternary tensor vectors for bit-exact RTL comparison.

Line 147: `write_hex(fixture_dir / "tensor_activations.mem", activation_words, 64)` This calls ‘write_hex‘ with ‘fixture_dir / "tensor_activations.mem", activation_words, 64‘ inside the function main, which handles main. The call advances the host-side job that builds deterministic dense, binary, and ternary tensor vectors for bit-exact RTL comparison.

Line 148: `write_hex(fixture_dir / "tensor_weights.mem", weight_words, COLUMN_LANES * ROW_LANES * 8)` This calls ‘write_hex‘ with ‘fixture_dir / "tensor_weights.mem", weight_words, COLUMN_LANES * ROW_LANES * 8‘ inside the function main, which handles main. The call advances the host-side job that builds deterministic dense, binary, and ternary tensor vectors for bit-exact RTL comparison.

Line 149: `write_hex(fixture_dir / "tensor_expected.mem", expected_values, 64)` This calls ‘write_hex‘ with ‘fixture_dir / "tensor_expected.mem", expected_values, 64‘ inside the function main, which handles main. The call advances the host-side job that builds deterministic dense, binary, and ternary tensor vectors for bit-exact RTL comparison.

Line 150: `(fixture_dir / "tensor_tile_params.svh").write_text(` This statement continues through source line 157; the explanation uses the complete expression rather than only the first visual fragment. Inside the function main, which handles main, this statement advances the host implementation that builds deterministic dense, binary, and ternary tensor vectors for bit-exact RTL comparison. The important operands are fixture_dir: the value named ’fixture dir’ in this block; tensor_tile_params: the value named ’tensor tile params’ in this block; svh: the value named ’svh’ in this block.

Line 151: `"‘define NEURAEDGE_TENSOR_CASES %d\n"` This is continuation line 2 of the 8-line logical statement that begins at source line 150. Its exact fragment is ‘"‘define NEURAEDGE_TENSOR_CASES %d\n"‘. The important operands are define: the value named ’define’ in this block; NEURAEDGE_TENSOR_CASES: the value named ’neuraedge tensor cases’ in this block; d: the value named ’d’ in this block. Read together, the complete operation is: Inside the function main, which handles main, this statement advances the host implementation that builds deterministic dense, binary, and ternary tensor vectors for bit-exact RTL comparison. The important operands are fixture_dir: the value named ’fixture dir’ in this block; tensor_tile_params: the value named ’tensor tile params’ in this block; svh: the value named ’svh’ in this block.

Line 152: `"‘define NEURAEDGE_TENSOR_ISSUES %d\n"` This is continuation line 3 of the 8-line logical statement that begins at source line 150. Its exact fragment is ‘"‘define NEURAEDGE_TENSOR_ISSUES %d\n"‘. The important operands are define: the value named ’define’ in this block; NEURAEDGE_TENSOR_ISSUES: the value named ’neuraedge tensor issues’ in this block; d: the value named ’d’ in this block. Read together, the complete operation is: Inside the function main, which handles main, this statement advances the host implementation that builds deterministic dense, binary, and ternary tensor vectors for bit-exact RTL comparison. The important operands are fixture_dir: the value named ’fixture dir’ in this block; tensor_tile_params: the value named ’tensor tile params’ in this block; svh: the value named ’svh’ in this block.

Line 153: `"‘define NEURAEDGE_TENSOR_RESULTS %d\n"` This is continuation line 4 of the 8-line logical statement that begins at source line 150. Its exact fragment is ‘"‘define NEURAEDGE_TENSOR_RESULTS %d\n"‘. The important operands are define: the value named ’define’ in this block; NEURAEDGE_TENSOR_RESULTS: the value named ’neuraedge tensor results’ in this block; d: the value named ’d’ in this block. Read together, the complete operation is: Inside the function main, which handles main, this statement advances the host implementation that builds deterministic dense, binary, and ternary tensor vectors for bit-exact RTL comparison. The important operands are fixture_dir: the value named ’fixture dir’ in this block; tensor_tile_params: the value named ’tensor tile params’ in this block; svh: the value named ’svh’ in this block.

Line 154: `"‘define NEURAEDGE_COLUMN_LANES %d\n"` This is continuation line 5 of the 8-line logical statement that begins at source line 150. Its exact fragment is ‘"‘define NEURAEDGE_COLUMN_LANES %d\n"‘. The important operands are define: the value named ’define’ in this block; NEURAEDGE_COLUMN_LANES: one parallel arithmetic element within a vector or tensor datapath; d: the value named ’d’ in this block. Read together, the complete operation is: Inside the function main, which handles main, this statement advances the host implementation that builds deterministic dense, binary, and ternary tensor vectors for bit-exact RTL comparison. The important operands are fixture_dir: the value named ’fixture dir’ in this block; tensor_tile_params: the value named ’tensor tile params’ in this block; svh: the value named ’svh’ in this block.

Line 155: `% (len(cases), len(activation_words), len(expected_values), COLUMN_LANES),` This is continuation line 6 of the 8-line logical statement that begins at source line 150. Its exact fragment is ‘% (len(cases), len(activation_words), len(expected_values), COLUMN_LANES),‘. The important operands are len: the value named ’len’ in this block; cases:

the value named 'cases' in this block; activation_words: an input feature value consumed by a neuron or multiply-accumulate operation. Read together, the complete operation is: Inside the function main, which handles main, this statement advances the host implementation that builds deterministic dense, binary, and ternary tensor vectors for bit-exact RTL comparison. The important operands are fixture_dir: the value named 'fixture dir' in this block; tensor_tile_params: the value named 'tensor tile params' in this block; svh: the value named 'svh' in this block.

Line 156: `encoding="ascii",` This is continuation line 7 of the 8-line logical statement that begins at source line 150. Its exact fragment is 'encoding="ascii",'. The important operands are encoding: the value named 'encoding' in this block; ascii: the value named 'ascii' in this block. Read together, the complete operation is: Inside the function main, which handles main, this statement advances the host implementation that builds deterministic dense, binary, and ternary tensor vectors for bit-exact RTL comparison. The important operands are fixture_dir: the value named 'fixture dir' in this block; tensor_tile_params: the value named 'tensor tile params' in this block; svh: the value named 'svh' in this block.

Line 157: `)` This is continuation line 8 of the 8-line logical statement that begins at source line 150. Its exact fragment is ')'. The expression is a literal or structural operator and has no hidden software state. Read together, the complete operation is: Inside the function main, which handles main, this statement advances the host implementation that builds deterministic dense, binary, and ternary tensor vectors for bit-exact RTL comparison. The important operands are fixture_dir: the value named 'fixture dir' in this block; tensor_tile_params: the value named 'tensor tile params' in this block; svh: the value named 'svh' in this block.

Line 159: `manifest = {` This statement continues through source line 179; the explanation uses the complete expression rather than only the first visual fragment. Inside the function main, which handles main, this statement advances the host implementation that builds deterministic dense, binary, and ternary tensor vectors for bit-exact RTL comparison. The important operands are manifest: the value named 'manifest' in this block; seed: the value named 'seed' in this block; case_count: an integer count retained for control or measurable telemetry.

Line 160: `"seed": "0x4E455552",` This is continuation line 2 of the 21-line logical statement that begins at source line 159. Its exact fragment is '"seed": "0x4E455552",'. The important operands are seed: the value named 'seed' in this block. Read together, the complete operation is: Inside the function main, which handles main, this statement advances the host implementation that builds deterministic dense, binary, and ternary tensor vectors for bit-exact RTL comparison. The important operands are manifest: the value named 'manifest' in this block; seed: the value named 'seed' in this block; case_count: an integer count retained for control or measurable telemetry.

Line 161: `"case_count": len(cases),` This is continuation line 3 of the 21-line logical statement that begins at source line 159. Its exact fragment is '"case_count": len(cases),'. The important operands are case_count: an integer count retained for control or measurable telemetry; len: the value named 'len' in this block; cases: the value named 'cases' in this block. Read together, the complete operation is: Inside the function main, which handles main, this statement advances the host implementation that builds deterministic dense, binary, and ternary tensor vectors for bit-exact RTL comparison. The important operands are manifest: the value named 'manifest' in this block; seed: the value named 'seed' in this block; case_count: an integer count retained for control or measurable telemetry.

Line 162: `"issue_count": len(activation_words),` This is continuation line 4 of the 21-line logical statement that begins at source line 159. Its exact fragment is '"issue_count": len(activation_words),'. The important operands are issue_count: an integer count retained for control or measurable telemetry; len: the value named 'len' in this block; activation_words: an input feature value consumed by a neuron or multiply-accumulate operation. Read together, the complete operation is: Inside the function main, which handles main, this statement advances the host implementation that builds deterministic dense, binary, and ternary tensor vectors for bit-exact RTL comparison. The important operands are manifest: the value named 'manifest' in this block; seed: the value named 'seed' in this block; case_count: an integer count retained for control or measurable telemetry.

Line 163: `"result_count": len(expected_values),` This is continuation line 5 of the 21-line logical statement that begins at source line 159. Its exact fragment is '"result_count": len(expected_values),'. The important operands are result_count: an integer count retained for control or measurable telemetry; len: the value named 'len' in this block; expected_values: the value named 'expected values' in this block. Read together, the complete operation is: Inside the function main, which handles main, this statement advances the host implementation that builds deterministic dense,

binary, and ternary tensor vectors for bit-exact RTL comparison. The important operands are manifest: the value named 'manifest' in this block; seed: the value named 'seed' in this block; case_count: an integer count retained for control or measurable telemetry.

Line 164: `"cases": [` This is continuation line 6 of the 21-line logical statement that begins at source line 159. Its exact fragment is '"cases": [‘. The important operands are cases: the value named 'cases' in this block. Read together, the complete operation is: Inside the function main, which handles main, this statement advances the host implementation that builds deterministic dense, binary, and ternary tensor vectors for bit-exact RTL comparison. The important operands are manifest: the value named 'manifest' in this block; seed: the value named 'seed' in this block; case_count: an integer count retained for control or measurable telemetry.

Line 165: `{` This is continuation line 7 of the 21-line logical statement that begins at source line 159. Its exact fragment is '{‘. The expression is a literal or structural operator and has no hidden software state. Read together, the complete operation is: Inside the function main, which handles main, this statement advances the host implementation that builds deterministic dense, binary, and ternary tensor vectors for bit-exact RTL comparison. The important operands are manifest: the value named 'manifest' in this block; seed: the value named 'seed' in this block; case_count: an integer count retained for control or measurable telemetry.

Line 166: `"name": case.name,` This is continuation line 8 of the 21-line logical statement that begins at source line 159. Its exact fragment is '"name": case.name,‘. The important operands are name: the value named 'name' in this block; case: the value named 'case' in this block. Read together, the complete operation is: Inside the function main, which handles main, this statement advances the host implementation that builds deterministic dense, binary, and ternary tensor vectors for bit-exact RTL comparison. The important operands are manifest: the value named 'manifest' in this block; seed: the value named 'seed' in this block; case_count: an integer count retained for control or measurable telemetry.

Line 167: `"mode": case.mode.name,` This is continuation line 9 of the 21-line logical statement that begins at source line 159. Its exact fragment is '"mode": case.mode.name,‘. The important operands are mode: the value named 'mode' in this block; case: the value named 'case' in this block; name: the value named 'name' in this block. Read together, the complete operation is: Inside the function main, which handles main, this statement advances the host implementation that builds deterministic dense, binary, and ternary tensor vectors for bit-exact RTL comparison. The important operands are manifest: the value named 'manifest' in this block; seed: the value named 'seed' in this block; case_count: an integer count retained for control or measurable telemetry.

Line 168: `"rows": case.rows,` This is continuation line 10 of the 21-line logical statement that begins at source line 159. Its exact fragment is '"rows": case.rows,‘. The important operands are rows: one output-row position processed by the tensor tile; case: the value named 'case' in this block. Read together, the complete operation is: Inside the function main, which handles main, this statement advances the host implementation that builds deterministic dense, binary, and ternary tensor vectors for bit-exact RTL comparison. The important operands are manifest: the value named 'manifest' in this block; seed: the value named 'seed' in this block; case_count: an integer count retained for control or measurable telemetry.

Line 169: `"columns": case.columns,` This is continuation line 11 of the 21-line logical statement that begins at source line 159. Its exact fragment is '"columns": case.columns,‘. The important operands are columns: one output-feature position processed in parallel; case: the value named 'case' in this block. Read together, the complete operation is: Inside the function main, which handles main, this statement advances the host implementation that builds deterministic dense, binary, and ternary tensor vectors for bit-exact RTL comparison. The important operands are manifest: the value named 'manifest' in this block; seed: the value named 'seed' in this block; case_count: an integer count retained for control or measurable telemetry.

Line 170: `"issues": len(case.activation_words),` This is continuation line 12 of the 21-line logical statement that begins at source line 159. Its exact fragment is '"issues": len(case.activation_words),‘. The important operands are issues: the value named 'issues' in this block; len: the value named 'len' in this block; case: the value named 'case' in this block. Read together, the complete operation is: Inside the function main, which handles main, this statement advances the host implementation that builds deterministic dense, binary, and ternary tensor vectors for bit-exact RTL

comparison. The important operands are manifest: the value named 'manifest' in this block; seed: the value named 'seed' in this block; case_count: an integer count retained for control or measurable telemetry.

Line 171: `"activation_zero_point": case.activation_zero_point,` This is continuation line 13 of the 21-line logical statement that begins at source line 159. Its exact fragment is '"activation_zero_point": case.activation_zero_point,'. The important operands are activation_zero_point: an input feature value consumed by a neuron or multiply-accumulate operation; case: the value named 'case' in this block. Read together, the complete operation is: Inside the function main, which handles main, this statement advances the host implementation that builds deterministic dense, binary, and ternary tensor vectors for bit-exact RTL comparison. The important operands are manifest: the value named 'manifest' in this block; seed: the value named 'seed' in this block; case_count: an integer count retained for control or measurable telemetry.

Line 172: `"weight_zero_point": case.weight_zero_point,` This is continuation line 14 of the 21-line logical statement that begins at source line 159. Its exact fragment is '"weight_zero_point": case.weight_zero_point,'. The important operands are weight_zero_point: a learned coefficient multiplied by an activation; case: the value named 'case' in this block. Read together, the complete operation is: Inside the function main, which handles main, this statement advances the host implementation that builds deterministic dense, binary, and ternary tensor vectors for bit-exact RTL comparison. The important operands are manifest: the value named 'manifest' in this block; seed: the value named 'seed' in this block; case_count: an integer count retained for control or measurable telemetry.

Line 173: `"skipped_zero_issues": sum(word == pack_bytes([case.activation_zero_point] * ROW_LANES) for word in case.ac...` This is continuation line 15 of the 21-line logical statement that begins at source line 159. Its exact fragment is '"skipped_zero_issues": sum(word == pack_bytes([case.activation_zero_point] * ROW_LANES) for word in case.activation_words)'. The important operands are skipped_zero_issues: the value named 'skipped zero issues' in this block; sum: the value named 'sum' in this block; word: the value named 'word' in this block. Read together, the complete operation is: Inside the function main, which handles main, this statement advances the host implementation that builds deterministic dense, binary, and ternary tensor vectors for bit-exact RTL comparison. The important operands are manifest: the value named 'manifest' in this block; seed: the value named 'seed' in this block; case_count: an integer count retained for control or measurable telemetry.

Line 174: `if case.mode in (ComputeMode.DENSE_OUTER, ComputeMode.DENSE_DOT8)` This is continuation line 16 of the 21-line logical statement that begins at source line 159. Its exact fragment is 'if case.mode in (ComputeMode.DENSE_OUTER, ComputeMode.DENSE_DOT8)'. The important operands are case: the value named 'case' in this block; mode: the value named 'mode' in this block; in: the value named 'in' in this block. Read together, the complete operation is: Inside the function main, which handles main, this statement advances the host implementation that builds deterministic dense, binary, and ternary tensor vectors for bit-exact RTL comparison. The important operands are manifest: the value named 'manifest' in this block; seed: the value named 'seed' in this block; case_count: an integer count retained for control or measurable telemetry.

Line 175: `else sum(word == 0 for word in case.activation_words),` This is continuation line 17 of the 21-line logical statement that begins at source line 159. Its exact fragment is 'else sum(word == 0 for word in case.activation_words),'. The important operands are sum: the value named 'sum' in this block; word: the value named 'word' in this block; for: the value named 'for' in this block. Read together, the complete operation is: Inside the function main, which handles main, this statement advances the host implementation that builds deterministic dense, binary, and ternary tensor vectors for bit-exact RTL comparison. The important operands are manifest: the value named 'manifest' in this block; seed: the value named 'seed' in this block; case_count: an integer count retained for control or measurable telemetry.

Line 176: `}` This is continuation line 18 of the 21-line logical statement that begins at source line 159. Its exact fragment is '}'. The expression is a literal or structural operator and has no hidden software state. Read together, the complete operation is: Inside the function main, which handles main, this statement advances the host implementation that builds deterministic dense, binary, and ternary tensor vectors for bit-exact RTL comparison. The important operands are manifest: the value named 'manifest' in this block; seed: the value named 'seed' in this block; case_count: an integer count retained for control or measurable telemetry.

Line 177: `for case in cases` This is continuation line 19 of the 21-line logical statement that begins at source line 159. Its exact fragment is 'for case in cases'. The important operands are for: the value named 'for' in this block; case:

the value named 'case' in this block; in: the value named 'in' in this block. Read together, the complete operation is: Inside the function main, which handles main, this statement advances the host implementation that builds deterministic dense, binary, and ternary tensor vectors for bit-exact RTL comparison. The important operands are manifest: the value named 'manifest' in this block; seed: the value named 'seed' in this block; case_count: an integer count retained for control or measurable telemetry.

Line 178: `],` This is continuation line 20 of the 21-line logical statement that begins at source line 159. Its exact fragment is '],'. The expression is a literal or structural operator and has no hidden software state. Read together, the complete operation is: Inside the function main, which handles main, this statement advances the host implementation that builds deterministic dense, binary, and ternary tensor vectors for bit-exact RTL comparison. The important operands are manifest: the value named 'manifest' in this block; seed: the value named 'seed' in this block; case_count: an integer count retained for control or measurable telemetry.

Line 179: `}` This is continuation line 21 of the 21-line logical statement that begins at source line 159. Its exact fragment is '}'. The expression is a literal or structural operator and has no hidden software state. Read together, the complete operation is: Inside the function main, which handles main, this statement advances the host implementation that builds deterministic dense, binary, and ternary tensor vectors for bit-exact RTL comparison. The important operands are manifest: the value named 'manifest' in this block; seed: the value named 'seed' in this block; case_count: an integer count retained for control or measurable telemetry.

Line 180: `(fixture_dir / "tensor_fixture_manifest.json").write_text(json.dumps(manifest, indent=2), encoding="utf-8")` Inside the function main, which handles main, this statement advances the host implementation that builds deterministic dense, binary, and ternary tensor vectors for bit-exact RTL comparison. The important operands are fixture_dir: the value named 'fixture dir' in this block; tensor_fixture_manifest: the value named 'tensor fixture manifest' in this block; json: the value named 'json' in this block.

Line 181: `print(json.dumps(manifest, indent=2))` This calls 'print' with 'json.dumps(manifest, indent=2)' inside the function main, which handles main. The call advances the host-side job that builds deterministic dense, binary, and ternary tensor vectors for bit-exact RTL comparison.

Line 184: `if __name__ == "__main__":` This executes the following indented host-code branch only when '___name___ == "___main___"' is true. The important operands are ___name___: the value named 'name' in this block; ___main___: the value named 'main' in this block. Context: the file whose role is to builds deterministic dense, binary, and ternary tensor vectors for bit-exact RTL comparison.

Line 185: `main()` This calls 'main' with " inside the file whose role is to builds deterministic dense, binary, and ternary tensor vectors for bit-exact RTL comparison. The call advances the host-side job that builds deterministic dense, binary, and ternary tensor vectors for bit-exact RTL comparison.

33 software/generate_training_coverage.py

Role in the complete system: records which Spikingformer parameters receive hardware gradients and optimizer updates in each training policy.

33.1 Beginner architecture map

Dataflow responsibility This file's end-to-end responsibility is to records which Spikingformer parameters receive hardware gradients and optimizer updates in each training policy.

Where it runs This is sequential host software. Python objects live in CPU memory; they become FPGA work only when the compiler packs a command or payload and the PYNQ driver transfers those bytes through AXI DMA or AXI-Lite.

Public structure Classes: none. Functions: main. Each function annotation below names its enclosing function so an array operation is tied to the model, compiler, driver, test, or report phase that uses it.

Numeric and failure boundary Shapes, signedness, byte order, scaling, and saturation are part of the hardware contract. Validation exceptions are functional safety checks: rejecting malformed input before DMA is different from silently clipping, reshaping, or continuing with an incompatible artifact.

33.2 Complete source

```
"""Generate the audited full-graph NeuraEdge training coverage manifest."""

from __future__ import annotations

        f"learned_groups={summary['learned_affine_group_count']} "
        f"parameters={summary['trainable_deployed_parameter_elements']} "
        f"output={output}"
    )

if __name__ == "__main__":
    main()
```

33.3 Line annotations

Line 1: `"""Generate the audited full-graph NeuraEdge training coverage manifest."""` This is executable documentation attached to the file whose role is to records which Spikingformer parameters receive hardware gradients and optimizer updates in each training policy. It states the intended contract that tests and callers should enforce, but the text itself does not transform data or issue hardware work.

Line 3: `from __future__ import annotations` This imports the named Python API so the file whose role is to records which Spikingformer parameters receive hardware gradients and optimizer updates in each training policy can use it explicitly. Imports execute on the host processor and create no FPGA hardware.

Line 5: `import argparse` This imports the named Python API so the file whose role is to records which Spikingformer parameters receive hardware gradients and optimizer updates in each training policy can use it explicitly. Imports execute on the host processor and create no FPGA hardware.

Line 6: `import json` This imports the named Python API so the file whose role is to records which Spikingformer parameters receive hardware gradients and optimizer updates in each training policy can use it explicitly. Imports execute on the host processor and create no FPGA hardware.

Line 7: `from pathlib import Path` This imports the named Python API so the file whose role is to records which Spikingformer parameters receive hardware gradients and optimizer updates in each training policy can use it explicitly. Imports execute on the host processor and create no FPGA hardware.

Line 9: `from neuraedge_training import build_spikingformer_training_coverage` This imports the named Python API so the file whose role is to records which Spikingformer parameters receive hardware gradients and optimizer updates in each training policy can use it explicitly. Imports execute on the host processor and create no FPGA hardware.

Line 12: `def main() -> None:` This starts function main. Its indented body performs main as part of the file that records which Spikingformer parameters receive hardware gradients and optimizer updates in each training policy; it runs only when called.

Line 13: `parser = argparse.ArgumentParser()` This assigns ‘argparse.ArgumentParser()‘ to ‘parser ‘ in host memory. Here parser means the value named ’parser’ in this block. The important operands are argparse: the value named ’argparse’ in this block; ArgumentParser: the value named ’argument parser’ in this block. Context: the function main, which handles main.

Line 14: `parser.add_argument("-execution-manifest", required=True, type=Path)` This declares a command-line option for the function main, which handles main. Its name, type, default, and required status make the run configuration explicit and reproducible instead of relying on an invisible interactive setting.

Line 15: `parser.add_argument("-parameter-manifest", required=True, type=Path)` This declares a command-line option for the function main, which handles main. Its name, type, default, and required status make the run configuration explicit and reproducible instead of relying on an invisible interactive setting.

Line 16: `parser.add_argument("-output", required=True, type=Path)` This declares a command-line option for the function main, which handles main. Its name, type, default, and required status make the run configuration explicit and reproducible instead of relying on an invisible interactive setting.

Line 17: `arguments = parser.parse_args()` This assigns ‘parser.parse_args()‘ to ‘arguments ‘ in host memory. Here arguments means the value named ’arguments’ in this block. The important operands are parser: the value named ’parser’ in this block; parse_args: the value named ’parse args’ in this block. Context: the function main, which handles main.

Line 18: `result = build_spikingformer_training_coverage(` This statement continues through source line 21; the explanation uses the complete expression rather than only the first visual fragment. This assigns ‘build_spikingformer_training_cove arguments.execution_manifest, arguments.parameter_manifest,)‘ to ‘result ‘ in host memory. Here result means the value named ’result’ in this block. The important operands are build_spikingformer_training_coverage: the value named ’build spikingformer training coverage’ in this block; arguments: the value named ’arguments’ in this block; execution_manifest: the value named ’execution manifest’ in this block. Context: the function main, which handles main.

Line 19: `arguments.execution_manifest,` This is continuation line 2 of the 4-line logical statement that begins at source line 18. Its exact fragment is ‘arguments.execution_manifest,‘. The important operands are arguments: the value named ’arguments’ in this block; execution_manifest: the value named ’execution manifest’ in this block. Read together, the complete operation is: This assigns ‘build_spikingformer_training_coverage(arguments.execution_manifest, arguments.parameter_manifest,)‘ to ‘result ‘ in host memory. Here result means the value named ’result’ in this block. The important operands are build_spikingformer_training_coverage: the value named ’build spikingformer training coverage’ in this block; arguments: the value named ’arguments’ in this block; execution_manifest: the value named ’execution manifest’ in this block. Context: the function main, which handles main.

Line 20: `arguments.parameter_manifest,` This is continuation line 3 of the 4-line logical statement that begins at source line 18. Its exact fragment is ‘arguments.parameter_manifest,‘. The important operands are arguments: the value named ’arguments’ in this block; parameter_manifest: the value named ’parameter manifest’ in this block. Read together, the complete operation is: This assigns ‘build_spikingformer_training_coverage(arguments.execution_manifest, arguments.parameter_manifest,)‘ to ‘result ‘ in host memory. Here result means the value named ’result’ in this block. The important operands are build_spikingformer_training_coverage: the value named ’build spikingformer training coverage’ in this block; arguments: the value named ’arguments’ in this block; execution_manifest: the value named ’execution manifest’ in this block. Context: the function main, which handles main.

Line 21: `)` This is continuation line 4 of the 4-line logical statement that begins at source line 18. Its exact fragment is ‘)‘. The expression is a literal or structural operator and has no hidden software state. Read together, the complete operation is: This assigns ‘build_spikingformer_training_coverage(arguments.execution_manifest, arguments.parameter_manifest,)‘ to ‘result ‘ in host memory. Here result means the value named ’result’ in this block. The important operands are build_spikingformer_training_coverage: the value named ’build spikingformer training coverage’ in this block; arguments: the value named ’arguments’ in this block; execution_manifest: the value named ’execution manifest’ in this block. Context: the function main, which handles main.

Line 22: `output = arguments.output.expanduser().resolve()` This assigns ‘arguments.output.expanduser().resolve()‘ to ‘output ‘ in host memory. Here output means the value named ’output’ in this block. The important operands are arguments: the value named ’arguments’ in this block; output: the value named ’output’ in this block; expanduser: the value named ’expanduser’ in this block. Context: the function main, which handles main.

Line 23: `output.parent.mkdir(parents=True, exist_ok=True)` This calls ‘output.parent.mkdir‘ with ‘parents=True, exist_ok=True‘ inside the function main, which handles main. The call advances the host-side job that records which Spikingformer parameters receive hardware gradients and optimizer updates in each training policy.

Line 24: `output.write_text(json.dumps(result, indent=2) + "\n", encoding="ascii")` This calls ‘output.write_text‘ with ‘json.dumps(result, indent=2) + "\n", encoding="ascii"‘ inside the function main, which handles main. The call advances the host-side job that records which Spikingformer parameters receive hardware gradients and optimizer updates in each training policy.

Line 25: `summary = result["summary"]` This assigns ‘result["summary"]‘ to ‘summary ‘ in host memory. Here summary means the value named ’summary’ in this block. The important operands are result: the value named ’result’ in this block; summary: the value named ’summary’ in this block. Context: the function main, which handles main.

Line 26: `print(` This statement continues through source line 32; the explanation uses the complete expression rather than only the first visual fragment. This calls ‘print‘ with ‘ "NEURAEDGE_TRAINING_COVERAGE_PASSED " f"operators={summary['covered_execution_operator_count']} " f"learned_groups={summary['learned_affine_group_count']} " f"parameters={summary['trainable_deployed_parameter_elements']} " f"output={output}" ‘ inside the function main, which handles main. The call advances the host-side job that records which Spikingformer parameters receive hardware gradients and optimizer updates in each training policy.

Line 27: `"NEURAEDGE_TRAINING_COVERAGE_PASSED "` This is continuation line 2 of the 7-line logical statement that begins at source line 26. Its exact fragment is ‘"NEURAEDGE_TRAINING_COVERAGE_PASSED "‘. The important operands are NEURAEDGE_TRAINING_COVERAGE_PASSED: the value named ’neuraedge training coverage passed’ in this block. Read together, the complete operation is: This calls ‘print‘ with ‘ "NEURAEDGE_TRAINING_COVERAGE_

" f"operators={summary['covered_execution_operator_count']} " f"learned_groups={summary['learned_affine_group_count']}
" f"parameters={summary['trainable_deployed_parameter_elements']} " f"output={output}" ‘ inside the function main,
which handles main. The call advances the host-side job that records which Spikingformer parameters receive hardware
gradients and optimizer updates in each training policy.

Line 28: `f"operators={summary['covered_execution_operator_count']} "` This is continuation line 3 of the 7-
line logical statement that begins at source line 26. Its exact fragment is ‘f"operators={summary['covered_execution_operator_coun
"‘. The important operands are f: the value named ’f’ in this block; operators: the value named ’operators’ in this block;
summary: the value named ’summary’ in this block. Read together, the complete operation is: This calls ‘print‘ with ‘
"NEURAEDGE_TRAINING_COVERAGE_PASSED " f"operators={summary['covered_execution_operator_count']}
" f"learned_groups={summary['learned_affine_group_count']} " f"parameters={summary['trainable_deployed_parameter_elemer
" f"output={output}" ‘ inside the function main, which handles main. The call advances the host-side job that records
which Spikingformer parameters receive hardware gradients and optimizer updates in each training policy.

Line 29: `f"learned_groups={summary['learned_affine_group_count']} "` This is continuation line 4 of the 7-line
logical statement that begins at source line 26. Its exact fragment is ‘f"learned_groups={summary['learned_affine_group_count']}
"‘. The important operands are f: the value named ’f’ in this block; learned_groups: the value named ’learned groups’ in
this block; summary: the value named ’summary’ in this block. Read together, the complete operation is: This calls ‘print‘
with ‘ "NEURAEDGE_TRAINING_COVERAGE_PASSED " f"operators={summary['covered_execution_operator_count']}

which Spikingformer parameters receive hardware gradients and optimizer updates in each training policy.

Line 35: `if __name__ == "__main__":` This executes the following indented host-code branch only when ‘___name___
== "___main___"‘ is true. The important operands are ___name___: the value named ’name’ in this block; ___main___:
the value named ’main’ in this block. Context: the file whose role is to records which Spikingformer parameters receive
hardware gradients and optimizer updates in each training policy.

Line 36: `main()` This calls ‘main‘ with “ inside the file whose role is to records which Spikingformer parameters receive
hardware gradients and optimizer updates in each training policy. The call advances the host-side job that records which
Spikingformer parameters receive hardware gradients and optimizer updates in each training policy.

34 software/neuraedge_compiler.py

Role in the complete system: tiles matrices and convolutions into validated accelerator commands and packed stream payloads.

34.1 Beginner architecture map

Dataflow responsibility Validated NumPy tensors are tiled into hardware-sized activation and weight loads followed by compute records. The compiler chooses outer or dot8 reuse from traffic, lowers grouped convolution through im2col, packs little-endian stream beats, and rejects dimensions the RTL cannot represent.

Where it runs This is sequential host software. Python objects live in CPU memory; they become FPGA work only when the compiler packs a command or payload and the PYNQ driver transfers those bytes through AXI DMA or AXI-Lite.

Public structure Classes: CommandExecutor, ProgramExecutor, TensorInstruction, ResultBinding, CompiledGemm, ConvGroupProgram, CompiledConv2d. Functions: _pack_compiler_u8_rows, _accumulate_tensor_tile, _as_u8_matrix, _u8, _pair, _im2col_nchw, compile_u8_gemm, compile_spike_gemm, compile_u8_conv2d, compile_spike_conv2d, execute, execute_program, execute, execute_batched, execute, execute_batched, mathematical_macs, estimated_input_byte estimated_spike_adds, append_load, append_compute, append_load, activation_load, weight_load. Each function annotation below names its enclosing function so an array operation is tied to the model, compiler, driver, test, or report phase that uses it.

Numeric and failure boundary Shapes, signedness, byte order, scaling, and saturation are part of the hardware contract. Validation exceptions are functional safety checks: rejecting malformed input before DMA is different from silently clipping, reshaping, or continuing with an incompatible artifact.

34.2 Complete source

```
"""Tiled uint8 GEMM compiler for the NeuraEdge tensor engine.

The compiler turns a mathematical ``(A - za) @ (B - zb) + bias`` operation
into the exact load/compute transactions accepted by the RTL.  It deliberately
keeps compilation separate from execution: plans can be inspected, tested,
serialized, or sent to a PYNQ board through :class:`NeuraEdgeDriver`.

34.3 Line annotations

Line 1: `"""Tiled uint8 GEMM compiler for the NeuraEdge tensor engine.` This is executable documentation attached to the file whose role is to tiles matrices and convolutions into validated accelerator commands and packed stream payloads. It states the intended contract that tests and callers should enforce, but the text itself does not transform data or issue hardware work.

Line 3: `The compiler turns a mathematical "(A - za) @ (B - zb) + bias" operation` Inside the file whose role is to tiles matrices and convolutions into validated accelerator commands and packed stream payloads, this statement advances the host implementation that tiles matrices and convolutions into validated accelerator commands and packed stream payloads. The important operands are The: the value named 'the' in this block; compiler: the value named 'compiler' in this block; turns: the value named 'turns' in this block.

Line 4: `into the exact load/compute transactions accepted by the RTL. It deliberately` Inside the file whose role is to tiles matrices and convolutions into validated accelerator commands and packed stream payloads, this statement advances the host implementation that tiles matrices and convolutions into validated accelerator commands and packed stream payloads. The important operands are into: the value named 'into' in this block; the: the value named 'the' in this block; exact: the value named 'exact' in this block.

Line 5: `keeps compilation separate from execution: plans can be inspected, tested,` Inside the file whose role is to tiles matrices and convolutions into validated accelerator commands and packed stream payloads, this statement advances the host implementation that tiles matrices and convolutions into validated accelerator commands and packed stream payloads. The important operands are keeps: the value named 'keeps' in this block; compilation: the value named 'compilation' in this block; separate: the value named 'separate' in this block.

Line 6: `serialized, or sent to a PYNQ board through :class:‘NeuraEdgeDriver‘.` Inside the file whose role is to tiles matrices and convolutions into validated accelerator commands and packed stream payloads, this statement

advances the host implementation that tiles matrices and convolutions into validated accelerator commands and packed stream payloads. The important operands are serialized: the value named 'serialized' in this block; or: the value named 'or' in this block; sent: the value named 'sent' in this block.

Line 7: `"""` This is executable documentation attached to the file whose role is to tiles matrices and convolutions into validated accelerator commands and packed stream payloads. It states the intended contract that tests and callers should enforce, but the text itself does not transform data or issue hardware work.

Line 9: `from __future__ import annotations` This imports the named Python API so the file whose role is to tiles matrices and convolutions into validated accelerator commands and packed stream payloads can use it explicitly. Imports execute on the host processor and create no FPGA hardware.

Line 11: `from dataclasses import dataclass` This imports the named Python API so the file whose role is to tiles matrices and convolutions into validated accelerator commands and packed stream payloads can use it explicitly. Imports execute on the host processor and create no FPGA hardware.

Line 12: `from typing import Protocol, Sequence` This imports the named Python API so the file whose role is to tiles matrices and convolutions into validated accelerator commands and packed stream payloads can use it explicitly. Imports execute on the host processor and create no FPGA hardware.

Line 14: `import numpy as np` This imports the named Python API so the file whose role is to tiles matrices and convolutions into validated accelerator commands and packed stream payloads can use it explicitly. Imports execute on the host processor and create no FPGA hardware.

Line 16: `from neuraedge_golden import Dataflow, choose_dataflow` This imports the named Python API so the file whose role is to tiles matrices and convolutions into validated accelerator commands and packed stream payloads can use it explicitly. Imports execute on the host processor and create no FPGA hardware.

Line 17: `from neuraedge_protocol import (` This statement continues through source line 25; the explanation uses the complete expression rather than only the first visual fragment. This imports the named Python API so the file whose role is to tiles matrices and convolutions into validated accelerator commands and packed stream payloads can use it explicitly. Imports execute on the host processor and create no FPGA hardware.

Line 18: `Command128,` This is continuation line 2 of the 9-line logical statement that begins at source line 17. Its exact fragment is 'Command128,'. The important operands are Command128: the 128-bit instruction selecting an engine, shape, mode, and numeric parameters. Read together, the complete operation is: This imports the named Python API so the file whose role is to tiles matrices and convolutions into validated accelerator commands and packed stream payloads can use it explicitly. Imports execute on the host processor and create no FPGA hardware.

Line 19: `Opcode,` This is continuation line 3 of the 9-line logical statement that begins at source line 17. Its exact fragment is 'Opcode,'. The important operands are Opcode: the value named 'opcode' in this block. Read together, the complete operation is: This imports the named Python API so the file whose role is to tiles matrices and convolutions into validated accelerator commands and packed stream payloads can use it explicitly. Imports execute on the host processor and create no FPGA hardware.

Line 20: `PackedStreamBeats,` This is continuation line 4 of the 9-line logical statement that begins at source line 17. Its exact fragment is 'PackedStreamBeats,'. The important operands are PackedStreamBeats: the value named 'packed stream beats' in this block. Read together, the complete operation is: This imports the named Python API so the file whose role is to tiles matrices and convolutions into validated accelerator commands and packed stream payloads can use it explicitly. Imports execute on the host processor and create no FPGA hardware.

Line 21: `ProgramRecord,` This is continuation line 5 of the 9-line logical statement that begins at source line 17. Its exact fragment is 'ProgramRecord,'. The important operands are ProgramRecord: the value named 'program record' in this block. Read together, the complete operation is: This imports the named Python API so the file whose role is to tiles matrices and convolutions into validated accelerator commands and packed stream payloads can use it explicitly. Imports execute on the host processor and create no FPGA hardware.

Line 22: `StreamBeat,` This is continuation line 6 of the 9-line logical statement that begins at source line 17. Its exact fragment is 'StreamBeat,'. The important operands are StreamBeat: the value named 'stream beat' in this block. Read together, the complete operation is: This imports the named Python API so the file whose role is to tiles matrices and convolutions into validated accelerator commands and packed stream payloads can use it explicitly. Imports execute on the host processor and create no FPGA hardware.

Line 23: `tensor_command,` This is continuation line 7 of the 9-line logical statement that begins at source line 17. Its exact fragment is 'tensor_command,'. The important operands are tensor_command: the 128-bit instruction selecting an engine, shape, mode, and numeric parameters. Read together, the complete operation is: This imports the named Python API so the file whose role is to tiles matrices and convolutions into validated accelerator commands and packed stream payloads can use it explicitly. Imports execute on the host processor and create no FPGA hardware.

Line 24: `unpack_tensor_result,` This is continuation line 8 of the 9-line logical statement that begins at source line 17. Its exact fragment is 'unpack_tensor_result,'. The important operands are unpack_tensor_result: the value named 'unpack tensor result' in this block. Read together, the complete operation is: This imports the named Python API so the file whose role is to tiles matrices and convolutions into validated accelerator commands and packed stream payloads can use it explicitly. Imports execute on the host processor and create no FPGA hardware.

Line 25: `)` This is continuation line 9 of the 9-line logical statement that begins at source line 17. Its exact fragment is ')'. The expression is a literal or structural operator and has no hidden software state. Read together, the complete operation is: This imports the named Python API so the file whose role is to tiles matrices and convolutions into validated accelerator commands and packed stream payloads can use it explicitly. Imports execute on the host processor and create no FPGA hardware.

Line 28: `ROW_TILE = 8` This assigns '8' to 'ROW_TILE ' in host memory. Here ROW_TILE means one output-row position processed by the tensor tile. The expression is a literal or structural operator and has no hidden software state. Context: the file whose role is to tiles matrices and convolutions into validated accelerator commands and packed stream payloads.

Line 29: `COLUMN_TILE = 16` This assigns '16' to 'COLUMN_TILE ' in host memory. Here COLUMN_TILE means one output-feature position processed in parallel. The expression is a literal or structural operator and has no hidden software state. Context: the file whose role is to tiles matrices and convolutions into validated accelerator commands and packed stream payloads.

Line 30: `MAX_REDUCTION = 2048` This assigns '2048' to 'MAX_REDUCTION ' in host memory. Here MAX_REDUCTION means the value named 'max reduction' in this block. The expression is a literal or structural operator and has no hidden software state. Context: the file whose role is to tiles matrices and convolutions into validated accelerator commands and packed stream payloads.

Line 33: `def _pack_compiler_u8_rows(values: np.ndarray, row_bytes: int) -> PackedStreamBeats:` This starts function _pack_compiler_u8_rows. Its indented body performs pack compiler u8 rows as part of the file that tiles matrices and convolutions into validated accelerator commands and packed stream payloads; it runs only when called.

Line 34: `"""Pack validated uint8 rows into 64-bit stream words without Python lane loops."""` This is executable documentation attached to the function _pack_compiler_u8_rows, which handles pack compiler u8 rows. It states the intended contract that tests and callers should enforce, but the text itself does not transform data or issue hardware work.

Line 36: `array = np.asarray(values)` This assigns ‘np.asarray(values)‘ to ‘array ‘ in host memory. Here array means the value named ’array’ in this block. The important operands are asarray: the value named ’asarray’ in this block; values: the value named ’values’ in this block. Context: the function _pack_compiler_u8_rows, which handles pack compiler u8 rows.

Line 37: `if array.dtype != np.uint8 or array.ndim < 2 or array.shape[-1] != row_bytes:` This executes the following indented host-code branch only when ‘array.dtype != np.uint8 or array.ndim < 2 or array.shape[-1] != row_bytes‘ is true. The important operands are array: the value named ’array’ in this block; dtype: the value named ’dtype’ in this block; uint8: the value named ’uint8’ in this block. Context: the function _pack_compiler_u8_rows, which handles pack compiler u8 rows.

Line 38: `raise ValueError(f"compiler stream tensor must be uint8 with final dimension {row_bytes}")` This rejects an invalid state by raising ‘ValueError(f"compiler stream tensor must be uint8 with final dimension {row_bytes}")‘. Failing before DMA prevents malformed shapes or artifacts from silently becoming hardware results.

Line 39: `if row_bytes % 8:` This executes the following indented host-code branch only when ‘row_bytes % 8‘ is true. The important operands are row_bytes: one output-row position processed by the tensor tile. Context: the function _pack_compiler_u8_rows, which handles pack compiler u8 rows.

Line 40: `raise ValueError("compiler stream row width must be a multiple of eight")` This rejects an invalid state by raising ‘ValueError("compiler stream row width must be a multiple of eight")‘. Failing before DMA prevents malformed shapes or artifacts from silently becoming hardware results.

Line 41: `lanes = np.ascontiguousarray(array).reshape(-1, 8).astype(np.uint64)` This assigns ‘np.ascontiguousarray(ar 1, 8).astype(np.uint64)‘ to ‘lanes ‘ in host memory. Here lanes means one parallel arithmetic element within a vector or tensor datapath. The important operands are ascontiguousarray: the value named ’ascontiguousarray’ in this block; array: the value named ’array’ in this block; reshape: the value named ’reshape’ in this block. Context: the function _pack_compiler_u8_rows, which handles pack compiler u8 rows.

Line 42: `shifts = (np.arange(8, dtype=np.uint64) * np.uint64(8)).reshape(1, 8)` This assigns ‘(np.arange(8, dtype=np.uint64) * np.uint64(8)).reshape(1, 8)‘ to ‘shifts ‘ in host memory. Here shifts means the value named ’shifts’ in this block. The important operands are arange: the value named ’arange’ in this block; dtype: the value named ’dtype’ in this block; uint64: the value named ’uint64’ in this block. Context: the function _pack_compiler_u8_rows, which handles pack compiler u8 rows.

Line 43: `words = np.bitwise_or.reduce(lanes << shifts, axis=1).astype("<u8", copy=False)` This assigns ‘np.bitwise_or.reduce(lanes << shifts, axis=1).astype("<u8", copy=False)‘ to ‘words ‘ in host memory. Here words means the value named ’words’ in this block. The important operands are bitwise_or: the value named ’bitwise or’ in this block; reduce: the value named ’reduce’ in this block; lanes: one parallel arithmetic element within a vector or tensor datapath. Context: the function _pack_compiler_u8_rows, which handles pack compiler u8 rows.

Line 44: `return PackedStreamBeats.from_little_endian_bytes(words.tobytes(order="C"))` This returns ‘PackedStreamBeats.from_little_endian_bytes(words.tobytes(order="C"))‘ to the caller of the function _pack_compiler_u8_rows, which handles pack compiler u8 rows, ending this invocation. The important operands are PackedStreamBeats: the value named ’packed stream beats’ in this block; from_little_endian_bytes: the value named ’from little endian bytes’ in this block; words: the value named ’words’ in this block.

Line 47: `class CommandExecutor(Protocol):` This defines class CommandExecutor, which groups data and methods for command executor. Instances exist in host memory and organize the flow that tiles matrices and convolutions into validated accelerator commands and packed stream payloads.

Line 48: `"""Smallest driver surface required to run a compiled program."""` This is executable documentation attached to the class CommandExecutor, which handles command executor. It states the intended contract that tests and callers should enforce, but the text itself does not transform data or issue hardware work.

Line 50: `def execute(` This starts function execute. Its indented body performs execute as part of the file that tiles matrices and convolutions into validated accelerator commands and packed stream payloads; it runs only when called.

Line 51: `self,` Inside the function execute, which handles execute, this statement advances the host implementation that tiles matrices and convolutions into validated accelerator commands and packed stream payloads. The expression is a literal or structural operator and has no hidden software state.

Line 52: `command: Command128,` Inside the function execute, which handles execute, this statement advances the host implementation that tiles matrices and convolutions into validated accelerator commands and packed stream payloads. The important operands are command: the 128-bit instruction selecting an engine, shape, mode, and numeric parameters; Command128: the 128-bit instruction selecting an engine, shape, mode, and numeric parameters.

Line 53: `input_beats: Sequence[StreamBeat] = (),` This assigns '(),' to 'input_beats' in host memory. Here input_beats means the value named 'input beats' in this block. The expression is a literal or structural operator and has no hidden software state. Context: the function execute, which handles execute.

Line 54: `*,` Inside the function execute, which handles execute, this statement advances the host implementation that tiles matrices and convolutions into validated accelerator commands and packed stream payloads. The expression is a literal or structural operator and has no hidden software state.

Line 55: `output_beats: int = 0,` This assigns '0,' to 'output_beats' in host memory. Here output_beats means the value named 'output beats' in this block. The expression is a literal or structural operator and has no hidden software state. Context: the function execute, which handles execute.

Line 56: `timeout_seconds: float = 5.0,` This assigns '5.0,' to 'timeout_seconds' in host memory. Here timeout_seconds means the value named 'timeout seconds' in this block. The expression is a literal or structural operator and has no hidden software state. Context: the function execute, which handles execute.

Line 57: `) -> tuple[int, ...]: ...` Inside the function execute, which handles execute, this statement advances the host implementation that tiles matrices and convolutions into validated accelerator commands and packed stream payloads. The important operands are tuple: the value named 'tuple' in this block.

Line 60: `class ProgramExecutor(CommandExecutor, Protocol):` This defines class ProgramExecutor, which groups data and methods for program executor. Instances exist in host memory and organize the flow that tiles matrices and convolutions into validated accelerator commands and packed stream payloads.

Line 61: `def execute_program(` This starts function execute_program. Its indented body performs execute program as part of the file that tiles matrices and convolutions into validated accelerator commands and packed stream payloads; it runs only when called.

Line 62: `self,` Inside the function execute_program, which handles execute program, this statement advances the host implementation that tiles matrices and convolutions into validated accelerator commands and packed stream payloads. The expression is a literal or structural operator and has no hidden software state.

Line 63: `records: Sequence[ProgramRecord],` Inside the function execute_program, which handles execute program, this statement advances the host implementation that tiles matrices and convolutions into validated accelerator commands and packed stream payloads. The important operands are records: the number of descriptor records accepted since program start; Sequence: the value named 'sequence' in this block; ProgramRecord: the value named 'program record' in this block.

Line 64: `*,` Inside the function execute_program, which handles execute program, this statement advances the host implementation that tiles matrices and convolutions into validated accelerator commands and packed stream payloads. The expression is a literal or structural operator and has no hidden software state.

Line 65: `timeout_seconds: float = 30.0,` This assigns ‘30.0,‘ to ‘timeout_seconds‘ in host memory. Here timeout_seconds means the value named ’timeout seconds’ in this block. The expression is a literal or structural operator and has no hidden software state. Context: the function execute_program, which handles execute program.

Line 66: `) -> tuple[int, ...]: ...` Inside the function execute_program, which handles execute program, this statement advances the host implementation that tiles matrices and convolutions into validated accelerator commands and packed stream payloads. The important operands are tuple: the value named ’tuple’ in this block.

Line 69: `@dataclass(frozen=True)` This decorator changes how the following class or function is constructed. ‘@dataclass(frozen=True)‘ is applied at import time on the host and is part of the file whose role is to tiles matrices and convolutions into validated accelerator commands and packed stream payloads; it creates no FPGA circuit by itself.

Line 70: `class TensorInstruction:` This defines class TensorInstruction, which groups data and methods for tensor instruction. Instances exist in host memory and organize the flow that tiles matrices and convolutions into validated accelerator commands and packed stream payloads.

Line 71: `"""One atomic command, its input stream, and expected output length."""` This is executable documentation attached to the class TensorInstruction, which handles tensor instruction. It states the intended contract that tests and callers should enforce, but the text itself does not transform data or issue hardware work.

Line 73: `command: Command128` Inside the class TensorInstruction, which handles tensor instruction, this statement advances the host implementation that tiles matrices and convolutions into validated accelerator commands and packed stream payloads. The important operands are command: the 128-bit instruction selecting an engine, shape, mode, and numeric parameters; Command128: the 128-bit instruction selecting an engine, shape, mode, and numeric parameters.

Line 74: `input_beats: Sequence[StreamBeat] = ()` This assigns ‘()‘ to ‘input_beats‘ in host memory. Here input_beats means the value named ’input beats’ in this block. The expression is a literal or structural operator and has no hidden software state. Context: the class TensorInstruction, which handles tensor instruction.

Line 75: `output_beats: int = 0` This assigns ‘0‘ to ‘output_beats‘ in host memory. Here output_beats means the value named ’output beats’ in this block. The expression is a literal or structural operator and has no hidden software state. Context: the class TensorInstruction, which handles tensor instruction.

Line 76: `description: str = ""` This assigns ‘""‘ to ‘description‘ in host memory. Here description means the value named ’description’ in this block. The expression is a literal or structural operator and has no hidden software state. Context: the class TensorInstruction, which handles tensor instruction.

Line 79: `@dataclass(frozen=True)` This decorator changes how the following class or function is constructed. ‘@dataclass(frozen=True)‘ is applied at import time on the host and is part of the file whose role is to tiles matrices and convolutions into validated accelerator commands and packed stream payloads; it creates no FPGA circuit by itself.

Line 80: `class ResultBinding:` This defines class ResultBinding, which groups data and methods for result binding. Instances exist in host memory and organize the flow that tiles matrices and convolutions into validated accelerator commands and packed stream payloads.

Line 81: `"""Maps local row/column result tags back to the destination matrix."""` This is executable documentation attached to the class ResultBinding, which handles result binding. It states the intended contract that tests and callers should enforce, but the text itself does not transform data or issue hardware work.

Line 83: `instruction_index: int` Inside the class ResultBinding, which handles result binding, this statement advances the host implementation that tiles matrices and convolutions into validated accelerator commands and packed stream payloads. The important operands are instruction_index: an integer selecting one tensor element, lane, bank, or state entry.

Line 84: `row_start: int` Inside the class ResultBinding, which handles result binding, this statement advances the host implementation that tiles matrices and convolutions into validated accelerator commands and packed stream payloads. The important operands are row_start: one output-row position processed by the tensor tile.

Line 85: `column_start: int` Inside the class ResultBinding, which handles result binding, this statement advances the host implementation that tiles matrices and convolutions into validated accelerator commands and packed stream payloads. The important operands are column_start: one output-feature position processed in parallel.

Line 86: `rows: int` Inside the class ResultBinding, which handles result binding, this statement advances the host implementation that tiles matrices and convolutions into validated accelerator commands and packed stream payloads. The important operands are rows: one output-row position processed by the tensor tile.

Line 87: `columns: int` Inside the class ResultBinding, which handles result binding, this statement advances the host implementation that tiles matrices and convolutions into validated accelerator commands and packed stream payloads. The important operands are columns: one output-feature position processed in parallel.

Line 88: `reduction_start: int` Inside the class ResultBinding, which handles result binding, this statement advances the host implementation that tiles matrices and convolutions into validated accelerator commands and packed stream payloads. The important operands are reduction_start: the value named 'reduction start' in this block.

Line 89: `reduction_count: int` Inside the class ResultBinding, which handles result binding, this statement advances the host implementation that tiles matrices and convolutions into validated accelerator commands and packed stream payloads. The important operands are reduction_count: an integer count retained for control or measurable telemetry.

Line 92: `@dataclass(frozen=True)` This decorator changes how the following class or function is constructed. '@dataclass(frozen=True)' is applied at import time on the host and is part of the file whose role is to tiles matrices and convolutions into validated accelerator commands and packed stream payloads; it creates no FPGA circuit by itself.

Line 93: `class CompiledGemm:` This defines class CompiledGemm, which groups data and methods for compiled gemm. Instances exist in host memory and organize the flow that tiles matrices and convolutions into validated accelerator commands and packed stream payloads.

Line 94: `"""Executable, inspectable transaction program for one uint8 GEMM."""` This is executable documentation attached to the class CompiledGemm, which handles compiled gemm. It states the intended contract that tests and callers should enforce, but the text itself does not transform data or issue hardware work.

Line 96: `shape: tuple[int, int, int]` Inside the class CompiledGemm, which handles compiled gemm, this statement advances the host implementation that tiles matrices and convolutions into validated accelerator commands and packed stream payloads. The important operands are shape: the value named 'shape' in this block; tuple: the value named 'tuple' in this block.

Line 97: `activation_zero_point: int` Inside the class CompiledGemm, which handles compiled gemm, this statement advances the host implementation that tiles matrices and convolutions into validated accelerator commands and packed stream payloads. The important operands are activation_zero_point: an input feature value consumed by a neuron or multiply-accumulate operation.

Line 98: `weight_zero_point: int` Inside the class CompiledGemm, which handles compiled gemm, this statement advances the host implementation that tiles matrices and convolutions into validated accelerator commands and packed stream payloads. The important operands are weight_zero_point: a learned coefficient multiplied by an activation.

Line 99: `instructions: tuple[TensorInstruction, ...]` Inside the class CompiledGemm, which handles compiled gemm, this statement advances the host implementation that tiles matrices and convolutions into validated accelerator commands and packed stream payloads. The important operands are instructions: the value named 'instructions' in this block; tuple: the value named 'tuple' in this block; TensorInstruction: the value named 'tensor instruction' in this block.

Line 100: `result_bindings: tuple[ResultBinding, ...]` Inside the class CompiledGemm, which handles compiled gemm, this statement advances the host implementation that tiles matrices and convolutions into validated accelerator commands and packed stream payloads. The important operands are result_bindings: the value named 'result bindings' in this block; tuple: the value named 'tuple' in this block; ResultBinding: the value named 'result binding' in this block.

Line 101: `bias: tuple[int, ...] | None` Inside the class CompiledGemm, which handles compiled gemm, this statement advances the host implementation that tiles matrices and convolutions into validated accelerator commands and packed stream payloads. The important operands are bias: an additive learned offset applied after accumulation; tuple: the value named 'tuple' in this block; None: the value named 'none' in this block.

Line 102: `estimated_input_bytes: int` Inside the class CompiledGemm, which handles compiled gemm, this statement advances the host implementation that tiles matrices and convolutions into validated accelerator commands and packed stream payloads. The important operands are estimated_input_bytes: the value named 'estimated input bytes' in this block.

Line 103: `mathematical_macs: int` Inside the class CompiledGemm, which handles compiled gemm, this statement advances the host implementation that tiles matrices and convolutions into validated accelerator commands and packed stream payloads. The important operands are mathematical_macs: the value named 'mathematical macs' in this block.

Line 104: `estimated_spike_adds: int = 0` This assigns ‘0‘ to ‘estimated_spike_adds‘ in host memory. Here estimated_spike_adds means a binary event produced when a neuron crosses its threshold. The expression is a literal or structural operator and has no hidden software state. Context: the class CompiledGemm, which handles compiled gemm.

Line 106: `def execute(self, driver: CommandExecutor, *, timeout_seconds: float = 5.0) -> np.ndarray:` This starts function execute. Its indented body performs execute as part of the file that tiles matrices and convolutions into validated accelerator commands and packed stream payloads; it runs only when called.

Line 107: `"""Run every transaction and reconstruct the signed int64 matrix."""` This is executable documentation attached to the function execute, which handles execute. It states the intended contract that tests and callers should enforce, but the text itself does not transform data or issue hardware work.

Line 108: `rows, _, columns = self.shape` This assigns ‘self.shape‘ to ‘rows, _, columns ‘ in host memory. Here rows means one output-row position processed by the tensor tile. The important operands are shape: the value named 'shape' in this block. Context: the function execute, which handles execute.

Line 109: `output = np.zeros((rows, columns), dtype=np.int64)` This assigns ‘np.zeros((rows, columns), dtype=np.int64)‘ to ‘output ‘ in host memory. Here output means the value named 'output' in this block. The important operands are zeros: the value named 'zeros' in this block; rows: one output-row position processed by the tensor tile; columns: one output-feature position processed in parallel. Context: the function execute, which handles execute.

Line 110: `bindings = {binding.instruction_index: binding for binding in self.result_bindings}` This assigns ‘{binding.instruction_index: binding for binding in self.result_bindings}‘ to ‘bindings ‘ in host memory. Here bindings means the value named 'bindings' in this block. The important operands are binding: the value named 'binding' in this block; instruction_index: an integer selecting one tensor element, lane, bank, or state entry; for: the value named 'for' in this block. Context: the function execute, which handles execute.

Line 112: `for instruction_index, instruction in enumerate(self.instructions):` This iterates instruction_index, instruction over ‘enumerate(self.instructions)‘. Each iteration repeats the indented host operation, commonly once per layer, tile, timestep, or test case in the function execute, which handles execute.

Line 113: `words = driver.execute(` This statement continues through source line 118; the explanation uses the complete expression rather than only the first visual fragment. This assigns ‘driver.execute(instruction.command, instruction.input_beats, output_beats=instruction.output_beats, timeout_seconds=timeout_seconds,)‘ to ‘words ‘ in host memory. Here words means the value named ’words’ in this block. The important operands are driver: the value named ’driver’ in this block; execute: the value named ’execute’ in this block; instruction: the value named ’instruction’ in this block. Context: the function execute, which handles execute.

Line 114: `instruction.command,` This is continuation line 2 of the 6-line logical statement that begins at source line 113. Its exact fragment is ‘instruction.command,‘. The important operands are instruction: the value named ’instruction’ in this block; command: the 128-bit instruction selecting an engine, shape, mode, and numeric parameters. Read together, the complete operation is: This assigns ‘driver.execute(instruction.command, instruction.input_beats, output_beats=instruction.output_beats, timeout_seconds=timeout_seconds,)‘ to ‘words ‘ in host memory. Here words means the value named ’words’ in this block. The important operands are driver: the value named ’driver’ in this block; execute: the value named ’execute’ in this block; instruction: the value named ’instruction’ in this block. Context: the function execute, which handles execute.

Line 115: `instruction.input_beats,` This is continuation line 3 of the 6-line logical statement that begins at source line 113. Its exact fragment is ‘instruction.input_beats,‘. The important operands are instruction: the value named ’instruction’ in this block; input_beats: the value named ’input beats’ in this block. Read together, the complete operation is: This assigns ‘driver.execute(instruction.command, instruction.input_beats, output_beats=instruction.output_beats, timeout_seconds=timeout_seconds,)‘ to ‘words ‘ in host memory. Here words means the value named ’words’ in this block. The important operands are driver: the value named ’driver’ in this block; execute: the value named ’execute’ in this block; instruction: the value named ’instruction’ in this block. Context: the function execute, which handles execute.

Line 116: `output_beats=instruction.output_beats,` This is continuation line 4 of the 6-line logical statement that begins at source line 113. Its exact fragment is ‘output_beats=instruction.output_beats,‘. The important operands are output_beats: the value named ’output beats’ in this block; instruction: the value named ’instruction’ in this block. Read together, the complete operation is: This assigns ‘driver.execute(instruction.command, instruction.input_beats, output_beats=instruction.output_beats, timeout_seconds=timeout_seconds,)‘ to ‘words ‘ in host memory. Here words means the value named ’words’ in this block. The important operands are driver: the value named ’driver’ in this block; execute: the value named ’execute’ in this block; instruction: the value named ’instruction’ in this block. Context: the function execute, which handles execute.

Line 117: `timeout_seconds=timeout_seconds,` This is continuation line 5 of the 6-line logical statement that begins at source line 113. Its exact fragment is ‘timeout_seconds=timeout_seconds,‘. The important operands are timeout_seconds: the value named ’timeout seconds’ in this block. Read together, the complete operation is: This assigns ‘driver.execute(instruction.command, instruction.input_beats, output_beats=instruction.output_beats, timeout_seconds=timeout_seconds,)‘ to ‘words ‘ in host memory. Here words means the value named ’words’ in this block. The important operands are driver: the value named ’driver’ in this block; execute: the value named ’execute’ in this block; instruction: the value named ’instruction’ in this block. Context: the function execute, which handles execute.

Line 118: `)` This is continuation line 6 of the 6-line logical statement that begins at source line 113. Its exact fragment is ‘)‘. The expression is a literal or structural operator and has no hidden software state. Read together, the complete operation is: This assigns ‘driver.execute(instruction.command, instruction.input_beats, output_beats=instruction.output_beats, timeout_seconds=timeout_seconds,)‘ to ‘words ‘ in host memory. Here words means the value named ’words’ in this block. The important operands are driver: the value named ’driver’ in this block; execute: the value named ’execute’ in this block; instruction: the value named ’instruction’ in this block. Context: the function execute, which handles execute.

Line 119: `if len(words) != instruction.output_beats:` This executes the following indented host-code branch only when ‘len(words) != instruction.output_beats‘ is true. The important operands are len: the value named ’len’ in

this block; words: the value named 'words' in this block; instruction: the value named 'instruction' in this block. Context: the function execute, which handles execute.

Line 120: `raise RuntimeError(` This statement continues through source line 123; the explanation uses the complete expression rather than only the first visual fragment. This rejects an invalid state by raising ‘RuntimeError(f"instruction {instruction_index} returned {len(words)} beats; " f"expected {instruction.output_beats}")‘. Failing before DMA prevents malformed shapes or artifacts from silently becoming hardware results.

Line 121: `f"instruction {instruction_index} returned {len(words)} beats; "` This is continuation line 2 of the 4-line logical statement that begins at source line 120. Its exact fragment is ‘f"instruction {instruction_index} returned {len(words)} beats; "‘. The important operands are f: the value named 'f' in this block; instruction: the value named 'instruction' in this block; instruction_index: an integer selecting one tensor element, lane, bank, or state entry. Read together, the complete operation is: This rejects an invalid state by raising ‘RuntimeError(f"instruction {instruction_index} returned {len(words)} beats; " f"expected {instruction.output_beats}")‘. Failing before DMA prevents malformed shapes or artifacts from silently becoming hardware results.

Line 122: `f"expected {instruction.output_beats}"` This is continuation line 3 of the 4-line logical statement that begins at source line 120. Its exact fragment is ‘f"expected {instruction.output_beats}"‘. The important operands are f: the value named 'f' in this block; expected: the value named 'expected' in this block; instruction: the value named 'instruction' in this block. Read together, the complete operation is: This rejects an invalid state by raising ‘RuntimeError(f"instruction {instruction_index} returned {len(words)} beats; " f"expected {instruction.output_beats}")‘. Failing before DMA prevents malformed shapes or artifacts from silently becoming hardware results.

Line 123: `)` This is continuation line 4 of the 4-line logical statement that begins at source line 120. Its exact fragment is ‘)‘. The expression is a literal or structural operator and has no hidden software state. Read together, the complete operation is: This rejects an invalid state by raising ‘RuntimeError(f"instruction {instruction_index} returned {len(words)} beats; " f"expected {instruction.output_beats}")‘. Failing before DMA prevents malformed shapes or artifacts from silently becoming hardware results.

Line 124: `binding = bindings.get(instruction_index)` This assigns ‘bindings.get(instruction_index)‘ to ‘binding ‘ in host memory. Here binding means the value named 'binding' in this block. The important operands are bindings: the value named 'bindings' in this block; get: the value named 'get' in this block; instruction_index: an integer selecting one tensor element, lane, bank, or state entry. Context: the function execute, which handles execute.

Line 125: `if binding is None:` This executes the following indented host-code branch only when ‘binding is None‘ is true. The important operands are binding: the value named 'binding' in this block; is: the value named 'is' in this block; None: the value named 'none' in this block. Context: the function execute, which handles execute.

Line 126: `continue` Inside the function execute, which handles execute, this statement advances the host implementation that tiles matrices and convolutions into validated accelerator commands and packed stream payloads. The important operands are continue: the value named 'continue' in this block.

Line 128: `_accumulate_tensor_tile(output, binding, words)` This calls ‘_accumulate_tensor_tile‘ with ‘output, binding, words‘ inside the function execute, which handles execute. The call advances the host-side job that tiles matrices and convolutions into validated accelerator commands and packed stream payloads.

Line 130: `if self.bias is not None:` This executes the following indented host-code branch only when ‘self.bias is not None‘ is true. The important operands are bias: an additive learned offset applied after accumulation; is: the value named 'is' in this block; not: the value named 'not' in this block. Context: the function execute, which handles execute.

Line 131: `output += np.asarray(self.bias, dtype=np.int64).reshape(1, columns)` Inside the function execute, which handles execute, this statement advances the host implementation that tiles matrices and convolutions into validated accelerator commands and packed stream payloads. The important operands are output: the value named 'output' in this block; asarray: the value named 'asarray' in this block; bias: an additive learned offset applied after accumulation.

Line 132: `return output` This returns ‘output‘ to the caller of the function execute, which handles execute, ending this invocation. The important operands are output: the value named ’output’ in this block.

Line 134: `def execute_batched(` This starts function execute_batched. Its indented body performs execute batched as part of the file that tiles matrices and convolutions into validated accelerator commands and packed stream payloads; it runs only when called.

Line 135: `self,` Inside the function execute_batched, which handles execute batched, this statement advances the host implementation that tiles matrices and convolutions into validated accelerator commands and packed stream payloads. The expression is a literal or structural operator and has no hidden software state.

Line 136: `driver: ProgramExecutor,` Inside the function execute_batched, which handles execute batched, this statement advances the host implementation that tiles matrices and convolutions into validated accelerator commands and packed stream payloads. The important operands are driver: the value named ’driver’ in this block; ProgramExecutor: the value named ’program executor’ in this block.

Line 137: `*,` Inside the function execute_batched, which handles execute batched, this statement advances the host implementation that tiles matrices and convolutions into validated accelerator commands and packed stream payloads. The expression is a literal or structural operator and has no hidden software state.

Line 138: `timeout_seconds: float = 30.0,` This assigns ‘30.0,‘ to ‘timeout_seconds‘ in host memory. Here timeout_seconds means the value named ’timeout seconds’ in this block. The expression is a literal or structural operator and has no hidden software state. Context: the function execute_batched, which handles execute batched.

Line 139: `) -> np.ndarray:` Inside the function execute_batched, which handles execute batched, this statement advances the host implementation that tiles matrices and convolutions into validated accelerator commands and packed stream payloads. The important operands are ndarray: the value named ’ndarray’ in this block.

Line 140: `"""Run every tile through one descriptor-program DMA transaction."""` This is executable documentation attached to the function execute_batched, which handles execute batched. It states the intended contract that tests and callers should enforce, but the text itself does not transform data or issue hardware work.

Line 142: `rows, _, columns = self.shape` This assigns ‘self.shape‘ to ‘rows, _, columns ‘ in host memory. Here rows means one output-row position processed by the tensor tile. The important operands are shape: the value named ’shape’ in this block. Context: the function execute_batched, which handles execute batched.

Line 143: `records = tuple(ProgramRecord(` This statement continues through source line 147; the explanation uses the complete expression rather than only the first visual fragment. This assigns ‘tuple(ProgramRecord(instruction.command, instruction.input_beats, instruction.output_beats,) for instruction in self.instructions)‘ to ‘records ‘ in host memory. Here records means the number of descriptor records accepted since program start. The important operands are tuple: the value named ’tuple’ in this block; ProgramRecord: the value named ’program record’ in this block; instruction: the value named ’instruction’ in this block. Context: the function execute_batched, which handles execute batched.

Line 144: `instruction.command,` This is continuation line 2 of the 5-line logical statement that begins at source line 143. Its exact fragment is ‘instruction.command,‘. The important operands are instruction: the value named ’instruction’ in this block; command: the 128-bit instruction selecting an engine, shape, mode, and numeric parameters. Read together, the complete operation is: This assigns ‘tuple(ProgramRecord(instruction.command, instruction.input_beats, instruction.output_beats,) for instruction in self.instructions)‘ to ‘records ‘ in host memory. Here records means the number of descriptor records accepted since program start. The important operands are tuple: the value named ’tuple’ in this block; ProgramRecord: the value named ’program record’ in this block; instruction: the value named ’instruction’ in this block. Context: the function execute_batched, which handles execute batched.

Line 145: `instruction.input_beats,` This is continuation line 3 of the 5-line logical statement that begins at source line 143. Its exact fragment is ‘instruction.input_beats,‘. The important operands are instruction: the value named ’instruction’ in this block; input_beats: the value named ’input beats’ in this block. Read together, the complete operation is: This assigns ‘tuple(ProgramRecord(instruction.command, instruction.input_beats, instruction.output_beats,) for instruction in self.instructions)‘ to ‘records ‘ in host memory. Here records means the number of descriptor records accepted since program start. The important operands are tuple: the value named ’tuple’ in this block; ProgramRecord: the value named ’program record’ in this block; instruction: the value named ’instruction’ in this block. Context: the function execute_batched, which handles execute batched.

Line 146: `instruction.output_beats,` This is continuation line 4 of the 5-line logical statement that begins at source line 143. Its exact fragment is ‘instruction.output_beats,‘. The important operands are instruction: the value named ’instruction’ in this block; output_beats: the value named ’output beats’ in this block. Read together, the complete operation is: This assigns ‘tuple(ProgramRecord(instruction.command, instruction.input_beats, instruction.output_beats,) for instruction in self.instructions)‘ to ‘records ‘ in host memory. Here records means the number of descriptor records accepted since program start. The important operands are tuple: the value named ’tuple’ in this block; ProgramRecord: the value named ’program record’ in this block; instruction: the value named ’instruction’ in this block. Context: the function execute_batched, which handles execute batched.

Line 147: `)  for instruction in self.instructions)` This is continuation line 5 of the 5-line logical statement that begins at source line 143. Its exact fragment is ‘) for instruction in self.instructions)‘. The important operands are for: the value named ’for’ in this block; instruction: the value named ’instruction’ in this block; in: the value named ’in’ in this block. Read together, the complete operation is: This assigns ‘tuple(ProgramRecord(instruction.command, instruction.input_beats, instruction.output_beats,) for instruction in self.instructions)‘ to ‘records ‘ in host memory. Here records means the number of descriptor records accepted since program start. The important operands are tuple: the value named ’tuple’ in this block; ProgramRecord: the value named ’program record’ in this block; instruction: the value named ’instruction’ in this block. Context: the function execute_batched, which handles execute batched.

Line 148: `flat_words = driver.execute_program(records, timeout_seconds=timeout_seconds)` This assigns ‘driver.execute_program(records, timeout_seconds=timeout_seconds)‘ to ‘flat_words ‘ in host memory. Here flat_words means the value named ’flat words’ in this block. The important operands are driver: the value named ’driver’ in this block; execute_program: the value named ’execute program’ in this block; records: the number of descriptor records accepted since program start. Context: the function execute_batched, which handles execute batched.

Line 149: `expected_words = sum(instruction.output_beats for instruction in self.instructions)` This assigns ‘sum(instruction.output_beats for instruction in self.instructions)‘ to ‘expected_words ‘ in host memory. Here expected_words means the value named ’expected words’ in this block. The important operands are sum: the value named ’sum’ in this block; instruction: the value named ’instruction’ in this block; output_beats: the value named ’output beats’ in this block. Context: the function execute_batched, which handles execute batched.

Line 150: `if len(flat_words) != expected_words:` This executes the following indented host-code branch only when ‘len(flat_words) != expected_words‘ is true. The important operands are len: the value named ’len’ in this block; flat_words: the value named ’flat words’ in this block; expected_words: the value named ’expected words’ in this block. Context: the function execute_batched, which handles execute batched.

Line 151: `raise RuntimeError(` This statement continues through source line 152; the explanation uses the complete expression rather than only the first visual fragment. This rejects an invalid state by raising ‘RuntimeError(f"descriptor program returned {len(flat_words)} beats; expected {expected_words}")‘. Failing before DMA prevents malformed shapes or artifacts from silently becoming hardware results.

Line 152: `f"descriptor program returned {len(flat_words)} beats; expected {expected_words}")` This is continuation line 2 of the 2-line logical statement that begins at source line 151. Its exact fragment is ‘f"descriptor program returned {len(flat_words)} beats; expected {expected_words}")‘. The important operands are f: the value named ’f’ in this block; descriptor: a DMA record header plus one command and its declared payload; program: the value named ’program’ in this block. Read together, the complete operation is: This rejects an invalid state by raising ‘RuntimeError(f"descriptor program returned {len(flat_words)} beats; expected {expected_words}")‘. Failing before DMA prevents malformed shapes or artifacts from silently becoming hardware results.

Line 153: `output = np.zeros((rows, columns), dtype=np.int64)` This assigns ‘np.zeros((rows, columns), dtype=np.int64)‘ to ‘output ‘ in host memory. Here output means the value named ’output’ in this block. The important operands are zeros: the value named ’zeros’ in this block; rows: one output-row position processed by the tensor tile; columns: one output-feature position processed in parallel. Context: the function execute_batched, which handles execute batched.

Line 154: `bindings = {binding.instruction_index: binding for binding in self.result_bindings}` This assigns ‘{binding.instruction_index: binding for binding in self.result_bindings}‘ to ‘bindings ‘ in host memory. Here bindings means the value named ’bindings’ in this block. The important operands are binding: the value named ’binding’ in this block; instruction_index: an integer selecting one tensor element, lane, bank, or state entry; for: the value named ’for’ in this block. Context: the function execute_batched, which handles execute batched.

Line 155: `word_offset = 0` This assigns ‘0‘ to ‘word_offset ‘ in host memory. Here word_offset means the value named ’word offset’ in this block. The expression is a literal or structural operator and has no hidden software state. Context: the function execute_batched, which handles execute batched.

Line 156: `for instruction_index, instruction in enumerate(self.instructions):` This iterates instruction_index, instruction over ‘enumerate(self.instructions)‘. Each iteration repeats the indented host operation, commonly once per layer, tile, timestep, or test case in the function execute_batched, which handles execute batched.

Line 157: `word_end = word_offset + instruction.output_beats` This assigns ‘word_offset + instruction.output_beats‘ to ‘word_end ‘ in host memory. Here word_end means the value named ’word end’ in this block. The important operands are word_offset: the value named ’word offset’ in this block; instruction: the value named ’instruction’ in this block; output_beats: the value named ’output beats’ in this block. Context: the function execute_batched, which handles execute batched.

Line 158: `words = flat_words[word_offset:word_end]` This assigns ‘flat_words[word_offset:word_end]‘ to ‘words ‘ in host memory. Here words means the value named ’words’ in this block. The important operands are flat_words: the value named ’flat words’ in this block; word_offset: the value named ’word offset’ in this block; word_end: the value named ’word end’ in this block. Context: the function execute_batched, which handles execute batched.

Line 159: `binding = bindings.get(instruction_index)` This assigns ‘bindings.get(instruction_index)‘ to ‘binding ‘ in host memory. Here binding means the value named ’binding’ in this block. The important operands are bindings: the value named ’bindings’ in this block; get: the value named ’get’ in this block; instruction_index: an integer selecting one tensor element, lane, bank, or state entry. Context: the function execute_batched, which handles execute batched.

Line 160: `if binding is not None:` This executes the following indented host-code branch only when ‘binding is not None‘ is true. The important operands are binding: the value named ’binding’ in this block; is: the value named ’is’ in this block; not: the value named ’not’ in this block. Context: the function execute_batched, which handles execute batched.

Line 161: `_accumulate_tensor_tile(output, binding, words)` This calls ‘_accumulate_tensor_tile‘ with ‘output, binding, words‘ inside the function execute_batched, which handles execute batched. The call advances the host-side job that tiles matrices and convolutions into validated accelerator commands and packed stream payloads.

Line 162: `word_offset = word_end` This assigns ‘word_end‘ to ‘word_offset ‘ in host memory. Here word_offset means the value named ’word offset’ in this block. The important operands are word_end: the value named ’word end’ in this block. Context: the function execute_batched, which handles execute batched.

Line 163: `if self.bias is not None:` This executes the following indented host-code branch only when ‘self.bias is not None‘ is true. The important operands are bias: an additive learned offset applied after accumulation; is: the value named ’is’ in this block; not: the value named ’not’ in this block. Context: the function execute_batched, which handles execute batched.

Line 164: `output += np.asarray(self.bias, dtype=np.int64).reshape(1, columns)` Inside the function execute_batched, which handles execute batched, this statement advances the host implementation that tiles matrices and convolutions into validated accelerator commands and packed stream payloads. The important operands are output: the value named 'output' in this block; asarray: the value named 'asarray' in this block; bias: an additive learned offset applied after accumulation.

Line 165: `return output` This returns ‘output‘ to the caller of the function execute_batched, which handles execute batched, ending this invocation. The important operands are output: the value named 'output' in this block.

Line 168: `def _accumulate_tensor_tile(` This starts function _accumulate_tensor_tile. Its indented body performs accumulate tensor tile as part of the file that tiles matrices and convolutions into validated accelerator commands and packed stream payloads; it runs only when called.

Line 169: `output: np.ndarray,` Inside the function _accumulate_tensor_tile, which handles accumulate tensor tile, this statement advances the host implementation that tiles matrices and convolutions into validated accelerator commands and packed stream payloads. The important operands are output: the value named 'output' in this block; ndarray: the value named 'ndarray' in this block.

Line 170: `binding: ResultBinding,` Inside the function _accumulate_tensor_tile, which handles accumulate tensor tile, this statement advances the host implementation that tiles matrices and convolutions into validated accelerator commands and packed stream payloads. The important operands are binding: the value named 'binding' in this block; ResultBinding: the value named 'result binding' in this block.

Line 171: `words: Sequence[int],` Inside the function _accumulate_tensor_tile, which handles accumulate tensor tile, this statement advances the host implementation that tiles matrices and convolutions into validated accelerator commands and packed stream payloads. The important operands are words: the value named 'words' in this block; Sequence: the value named 'sequence' in this block.

Line 172: `) -> None:` Inside the function _accumulate_tensor_tile, which handles accumulate tensor tile, this statement advances the host implementation that tiles matrices and convolutions into validated accelerator commands and packed stream payloads. The important operands are None: the value named 'none' in this block.

Line 173: `seen: set[tuple[int, int]] = set()` This assigns ‘set()‘ to ‘seen‘ in host memory. Here seen means the value named 'seen' in this block. The important operands are set: the value named 'set' in this block. Context: the function _accumulate_tensor_tile, which handles accumulate tensor tile.

Line 174: `for beat_index, word in enumerate(words):` This iterates beat_index, word over ‘enumerate(words)‘. Each iteration repeats the indented host operation, commonly once per layer, tile, timestep, or test case in the function _accumulate_tensor_tile, which handles accumulate tensor tile.

Line 175: `value, local_row, local_column, last = unpack_tensor_result(word)` This assigns ‘unpack_tensor_result(wo to ‘value, local_row, local_column, last ‘ in host memory. Here value means the value named 'value' in this block. The important operands are unpack_tensor_result: the value named 'unpack tensor result' in this block; word: the value named 'word' in this block. Context: the function _accumulate_tensor_tile, which handles accumulate tensor tile.

Line 176: `if local_row >= binding.rows or local_column >= binding.columns:` This executes the following indented host-code branch only when ‘local_row >= binding.rows or local_column >= binding.columns‘ is true. The important operands are local_row: one output-row position processed by the tensor tile; binding: the value named 'binding' in this block; rows: one output-row position processed by the tensor tile. Context: the function _accumulate_tensor_tile, which handles accumulate tensor tile.

Line 177: `raise RuntimeError(` This statement continues through source line 179; the explanation uses the complete expression rather than only the first visual fragment. This rejects an invalid state by raising ‘RuntimeError(f"out-of-range tensor tag ({local_row},{local_column}) " f"for {binding.rows}x{binding.columns} result tile")‘. Failing before DMA prevents malformed shapes or artifacts from silently becoming hardware results.

Line 178: `f"out-of-range tensor tag ({local_row},{local_column}) "` This is continuation line 2 of the 3-line logical statement that begins at source line 177. Its exact fragment is ‘f"out-of-range tensor tag ({local_row},{local_column}) "‘. The important operands are f: the value named ’f’ in this block; out: the value named ’out’ in this block; of: the value named ’of’ in this block. Read together, the complete operation is: This rejects an invalid state by raising ‘RuntimeError(f"out-of-range tensor tag ({local_row},{local_column}) " f"for {binding.rows}x{binding.columns} result tile")‘. Failing before DMA prevents malformed shapes or artifacts from silently becoming hardware results.

Line 179: `f"for {binding.rows}x{binding.columns} result tile")` This is continuation line 3 of the 3-line logical statement that begins at source line 177. Its exact fragment is ‘f"for {binding.rows}x{binding.columns} result tile")‘. The important operands are f: the value named ’f’ in this block; for: the value named ’for’ in this block; binding: the value named ’binding’ in this block. Read together, the complete operation is: This rejects an invalid state by raising ‘RuntimeError(f"out-of-range tensor tag ({local_row},{local_column}) " f"for {binding.rows}x{binding.columns} result tile")‘. Failing before DMA prevents malformed shapes or artifacts from silently becoming hardware results.

Line 180: `tag = (local_row, local_column)` This assigns ‘(local_row, local_column)‘ to ‘tag ‘ in host memory. Here tag means the value named ’tag’ in this block. The important operands are local_row: one output-row position processed by the tensor tile; local_column: one output-feature position processed in parallel. Context: the function _accumulate_tensor_tile, which handles accumulate tensor tile.

Line 181: `if tag in seen:` This executes the following indented host-code branch only when ‘tag in seen‘ is true. The important operands are tag: the value named ’tag’ in this block; in: the value named ’in’ in this block; seen: the value named ’seen’ in this block. Context: the function _accumulate_tensor_tile, which handles accumulate tensor tile.

Line 182: `raise RuntimeError(f"duplicate tensor result tag {tag}")` This rejects an invalid state by raising ‘RuntimeError(f"duplicate tensor result tag {tag}")‘. Failing before DMA prevents malformed shapes or artifacts from silently becoming hardware results.

Line 183: `if last != (beat_index == len(words) - 1):` This executes the following indented host-code branch only when ‘last != (beat_index == len(words) - 1)‘ is true. The important operands are last: the AXI-Stream marker for the final beat of a packet or command payload; beat_index: an integer selecting one tensor element, lane, bank, or state entry; len: the value named ’len’ in this block. Context: the function _accumulate_tensor_tile, which handles accumulate tensor tile.

Line 184: `raise RuntimeError("tensor TLAST metadata does not match the final result beat")` This rejects an invalid state by raising ‘RuntimeError("tensor TLAST metadata does not match the final result beat")‘. Failing before DMA prevents malformed shapes or artifacts from silently becoming hardware results.

Line 185: `seen.add(tag)` This calls ‘seen.add‘ with ‘tag‘ inside the function _accumulate_tensor_tile, which handles accumulate tensor tile. The call advances the host-side job that tiles matrices and convolutions into validated accelerator commands and packed stream payloads.

Line 186: `output[binding.row_start + local_row,` This statement continues through source line 187; the explanation uses the complete expression rather than only the first visual fragment. Inside the function _accumulate_tensor_tile, which handles accumulate tensor tile, this statement advances the host implementation that tiles matrices and convolutions into validated accelerator commands and packed stream payloads. The important operands are output: the value named ’output’ in this block; binding: the value named ’binding’ in this block; row_start: one output-row position processed by the tensor tile.

Line 187: `binding.column_start + local_column] += value` This is continuation line 2 of the 2-line logical statement that begins at source line 186. Its exact fragment is ‘binding.column_start + local_column] += value‘. The important operands are binding: the value named ’binding’ in this block; column_start: one output-feature position processed in parallel; local_column: one output-feature position processed in parallel. Read together, the complete operation is: Inside the function _accumulate_tensor_tile, which handles accumulate tensor tile, this statement advances the host implementation that tiles matrices and convolutions into validated accelerator commands and packed stream payloads.

The important operands are output: the value named 'output' in this block; binding: the value named 'binding' in this block; row_start: one output-row position processed by the tensor tile.

Line 188: `if len(seen) != binding.rows * binding.columns:` This executes the following indented host-code branch only when 'len(seen) != binding.rows * binding.columns' is true. The important operands are len: the value named 'len' in this block; seen: the value named 'seen' in this block; binding: the value named 'binding' in this block. Context: the function _accumulate_tensor_tile, which handles accumulate tensor tile.

Line 189: `raise RuntimeError("tensor result tile did not contain every row/column tag")` This rejects an invalid state by raising 'RuntimeError("tensor result tile did not contain every row/column tag")'. Failing before DMA prevents malformed shapes or artifacts from silently becoming hardware results.

Line 192: `@dataclass(frozen=True)` This decorator changes how the following class or function is constructed. '@dataclass(frozen=True)' is applied at import time on the host and is part of the file whose role is to tiles matrices and convolutions into validated accelerator commands and packed stream payloads; it creates no FPGA circuit by itself.

Line 193: `class ConvGroupProgram:` This defines class ConvGroupProgram, which groups data and methods for conv group program. Instances exist in host memory and organize the flow that tiles matrices and convolutions into validated accelerator commands and packed stream payloads.

Line 194: `output_channel_start: int` Inside the class ConvGroupProgram, which handles conv group program, this statement advances the host implementation that tiles matrices and convolutions into validated accelerator commands and packed stream payloads. The important operands are output_channel_start: the value named 'output channel start' in this block.

Line 195: `output_channel_count: int` Inside the class ConvGroupProgram, which handles conv group program, this statement advances the host implementation that tiles matrices and convolutions into validated accelerator commands and packed stream payloads. The important operands are output_channel_count: an integer count retained for control or measurable telemetry.

Line 196: `gemm: CompiledGemm` Inside the class ConvGroupProgram, which handles conv group program, this statement advances the host implementation that tiles matrices and convolutions into validated accelerator commands and packed stream payloads. The important operands are gemm: the value named 'gemm' in this block; CompiledGemm: the value named 'compiled gemm' in this block.

Line 199: `@dataclass(frozen=True)` This decorator changes how the following class or function is constructed. '@dataclass(frozen=True)' is applied at import time on the host and is part of the file whose role is to tiles matrices and convolutions into validated accelerator commands and packed stream payloads; it creates no FPGA circuit by itself.

Line 200: `class CompiledConv2d:` This defines class CompiledConv2d, which groups data and methods for compiled conv2d. Instances exist in host memory and organize the flow that tiles matrices and convolutions into validated accelerator commands and packed stream payloads.

Line 201: `"""One or more GEMM programs plus the exact NCHW reconstruction map."""` This is executable documentation attached to the class CompiledConv2d, which handles compiled conv2d. It states the intended contract that tests and callers should enforce, but the text itself does not transform data or issue hardware work.

Line 203: `input_shape: tuple[int, int, int, int]` Inside the class CompiledConv2d, which handles compiled conv2d, this statement advances the host implementation that tiles matrices and convolutions into validated accelerator commands and packed stream payloads. The important operands are input_shape: the value named 'input shape' in this block; tuple: the value named 'tuple' in this block.

Line 204: `output_shape: tuple[int, int, int, int]` Inside the class CompiledConv2d, which handles compiled conv2d, this statement advances the host implementation that tiles matrices and convolutions into validated accelerator commands and packed stream payloads. The important operands are output_shape: the value named 'output shape' in this block; tuple: the value named 'tuple' in this block.

Line 205: `kernel: tuple[int, int]` Inside the class CompiledConv2d, which handles compiled conv2d, this statement advances the host implementation that tiles matrices and convolutions into validated accelerator commands and packed stream payloads. The important operands are kernel: the value named 'kernel' in this block; tuple: the value named 'tuple' in this block.

Line 206: `stride: tuple[int, int]` Inside the class CompiledConv2d, which handles compiled conv2d, this statement advances the host implementation that tiles matrices and convolutions into validated accelerator commands and packed stream payloads. The important operands are stride: the value named 'stride' in this block; tuple: the value named 'tuple' in this block.

Line 207: `padding: tuple[int, int]` Inside the class CompiledConv2d, which handles compiled conv2d, this statement advances the host implementation that tiles matrices and convolutions into validated accelerator commands and packed stream payloads. The important operands are padding: the value named 'padding' in this block; tuple: the value named 'tuple' in this block.

Line 208: `dilation: tuple[int, int]` Inside the class CompiledConv2d, which handles compiled conv2d, this statement advances the host implementation that tiles matrices and convolutions into validated accelerator commands and packed stream payloads. The important operands are dilation: the value named 'dilation' in this block; tuple: the value named 'tuple' in this block.

Line 209: `groups: int` Inside the class CompiledConv2d, which handles compiled conv2d, this statement advances the host implementation that tiles matrices and convolutions into validated accelerator commands and packed stream payloads. The important operands are groups: the value named 'groups' in this block.

Line 210: `group_programs: tuple[ConvGroupProgram, ...]` Inside the class CompiledConv2d, which handles compiled conv2d, this statement advances the host implementation that tiles matrices and convolutions into validated accelerator commands and packed stream payloads. The important operands are group_programs: the value named 'group programs' in this block; tuple: the value named 'tuple' in this block; ConvGroupProgram: the value named 'conv group program' in this block.

Line 212: `def execute(self, driver: CommandExecutor, *, timeout_seconds: float = 5.0) -> np.ndarray:` This starts function execute. Its indented body performs execute as part of the file that tiles matrices and convolutions into validated accelerator commands and packed stream payloads; it runs only when called.

Line 213: `batch, output_channels, output_height, output_width = self.output_shape` This assigns 'self.output_shape' to 'batch, output_channels, output_height, output_width ' in host memory. Here batch means the value named 'batch' in this block. The important operands are output_shape: the value named 'output shape' in this block. Context: the function execute, which handles execute.

Line 214: `spatial_rows = batch * output_height * output_width` This assigns 'batch * output_height * output_width' to 'spatial_rows ' in host memory. Here spatial_rows means one output-row position processed by the tensor tile. The important operands are batch: the value named 'batch' in this block; output_height: the value named 'output height' in this block; output_width: the value named 'output width' in this block. Context: the function execute, which handles execute.

Line 215: `flat = np.zeros((spatial_rows, output_channels), dtype=np.int64)` This assigns 'np.zeros((spatial_rows, output_channels), dtype=np.int64)' to 'flat ' in host memory. Here flat means the value named 'flat' in this block. The important operands are zeros: the value named 'zeros' in this block; spatial_rows: one output-row position processed by the tensor tile; output_channels: the value named 'output channels' in this block. Context: the function execute, which handles execute.

Line 216: `for group in self.group_programs:` This iterates group over ‘self.group_programs‘. Each iteration repeats the indented host operation, commonly once per layer, tile, timestep, or test case in the function execute, which handles execute.

Line 217: `values = group.gemm.execute(driver, timeout_seconds=timeout_seconds)` This assigns ‘group.gemm.execute(d timeout_seconds=timeout_seconds)‘ to ‘values ‘ in host memory. Here values means the value named ’values’ in this block. The important operands are group: the value named ’group’ in this block; gemm: the value named ’gemm’ in this block; execute: the value named ’execute’ in this block. Context: the function execute, which handles execute.

Line 218: `start = group.output_channel_start` This assigns ‘group.output_channel_start‘ to ‘start ‘ in host memory. Here start means the value named ’start’ in this block. The important operands are group: the value named ’group’ in this block; output_channel_start: the value named ’output channel start’ in this block. Context: the function execute, which handles execute.

Line 219: `flat[:, start:start + group.output_channel_count] = values` This assigns ‘values‘ to ‘flat[‘ in host memory. Here flat means the value named ’flat’ in this block. The important operands are values: the value named ’values’ in this block. Context: the function execute, which handles execute.

Line 220: `return flat.reshape(batch, output_height, output_width, output_channels).transpose(0, 3, 1, 2)` This returns ‘flat.reshape(batch, output_height, output_width, output_channels).transpose(0, 3, 1, 2)‘ to the caller of the function execute, which handles execute, ending this invocation. The important operands are flat: the value named ’flat’ in this block; reshape: the value named ’reshape’ in this block; batch: the value named ’batch’ in this block.

Line 222: `def execute_batched(` This starts function execute_batched. Its indented body performs execute batched as part of the file that tiles matrices and convolutions into validated accelerator commands and packed stream payloads; it runs only when called.

Line 223: `self,` Inside the function execute_batched, which handles execute batched, this statement advances the host implementation that tiles matrices and convolutions into validated accelerator commands and packed stream payloads. The expression is a literal or structural operator and has no hidden software state.

Line 224: `driver: ProgramExecutor,` Inside the function execute_batched, which handles execute batched, this statement advances the host implementation that tiles matrices and convolutions into validated accelerator commands and packed stream payloads. The important operands are driver: the value named ’driver’ in this block; ProgramExecutor: the value named ’program executor’ in this block.

Line 225: `*,` Inside the function execute_batched, which handles execute batched, this statement advances the host implementation that tiles matrices and convolutions into validated accelerator commands and packed stream payloads. The expression is a literal or structural operator and has no hidden software state.

Line 226: `timeout_seconds: float = 30.0,` This assigns ‘30.0,‘ to ‘timeout_seconds‘ in host memory. Here timeout_seconds means the value named ’timeout seconds’ in this block. The expression is a literal or structural operator and has no hidden software state. Context: the function execute_batched, which handles execute batched.

Line 227: `) -> np.ndarray:` Inside the function execute_batched, which handles execute batched, this statement advances the host implementation that tiles matrices and convolutions into validated accelerator commands and packed stream payloads. The important operands are ndarray: the value named ’ndarray’ in this block.

Line 228: `batch, output_channels, output_height, output_width = self.output_shape` This assigns ‘self.output_shape‘ to ‘batch, output_channels, output_height, output_width ‘ in host memory. Here batch means the value named ’batch’ in this block. The important operands are output_shape: the value named ’output shape’ in this block. Context: the function execute_batched, which handles execute batched.

Line 229: `spatial_rows = batch * output_height * output_width` This assigns ‘batch * output_height * output_width‘ to ‘spatial_rows ‘ in host memory. Here spatial_rows means one output-row position processed by the tensor tile. The important operands are batch: the value named ’batch’ in this block; output_height: the value named ’output height’ in this block; output_width: the value named ’output width’ in this block. Context: the function execute_batched, which handles execute batched.

Line 230: `flat = np.zeros((spatial_rows, output_channels), dtype=np.int64)` This assigns ‘np.zeros((spatial_rows, output_channels), dtype=np.int64)‘ to ‘flat ‘ in host memory. Here flat means the value named ’flat’ in this block. The important operands are zeros: the value named ’zeros’ in this block; spatial_rows: one output-row position processed by the tensor tile; output_channels: the value named ’output channels’ in this block. Context: the function execute_batched, which handles execute batched.

Line 231: `for group in self.group_programs:` This iterates group over ‘self.group_programs‘. Each iteration repeats the indented host operation, commonly once per layer, tile, timestep, or test case in the function execute_batched, which handles execute batched.

Line 232: `values = group.gemm.execute_batched(` This statement continues through source line 233; the explanation uses the complete expression rather than only the first visual fragment. This assigns ‘group.gemm.execute_batched(driver, timeout_seconds=timeout_seconds)‘ to ‘values ‘ in host memory. Here values means the value named ’values’ in this block. The important operands are group: the value named ’group’ in this block; gemm: the value named ’gemm’ in this block; execute_batched: the value named ’execute batched’ in this block. Context: the function execute_batched, which handles execute batched.

Line 233: `driver, timeout_seconds=timeout_seconds)` This is continuation line 2 of the 2-line logical statement that begins at source line 232. Its exact fragment is ‘driver, timeout_seconds=timeout_seconds)‘. The important operands are driver: the value named ’driver’ in this block; timeout_seconds: the value named ’timeout seconds’ in this block. Read together, the complete operation is: This assigns ‘group.gemm.execute_batched(driver, timeout_seconds=timeout_seconds)‘ to ‘values ‘ in host memory. Here values means the value named ’values’ in this block. The important operands are group: the value named ’group’ in this block; gemm: the value named ’gemm’ in this block; execute_batched: the value named ’execute batched’ in this block. Context: the function execute_batched, which handles execute batched.

Line 234: `start = group.output_channel_start` This assigns ‘group.output_channel_start‘ to ‘start ‘ in host memory. Here start means the value named ’start’ in this block. The important operands are group: the value named ’group’ in this block; output_channel_start: the value named ’output channel start’ in this block. Context: the function execute_batched, which handles execute batched.

Line 235: `flat[:, start:start + group.output_channel_count] = values` This assigns ‘values‘ to ‘flat[‘ in host memory. Here flat means the value named ’flat’ in this block. The important operands are values: the value named ’values’ in this block. Context: the function execute_batched, which handles execute batched.

Line 236: `return flat.reshape(batch, output_height, output_width, output_channels).transpose(0, 3, 1, 2)` This returns ‘flat.reshape(batch, output_height, output_width, output_channels).transpose(0, 3, 1, 2)‘ to the caller of the function execute_batched, which handles execute batched, ending this invocation. The important operands are flat: the value named ’flat’ in this block; reshape: the value named ’reshape’ in this block; batch: the value named ’batch’ in this block.

Line 238: `@property` This decorator changes how the following class or function is constructed. ‘@property‘ is applied at import time on the host and is part of the class CompiledConv2d, which handles compiled conv2d; it creates no FPGA circuit by itself.

Line 239: `def mathematical_macs(self) -> int:` This starts function mathematical_macs. Its indented body performs mathematical macs as part of the file that tiles matrices and convolutions into validated accelerator commands and packed stream payloads; it runs only when called.

Line 240: `return sum(group.gemm.mathematical_macs for group in self.group_programs)` This returns ‘sum(group.gemm for group in self.group_programs)‘ to the caller of the function mathematical_macs, which handles mathematical macs, ending this invocation. The important operands are sum: the value named ’sum’ in this block; group: the value named ’group’ in this block; gemm: the value named ’gemm’ in this block.

Line 242: `@property` This decorator changes how the following class or function is constructed. ‘@property‘ is applied at import time on the host and is part of the class CompiledConv2d, which handles compiled conv2d; it creates no FPGA circuit by itself.

Line 243: `def estimated_input_bytes(self) -> int:` This starts function estimated_input_bytes. Its indented body performs estimated input bytes as part of the file that tiles matrices and convolutions into validated accelerator commands and packed stream payloads; it runs only when called.

Line 244: `return sum(group.gemm.estimated_input_bytes for group in self.group_programs)` This returns ‘sum(group.gemm.estimated_input_bytes for group in self.group_programs)‘ to the caller of the function estimated_input_bytes, which handles estimated input bytes, ending this invocation. The important operands are sum: the value named ’sum’ in this block; group: the value named ’group’ in this block; gemm: the value named ’gemm’ in this block.

Line 246: `@property` This decorator changes how the following class or function is constructed. ‘@property‘ is applied at import time on the host and is part of the class CompiledConv2d, which handles compiled conv2d; it creates no FPGA circuit by itself.

Line 247: `def estimated_spike_adds(self) -> int:` This starts function estimated_spike_adds. Its indented body performs estimated spike adds as part of the file that tiles matrices and convolutions into validated accelerator commands and packed stream payloads; it runs only when called.

Line 248: `return sum(group.gemm.estimated_spike_adds for group in self.group_programs)` This returns ‘sum(group.gemm for group in self.group_programs)‘ to the caller of the function estimated_spike_adds, which handles estimated spike adds, ending this invocation. The important operands are sum: the value named ’sum’ in this block; group: the value named ’group’ in this block; gemm: the value named ’gemm’ in this block.

Line 251: `def _as_u8_matrix(name: str, value: np.ndarray | Sequence[Sequence[int]]) -> np.ndarray:` This starts function _as_u8_matrix. Its indented body performs as u8 matrix as part of the file that tiles matrices and convolutions into validated accelerator commands and packed stream payloads; it runs only when called.

Line 252: `array = np.asarray(value)` This assigns ‘np.asarray(value)‘ to ‘array ‘ in host memory. Here array means the value named ’array’ in this block. The important operands are asarray: the value named ’asarray’ in this block; value: the value named ’value’ in this block. Context: the function _as_u8_matrix, which handles as u8 matrix.

Line 253: `if array.ndim != 2:` This executes the following indented host-code branch only when ‘array.ndim != 2‘ is true. The important operands are array: the value named ’array’ in this block; ndim: the value named ’ndim’ in this block. Context: the function _as_u8_matrix, which handles as u8 matrix.

Line 254: `raise ValueError(f"{name} must be a two-dimensional matrix")` This rejects an invalid state by raising ‘ValueError(f"{name} must be a two-dimensional matrix")‘. Failing before DMA prevents malformed shapes or artifacts from silently becoming hardware results.

Line 255: `if array.size == 0:` This executes the following indented host-code branch only when ‘array.size == 0‘ is true. The important operands are array: the value named ’array’ in this block; size: the value named ’size’ in this block. Context: the function _as_u8_matrix, which handles as u8 matrix.

Line 256: `raise ValueError(f"{name} must not be empty")` This rejects an invalid state by raising ‘ValueError(f"{name} must not be empty")‘. Failing before DMA prevents malformed shapes or artifacts from silently becoming hardware results.

Line 257: `if not np.issubdtype(array.dtype, np.integer):` This executes the following indented host-code branch only when ‘not np.issubdtype(array.dtype, np.integer)‘ is true. The important operands are not: the value named ’not’ in this block; issubdtype: the value named ’issubdtype’ in this block; array: the value named ’array’ in this block. Context: the function _as_u8_matrix, which handles as u8 matrix.

Line 258: `raise ValueError(f"{name} must contain integers")` This rejects an invalid state by raising ‘ValueError(f"{name} must contain integers")‘. Failing before DMA prevents malformed shapes or artifacts from silently becoming hardware results.

Line 259: `as_i64 = array.astype(np.int64)` This assigns ‘array.astype(np.int64)‘ to ‘as_i64 ‘ in host memory. Here as_i64 means the value named ’as i64’ in this block. The important operands are array: the value named ’array’ in this block; astype: the value named ’astype’ in this block; int64: the value named ’int64’ in this block. Context: the function _as_u8_matrix, which handles as u8 matrix.

Line 260: `if np.any(as_i64 < 0) or np.any(as_i64 > 255):` This executes the following indented host-code branch only when ‘np.any(as_i64 $<$ 0) or np.any(as_i64 $>$ 255)‘ is true. The important operands are any: the value named ’any’ in this block; as_i64: the value named ’as i64’ in this block; or: the value named ’or’ in this block. Context: the function _as_u8_matrix, which handles as u8 matrix.

Line 261: `raise ValueError(f"{name} entries must be in [0,255]")` This rejects an invalid state by raising ‘ValueError(f"{name} entries must be in [0,255]")‘. Failing before DMA prevents malformed shapes or artifacts from silently becoming hardware results.

Line 262: `return as_i64.astype(np.uint8)` This returns ‘as_i64.astype(np.uint8)‘ to the caller of the function _as_u8_matrix, which handles as u8 matrix, ending this invocation. The important operands are as_i64: the value named ’as i64’ in this block; astype: the value named ’astype’ in this block; uint8: the value named ’uint8’ in this block.

Line 265: `def _u8(name: str, value: int) -> int:` This starts function _u8. Its indented body performs u8 as part of the file that tiles matrices and convolutions into validated accelerator commands and packed stream payloads; it runs only when called.

Line 266: `integer = int(value)` This assigns ‘int(value)‘ to ‘integer ‘ in host memory. Here integer means the value named ’integer’ in this block. The important operands are value: the value named ’value’ in this block. Context: the function _u8, which handles u8.

Line 267: `if integer < 0 or integer > 255:` This executes the following indented host-code branch only when ‘integer $<$ 0 or integer $>$ 255‘ is true. The important operands are integer: the value named ’integer’ in this block; or: the value named ’or’ in this block. Context: the function _u8, which handles u8.

Line 268: `raise ValueError(f"{name} must be in [0,255]")` This rejects an invalid state by raising ‘ValueError(f"{name} must be in [0,255]")‘. Failing before DMA prevents malformed shapes or artifacts from silently becoming hardware results.

Line 269: `return integer` This returns ‘integer‘ to the caller of the function _u8, which handles u8, ending this invocation. The important operands are integer: the value named ’integer’ in this block.

Line 272: `def _pair(name: str, value: int | Sequence[int], *, allow_zero: bool = False) -> tuple[int, int]:` This starts function _pair. Its indented body performs pair as part of the file that tiles matrices and convolutions into validated accelerator commands and packed stream payloads; it runs only when called.

Line 273: `if isinstance(value, Sequence) and not isinstance(value, (str, bytes)):` This executes the following indented host-code branch only when ‘isinstance(value, Sequence) and not isinstance(value, (str, bytes))‘ is true. The important operands are isinstance: the value named ’isinstance’ in this block; value: the value named ’value’ in this block; Sequence: the value named ’sequence’ in this block. Context: the function _pair, which handles pair.

Line 274: `if len(value) != 2:` This executes the following indented host-code branch only when ‘len(value) != 2‘ is true. The important operands are len: the value named ’len’ in this block; value: the value named ’value’ in this block. Context: the function _pair, which handles pair.

Line 275: `raise ValueError(f"{name} must be an integer or a two-element sequence")` This rejects an invalid state by raising ‘ValueError(f"{name} must be an integer or a two-element sequence")‘. Failing before DMA prevents malformed shapes or artifacts from silently becoming hardware results.

Line 276: `pair = (int(value[0]), int(value[1]))` This assigns ‘(int(value[0]), int(value[1]))‘ to ‘pair ‘ in host memory. Here pair means the value named ’pair’ in this block. The important operands are value: the value named ’value’ in this block. Context: the function _pair, which handles pair.

Line 277: `else:` This begins the alternative host-code branch when the preceding condition was false, still inside the function _pair, which handles pair.

Line 278: `pair = (int(value), int(value))` This assigns ‘(int(value), int(value))‘ to ‘pair ‘ in host memory. Here pair means the value named ’pair’ in this block. The important operands are value: the value named ’value’ in this block. Context: the function _pair, which handles pair.

Line 279: `minimum = 0 if allow_zero else 1` This assigns ‘0 if allow_zero else 1‘ to ‘minimum ‘ in host memory. Here minimum means the value named ’minimum’ in this block. The important operands are allow_zero: the value named ’allow zero’ in this block. Context: the function _pair, which handles pair.

Line 280: `if pair[0] < minimum or pair[1] < minimum:` This executes the following indented host-code branch only when ‘pair[0] < minimum or pair[1] < minimum‘ is true. The important operands are pair: the value named ’pair’ in this block; minimum: the value named ’minimum’ in this block; or: the value named ’or’ in this block. Context: the function _pair, which handles pair.

Line 281: `raise ValueError(f"{name} values must be at least {minimum}")` This rejects an invalid state by raising ‘ValueError(f"{name} values must be at least {minimum}")‘. Failing before DMA prevents malformed shapes or artifacts from silently becoming hardware results.

Line 282: `return pair` This returns ‘pair‘ to the caller of the function _pair, which handles pair, ending this invocation. The important operands are pair: the value named ’pair’ in this block.

Line 285: `def _im2col_nchw(` This starts function _im2col_nchw. Its indented body performs im2col nchw as part of the file that tiles matrices and convolutions into validated accelerator commands and packed stream payloads; it runs only when called.

Line 286: `activations: np.ndarray,` Inside the function _im2col_nchw, which handles im2col nchw, this statement advances the host implementation that tiles matrices and convolutions into validated accelerator commands and packed stream payloads. The important operands are activations: an input feature value consumed by a neuron or multiply-accumulate operation; ndarray: the value named ’ndarray’ in this block.

Line 287: `kernel: tuple[int, int],` Inside the function _im2col_nchw, which handles im2col nchw, this statement advances the host implementation that tiles matrices and convolutions into validated accelerator commands and packed stream payloads. The important operands are kernel: the value named ’kernel’ in this block; tuple: the value named ’tuple’ in this block.

Line 288: `stride: tuple[int, int],` Inside the function _im2col_nchw, which handles im2col nchw, this statement advances the host implementation that tiles matrices and convolutions into validated accelerator commands and packed stream payloads. The important operands are stride: the value named ’stride’ in this block; tuple: the value named ’tuple’ in this block.

Line 289: `padding: tuple[int, int],` Inside the function _im2col_nchw, which handles im2col nchw, this statement advances the host implementation that tiles matrices and convolutions into validated accelerator commands and packed stream payloads. The important operands are padding: the value named 'padding' in this block; tuple: the value named 'tuple' in this block.

Line 290: `dilation: tuple[int, int],` Inside the function _im2col_nchw, which handles im2col nchw, this statement advances the host implementation that tiles matrices and convolutions into validated accelerator commands and packed stream payloads. The important operands are dilation: the value named 'dilation' in this block; tuple: the value named 'tuple' in this block.

Line 291: `pad_value: int,` Inside the function _im2col_nchw, which handles im2col nchw, this statement advances the host implementation that tiles matrices and convolutions into validated accelerator commands and packed stream payloads. The important operands are pad_value: the value named 'pad value' in this block.

Line 292: `) -> tuple[np.ndarray, int, int]:` Inside the function _im2col_nchw, which handles im2col nchw, this statement advances the host implementation that tiles matrices and convolutions into validated accelerator commands and packed stream payloads. The important operands are tuple: the value named 'tuple' in this block; ndarray: the value named 'ndarray' in this block.

Line 293: `batch, channels, height, width = activations.shape` This assigns 'activations.shape' to 'batch, channels, height, width ' in host memory. Here batch means the value named 'batch' in this block. The important operands are activations: an input feature value consumed by a neuron or multiply-accumulate operation; shape: the value named 'shape' in this block. Context: the function _im2col_nchw, which handles im2col nchw.

Line 294: `kernel_height, kernel_width = kernel` This assigns 'kernel' to 'kernel_height, kernel_width ' in host memory. Here kernel_height means the value named 'kernel height' in this block. The important operands are kernel: the value named 'kernel' in this block. Context: the function _im2col_nchw, which handles im2col nchw.

Line 295: `effective_height = dilation[0] * (kernel_height - 1) + 1` This assigns 'dilation[0] * (kernel_height - 1) + 1' to 'effective_height ' in host memory. Here effective_height means the value named 'effective height' in this block. The important operands are dilation: the value named 'dilation' in this block; kernel_height: the value named 'kernel height' in this block. Context: the function _im2col_nchw, which handles im2col nchw.

Line 296: `effective_width = dilation[1] * (kernel_width - 1) + 1` This assigns 'dilation[1] * (kernel_width - 1) + 1' to 'effective_width ' in host memory. Here effective_width means the value named 'effective width' in this block. The important operands are dilation: the value named 'dilation' in this block; kernel_width: the value named 'kernel width' in this block. Context: the function _im2col_nchw, which handles im2col nchw.

Line 297: `numerator_height = height + 2 * padding[0] - effective_height` This assigns 'height + 2 * padding[0] - effective_height' to 'numerator_height ' in host memory. Here numerator_height means the value named 'numerator height' in this block. The important operands are height: the value named 'height' in this block; padding: the value named 'padding' in this block; effective_height: the value named 'effective height' in this block. Context: the function _im2col_nchw, which handles im2col nchw.

Line 298: `numerator_width = width + 2 * padding[1] - effective_width` This assigns 'width + 2 * padding[1] - effective_width' to 'numerator_width ' in host memory. Here numerator_width means the value named 'numerator width' in this block. The important operands are width: the value named 'width' in this block; padding: the value named 'padding' in this block; effective_width: the value named 'effective width' in this block. Context: the function _im2col_nchw, which handles im2col nchw.

Line 299: `if numerator_height < 0 or numerator_width < 0:` This executes the following indented host-code branch only when 'numerator_height $<$ 0 or numerator_width $<$ 0' is true. The important operands are numerator_height: the value named 'numerator height' in this block; or: the value named 'or' in this block; numerator_width: the value named 'numerator width' in this block. Context: the function _im2col_nchw, which handles im2col nchw.

Line 300: `raise ValueError("effective convolution kernel is larger than the padded input")` This rejects an invalid state by raising ‘ValueError("effective convolution kernel is larger than the padded input")‘. Failing before DMA prevents malformed shapes or artifacts from silently becoming hardware results.

Line 301: `output_height = numerator_height // stride[0] + 1` This assigns ‘numerator_height // stride[0] + 1‘ to ‘output_height ‘ in host memory. Here output_height means the value named ’output height’ in this block. The important operands are numerator_height: the value named ’numerator height’ in this block; stride: the value named ’stride’ in this block. Context: the function _im2col_nchw, which handles im2col nchw.

Line 302: `output_width = numerator_width // stride[1] + 1` This assigns ‘numerator_width // stride[1] + 1‘ to ‘output_width ‘ in host memory. Here output_width means the value named ’output width’ in this block. The important operands are numerator_width: the value named ’numerator width’ in this block; stride: the value named ’stride’ in this block. Context: the function _im2col_nchw, which handles im2col nchw.

Line 303: `padded = np.full(` This statement continues through source line 307; the explanation uses the complete expression rather than only the first visual fragment. This assigns ‘np.full((batch, channels, height + 2 * padding[0], width + 2 * padding[1]), pad_value, dtype=activations.dtype,)‘ to ‘padded ‘ in host memory. Here padded means the value named ’padded’ in this block. The important operands are full: the value named ’full’ in this block; batch: the value named ’batch’ in this block; channels: the value named ’channels’ in this block. Context: the function _im2col_nchw, which handles im2col nchw.

Line 304: `(batch, channels, height + 2 * padding[0], width + 2 * padding[1]),` This is continuation line 2 of the 5-line logical statement that begins at source line 303. Its exact fragment is ‘(batch, channels, height + 2 * padding[0], width + 2 * padding[1]),‘. The important operands are batch: the value named ’batch’ in this block; channels: the value named ’channels’ in this block; height: the value named ’height’ in this block. Read together, the complete operation is: This assigns ‘np.full((batch, channels, height + 2 * padding[0], width + 2 * padding[1]), pad_value, dtype=activations.dtype,)‘ to ‘padded ‘ in host memory. Here padded means the value named ’padded’ in this block. The important operands are full: the value named ’full’ in this block; batch: the value named ’batch’ in this block; channels: the value named ’channels’ in this block. Context: the function _im2col_nchw, which handles im2col nchw.

Line 305: `pad_value,` This is continuation line 3 of the 5-line logical statement that begins at source line 303. Its exact fragment is ‘pad_value,‘. The important operands are pad_value: the value named ’pad value’ in this block. Read together, the complete operation is: This assigns ‘np.full((batch, channels, height + 2 * padding[0], width + 2 * padding[1]), pad_value, dtype=activations.dtype,)‘ to ‘padded ‘ in host memory. Here padded means the value named ’padded’ in this block. The important operands are full: the value named ’full’ in this block; batch: the value named ’batch’ in this block; channels: the value named ’channels’ in this block. Context: the function _im2col_nchw, which handles im2col nchw.

Line 306: `dtype=activations.dtype,` This is continuation line 4 of the 5-line logical statement that begins at source line 303. Its exact fragment is ‘dtype=activations.dtype,‘. The important operands are dtype: the value named ’dtype’ in this block; activations: an input feature value consumed by a neuron or multiply-accumulate operation. Read together, the complete operation is: This assigns ‘np.full((batch, channels, height + 2 * padding[0], width + 2 * padding[1]), pad_value, dtype=activations.dtype,)‘ to ‘padded ‘ in host memory. Here padded means the value named ’padded’ in this block. The important operands are full: the value named ’full’ in this block; batch: the value named ’batch’ in this block; channels: the value named ’channels’ in this block. Context: the function _im2col_nchw, which handles im2col nchw.

Line 307: `)` This is continuation line 5 of the 5-line logical statement that begins at source line 303. Its exact fragment is ‘)‘. The expression is a literal or structural operator and has no hidden software state. Read together, the complete operation is: This assigns ‘np.full((batch, channels, height + 2 * padding[0], width + 2 * padding[1]), pad_value, dtype=activations.dtype,)‘ to ‘padded ‘ in host memory. Here padded means the value named ’padded’ in this block. The important operands are full: the value named ’full’ in this block; batch: the value named ’batch’ in this block; channels: the value named ’channels’ in this block. Context: the function _im2col_nchw, which handles im2col nchw.

Line 308: `padded[:, :, padding[0]:padding[0] + height, padding[1]:padding[1] + width] = activations` This assigns ‘activations‘ to ‘padded[‘ in host memory. Here padded means the value named ’padded’ in this block. The important operands are activations: an input feature value consumed by a neuron or multiply-accumulate operation. Context: the function _im2col_nchw, which handles im2col nchw.

Line 309: `columns = np.empty(` This statement continues through source line 312; the explanation uses the complete expression rather than only the first visual fragment. This assigns ‘np.empty((batch * output_height * output_width, channels * kernel_height * kernel_width), dtype=activations.dtype,)‘ to ‘columns ‘ in host memory. Here columns means one output-feature position processed in parallel. The important operands are empty: the value named ’empty’ in this block; batch: the value named ’batch’ in this block; output_height: the value named ’output height’ in this block. Context: the function _im2col_nchw, which handles im2col nchw.

Line 310: `(batch * output_height * output_width, channels * kernel_height * kernel_width),` This is continuation line 2 of the 4-line logical statement that begins at source line 309. Its exact fragment is ‘(batch * output_height * output_width, channels * kernel_height * kernel_width),‘. The important operands are batch: the value named ’batch’ in this block; output_height: the value named ’output height’ in this block; output_width: the value named ’output width’ in this block. Read together, the complete operation is: This assigns ‘np.empty((batch * output_height * output_width, channels * kernel_height * kernel_width), dtype=activations.dtype,)‘ to ‘columns ‘ in host memory. Here columns means one output-feature position processed in parallel. The important operands are empty: the value named ’empty’ in this block; batch: the value named ’batch’ in this block; output_height: the value named ’output height’ in this block. Context: the function _im2col_nchw, which handles im2col nchw.

Line 311: `dtype=activations.dtype,` This is continuation line 3 of the 4-line logical statement that begins at source line 309. Its exact fragment is ‘dtype=activations.dtype,‘. The important operands are dtype: the value named ’dtype’ in this block; activations: an input feature value consumed by a neuron or multiply-accumulate operation. Read together, the complete operation is: This assigns ‘np.empty((batch * output_height * output_width, channels * kernel_height * kernel_width), dtype=activations.dtype,)‘ to ‘columns ‘ in host memory. Here columns means one output-feature position processed in parallel. The important operands are empty: the value named ’empty’ in this block; batch: the value named ’batch’ in this block; output_height: the value named ’output height’ in this block. Context: the function _im2col_nchw, which handles im2col nchw.

Line 312: `)` This is continuation line 4 of the 4-line logical statement that begins at source line 309. Its exact fragment is ‘)‘. The expression is a literal or structural operator and has no hidden software state. Read together, the complete operation is: This assigns ‘np.empty((batch * output_height * output_width, channels * kernel_height * kernel_width), dtype=activations.dtype,)‘ to ‘columns ‘ in host memory. Here columns means one output-feature position processed in parallel. The important operands are empty: the value named ’empty’ in this block; batch: the value named ’batch’ in this block; output_height: the value named ’output height’ in this block. Context: the function _im2col_nchw, which handles im2col nchw.

Line 313: `row = 0` This assigns ‘0‘ to ‘row ‘ in host memory. Here row means one output-row position processed by the tensor tile. The expression is a literal or structural operator and has no hidden software state. Context: the function _im2col_nchw, which handles im2col nchw.

Line 314: `for batch_index in range(batch):` This iterates batch_index over ‘range(batch)‘. Each iteration repeats the indented host operation, commonly once per layer, tile, timestep, or test case in the function _im2col_nchw, which handles im2col nchw.

Line 315: `for output_y in range(output_height):` This iterates output_y over ‘range(output_height)‘. Each iteration repeats the indented host operation, commonly once per layer, tile, timestep, or test case in the function _im2col_nchw, which handles im2col nchw.

Line 316: `input_y = output_y * stride[0]` This assigns ‘output_y * stride[0]‘ to ‘input_y ‘ in host memory. Here input_y means the value named ’input y’ in this block. The important operands are output_y: the value named ’output y’ in this block; stride: the value named ’stride’ in this block. Context: the function _im2col_nchw, which handles im2col nchw.

Line 317: `for output_x in range(output_width):` This iterates output_x over ‘range(output_width)‘. Each iteration repeats the indented host operation, commonly once per layer, tile, timestep, or test case in the function _im2col_nchw, which handles im2col nchw.

Line 318: `input_x = output_x * stride[1]` This assigns ‘output_x * stride[1]‘ to ‘input_x ‘ in host memory. Here input_x means the value named ’input x’ in this block. The important operands are output_x: the value named ’output x’ in this block; stride: the value named ’stride’ in this block. Context: the function _im2col_nchw, which handles im2col nchw.

Line 319: `column = 0` This assigns ‘0‘ to ‘column ‘ in host memory. Here column means one output-feature position processed in parallel. The expression is a literal or structural operator and has no hidden software state. Context: the function _im2col_nchw, which handles im2col nchw.

Line 320: `for channel in range(channels):` This iterates channel over ‘range(channels)‘. Each iteration repeats the indented host operation, commonly once per layer, tile, timestep, or test case in the function _im2col_nchw, which handles im2col nchw.

Line 321: `for kernel_y in range(kernel_height):` This iterates kernel_y over ‘range(kernel_height)‘. Each iteration repeats the indented host operation, commonly once per layer, tile, timestep, or test case in the function _im2col_nchw, which handles im2col nchw.

Line 322: `y = input_y + kernel_y * dilation[0]` This assigns ‘input_y + kernel_y * dilation[0]‘ to ‘y ‘ in host memory. Here y means the value named ’y’ in this block. The important operands are input_y: the value named ’input y’ in this block; kernel_y: the value named ’kernel y’ in this block; dilation: the value named ’dilation’ in this block. Context: the function _im2col_nchw, which handles im2col nchw.

Line 323: `for kernel_x in range(kernel_width):` This iterates kernel_x over ‘range(kernel_width)‘. Each iteration repeats the indented host operation, commonly once per layer, tile, timestep, or test case in the function _im2col_nchw, which handles im2col nchw.

Line 324: `x = input_x + kernel_x * dilation[1]` This assigns ‘input_x + kernel_x * dilation[1]‘ to ‘x ‘ in host memory. Here x means the value named ’x’ in this block. The important operands are input_x: the value named ’input x’ in this block; kernel_x: the value named ’kernel x’ in this block; dilation: the value named ’dilation’ in this block. Context: the function _im2col_nchw, which handles im2col nchw.

Line 325: `columns[row, column] = padded[batch_index, channel, y, x]` This assigns ‘padded[batch_index, channel, y, x]‘ to ‘columns[row, column] ‘ in host memory. Here columns means one output-feature position processed in parallel. The important operands are padded: the value named ’padded’ in this block; batch_index: an integer selecting one tensor element, lane, bank, or state entry; channel: the value named ’channel’ in this block. Context: the function _im2col_nchw, which handles im2col nchw.

Line 326: `column += 1` Inside the function _im2col_nchw, which handles im2col nchw, this statement advances the host implementation that tiles matrices and convolutions into validated accelerator commands and packed stream payloads. The important operands are column: one output-feature position processed in parallel.

Line 327: `row += 1` Inside the function _im2col_nchw, which handles im2col nchw, this statement advances the host implementation that tiles matrices and convolutions into validated accelerator commands and packed stream payloads. The important operands are row: one output-row position processed by the tensor tile.

Line 328: `return columns, output_height, output_width` This returns ‘columns, output_height, output_width‘ to the caller of the function _im2col_nchw, which handles im2col nchw, ending this invocation. The important operands are columns: one output-feature position processed in parallel; output_height: the value named ’output height’ in this block; output_width: the value named ’output width’ in this block.

Line 331: `def compile_u8_gemm(` This starts function compile_u8_gemm. Its indented body performs compile u8 gemm as part of the file that tiles matrices and convolutions into validated accelerator commands and packed stream payloads; it runs only when called.

Line 332: `activations: np.ndarray | Sequence[Sequence[int]],` Inside the function compile_u8_gemm, which handles compile u8 gemm, this statement advances the host implementation that tiles matrices and convolutions into validated accelerator commands and packed stream payloads. The important operands are activations: an input feature value consumed by a neuron or multiply-accumulate operation; ndarray: the value named 'ndarray' in this block; Sequence: the value named 'sequence' in this block.

Line 333: `weights: np.ndarray | Sequence[Sequence[int]],` Inside the function compile_u8_gemm, which handles compile u8 gemm, this statement advances the host implementation that tiles matrices and convolutions into validated accelerator commands and packed stream payloads. The important operands are weights: a learned coefficient multiplied by an activation; ndarray: the value named 'ndarray' in this block; Sequence: the value named 'sequence' in this block.

Line 334: `*,` Inside the function compile_u8_gemm, which handles compile u8 gemm, this statement advances the host implementation that tiles matrices and convolutions into validated accelerator commands and packed stream payloads. The expression is a literal or structural operator and has no hidden software state.

Line 335: `activation_zero_point: int = 0,` This assigns '0,' to 'activation_zero_point' in host memory. Here activation_zero_point means an input feature value consumed by a neuron or multiply-accumulate operation. The expression is a literal or structural operator and has no hidden software state. Context: the function compile_u8_gemm, which handles compile u8 gemm.

Line 336: `weight_zero_point: int = 0,` This assigns '0,' to 'weight_zero_point' in host memory. Here weight_zero_point means a learned coefficient multiplied by an activation. The expression is a literal or structural operator and has no hidden software state. Context: the function compile_u8_gemm, which handles compile u8 gemm.

Line 337: `bias: Sequence[int] | np.ndarray | None = None,` This assigns 'None,' to 'bias' in host memory. Here bias means an additive learned offset applied after accumulation. The important operands are None: the value named 'none' in this block. Context: the function compile_u8_gemm, which handles compile u8 gemm.

Line 338: `dataflow: Dataflow | None = None,` This assigns 'None,' to 'dataflow' in host memory. Here dataflow means the value named 'dataflow' in this block. The important operands are None: the value named 'none' in this block. Context: the function compile_u8_gemm, which handles compile u8 gemm.

Line 339: `) -> CompiledGemm:` Inside the function compile_u8_gemm, which handles compile u8 gemm, this statement advances the host implementation that tiles matrices and convolutions into validated accelerator commands and packed stream payloads. The important operands are CompiledGemm: the value named 'compiled gemm' in this block.

Line 340: `"""Compile an exact asymmetric-uint8 matrix multiplication.` This is executable documentation attached to the function compile_u8_gemm, which handles compile u8 gemm. It states the intended contract that tests and callers should enforce, but the text itself does not transform data or issue hardware work.

Line 342: `Reduction dimensions above 2,048 are split into independently corrected` Inside the function compile_u8_gemm, which handles compile u8 gemm, this statement advances the host implementation that tiles matrices and convolutions into validated accelerator commands and packed stream payloads. The important operands are Reduction: the value named 'reduction' in this block; dimensions: the value named 'dimensions' in this block; above: the value named 'above' in this block.

Line 343: `chunks and accumulated by the runtime.  A single-row matrix uses Dot8 mode;` Inside the function compile_u8_gemm, which handles compile u8 gemm, this statement advances the host implementation that tiles matrices and convolutions into validated accelerator commands and packed stream payloads. The important operands are chunks: the value named 'chunks' in this block; and: the value named 'and' in this block; accumulated: the value named 'accumulated' in this block.

Line 344: `all other shapes use the 8x16 outer-product mode.` Inside the function compile_u8_gemm, which handles compile u8 gemm, this statement advances the host implementation that tiles matrices and convolutions into validated accelerator commands and packed stream payloads. The important operands are all: the value named 'all' in this block; other: the value named 'other' in this block; shapes: the value named 'shapes' in this block.

Line 345: `"""` This is executable documentation attached to the function compile_u8_gemm, which handles compile u8 gemm. It states the intended contract that tests and callers should enforce, but the text itself does not transform data or issue hardware work.

Line 346: `a = _as_u8_matrix("activations", activations)` This assigns '_as_u8_matrix("activations", activations)' to 'a ' in host memory. Here a means the value named 'a' in this block. The important operands are _as_u8_matrix: the value named 'as u8 matrix' in this block; activations: an input feature value consumed by a neuron or multiply-accumulate operation. Context: the function compile_u8_gemm, which handles compile u8 gemm.

Line 347: `b = _as_u8_matrix("weights", weights)` This assigns '_as_u8_matrix("weights", weights)' to 'b ' in host memory. Here b means the value named 'b' in this block. The important operands are _as_u8_matrix: the value named 'as u8 matrix' in this block; weights: a learned coefficient multiplied by an activation. Context: the function compile_u8_gemm, which handles compile u8 gemm.

Line 348: `rows, reduction = a.shape` This assigns 'a.shape' to 'rows, reduction ' in host memory. Here rows means one output-row position processed by the tensor tile. The important operands are a: the value named 'a' in this block; shape: the value named 'shape' in this block. Context: the function compile_u8_gemm, which handles compile u8 gemm.

Line 349: `weight_reduction, columns = b.shape` This assigns 'b.shape' to 'weight_reduction, columns ' in host memory. Here weight_reduction means a learned coefficient multiplied by an activation. The important operands are b: the value named 'b' in this block; shape: the value named 'shape' in this block. Context: the function compile_u8_gemm, which handles compile u8 gemm.

Line 350: `if reduction != weight_reduction:` This executes the following indented host-code branch only when 'reduction != weight_reduction' is true. The important operands are reduction: the value named 'reduction' in this block; weight_reduction: a learned coefficient multiplied by an activation. Context: the function compile_u8_gemm, which handles compile u8 gemm.

Line 351: `raise ValueError("activation columns must equal weight rows")` This rejects an invalid state by raising 'ValueError("activation columns must equal weight rows")'. Failing before DMA prevents malformed shapes or artifacts from silently becoming hardware results.

Line 352: `za = _u8("activation_zero_point", activation_zero_point)` This assigns '_u8("activation_zero_point", activation_zero_point)' to 'za ' in host memory. Here za means the value named 'za' in this block. The important operands are _u8: the value named 'u8' in this block; activation_zero_point: an input feature value consumed by a neuron or multiply-accumulate operation. Context: the function compile_u8_gemm, which handles compile u8 gemm.

Line 353: `zb = _u8("weight_zero_point", weight_zero_point)` This assigns '_u8("weight_zero_point", weight_zero_point to 'zb ' in host memory. Here zb means the value named 'zb' in this block. The important operands are _u8: the value named 'u8' in this block; weight_zero_point: a learned coefficient multiplied by an activation. Context: the function compile_u8_gemm, which handles compile u8 gemm.

Line 355: `bias_tuple: tuple[int, ...] | None = None` This assigns ‘None‘ to ‘bias_tuple‘ in host memory. Here bias_tuple means an additive learned offset applied after accumulation. The important operands are None: the value named ’none’ in this block. Context: the function compile_u8_gemm, which handles compile u8 gemm.

Line 356: `if bias is not None:` This executes the following indented host-code branch only when ‘bias is not None‘ is true. The important operands are bias: an additive learned offset applied after accumulation; is: the value named ’is’ in this block; not: the value named ’not’ in this block. Context: the function compile_u8_gemm, which handles compile u8 gemm.

Line 357: `bias_array = np.asarray(bias)` This assigns ‘np.asarray(bias)‘ to ‘bias_array ‘ in host memory. Here bias_array means an additive learned offset applied after accumulation. The important operands are asarray: the value named ’asarray’ in this block; bias: an additive learned offset applied after accumulation. Context: the function compile_u8_gemm, which handles compile u8 gemm.

Line 358: `if bias_array.ndim != 1 or len(bias_array) != columns:` This executes the following indented host-code branch only when ‘bias_array.ndim != 1 or len(bias_array) != columns‘ is true. The important operands are bias_array: an additive learned offset applied after accumulation; ndim: the value named ’ndim’ in this block; or: the value named ’or’ in this block. Context: the function compile_u8_gemm, which handles compile u8 gemm.

Line 359: `raise ValueError("bias must be a one-dimensional vector with one entry per output column")` This rejects an invalid state by raising ‘ValueError("bias must be a one-dimensional vector with one entry per output column")‘. Failing before DMA prevents malformed shapes or artifacts from silently becoming hardware results.

Line 360: `if not np.issubdtype(bias_array.dtype, np.integer):` This executes the following indented host-code branch only when ‘not np.issubdtype(bias_array.dtype, np.integer)‘ is true. The important operands are not: the value named ’not’ in this block; issubdtype: the value named ’issubdtype’ in this block; bias_array: an additive learned offset applied after accumulation. Context: the function compile_u8_gemm, which handles compile u8 gemm.

Line 361: `raise ValueError("bias must contain integers")` This rejects an invalid state by raising ‘ValueError("bias must contain integers")‘. Failing before DMA prevents malformed shapes or artifacts from silently becoming hardware results.

Line 362: `bias_tuple = tuple(int(value) for value in bias_array)` This assigns ‘tuple(int(value) for value in bias_array)‘ to ‘bias_tuple ‘ in host memory. Here bias_tuple means an additive learned offset applied after accumulation. The important operands are tuple: the value named ’tuple’ in this block; value: the value named ’value’ in this block; for: the value named ’for’ in this block. Context: the function compile_u8_gemm, which handles compile u8 gemm.

Line 364: `instructions: list[TensorInstruction] = []` This assigns ‘[]‘ to ‘instructions‘ in host memory. Here instructions means the value named ’instructions’ in this block. The expression is a literal or structural operator and has no hidden software state. Context: the function compile_u8_gemm, which handles compile u8 gemm.

Line 365: `bindings: list[ResultBinding] = []` This assigns ‘[]‘ to ‘bindings‘ in host memory. Here bindings means the value named ’bindings’ in this block. The expression is a literal or structural operator and has no hidden software state. Context: the function compile_u8_gemm, which handles compile u8 gemm.

Line 366: `estimated_bytes = 0` This assigns ‘0‘ to ‘estimated_bytes ‘ in host memory. Here estimated_bytes means the value named ’estimated bytes’ in this block. The expression is a literal or structural operator and has no hidden software state. Context: the function compile_u8_gemm, which handles compile u8 gemm.

Line 368: `def append_load(command: Command128, beats: Sequence[StreamBeat], description: str) -> None:` This starts function append_load. Its indented body performs append load as part of the file that tiles matrices and convolutions into validated accelerator commands and packed stream payloads; it runs only when called.

Line 369: `nonlocal estimated_bytes` Inside the function append_load, which handles append load, this statement advances the host implementation that tiles matrices and convolutions into validated accelerator commands and packed stream payloads. The important operands are nonlocal: the value named 'nonlocal' in this block; estimated_bytes: the value named 'estimated bytes' in this block.

Line 370: `instructions.append(TensorInstruction(command, beats, 0, description))` This calls 'instructions.append' with 'TensorInstruction(command, beats, 0, description)' inside the function append_load, which handles append load. The call advances the host-side job that tiles matrices and convolutions into validated accelerator commands and packed stream payloads.

Line 371: `estimated_bytes += 8 * len(beats)` Inside the function append_load, which handles append load, this statement advances the host implementation that tiles matrices and convolutions into validated accelerator commands and packed stream payloads. The important operands are estimated_bytes: the value named 'estimated bytes' in this block; len: the value named 'len' in this block; beats: the value named 'beats' in this block.

Line 373: `def append_compute(` This starts function append_compute. Its indented body performs append compute as part of the file that tiles matrices and convolutions into validated accelerator commands and packed stream payloads; it runs only when called.

Line 374: `command: Command128,` Inside the function append_compute, which handles append compute, this statement advances the host implementation that tiles matrices and convolutions into validated accelerator commands and packed stream payloads. The important operands are command: the 128-bit instruction selecting an engine, shape, mode, and numeric parameters; Command128: the 128-bit instruction selecting an engine, shape, mode, and numeric parameters.

Line 375: `row_start: int,` Inside the function append_compute, which handles append compute, this statement advances the host implementation that tiles matrices and convolutions into validated accelerator commands and packed stream payloads. The important operands are row_start: one output-row position processed by the tensor tile.

Line 376: `column_start: int,` Inside the function append_compute, which handles append compute, this statement advances the host implementation that tiles matrices and convolutions into validated accelerator commands and packed stream payloads. The important operands are column_start: one output-feature position processed in parallel.

Line 377: `tile_rows: int,` Inside the function append_compute, which handles append compute, this statement advances the host implementation that tiles matrices and convolutions into validated accelerator commands and packed stream payloads. The important operands are tile_rows: one output-row position processed by the tensor tile.

Line 378: `tile_columns: int,` Inside the function append_compute, which handles append compute, this statement advances the host implementation that tiles matrices and convolutions into validated accelerator commands and packed stream payloads. The important operands are tile_columns: one output-feature position processed in parallel.

Line 379: `reduction_start: int,` Inside the function append_compute, which handles append compute, this statement advances the host implementation that tiles matrices and convolutions into validated accelerator commands and packed stream payloads. The important operands are reduction_start: the value named 'reduction start' in this block.

Line 380: `reduction_count: int,` Inside the function append_compute, which handles append compute, this statement advances the host implementation that tiles matrices and convolutions into validated accelerator commands and packed stream payloads. The important operands are reduction_count: an integer count retained for control or measurable telemetry.

Line 381: `) -> None:` Inside the function append_compute, which handles append compute, this statement advances the host implementation that tiles matrices and convolutions into validated accelerator commands and packed stream payloads. The important operands are None: the value named 'none' in this block.

Line 382: `instruction_index = len(instructions)` This assigns ‘len(instructions)‘ to ‘instruction_index ‘ in host memory. Here instruction_index means an integer selecting one tensor element, lane, bank, or state entry. The important operands are len: the value named ’len’ in this block; instructions: the value named ’instructions’ in this block. Context: the function append_compute, which handles append compute.

Line 383: `instructions.append(TensorInstruction(` This statement continues through source line 388; the explanation uses the complete expression rather than only the first visual fragment. This calls ‘instructions.append‘ with ‘TensorInstruction(command, (), tile_rows * tile_columns, f"compute C[{row_start}:{row_start + tile_rows}," f"{column_start}:{column_start + tile_columns}] " f"from K[{reduction_start}:{reduction_start + reduction_count}]",)‘ inside the function append_compute, which handles append compute. The call advances the host-side job that tiles matrices and convolutions into validated accelerator commands and packed stream payloads.

Line 384: `command, (), tile_rows * tile_columns,` This is continuation line 2 of the 6-line logical statement that begins at source line 383. Its exact fragment is ‘command, (), tile_rows * tile_columns,‘. The important operands are command: the 128-bit instruction selecting an engine, shape, mode, and numeric parameters; tile_rows: one output-row position processed by the tensor tile; tile_columns: one output-feature position processed in parallel. Read together, the complete operation is: This calls ‘instructions.append‘ with ‘TensorInstruction(command, (), tile_rows * tile_columns, f"compute C[{row_start}:{row_start + tile_rows}," f"{column_start}:{column_start + tile_columns}] " f"from K[{reduction_start}:{reduction_start + reduction_count}]",)‘ inside the function append_compute, which handles append compute. The call advances the host-side job that tiles matrices and convolutions into validated accelerator commands and packed stream payloads.

Line 385: `f"compute C[{row_start}:{row_start + tile_rows},"` This is continuation line 3 of the 6-line logical statement that begins at source line 383. Its exact fragment is ‘f"compute C[{row_start}:{row_start + tile_rows},"‘. The important operands are f: the value named ’f’ in this block; compute: the value named ’compute’ in this block; C: the value named ’c’ in this block. Read together, the complete operation is: This calls ‘instructions.append‘ with ‘TensorInstruction(command, (), tile_rows * tile_columns, f"compute C[{row_start}:{row_start + tile_rows}," f"{column_start}:{column_start + tile_columns}] " f"from K[{reduction_start}:{reduction_start + reduction_count}]",)‘ inside the function append_compute, which handles append compute. The call advances the host-side job that tiles matrices and convolutions into validated accelerator commands and packed stream payloads.

Line 386: `f"{column_start}:{column_start + tile_columns}] "` This is continuation line 4 of the 6-line logical statement that begins at source line 383. Its exact fragment is ‘f"{column_start}:{column_start + tile_columns}] "‘. The important operands are f: the value named ’f’ in this block; column_start: one output-feature position processed in parallel; tile_columns: one output-feature position processed in parallel. Read together, the complete operation is: This calls ‘instructions.append‘ with ‘TensorInstruction(command, (), tile_rows * tile_columns, f"compute C[{row_start}:{row_start + tile_rows}," f"{column_start}:{column_start + tile_columns}] " f"from K[{reduction_start}:{reducti + reduction_count}]",)‘ inside the function append_compute, which handles append compute. The call advances the host-side job that tiles matrices and convolutions into validated accelerator commands and packed stream payloads.

Line 387: `f"from K[{reduction_start}:{reduction_start + reduction_count}]",` This is continuation line 5 of the 6-line logical statement that begins at source line 383. Its exact fragment is ‘f"from K[{reduction_start}:{reduction_start + reduction_count}]",‘. The important operands are f: the value named ’f’ in this block; from: the value named ’from’ in this block; K: the value named ’k’ in this block. Read together, the complete operation is: This calls ‘instructions.append‘ with ‘TensorInstruction(command, (), tile_rows * tile_columns, f"compute C[{row_start}:{row_start + tile_rows}," f"{column_start}:{column_start + tile_columns}] " f"from K[{reduction_start}:{reduction_start + reduction_count}]",)‘ inside the function append_compute, which handles append compute. The call advances the host-side job that tiles matrices and convolutions into validated accelerator commands and packed stream payloads.

Line 388: `))` This is continuation line 6 of the 6-line logical statement that begins at source line 383. Its exact fragment is ‘))‘. The expression is a literal or structural operator and has no hidden software state. Read together, the complete operation is: This calls ‘instructions.append‘ with ‘TensorInstruction(command, (), tile_rows * tile_columns, f"compute C[{row_start}:{row_start + tile_rows}," f"{column_start}:{column_start + tile_columns}] " f"from K[{reduction_start}:{reduction_start + reduction_count}]",)‘ inside the function append_compute, which handles append compute. The call advances the host-side job that tiles matrices and convolutions into validated accelerator commands and packed stream payloads.

Line 389: `bindings.append(ResultBinding(` This statement continues through source line 392; the explanation uses the complete expression rather than only the first visual fragment. This calls ‘bindings.append‘ with ‘ResultBinding(instruction_index, row_start, column_start, tile_rows, tile_columns, reduction_start, reduction_count,)‘ inside the function append_compute, which handles append compute. The call advances the host-side job that tiles matrices and convolutions into validated accelerator commands and packed stream payloads.

Line 390: `instruction_index, row_start, column_start, tile_rows, tile_columns,` This is continuation line 2 of the 4-line logical statement that begins at source line 389. Its exact fragment is ‘instruction_index, row_start, column_start, tile_rows, tile_columns,‘. The important operands are instruction_index: an integer selecting one tensor element, lane, bank, or state entry; row_start: one output-row position processed by the tensor tile; column_start: one output-feature position processed in parallel. Read together, the complete operation is: This calls ‘bindings.append‘ with ‘ResultBinding(instruction_index, row_start, column_start, tile_rows, tile_columns, reduction_start, reduction_count,)‘ inside the function append_compute, which handles append compute. The call advances the host-side job that tiles matrices and convolutions into validated accelerator commands and packed stream payloads.

Line 391: `reduction_start, reduction_count,` This is continuation line 3 of the 4-line logical statement that begins at source line 389. Its exact fragment is ‘reduction_start, reduction_count,‘. The important operands are reduction_start: the value named ’reduction start’ in this block; reduction_count: an integer count retained for control or measurable telemetry. Read together, the complete operation is: This calls ‘bindings.append‘ with ‘ResultBinding(instruction_index, row_start, column_start, tile_rows, tile_columns, reduction_start, reduction_count,)‘ inside the function append_compute, which handles append compute. The call advances the host-side job that tiles matrices and convolutions into validated accelerator commands and packed stream payloads.

Line 392: `))` This is continuation line 4 of the 4-line logical statement that begins at source line 389. Its exact fragment is ‘))‘. The expression is a literal or structural operator and has no hidden software state. Read together, the complete operation is: This calls ‘bindings.append‘ with ‘ResultBinding(instruction_index, row_start, column_start, tile_rows, tile_columns, reduction_start, reduction_count,)‘ inside the function append_compute, which handles append compute. The call advances the host-side job that tiles matrices and convolutions into validated accelerator commands and packed stream payloads.

Line 394: `for reduction_start in range(0, reduction, MAX_REDUCTION):` This iterates reduction_start over ‘range(0, reduction, MAX_REDUCTION)‘. Each iteration repeats the indented host operation, commonly once per layer, tile, timestep, or test case in the function compile_u8_gemm, which handles compile u8 gemm.

Line 395: `reduction_count = min(MAX_REDUCTION, reduction - reduction_start)` This assigns ‘min(MAX_REDUCTION reduction - reduction_start)‘ to ‘reduction_count ‘ in host memory. Here reduction_count means an integer count retained for control or measurable telemetry. The important operands are min: the value named ’min’ in this block; MAX_REDUCTION: the value named ’max reduction’ in this block; reduction: the value named ’reduction’ in this block. Context: the function compile_u8_gemm, which handles compile u8 gemm.

Line 396: `selected = dataflow or choose_dataflow(rows, columns, reduction_count).mode` This assigns ‘dataflow or choose_dataflow(rows, columns, reduction_count).mode‘ to ‘selected ‘ in host memory. Here selected means the value named ’selected’ in this block. The important operands are dataflow: the value named ’dataflow’ in this block; or: the value named ’or’ in this block; choose_dataflow: the value named ’choose dataflow’ in this block. Context: the function compile_u8_gemm, which handles compile u8 gemm.

Line 397: `if selected not in {Dataflow.INPUT_BROADCAST, Dataflow.WEIGHT_BROADCAST}:` This executes the following indented host-code branch only when ‘selected not in {Dataflow.INPUT_BROADCAST, Dataflow.WEIGHT_BROADCAS is true. The important operands are selected: the value named ’selected’ in this block; not: the value named ’not’ in this block; in: the value named ’in’ in this block. Context: the function compile_u8_gemm, which handles compile u8 gemm.

Line 398: `raise ValueError(f"unsupported dataflow {selected}")` This rejects an invalid state by raising ‘ValueError(f"unsupported dataflow {selected}")‘. Failing before DMA prevents malformed shapes or artifacts from silently becoming hardware results.

Line 399: `use_dot8 = rows == 1` Inside the function compile_u8_gemm, which handles compile u8 gemm, this statement advances the host implementation that tiles matrices and convolutions into validated accelerator commands and packed stream payloads. The important operands are use_dot8: the value named 'use dot8' in this block; rows: one output-row position processed by the tensor tile.

Line 400: `issue_count = (reduction_count + 7) // 8 if use_dot8 else reduction_count` This assigns '(reduction_count + 7) // 8 if use_dot8 else reduction_count' to 'issue_count ' in host memory. Here issue_count means an integer count retained for control or measurable telemetry. The important operands are reduction_count: an integer count retained for control or measurable telemetry; use_dot8: the value named 'use dot8' in this block. Context: the function compile_u8_gemm, which handles compile u8 gemm.

Line 401: `load_weight_opcode = Opcode.LOAD_WEIGHTS_DOT8 if use_dot8 else Opcode.LOAD_WEIGHTS_OUTER` This assigns 'Opcode.LOAD_WEIGHTS_DOT8 if use_dot8 else Opcode.LOAD_WEIGHTS_OUTER' to 'load_weight_opcode ' in host memory. Here load_weight_opcode means a learned coefficient multiplied by an activation. The important operands are Opcode: the value named 'opcode' in this block; LOAD_WEIGHTS_DOT8: a learned coefficient multiplied by an activation; use_dot8: the value named 'use dot8' in this block. Context: the function compile_u8_gemm, which handles compile u8 gemm.

Line 402: `compute_opcode = Opcode.COMPUTE_DENSE_DOT8 if use_dot8 else Opcode.COMPUTE_DENSE_OUTER` This assigns 'Opcode.COMPUTE_DENSE_DOT8 if use_dot8 else Opcode.COMPUTE_DENSE_OUTER' to 'compute_opcode ' in host memory. Here compute_opcode means the value named 'compute opcode' in this block. The important operands are Opcode: the value named 'opcode' in this block; COMPUTE_DENSE_DOT8: the value named 'compute dense dot8' in this block; use_dot8: the value named 'use dot8' in this block. Context: the function compile_u8_gemm, which handles compile u8 gemm.

Line 404: `def activation_load(row_start: int) -> tuple[Command128, PackedStreamBeats]:` This starts function activation_load. Its indented body performs activation load as part of the file that tiles matrices and convolutions into validated accelerator commands and packed stream payloads; it runs only when called.

Line 405: `tile_rows = min(ROW_TILE, rows - row_start)` This assigns 'min(ROW_TILE, rows - row_start)' to 'tile_rows ' in host memory. Here tile_rows means one output-row position processed by the tensor tile. The important operands are min: the value named 'min' in this block; ROW_TILE: one output-row position processed by the tensor tile; rows: one output-row position processed by the tensor tile. Context: the function activation_load, which handles activation load.

Line 406: `if use_dot8:` This executes the following indented host-code branch only when 'use_dot8' is true. The important operands are use_dot8: the value named 'use dot8' in this block. Context: the function activation_load, which handles activation load.

Line 407: `padded = np.full(issue_count * 8, za, dtype=np.uint8)` This assigns 'np.full(issue_count * 8, za, dtype=np.uint8)' to 'padded ' in host memory. Here padded means the value named 'padded' in this block. The important operands are full: the value named 'full' in this block; issue_count: an integer count retained for control or measurable telemetry; za: the value named 'za' in this block. Context: the function activation_load, which handles activation load.

Line 408: `padded[:reduction_count] = a[row_start, reduction_start:reduction_start + reduction_count]` This assigns 'a[row_start, reduction_start:reduction_start + reduction_count]' to 'padded[' in host memory. Here padded means the value named 'padded' in this block. The important operands are a: the value named 'a' in this block; row_start: one output-row position processed by the tensor tile; reduction_start: the value named 'reduction start' in this block. Context: the function activation_load, which handles activation load.

Line 409: `vectors = padded.reshape(issue_count, 8)` This assigns 'padded.reshape(issue_count, 8)' to 'vectors ' in host memory. Here vectors means the value named 'vectors' in this block. The important operands are padded: the value named 'padded' in this block; reshape: the value named 'reshape' in this block; issue_count: an integer count retained for control or measurable telemetry. Context: the function activation_load, which handles activation load.

Line 410: `else:` This begins the alternative host-code branch when the preceding condition was false, still inside the function activation_load, which handles activation load.

Line 411: `vectors = np.full((reduction_count, ROW_TILE), za, dtype=np.uint8)` This assigns ‘np.full((reduction_count ROW_TILE), za, dtype=np.uint8)‘ to ‘vectors ‘ in host memory. Here vectors means the value named ’vectors’ in this block. The important operands are full: the value named ’full’ in this block; reduction_count: an integer count retained for control or measurable telemetry; ROW_TILE: one output-row position processed by the tensor tile. Context: the function activation_load, which handles activation load.

Line 412: `vectors[:, :tile_rows] = a[` This statement continues through source line 415; the explanation uses the complete expression rather than only the first visual fragment. This assigns ‘a[row_start:row_start + tile_rows, reduction_start:reduction_start + reduction_count,].T‘ to ‘vectors[‘ in host memory. Here vectors means the value named ’vectors’ in this block. The important operands are a: the value named ’a’ in this block; row_start: one output-row position processed by the tensor tile; tile_rows: one output-row position processed by the tensor tile. Context: the function activation_load, which handles activation load.

Line 413: `row_start:row_start + tile_rows,` This is continuation line 2 of the 4-line logical statement that begins at source line 412. Its exact fragment is ‘row_start:row_start + tile_rows,‘. The important operands are row_start: one output-row position processed by the tensor tile; tile_rows: one output-row position processed by the tensor tile. Read together, the complete operation is: This assigns ‘a[row_start:row_start + tile_rows, reduction_start:reduction_start + reduction_count,].T‘ to ‘vectors[‘ in host memory. Here vectors means the value named ’vectors’ in this block. The important operands are a: the value named ’a’ in this block; row_start: one output-row position processed by the tensor tile; tile_rows: one output-row position processed by the tensor tile. Context: the function activation_load, which handles activation load.

Line 414: `reduction_start:reduction_start + reduction_count,` This is continuation line 3 of the 4-line logical statement that begins at source line 412. Its exact fragment is ‘reduction_start:reduction_start + reduction_count,‘. The important operands are reduction_start: the value named ’reduction start’ in this block; reduction_count: an integer count retained for control or measurable telemetry. Read together, the complete operation is: This assigns ‘a[row_start:row_start + tile_rows, reduction_start:reduction_start + reduction_count,].T‘ to ‘vectors[‘ in host memory. Here vectors means the value named ’vectors’ in this block. The important operands are a: the value named ’a’ in this block; row_start: one output-row position processed by the tensor tile; tile_rows: one output-row position processed by the tensor tile. Context: the function activation_load, which handles activation load.

Line 415: `].T` This is continuation line 4 of the 4-line logical statement that begins at source line 412. Its exact fragment is ‘].T‘. The important operands are T: the value named ’t’ in this block. Read together, the complete operation is: This assigns ‘a[row_start:row_start + tile_rows, reduction_start:reduction_start + reduction_count,].T‘ to ‘vectors[‘ in host memory. Here vectors means the value named ’vectors’ in this block. The important operands are a: the value named ’a’ in this block; row_start: one output-row position processed by the tensor tile; tile_rows: one output-row position processed by the tensor tile. Context: the function activation_load, which handles activation load.

Line 416: `command = tensor_command(` This statement continues through source line 420; the explanation uses the complete expression rather than only the first visual fragment. This assigns ‘tensor_command(Opcode.LOAD_ACTIVATIONS, issue_count=issue_count, activation_zero_point=za,)‘ to ‘command ‘ in host memory. Here command means the 128-bit instruction selecting an engine, shape, mode, and numeric parameters. The important operands are tensor_command: the 128-bit instruction selecting an engine, shape, mode, and numeric parameters; Opcode: the value named ’opcode’ in this block; LOAD_ACTIVATIONS: an input feature value consumed by a neuron or multiply-accumulate operation. Context: the function activation_load, which handles activation load.

Line 417: `Opcode.LOAD_ACTIVATIONS,` This is continuation line 2 of the 5-line logical statement that begins at source line 416. Its exact fragment is ‘Opcode.LOAD_ACTIVATIONS,‘. The important operands are Opcode: the value named ’opcode’ in this block; LOAD_ACTIVATIONS: an input feature value consumed by a neuron or multiply-accumulate operation. Read together, the complete operation is: This assigns ‘tensor_command(Opcode.LOAD_ACTIVATIONS, issue_count=issue_count, activation_zero_point=za,)‘ to ‘command ‘ in host memory. Here command means the 128-bit instruction selecting an engine, shape, mode, and numeric parameters. The important operands are tensor_command: the 128-bit instruction selecting an engine, shape, mode, and numeric parameters; Opcode: the value named ’opcode’

in this block; LOAD_ACTIVATIONS: an input feature value consumed by a neuron or multiply-accumulate operation. Context: the function activation_load, which handles activation load.

Line 418: `issue_count=issue_count,` This is continuation line 3 of the 5-line logical statement that begins at source line 416. Its exact fragment is 'issue_count=issue_count,'. The important operands are issue_count: an integer count retained for control or measurable telemetry. Read together, the complete operation is: This assigns 'tensor_command(Opcode.LOAD_ACTIVATIONS, issue_count=issue_count, activation_zero_point=za,)' to 'command ' in host memory. Here command means the 128-bit instruction selecting an engine, shape, mode, and numeric parameters. The important operands are tensor_command: the 128-bit instruction selecting an engine, shape, mode, and numeric parameters; Opcode: the value named 'opcode' in this block; LOAD_ACTIVATIONS: an input feature value consumed by a neuron or multiply-accumulate operation. Context: the function activation_load, which handles activation load.

Line 419: `activation_zero_point=za,` This is continuation line 4 of the 5-line logical statement that begins at source line 416. Its exact fragment is 'activation_zero_point=za,'. The important operands are activation_zero_point: an input feature value consumed by a neuron or multiply-accumulate operation; za: the value named 'za' in this block. Read together, the complete operation is: This assigns 'tensor_command(Opcode.LOAD_ACTIVATIONS, issue_count=issue_count, activation_zero_point=za,)' to 'command ' in host memory. Here command means the 128-bit instruction selecting an engine, shape, mode, and numeric parameters. The important operands are tensor_command: the 128-bit instruction selecting an engine, shape, mode, and numeric parameters; Opcode: the value named 'opcode' in this block; LOAD_ACTIVATIONS: an input feature value consumed by a neuron or multiply-accumulate operation. Context: the function activation_load, which handles activation load.

Line 420: `)` This is continuation line 5 of the 5-line logical statement that begins at source line 416. Its exact fragment is ')'. The expression is a literal or structural operator and has no hidden software state. Read together, the complete operation is: This assigns 'tensor_command(Opcode.LOAD_ACTIVATIONS, issue_count=issue_count, activation_zero_point=za,)' to 'command ' in host memory. Here command means the 128-bit instruction selecting an engine, shape, mode, and numeric parameters. The important operands are tensor_command: the 128-bit instruction selecting an engine, shape, mode, and numeric parameters; Opcode: the value named 'opcode' in this block; LOAD_ACTIVATIONS: an input feature value consumed by a neuron or multiply-accumulate operation. Context: the function activation_load, which handles activation load.

Line 421: `return command, _pack_compiler_u8_rows(vectors, 8)` This returns 'command, _pack_compiler_u8_rows(vecto 8)' to the caller of the function activation_load, which handles activation load, ending this invocation. The important operands are command: the 128-bit instruction selecting an engine, shape, mode, and numeric parameters; _pack_compiler_u8_rows: one output-row position processed by the tensor tile; vectors: the value named 'vectors' in this block.

Line 423: `def weight_load(column_start: int) -> tuple[Command128, PackedStreamBeats]:` This starts function weight_load. Its indented body performs weight load as part of the file that tiles matrices and convolutions into validated accelerator commands and packed stream payloads; it runs only when called.

Line 424: `tile_columns = min(COLUMN_TILE, columns - column_start)` This assigns 'min(COLUMN_TILE, columns - column_start)' to 'tile_columns ' in host memory. Here tile_columns means one output-feature position processed in parallel. The important operands are min: the value named 'min' in this block; COLUMN_TILE: one output-feature position processed in parallel; columns: one output-feature position processed in parallel. Context: the function weight_load, which handles weight load.

Line 425: `if use_dot8:` This executes the following indented host-code branch only when 'use_dot8' is true. The important operands are use_dot8: the value named 'use dot8' in this block. Context: the function weight_load, which handles weight load.

Line 426: `tensor = np.full((issue_count, 8, COLUMN_TILE), zb, dtype=np.uint8)` This assigns 'np.full((issue_count, 8, COLUMN_TILE), zb, dtype=np.uint8)' to 'tensor ' in host memory. Here tensor means the value named 'tensor' in this block. The important operands are full: the value named 'full' in this block; issue_count: an integer count retained for control or measurable telemetry; COLUMN_TILE: one output-feature position processed in parallel. Context: the function weight_load, which handles weight load.

Line 427: `flat = tensor.reshape(issue_count * 8, COLUMN_TILE)` This assigns ‘tensor.reshape(issue_count * 8, COLUMN_TILE)‘ to ‘flat ‘ in host memory. Here flat means the value named ’flat’ in this block. The important operands are tensor: the value named ’tensor’ in this block; reshape: the value named ’reshape’ in this block; issue_count: an integer count retained for control or measurable telemetry. Context: the function weight_load, which handles weight load.

Line 428: `flat[:reduction_count, :tile_columns] = b[` This statement continues through source line 431; the explanation uses the complete expression rather than only the first visual fragment. This assigns ‘b[reduction_start:reduction_start + reduction_count, column_start:column_start + tile_columns,]‘ to ‘flat[‘ in host memory. Here flat means the value named ’flat’ in this block. The important operands are b: the value named ’b’ in this block; reduction_start: the value named ’reduction start’ in this block; reduction_count: an integer count retained for control or measurable telemetry. Context: the function weight_load, which handles weight load.

Line 429: `reduction_start:reduction_start + reduction_count,` This is continuation line 2 of the 4-line logical statement that begins at source line 428. Its exact fragment is ‘reduction_start:reduction_start + reduction_count,‘. The important operands are reduction_start: the value named ’reduction start’ in this block; reduction_count: an integer count retained for control or measurable telemetry. Read together, the complete operation is: This assigns ‘b[reduction_start:reduction_start + reduction_count, column_start:column_start + tile_columns,]‘ to ‘flat[‘ in host memory. Here flat means the value named ’flat’ in this block. The important operands are b: the value named ’b’ in this block; reduction_start: the value named ’reduction start’ in this block; reduction_count: an integer count retained for control or measurable telemetry. Context: the function weight_load, which handles weight load.

Line 430: `column_start:column_start + tile_columns,` This is continuation line 3 of the 4-line logical statement that begins at source line 428. Its exact fragment is ‘column_start:column_start + tile_columns,‘. The important operands are column_start: one output-feature position processed in parallel; tile_columns: one output-feature position processed in parallel. Read together, the complete operation is: This assigns ‘b[reduction_start:reduction_start + reduction_count, column_start:column_start + tile_columns,]‘ to ‘flat[‘ in host memory. Here flat means the value named ’flat’ in this block. The important operands are b: the value named ’b’ in this block; reduction_start: the value named ’reduction start’ in this block; reduction_count: an integer count retained for control or measurable telemetry. Context: the function weight_load, which handles weight load.

Line 431: `]` This is continuation line 4 of the 4-line logical statement that begins at source line 428. Its exact fragment is ‘]‘. The expression is a literal or structural operator and has no hidden software state. Read together, the complete operation is: This assigns ‘b[reduction_start:reduction_start + reduction_count, column_start:column_start + tile_columns,]‘ to ‘flat[‘ in host memory. Here flat means the value named ’flat’ in this block. The important operands are b: the value named ’b’ in this block; reduction_start: the value named ’reduction start’ in this block; reduction_count: an integer count retained for control or measurable telemetry. Context: the function weight_load, which handles weight load.

Line 432: `beats = _pack_compiler_u8_rows(tensor, 16)` This assigns ‘_pack_compiler_u8_rows(tensor, 16)‘ to ‘beats ‘ in host memory. Here beats means the value named ’beats’ in this block. The important operands are _pack_compiler_u8_rows: one output-row position processed by the tensor tile; tensor: the value named ’tensor’ in this block. Context: the function weight_load, which handles weight load.

Line 433: `else:` This begins the alternative host-code branch when the preceding condition was false, still inside the function weight_load, which handles weight load.

Line 434: `matrix = np.full((reduction_count, COLUMN_TILE), zb, dtype=np.uint8)` This assigns ‘np.full((reduction_cou COLUMN_TILE), zb, dtype=np.uint8)‘ to ‘matrix ‘ in host memory. Here matrix means the value named ’matrix’ in this block. The important operands are full: the value named ’full’ in this block; reduction_count: an integer count retained for control or measurable telemetry; COLUMN_TILE: one output-feature position processed in parallel. Context: the function weight_load, which handles weight load.

Line 435: `matrix[:, :tile_columns] = b[` This statement continues through source line 438; the explanation uses the complete expression rather than only the first visual fragment. This assigns ‘b[reduction_start:reduction_start +

reduction_count, column_start:column_start + tile_columns,]‘ to ‘matrix[‘ in host memory. Here matrix means the value named ’matrix’ in this block. The important operands are b: the value named ’b’ in this block; reduction_start: the value named ’reduction start’ in this block; reduction_count: an integer count retained for control or measurable telemetry. Context: the function weight_load, which handles weight load.

Line 436: `reduction_start:reduction_start + reduction_count,` This is continuation line 2 of the 4-line logical statement that begins at source line 435. Its exact fragment is ‘reduction_start:reduction_start + reduction_count,‘. The important operands are reduction_start: the value named ’reduction start’ in this block; reduction_count: an integer count retained for control or measurable telemetry. Read together, the complete operation is: This assigns ‘b[reduction_start:reduction_start + reduction_count, column_start:column_start + tile_columns,]‘ to ‘matrix[‘ in host memory. Here matrix means the value named ’matrix’ in this block. The important operands are b: the value named ’b’ in this block; reduction_start: the value named ’reduction start’ in this block; reduction_count: an integer count retained for control or measurable telemetry. Context: the function weight_load, which handles weight load.

Line 437: `column_start:column_start + tile_columns,` This is continuation line 3 of the 4-line logical statement that begins at source line 435. Its exact fragment is ‘column_start:column_start + tile_columns,‘. The important operands are column_start: one output-feature position processed in parallel; tile_columns: one output-feature position processed in parallel. Read together, the complete operation is: This assigns ‘b[reduction_start:reduction_start + reduction_count, column_start:column_start + tile_columns,]‘ to ‘matrix[‘ in host memory. Here matrix means the value named ’matrix’ in this block. The important operands are b: the value named ’b’ in this block; reduction_start: the value named ’reduction start’ in this block; reduction_count: an integer count retained for control or measurable telemetry. Context: the function weight_load, which handles weight load.

Line 438: `]` This is continuation line 4 of the 4-line logical statement that begins at source line 435. Its exact fragment is ‘]‘. The expression is a literal or structural operator and has no hidden software state. Read together, the complete operation is: This assigns ‘b[reduction_start:reduction_start + reduction_count, column_start:column_start + tile_columns,]‘ to ‘matrix[‘ in host memory. Here matrix means the value named ’matrix’ in this block. The important operands are b: the value named ’b’ in this block; reduction_start: the value named ’reduction start’ in this block; reduction_count: an integer count retained for control or measurable telemetry. Context: the function weight_load, which handles weight load.

Line 439: `beats = _pack_compiler_u8_rows(matrix, 16)` This assigns ‘_pack_compiler_u8_rows(matrix, 16)‘ to ‘beats ‘ in host memory. Here beats means the value named ’beats’ in this block. The important operands are _pack_compiler_u8_rows: one output-row position processed by the tensor tile; matrix: the value named ’matrix’ in this block. Context: the function weight_load, which handles weight load.

Line 440: `command = tensor_command(load_weight_opcode, issue_count=issue_count)` This assigns ‘tensor_command(loa issue_count=issue_count)‘ to ‘command ‘ in host memory. Here command means the 128-bit instruction selecting an engine, shape, mode, and numeric parameters. The important operands are tensor_command: the 128-bit instruction selecting an engine, shape, mode, and numeric parameters; load_weight_opcode: a learned coefficient multiplied by an activation; issue_count: an integer count retained for control or measurable telemetry. Context: the function weight_load, which handles weight load.

Line 441: `return command, beats` This returns ‘command, beats‘ to the caller of the function weight_load, which handles weight load, ending this invocation. The important operands are command: the 128-bit instruction selecting an engine, shape, mode, and numeric parameters; beats: the value named ’beats’ in this block.

Line 443: `def compute(row_start: int, column_start: int) -> None:` This starts function compute. Its indented body performs compute as part of the file that tiles matrices and convolutions into validated accelerator commands and packed stream payloads; it runs only when called.

Line 444: `tile_rows = min(ROW_TILE, rows - row_start)` This assigns ‘min(ROW_TILE, rows - row_start)‘ to ‘tile_rows ‘ in host memory. Here tile_rows means one output-row position processed by the tensor tile. The important operands are min: the value named ’min’ in this block; ROW_TILE: one output-row position processed by the tensor tile; rows: one output-row position processed by the tensor tile. Context: the function compute, which handles compute.

Line 445: `tile_columns = min(COLUMN_TILE, columns - column_start)` This assigns ‘min(COLUMN_TILE, columns - column_start)‘ to ‘tile_columns ‘ in host memory. Here tile_columns means one output-feature position processed in parallel. The important operands are min: the value named ’min’ in this block; COLUMN_TILE: one output-feature position processed in parallel; columns: one output-feature position processed in parallel. Context: the function compute, which handles compute.

Line 446: `command = tensor_command(` This statement continues through source line 453; the explanation uses the complete expression rather than only the first visual fragment. This assigns ‘tensor_command(compute_opcode, rows=tile_rows, columns=tile_columns, issue_count=issue_count, activation_zero_point=za, weight_zero_point=zb,)‘ to ‘command ‘ in host memory. Here command means the 128-bit instruction selecting an engine, shape, mode, and numeric parameters. The important operands are tensor_command: the 128-bit instruction selecting an engine, shape, mode, and numeric parameters; compute_opcode: the value named ’compute opcode’ in this block; rows: one output-row position processed by the tensor tile. Context: the function compute, which handles compute.

Line 447: `compute_opcode,` This is continuation line 2 of the 8-line logical statement that begins at source line 446. Its exact fragment is ‘compute_opcode,‘. The important operands are compute_opcode: the value named ’compute opcode’ in this block. Read together, the complete operation is: This assigns ‘tensor_command(compute_opcode, rows=tile_rows, columns=tile_columns, issue_count=issue_count, activation_zero_point=za, weight_zero_point=zb,)‘ to ‘command ‘ in host memory. Here command means the 128-bit instruction selecting an engine, shape, mode, and numeric parameters. The important operands are tensor_command: the 128-bit instruction selecting an engine, shape, mode, and numeric parameters; compute_opcode: the value named ’compute opcode’ in this block; rows: one output-row position processed by the tensor tile. Context: the function compute, which handles compute.

Line 448: `rows=tile_rows,` This is continuation line 3 of the 8-line logical statement that begins at source line 446. Its exact fragment is ‘rows=tile_rows,‘. The important operands are rows: one output-row position processed by the tensor tile; tile_rows: one output-row position processed by the tensor tile. Read together, the complete operation is: This assigns ‘tensor_command(compute_opcode, rows=tile_rows, columns=tile_columns, issue_count=issue_count, activation_zero_point=za, weight_zero_point=zb,)‘ to ‘command ‘ in host memory. Here command means the 128-bit instruction selecting an engine, shape, mode, and numeric parameters. The important operands are tensor_command: the 128-bit instruction selecting an engine, shape, mode, and numeric parameters; compute_opcode: the value named ’compute opcode’ in this block; rows: one output-row position processed by the tensor tile. Context: the function compute, which handles compute.

Line 449: `columns=tile_columns,` This is continuation line 4 of the 8-line logical statement that begins at source line 446. Its exact fragment is ‘columns=tile_columns,‘. The important operands are columns: one output-feature position processed in parallel; tile_columns: one output-feature position processed in parallel. Read together, the complete operation is: This assigns ‘tensor_command(compute_opcode, rows=tile_rows, columns=tile_columns, issue_count=issue_count, activation_zero_point=za, weight_zero_point=zb,)‘ to ‘command ‘ in host memory. Here command means the 128-bit instruction selecting an engine, shape, mode, and numeric parameters. The important operands are tensor_command: the 128-bit instruction selecting an engine, shape, mode, and numeric parameters; compute_opcode: the value named ’compute opcode’ in this block; rows: one output-row position processed by the tensor tile. Context: the function compute, which handles compute.

Line 450: `issue_count=issue_count,` This is continuation line 5 of the 8-line logical statement that begins at source line 446. Its exact fragment is ‘issue_count=issue_count,‘. The important operands are issue_count: an integer count retained for control or measurable telemetry. Read together, the complete operation is: This assigns ‘tensor_command(compute_opcode, rows=tile_rows, columns=tile_columns, issue_count=issue_count, activation_zero_point=za, weight_zero_po)‘ to ‘command ‘ in host memory. Here command means the 128-bit instruction selecting an engine, shape, mode, and numeric parameters. The important operands are tensor_command: the 128-bit instruction selecting an engine, shape, mode, and numeric parameters; compute_opcode: the value named ’compute opcode’ in this block; rows: one output-row position processed by the tensor tile. Context: the function compute, which handles compute.

Line 451: `activation_zero_point=za,` This is continuation line 6 of the 8-line logical statement that begins at source line 446. Its exact fragment is ‘activation_zero_point=za,‘. The important operands are activation_zero_point: an input feature value consumed by a neuron or multiply-accumulate operation; za: the value named ’za’ in this block. Read together, the complete operation is: This assigns ‘tensor_command(compute_opcode, rows=tile_rows,

columns=tile_columns, issue_count=issue_count, activation_zero_point=za, weight_zero_point=zb,)‘ to ‘command ‘ in host memory. Here command means the 128-bit instruction selecting an engine, shape, mode, and numeric parameters. The important operands are tensor_command: the 128-bit instruction selecting an engine, shape, mode, and numeric parameters; compute_opcode: the value named 'compute opcode' in this block; rows: one output-row position processed by the tensor tile. Context: the function compute, which handles compute.

Line 452: `weight_zero_point=zb,` This is continuation line 7 of the 8-line logical statement that begins at source line 446. Its exact fragment is ‘weight_zero_point=zb,‘. The important operands are weight_zero_point: a learned coefficient multiplied by an activation; zb: the value named 'zb' in this block. Read together, the complete operation is: This assigns ‘tensor_command(compute_opcode, rows=tile_rows, columns=tile_columns, issue_count=issue_count, activation_zero_point=za, weight_zero_point=zb,)‘ to ‘command ‘ in host memory. Here command means the 128-bit instruction selecting an engine, shape, mode, and numeric parameters. The important operands are tensor_command: the 128-bit instruction selecting an engine, shape, mode, and numeric parameters; compute_opcode: the value named 'compute opcode' in this block; rows: one output-row position processed by the tensor tile. Context: the function compute, which handles compute.

Line 453: `)` This is continuation line 8 of the 8-line logical statement that begins at source line 446. Its exact fragment is ‘)‘. The expression is a literal or structural operator and has no hidden software state. Read together, the complete operation is: This assigns ‘tensor_command(compute_opcode, rows=tile_rows, columns=tile_columns, issue_count=issue_count, activation_zero_point=za, weight_zero_point=zb,)‘ to ‘command ‘ in host memory. Here command means the 128-bit instruction selecting an engine, shape, mode, and numeric parameters. The important operands are tensor_command: the 128-bit instruction selecting an engine, shape, mode, and numeric parameters; compute_opcode: the value named 'compute opcode' in this block; rows: one output-row position processed by the tensor tile. Context: the function compute, which handles compute.

Line 454: `append_compute(` This statement continues through source line 457; the explanation uses the complete expression rather than only the first visual fragment. This calls ‘append_compute‘ with ‘ command, row_start, column_start, tile_rows, tile_columns, reduction_start, reduction_count, ‘ inside the function compute, which handles compute. The call advances the host-side job that tiles matrices and convolutions into validated accelerator commands and packed stream payloads.

Line 455: `command, row_start, column_start, tile_rows, tile_columns,` This is continuation line 2 of the 4-line logical statement that begins at source line 454. Its exact fragment is ‘command, row_start, column_start, tile_rows, tile_columns,‘. The important operands are command: the 128-bit instruction selecting an engine, shape, mode, and numeric parameters; row_start: one output-row position processed by the tensor tile; column_start: one output-feature position processed in parallel. Read together, the complete operation is: This calls ‘append_compute‘ with ‘ command, row_start, column_start, tile_rows, tile_columns, reduction_start, reduction_count, ‘ inside the function compute, which handles compute. The call advances the host-side job that tiles matrices and convolutions into validated accelerator commands and packed stream payloads.

Line 456: `reduction_start, reduction_count,` This is continuation line 3 of the 4-line logical statement that begins at source line 454. Its exact fragment is ‘reduction_start, reduction_count,‘. The important operands are reduction_start: the value named 'reduction start' in this block; reduction_count: an integer count retained for control or measurable telemetry. Read together, the complete operation is: This calls ‘append_compute‘ with ‘ command, row_start, column_start, tile_rows, tile_columns, reduction_start, reduction_count, ‘ inside the function compute, which handles compute. The call advances the host-side job that tiles matrices and convolutions into validated accelerator commands and packed stream payloads.

Line 457: `)` This is continuation line 4 of the 4-line logical statement that begins at source line 454. Its exact fragment is ‘)‘. The expression is a literal or structural operator and has no hidden software state. Read together, the complete operation is: This calls ‘append_compute‘ with ‘ command, row_start, column_start, tile_rows, tile_columns, reduction_start, reduction_count, ‘ inside the function compute, which handles compute. The call advances the host-side job that tiles matrices and convolutions into validated accelerator commands and packed stream payloads.

Line 459: `if selected == Dataflow.INPUT_BROADCAST:` This executes the following indented host-code branch only when ‘selected == Dataflow.INPUT_BROADCAST‘ is true. The important operands are selected: the value named

'selected' in this block; Dataflow: the value named 'dataflow' in this block; INPUT_BROADCAST: the value named 'input broadcast' in this block. Context: the function compile_u8_gemm, which handles compile u8 gemm.

Line 460: `for row_start in range(0, rows, ROW_TILE):` This iterates row_start over ‘range(0, rows, ROW_TILE)‘. Each iteration repeats the indented host operation, commonly once per layer, tile, timestep, or test case in the function compile_u8_gemm, which handles compile u8 gemm.

Line 461: `command, beats = activation_load(row_start)` This assigns ‘activation_load(row_start)‘ to ‘command, beats ‘ in host memory. Here command means the 128-bit instruction selecting an engine, shape, mode, and numeric parameters. The important operands are activation_load: an input feature value consumed by a neuron or multiply-accumulate operation; row_start: one output-row position processed by the tensor tile. Context: the function compile_u8_gemm, which handles compile u8 gemm.

Line 462: `append_load(command, beats, f"load activation tile at row {row_start}")` This calls ‘append_load‘ with ‘command, beats, f"load activation tile at row {row_start}"‘ inside the function compile_u8_gemm, which handles compile u8 gemm. The call advances the host-side job that tiles matrices and convolutions into validated accelerator commands and packed stream payloads.

Line 463: `for column_start in range(0, columns, COLUMN_TILE):` This iterates column_start over ‘range(0, columns, COLUMN_TILE)‘. Each iteration repeats the indented host operation, commonly once per layer, tile, timestep, or test case in the function compile_u8_gemm, which handles compile u8 gemm.

Line 464: `command, beats = weight_load(column_start)` This assigns ‘weight_load(column_start)‘ to ‘command, beats ‘ in host memory. Here command means the 128-bit instruction selecting an engine, shape, mode, and numeric parameters. The important operands are weight_load: a learned coefficient multiplied by an activation; column_start: one output-feature position processed in parallel. Context: the function compile_u8_gemm, which handles compile u8 gemm.

Line 465: `append_load(command, beats, f"load weight tile at column {column_start}")` This calls ‘append_load‘ with ‘command, beats, f"load weight tile at column {column_start}"‘ inside the function compile_u8_gemm, which handles compile u8 gemm. The call advances the host-side job that tiles matrices and convolutions into validated accelerator commands and packed stream payloads.

Line 466: `compute(row_start, column_start)` This calls ‘compute‘ with ‘row_start, column_start‘ inside the function compile_u8_gemm, which handles compile u8 gemm. The call advances the host-side job that tiles matrices and convolutions into validated accelerator commands and packed stream payloads.

Line 467: `else:` This begins the alternative host-code branch when the preceding condition was false, still inside the function compile_u8_gemm, which handles compile u8 gemm.

Line 468: `for column_start in range(0, columns, COLUMN_TILE):` This iterates column_start over ‘range(0, columns, COLUMN_TILE)‘. Each iteration repeats the indented host operation, commonly once per layer, tile, timestep, or test case in the function compile_u8_gemm, which handles compile u8 gemm.

Line 469: `command, beats = weight_load(column_start)` This assigns ‘weight_load(column_start)‘ to ‘command, beats ‘ in host memory. Here command means the 128-bit instruction selecting an engine, shape, mode, and numeric parameters. The important operands are weight_load: a learned coefficient multiplied by an activation; column_start: one output-feature position processed in parallel. Context: the function compile_u8_gemm, which handles compile u8 gemm.

Line 470: `append_load(command, beats, f"load weight tile at column {column_start}")` This calls ‘append_load‘ with ‘command, beats, f"load weight tile at column {column_start}"‘ inside the function compile_u8_gemm, which handles compile u8 gemm. The call advances the host-side job that tiles matrices and convolutions into validated accelerator commands and packed stream payloads.

Line 471: `for row_start in range(0, rows, ROW_TILE):` This iterates row_start over ‘range(0, rows, ROW_TILE)‘. Each iteration repeats the indented host operation, commonly once per layer, tile, timestep, or test case in the function compile_u8_gemm, which handles compile u8 gemm.

Line 472: `command, beats = activation_load(row_start)` This assigns ‘activation_load(row_start)‘ to ‘command, beats ‘ in host memory. Here command means the 128-bit instruction selecting an engine, shape, mode, and numeric parameters. The important operands are activation_load: an input feature value consumed by a neuron or multiply-accumulate operation; row_start: one output-row position processed by the tensor tile. Context: the function compile_u8_gemm, which handles compile u8 gemm.

Line 473: `append_load(command, beats, f"load activation tile at row {row_start}")` This calls ‘append_load‘ with ‘command, beats, f"load activation tile at row {row_start}"‘ inside the function compile_u8_gemm, which handles compile u8 gemm. The call advances the host-side job that tiles matrices and convolutions into validated accelerator commands and packed stream payloads.

Line 474: `compute(row_start, column_start)` This calls ‘compute‘ with ‘row_start, column_start‘ inside the function compile_u8_gemm, which handles compile u8 gemm. The call advances the host-side job that tiles matrices and convolutions into validated accelerator commands and packed stream payloads.

Line 476: `return CompiledGemm(` This statement continues through source line 479; the explanation uses the complete expression rather than only the first visual fragment. This returns ‘CompiledGemm((rows, reduction, columns), za, zb, tuple(instructions), tuple(bindings), bias_tuple, estimated_bytes, rows * reduction * columns,)‘ to the caller of the function compile_u8_gemm, which handles compile u8 gemm, ending this invocation. The important operands are CompiledGemm: the value named ’compiled gemm’ in this block; rows: one output-row position processed by the tensor tile; reduction: the value named ’reduction’ in this block.

Line 477: `(rows, reduction, columns), za, zb, tuple(instructions), tuple(bindings),` This is continuation line 2 of the 4-line logical statement that begins at source line 476. Its exact fragment is ‘(rows, reduction, columns), za, zb, tuple(instructions), tuple(bindings),‘. The important operands are rows: one output-row position processed by the tensor tile; reduction: the value named ’reduction’ in this block; columns: one output-feature position processed in parallel. Read together, the complete operation is: This returns ‘CompiledGemm((rows, reduction, columns), za, zb, tuple(instructions), tuple(bindings), bias_tuple, estimated_bytes, rows * reduction * columns,)‘ to the caller of the function compile_u8_gemm, which handles compile u8 gemm, ending this invocation. The important operands are CompiledGemm: the value named ’compiled gemm’ in this block; rows: one output-row position processed by the tensor tile; reduction: the value named ’reduction’ in this block.

Line 478: `bias_tuple, estimated_bytes, rows * reduction * columns,` This is continuation line 3 of the 4-line logical statement that begins at source line 476. Its exact fragment is ‘bias_tuple, estimated_bytes, rows * reduction * columns,‘. The important operands are bias_tuple: an additive learned offset applied after accumulation; estimated_bytes: the value named ’estimated bytes’ in this block; rows: one output-row position processed by the tensor tile. Read together, the complete operation is: This returns ‘CompiledGemm((rows, reduction, columns), za, zb, tuple(instructions), tuple(bindings), bias_tuple, estimated_bytes, rows * reduction * columns,)‘ to the caller of the function compile_u8_gemm, which handles compile u8 gemm, ending this invocation. The important operands are CompiledGemm: the value named ’compiled gemm’ in this block; rows: one output-row position processed by the tensor tile; reduction: the value named ’reduction’ in this block.

Line 479: `)` This is continuation line 4 of the 4-line logical statement that begins at source line 476. Its exact fragment is ‘)‘. The expression is a literal or structural operator and has no hidden software state. Read together, the complete operation is: This returns ‘CompiledGemm((rows, reduction, columns), za, zb, tuple(instructions), tuple(bindings), bias_tuple, estimated_bytes, rows * reduction * columns,)‘ to the caller of the function compile_u8_gemm, which handles compile u8 gemm, ending this invocation. The important operands are CompiledGemm: the value named ’compiled gemm’ in this block; rows: one output-row position processed by the tensor tile; reduction: the value named ’reduction’ in this block.

Line 482: `def compile_spike_gemm(` This starts function compile_spike_gemm. Its indented body performs compile spike gemm as part of the file that tiles matrices and convolutions into validated accelerator commands and packed stream payloads; it runs only when called.

Line 483: `spikes: np.ndarray | Sequence[Sequence[int]],` Inside the function compile_spike_gemm, which handles compile spike gemm, this statement advances the host implementation that tiles matrices and convolutions into validated accelerator commands and packed stream payloads. The important operands are spikes: a binary event produced when a neuron crosses its threshold; ndarray: the value named 'ndarray' in this block; Sequence: the value named 'sequence' in this block.

Line 484: `weights: np.ndarray | Sequence[Sequence[int]],` Inside the function compile_spike_gemm, which handles compile spike gemm, this statement advances the host implementation that tiles matrices and convolutions into validated accelerator commands and packed stream payloads. The important operands are weights: a learned coefficient multiplied by an activation; ndarray: the value named 'ndarray' in this block; Sequence: the value named 'sequence' in this block.

Line 485: `*,` Inside the function compile_spike_gemm, which handles compile spike gemm, this statement advances the host implementation that tiles matrices and convolutions into validated accelerator commands and packed stream payloads. The expression is a literal or structural operator and has no hidden software state.

Line 486: `ternary: bool = False,` This assigns 'False,' to 'ternary' in host memory. Here ternary means the value named 'ternary' in this block. The expression is a literal or structural operator and has no hidden software state. Context: the function compile_spike_gemm, which handles compile spike gemm.

Line 487: `bias: Sequence[int] | np.ndarray | None = None,` This assigns 'None,' to 'bias' in host memory. Here bias means an additive learned offset applied after accumulation. The important operands are None: the value named 'none' in this block. Context: the function compile_spike_gemm, which handles compile spike gemm.

Line 488: `dataflow: Dataflow | None = None,` This assigns 'None,' to 'dataflow' in host memory. Here dataflow means the value named 'dataflow' in this block. The important operands are None: the value named 'none' in this block. Context: the function compile_spike_gemm, which handles compile spike gemm.

Line 489: `) -> CompiledGemm:` Inside the function compile_spike_gemm, which handles compile spike gemm, this statement advances the host implementation that tiles matrices and convolutions into validated accelerator commands and packed stream payloads. The important operands are CompiledGemm: the value named 'compiled gemm' in this block.

Line 490: `"""Compile binary or ternary spikes times signed INT8 weights.` This is executable documentation attached to the function compile_spike_gemm, which handles compile spike gemm. It states the intended contract that tests and callers should enforce, but the text itself does not transform data or issue hardware work.

Line 492: `The RTL performs one signed addition for each non-zero spike/output-column` Inside the function compile_spike_gemm, which handles compile spike gemm, this statement advances the host implementation that tiles matrices and convolutions into validated accelerator commands and packed stream payloads. The important operands are The: the value named 'the' in this block; RTL: the value named 'rtl' in this block; performs: the value named 'performs' in this block.

Line 493: `pair and performs no multiplication. Ternary "-1" spikes select` Inside the function compile_spike_gemm which handles compile spike gemm, this statement advances the host implementation that tiles matrices and convolutions into validated accelerator commands and packed stream payloads. The important operands are pair: the value named 'pair' in this block; and: the value named 'and' in this block; performs: the value named 'performs' in this block.

Line 494: `subtraction.  Zero-spike K positions are compacted by the activation-load` Inside the function compile_spike_gemm, which handles compile spike gemm, this statement advances the host implementation that tiles matrices and convolutions into validated accelerator commands and packed stream payloads. The important operands are subtraction: the value named 'subtraction' in this block; Zero: the value named 'zero' in this block; spike: a binary event produced when a neuron crosses its threshold.

Line 495: `pipeline and do not reach the tensor tile.` Inside the function compile_spike_gemm, which handles compile spike gemm, this statement advances the host implementation that tiles matrices and convolutions into validated accelerator commands and packed stream payloads. The important operands are pipeline: the value named 'pipeline' in this block; and: the value named 'and' in this block; do: the value named 'do' in this block.

Line 496: `"""` This is executable documentation attached to the function compile_spike_gemm, which handles compile spike gemm. It states the intended contract that tests and callers should enforce, but the text itself does not transform data or issue hardware work.

Line 497: `spike_array = np.asarray(spikes)` This assigns ‘np.asarray(spikes)‘ to ‘spike_array ‘ in host memory. Here spike_array means a binary event produced when a neuron crosses its threshold. The important operands are asarray: the value named 'asarray' in this block; spikes: a binary event produced when a neuron crosses its threshold. Context: the function compile_spike_gemm, which handles compile spike gemm.

Line 498: `weight_array = np.asarray(weights)` This assigns ‘np.asarray(weights)‘ to ‘weight_array ‘ in host memory. Here weight_array means a learned coefficient multiplied by an activation. The important operands are asarray: the value named 'asarray' in this block; weights: a learned coefficient multiplied by an activation. Context: the function compile_spike_gemm, which handles compile spike gemm.

Line 499: `if spike_array.ndim != 2 or weight_array.ndim != 2:` This executes the following indented host-code branch only when ‘spike_array.ndim != 2 or weight_array.ndim != 2‘ is true. The important operands are spike_array: a binary event produced when a neuron crosses its threshold; ndim: the value named 'ndim' in this block; or: the value named 'or' in this block. Context: the function compile_spike_gemm, which handles compile spike gemm.

Line 500: `raise ValueError("spikes and weights must be two-dimensional matrices")` This rejects an invalid state by raising ‘ValueError("spikes and weights must be two-dimensional matrices")‘. Failing before DMA prevents malformed shapes or artifacts from silently becoming hardware results.

Line 501: `if spike_array.size == 0 or weight_array.size == 0:` This executes the following indented host-code branch only when ‘spike_array.size == 0 or weight_array.size == 0‘ is true. The important operands are spike_array: a binary event produced when a neuron crosses its threshold; size: the value named 'size' in this block; or: the value named 'or' in this block. Context: the function compile_spike_gemm, which handles compile spike gemm.

Line 502: `raise ValueError("spikes and weights must not be empty")` This rejects an invalid state by raising ‘ValueError("spikes and weights must not be empty")‘. Failing before DMA prevents malformed shapes or artifacts from silently becoming hardware results.

Line 503: `if not np.issubdtype(spike_array.dtype, np.integer) or not np.issubdtype(weight_array.dtype, np.integer):` This executes the following indented host-code branch only when ‘not np.issubdtype(spike_array.dtype, np.integer) or not np.issubdtype(weight_array.dtype, np.integer)‘ is true. The important operands are not: the value named 'not' in this block; issubdtype: the value named 'issubdtype' in this block; spike_array: a binary event produced when a neuron crosses its threshold. Context: the function compile_spike_gemm, which handles compile spike gemm.

Line 504: `raise ValueError("spikes and weights must contain integers")` This rejects an invalid state by raising ‘ValueError("spikes and weights must contain integers")‘. Failing before DMA prevents malformed shapes or artifacts from silently becoming hardware results.

Line 505: `spike_i64 = spike_array.astype(np.int64)` This assigns ‘spike_array.astype(np.int64)‘ to ‘spike_i64 ‘ in host memory. Here spike_i64 means a binary event produced when a neuron crosses its threshold. The important operands are spike_array: a binary event produced when a neuron crosses its threshold; astype: the value named ’astype’ in this block; int64: the value named ’int64’ in this block. Context: the function compile_spike_gemm, which handles compile spike gemm.

Line 506: `weight_i64 = weight_array.astype(np.int64)` This assigns ‘weight_array.astype(np.int64)‘ to ‘weight_i64 ‘ in host memory. Here weight_i64 means a learned coefficient multiplied by an activation. The important operands are weight_array: a learned coefficient multiplied by an activation; astype: the value named ’astype’ in this block; int64: the value named ’int64’ in this block. Context: the function compile_spike_gemm, which handles compile spike gemm.

Line 507: `allowed = np.isin(spike_i64, (-1, 0, 1) if ternary else (0, 1))` This assigns ‘np.isin(spike_i64, (-1, 0, 1) if ternary else (0, 1))‘ to ‘allowed ‘ in host memory. Here allowed means the value named ’allowed’ in this block. The important operands are isin: the value named ’isin’ in this block; spike_i64: a binary event produced when a neuron crosses its threshold; ternary: the value named ’ternary’ in this block. Context: the function compile_spike_gemm, which handles compile spike gemm.

Line 508: `if not np.all(allowed):` This executes the following indented host-code branch only when ‘not np.all(allowed)‘ is true. The important operands are not: the value named ’not’ in this block; all: the value named ’all’ in this block; allowed: the value named ’allowed’ in this block. Context: the function compile_spike_gemm, which handles compile spike gemm.

Line 509: `expected = "{-1,0,1}" if ternary else "{0,1}"` This assigns ‘"{-1,0,1}" if ternary else "{0,1}"‘ to ‘expected ‘ in host memory. Here expected means the value named ’expected’ in this block. The important operands are ternary: the value named ’ternary’ in this block. Context: the function compile_spike_gemm, which handles compile spike gemm.

Line 510: `raise ValueError(f"spikes must be in {expected}")` This rejects an invalid state by raising ‘ValueError(f"spikes must be in {expected}")‘. Failing before DMA prevents malformed shapes or artifacts from silently becoming hardware results.

Line 511: `if np.any(weight_i64 < -128) or np.any(weight_i64 > 127):` This executes the following indented host-code branch only when ‘np.any(weight_i64 < -128) or np.any(weight_i64 > 127)‘ is true. The important operands are any: the value named ’any’ in this block; weight_i64: a learned coefficient multiplied by an activation; or: the value named ’or’ in this block. Context: the function compile_spike_gemm, which handles compile spike gemm.

Line 512: `raise ValueError("sparse-mode weights must be signed INT8 values")` This rejects an invalid state by raising ‘ValueError("sparse-mode weights must be signed INT8 values")‘. Failing before DMA prevents malformed shapes or artifacts from silently becoming hardware results.

Line 514: `rows, reduction = spike_i64.shape` This assigns ‘spike_i64.shape‘ to ‘rows, reduction ‘ in host memory. Here rows means one output-row position processed by the tensor tile. The important operands are spike_i64: a binary event produced when a neuron crosses its threshold; shape: the value named ’shape’ in this block. Context: the function compile_spike_gemm, which handles compile spike gemm.

Line 515: `weight_reduction, columns = weight_i64.shape` This assigns ‘weight_i64.shape‘ to ‘weight_reduction, columns ‘ in host memory. Here weight_reduction means a learned coefficient multiplied by an activation. The important operands are weight_i64: a learned coefficient multiplied by an activation; shape: the value named ’shape’ in this block. Context: the function compile_spike_gemm, which handles compile spike gemm.

Line 516: `if reduction != weight_reduction:` This executes the following indented host-code branch only when ‘reduction != weight_reduction‘ is true. The important operands are reduction: the value named ’reduction’ in this block; weight_reduction: a learned coefficient multiplied by an activation. Context: the function compile_spike_gemm, which handles compile spike gemm.

Line 517: `raise ValueError("spike columns must equal weight rows")` This rejects an invalid state by raising ‘ValueError("spike columns must equal weight rows")‘. Failing before DMA prevents malformed shapes or artifacts from silently becoming hardware results.

Line 518: `bias_tuple: tuple[int, ...] | None = None` This assigns ‘None‘ to ‘bias_tuple‘ in host memory. Here bias_tuple means an additive learned offset applied after accumulation. The important operands are None: the value named ’none’ in this block. Context: the function compile_spike_gemm, which handles compile spike gemm.

Line 519: `if bias is not None:` This executes the following indented host-code branch only when ‘bias is not None‘ is true. The important operands are bias: an additive learned offset applied after accumulation; is: the value named ’is’ in this block; not: the value named ’not’ in this block. Context: the function compile_spike_gemm, which handles compile spike gemm.

Line 520: `bias_array = np.asarray(bias)` This assigns ‘np.asarray(bias)‘ to ‘bias_array ‘ in host memory. Here bias_array means an additive learned offset applied after accumulation. The important operands are asarray: the value named ’asarray’ in this block; bias: an additive learned offset applied after accumulation. Context: the function compile_spike_gemm, which handles compile spike gemm.

Line 521: `if bias_array.ndim != 1 or len(bias_array) != columns:` This executes the following indented host-code branch only when ‘bias_array.ndim != 1 or len(bias_array) != columns‘ is true. The important operands are bias_array: an additive learned offset applied after accumulation; ndim: the value named ’ndim’ in this block; or: the value named ’or’ in this block. Context: the function compile_spike_gemm, which handles compile spike gemm.

Line 522: `raise ValueError("bias must have one entry per output column")` This rejects an invalid state by raising ‘ValueError("bias must have one entry per output column")‘. Failing before DMA prevents malformed shapes or artifacts from silently becoming hardware results.

Line 523: `if not np.issubdtype(bias_array.dtype, np.integer):` This executes the following indented host-code branch only when ‘not np.issubdtype(bias_array.dtype, np.integer)‘ is true. The important operands are not: the value named ’not’ in this block; issubdtype: the value named ’issubdtype’ in this block; bias_array: an additive learned offset applied after accumulation. Context: the function compile_spike_gemm, which handles compile spike gemm.

Line 524: `raise ValueError("bias must contain integers")` This rejects an invalid state by raising ‘ValueError("bias must contain integers")‘. Failing before DMA prevents malformed shapes or artifacts from silently becoming hardware results.

Line 525: `bias_tuple = tuple(int(value) for value in bias_array)` This assigns ‘tuple(int(value) for value in bias_array)‘ to ‘bias_tuple ‘ in host memory. Here bias_tuple means an additive learned offset applied after accumulation. The important operands are tuple: the value named ’tuple’ in this block; value: the value named ’value’ in this block; for: the value named ’for’ in this block. Context: the function compile_spike_gemm, which handles compile spike gemm.

Line 527: `encoded_spikes = (spike_i64 & 0xFF).astype(np.uint8)` This assigns ‘(spike_i64 & 0xFF).astype(np.uint8)‘ to ‘encoded_spikes ‘ in host memory. Here encoded_spikes means a binary event produced when a neuron crosses its threshold. The important operands are spike_i64: a binary event produced when a neuron crosses its threshold; astype: the value named ’astype’ in this block; uint8: the value named ’uint8’ in this block. Context: the function compile_spike_gemm, which handles compile spike gemm.

Line 528: `encoded_weights = (weight_i64 & 0xFF).astype(np.uint8)` This assigns ‘(weight_i64 & 0xFF).astype(np.uint8)‘ to ‘encoded_weights ‘ in host memory. Here encoded_weights means a learned coefficient multiplied by an activation. The important operands are weight_i64: a learned coefficient multiplied by an activation; astype: the value named ’astype’ in this block; uint8: the value named ’uint8’ in this block. Context: the function compile_spike_gemm, which handles compile spike gemm.

Line 529: `instructions: list[TensorInstruction] = []` This assigns '[]' to 'instructions' in host memory. Here instructions means the value named 'instructions' in this block. The expression is a literal or structural operator and has no hidden software state. Context: the function compile_spike_gemm, which handles compile spike gemm.

Line 530: `bindings: list[ResultBinding] = []` This assigns '[]' to 'bindings' in host memory. Here bindings means the value named 'bindings' in this block. The expression is a literal or structural operator and has no hidden software state. Context: the function compile_spike_gemm, which handles compile spike gemm.

Line 531: `estimated_bytes = 0` This assigns '0' to 'estimated_bytes ' in host memory. Here estimated_bytes means the value named 'estimated bytes' in this block. The expression is a literal or structural operator and has no hidden software state. Context: the function compile_spike_gemm, which handles compile spike gemm.

Line 532: `compute_opcode = Opcode.COMPUTE_TERNARY if ternary else Opcode.COMPUTE_BINARY` This assigns 'Opcode.COMPUTE_TERNARY if ternary else Opcode.COMPUTE_BINARY' to 'compute_opcode ' in host memory. Here compute_opcode means the value named 'compute opcode' in this block. The important operands are Opcode: the value named 'opcode' in this block; COMPUTE_TERNARY: the value named 'compute ternary' in this block; ternary: the value named 'ternary' in this block. Context: the function compile_spike_gemm, which handles compile spike gemm.

Line 534: `def append_load(command: Command128, beats: Sequence[StreamBeat], description: str) -> None:` This starts function append_load. Its indented body performs append load as part of the file that tiles matrices and convolutions into validated accelerator commands and packed stream payloads; it runs only when called.

Line 535: `nonlocal estimated_bytes` Inside the function append_load, which handles append load, this statement advances the host implementation that tiles matrices and convolutions into validated accelerator commands and packed stream payloads. The important operands are nonlocal: the value named 'nonlocal' in this block; estimated_bytes: the value named 'estimated bytes' in this block.

Line 536: `instructions.append(TensorInstruction(command, beats, 0, description))` This calls 'instructions.append' with 'TensorInstruction(command, beats, 0, description)' inside the function append_load, which handles append load. The call advances the host-side job that tiles matrices and convolutions into validated accelerator commands and packed stream payloads.

Line 537: `estimated_bytes += 8 * len(beats)` Inside the function append_load, which handles append load, this statement advances the host implementation that tiles matrices and convolutions into validated accelerator commands and packed stream payloads. The important operands are estimated_bytes: the value named 'estimated bytes' in this block; len: the value named 'len' in this block; beats: the value named 'beats' in this block.

Line 539: `for reduction_start in range(0, reduction, MAX_REDUCTION):` This iterates reduction_start over 'range(0, reduction, MAX_REDUCTION)'. Each iteration repeats the indented host operation, commonly once per layer, tile, timestep, or test case in the function compile_spike_gemm, which handles compile spike gemm.

Line 540: `reduction_count = min(MAX_REDUCTION, reduction - reduction_start)` This assigns 'min(MAX_REDUCTION reduction - reduction_start)' to 'reduction_count ' in host memory. Here reduction_count means an integer count retained for control or measurable telemetry. The important operands are min: the value named 'min' in this block; MAX_REDUCTION: the value named 'max reduction' in this block; reduction: the value named 'reduction' in this block. Context: the function compile_spike_gemm, which handles compile spike gemm.

Line 541: `selected = dataflow or choose_dataflow(rows, columns, reduction_count).mode` This assigns 'dataflow or choose_dataflow(rows, columns, reduction_count).mode' to 'selected ' in host memory. Here selected means the value named 'selected' in this block. The important operands are dataflow: the value named 'dataflow' in this block; or: the value named 'or' in this block; choose_dataflow: the value named 'choose dataflow' in this block. Context: the function compile_spike_gemm, which handles compile spike gemm.

Line 542: `if selected not in {Dataflow.INPUT_BROADCAST, Dataflow.WEIGHT_BROADCAST}:` This executes the following indented host-code branch only when 'selected not in {Dataflow.INPUT_BROADCAST, Dataflow.WEIGHT_BROADCAS is true. The important operands are selected: the value named 'selected' in this block; not: the value named 'not' in this block; in: the value named 'in' in this block. Context: the function compile_spike_gemm, which handles compile spike gemm.

Line 543: `raise ValueError(f"unsupported dataflow {selected}")` This rejects an invalid state by raising 'ValueError(f"unsupported dataflow {selected}")'. Failing before DMA prevents malformed shapes or artifacts from silently becoming hardware results.

Line 545: `def load_activations(row_start: int) -> None:` This starts function load_activations. Its indented body performs load activations as part of the file that tiles matrices and convolutions into validated accelerator commands and packed stream payloads; it runs only when called.

Line 546: `tile_rows = min(ROW_TILE, rows - row_start)` This assigns 'min(ROW_TILE, rows - row_start)' to 'tile_rows ' in host memory. Here tile_rows means one output-row position processed by the tensor tile. The important operands are min: the value named 'min' in this block; ROW_TILE: one output-row position processed by the tensor tile; rows: one output-row position processed by the tensor tile. Context: the function load_activations, which handles load activations.

Line 547: `vectors = np.zeros((reduction_count, ROW_TILE), dtype=np.uint8)` This assigns 'np.zeros((reduction_count, ROW_TILE), dtype=np.uint8)' to 'vectors ' in host memory. Here vectors means the value named 'vectors' in this block. The important operands are zeros: the value named 'zeros' in this block; reduction_count: an integer count retained for control or measurable telemetry; ROW_TILE: one output-row position processed by the tensor tile. Context: the function load_activations, which handles load activations.

Line 548: `vectors[:, :tile_rows] = encoded_spikes[` This statement continues through source line 551; the explanation uses the complete expression rather than only the first visual fragment. This assigns 'encoded_spikes[row_start:row_start + tile_rows, reduction_start:reduction_start + reduction_count,].T' to 'vectors[' in host memory. Here vectors means the value named 'vectors' in this block. The important operands are encoded_spikes: a binary event produced when a neuron crosses its threshold; row_start: one output-row position processed by the tensor tile; tile_rows: one output-row position processed by the tensor tile. Context: the function load_activations, which handles load activations.

Line 549: `row_start:row_start + tile_rows,` This is continuation line 2 of the 4-line logical statement that begins at source line 548. Its exact fragment is 'row_start:row_start + tile_rows,'. The important operands are row_start: one output-row position processed by the tensor tile; tile_rows: one output-row position processed by the tensor tile. Read together, the complete operation is: This assigns 'encoded_spikes[row_start:row_start + tile_rows, reduction_start:reduction_start + reduction_count,].T' to 'vectors[' in host memory. Here vectors means the value named 'vectors' in this block. The important operands are encoded_spikes: a binary event produced when a neuron crosses its threshold; row_start: one output-row position processed by the tensor tile; tile_rows: one output-row position processed by the tensor tile. Context: the function load_activations, which handles load activations.

Line 550: `reduction_start:reduction_start + reduction_count,` This is continuation line 3 of the 4-line logical statement that begins at source line 548. Its exact fragment is 'reduction_start:reduction_start + reduction_count,'. The important operands are reduction_start: the value named 'reduction start' in this block; reduction_count: an integer count retained for control or measurable telemetry. Read together, the complete operation is: This assigns 'encoded_spikes[row_start:row_start + tile_rows, reduction_start:reduction_start + reduction_count,].T' to 'vectors[' in host memory. Here vectors means the value named 'vectors' in this block. The important operands are encoded_spikes: a binary event produced when a neuron crosses its threshold; row_start: one output-row position processed by the tensor tile; tile_rows: one output-row position processed by the tensor tile. Context: the function load_activations, which handles load activations.

Line 551: `].T` This is continuation line 4 of the 4-line logical statement that begins at source line 548. Its exact fragment is '].T'. The important operands are T: the value named 't' in this block. Read together, the complete operation is:

This assigns ‘encoded_spikes[row_start:row_start + tile_rows, reduction_start:reduction_start + reduction_count,].T‘ to ‘vectors[‘ in host memory. Here vectors means the value named ’vectors’ in this block. The important operands are encoded_spikes: a binary event produced when a neuron crosses its threshold; row_start: one output-row position processed by the tensor tile; tile_rows: one output-row position processed by the tensor tile. Context: the function load_activations, which handles load activations.

Line 552: `append_load(` This statement continues through source line 556; the explanation uses the complete expression rather than only the first visual fragment. This calls ‘append_load‘ with ‘ tensor_command(Opcode.LOAD_ACTIVATIONS, issue_count=reduction_count), _pack_compiler_u8_rows(vectors, 8), f"load {’ternary’ if ternary else ’binary’} spike tile at row {row_start}", ‘ inside the function load_activations, which handles load activations. The call advances the host-side job that tiles matrices and convolutions into validated accelerator commands and packed stream payloads.

Line 553: `tensor_command(Opcode.LOAD_ACTIVATIONS, issue_count=reduction_count),` This is continuation line 2 of the 5-line logical statement that begins at source line 552. Its exact fragment is ‘tensor_command(Opcode.LOAD_ACTIVATIO issue_count=reduction_count),‘. The important operands are tensor_command: the 128-bit instruction selecting an engine, shape, mode, and numeric parameters; Opcode: the value named ’opcode’ in this block; LOAD_ACTIVATIONS: an input feature value consumed by a neuron or multiply-accumulate operation. Read together, the complete operation is: This calls ‘append_load‘ with ‘ tensor_command(Opcode.LOAD_ACTIVATIONS, issue_count=reduction_count), _pack_compiler_u8_rows(vectors, 8), f"load {’ternary’ if ternary else ’binary’} spike tile at row {row_start}", ‘ inside the function load_activations, which handles load activations. The call advances the host-side job that tiles matrices and convolutions into validated accelerator commands and packed stream payloads.

Line 554: `_pack_compiler_u8_rows(vectors, 8),` This is continuation line 3 of the 5-line logical statement that begins at source line 552. Its exact fragment is ‘_pack_compiler_u8_rows(vectors, 8),‘. The important operands are _pack_compiler_u8_rows: one output-row position processed by the tensor tile; vectors: the value named ’vectors’ in this block. Read together, the complete operation is: This calls ‘append_load‘ with ‘ tensor_command(Opcode.LOAD_ACTIVATIONS, issue_count=reduction_count), _pack_compiler_u8_rows(vectors, 8), f"load {’ternary’ if ternary else ’binary’} spike tile at row {row_start}", ‘ inside the function load_activations, which handles load activations. The call advances the host-side job that tiles matrices and convolutions into validated accelerator commands and packed stream payloads.

Line 555: `f"load {’ternary’ if ternary else ’binary’} spike tile at row {row_start}",` This is continuation line 4 of the 5-line logical statement that begins at source line 552. Its exact fragment is ‘f"load {’ternary’ if ternary else ’binary’} spike tile at row {row_start}",‘. The important operands are f: the value named ’f’ in this block; load: the value named ’load’ in this block; ternary: the value named ’ternary’ in this block. Read together, the complete operation is: This calls ‘append_load‘ with ‘ tensor_command(Opcode.LOAD_ACTIVATIONS, issue_count=reduction_count), _pack_compiler_u8_rows(vectors, 8), f"load {’ternary’ if ternary else ’binary’} spike tile at row {row_start}", ‘ inside the function load_activations, which handles load activations. The call advances the host-side job that tiles matrices and convolutions into validated accelerator commands and packed stream payloads.

Line 556: `)` This is continuation line 5 of the 5-line logical statement that begins at source line 552. Its exact fragment is ‘)‘. The expression is a literal or structural operator and has no hidden software state. Read together, the complete operation is: This calls ‘append_load‘ with ‘ tensor_command(Opcode.LOAD_ACTIVATIONS, issue_count=reduction_count), _pack_compiler_u8_rows(vectors, 8), f"load {’ternary’ if ternary else ’binary’} spike tile at row {row_start}", ‘ inside the function load_activations, which handles load activations. The call advances the host-side job that tiles matrices and convolutions into validated accelerator commands and packed stream payloads.

Line 558: `def load_weights(column_start: int) -> None:` This starts function load_weights. Its indented body performs load weights as part of the file that tiles matrices and convolutions into validated accelerator commands and packed stream payloads; it runs only when called.

Line 559: `tile_columns = min(COLUMN_TILE, columns - column_start)` This assigns ‘min(COLUMN_TILE, columns - column_start)‘ to ‘tile_columns ‘ in host memory. Here tile_columns means one output-feature position processed in parallel. The important operands are min: the value named ’min’ in this block; COLUMN_TILE: one output-feature position processed in parallel; columns: one output-feature position processed in parallel. Context: the function load_weights, which handles load weights.

Line 560: `matrix = np.zeros((reduction_count, COLUMN_TILE), dtype=np.uint8)` This assigns ‘np.zeros((reduction_coun COLUMN_TILE), dtype=np.uint8)‘ to ‘matrix ‘ in host memory. Here matrix means the value named ’matrix’ in this block. The important operands are zeros: the value named ’zeros’ in this block; reduction_count: an integer count retained for control or measurable telemetry; COLUMN_TILE: one output-feature position processed in parallel. Context: the function load_weights, which handles load weights.

Line 561: `matrix[:, :tile_columns] = encoded_weights[` This statement continues through source line 564; the explanation uses the complete expression rather than only the first visual fragment. This assigns ‘encoded_weights[reduction_start:reduction_start + reduction_count, column_start:column_start + tile_columns,]‘ to ‘matrix[‘ in host memory. Here matrix means the value named ’matrix’ in this block. The important operands are encoded_weights: a learned coefficient multiplied by an activation; reduction_start: the value named ’reduction start’ in this block; reduction_count: an integer count retained for control or measurable telemetry. Context: the function load_weights, which handles load weights.

Line 562: `reduction_start:reduction_start + reduction_count,` This is continuation line 2 of the 4-line logical statement that begins at source line 561. Its exact fragment is ‘reduction_start:reduction_start + reduction_count,‘. The important operands are reduction_start: the value named ’reduction start’ in this block; reduction_count: an integer count retained for control or measurable telemetry. Read together, the complete operation is: This assigns ‘encoded_weights[reduction_start:reduction_start + reduction_count, column_start:column_start + tile_columns,]‘ to ‘matrix[‘ in host memory. Here matrix means the value named ’matrix’ in this block. The important operands are encoded_weights: a learned coefficient multiplied by an activation; reduction_start: the value named ’reduction start’ in this block; reduction_count: an integer count retained for control or measurable telemetry. Context: the function load_weights, which handles load weights.

Line 563: `column_start:column_start + tile_columns,` This is continuation line 3 of the 4-line logical statement that begins at source line 561. Its exact fragment is ‘column_start:column_start + tile_columns,‘. The important operands are column_start: one output-feature position processed in parallel; tile_columns: one output-feature position processed in parallel. Read together, the complete operation is: This assigns ‘encoded_weights[reduction_start:reduction_start + reduction_count, column_start:column_start + tile_columns,]‘ to ‘matrix[‘ in host memory. Here matrix means the value named ’matrix’ in this block. The important operands are encoded_weights: a learned coefficient multiplied by an activation; reduction_start: the value named ’reduction start’ in this block; reduction_count: an integer count retained for control or measurable telemetry. Context: the function load_weights, which handles load weights.

Line 564: `]` This is continuation line 4 of the 4-line logical statement that begins at source line 561. Its exact fragment is ‘]‘. The expression is a literal or structural operator and has no hidden software state. Read together, the complete operation is: This assigns ‘encoded_weights[reduction_start:reduction_start + reduction_count, column_start:column_start + tile_columns,]‘ to ‘matrix[‘ in host memory. Here matrix means the value named ’matrix’ in this block. The important operands are encoded_weights: a learned coefficient multiplied by an activation; reduction_start: the value named ’reduction start’ in this block; reduction_count: an integer count retained for control or measurable telemetry. Context: the function load_weights, which handles load weights.

Line 565: `append_load(` This statement continues through source line 569; the explanation uses the complete expression rather than only the first visual fragment. This calls ‘append_load‘ with ‘ tensor_command(Opcode.LOAD_WEIGHTS_OUTE issue_count=reduction_count), _pack_compiler_u8_rows(matrix, 16), f"load signed weight tile at column {column_start}", ‘ inside the function load_weights, which handles load weights. The call advances the host-side job that tiles matrices and convolutions into validated accelerator commands and packed stream payloads.

Line 566: `tensor_command(Opcode.LOAD_WEIGHTS_OUTER, issue_count=reduction_count),` This is continuation line 2 of the 5-line logical statement that begins at source line 565. Its exact fragment is ‘tensor_command(Opcode.LOAD_WEIGHT issue_count=reduction_count),‘. The important operands are tensor_command: the 128-bit instruction selecting an engine, shape, mode, and numeric parameters; Opcode: the value named ’opcode’ in this block; LOAD_WEIGHTS_OUTER: a learned coefficient multiplied by an activation. Read together, the complete operation is: This calls ‘append_load‘ with ‘ tensor_command(Opcode.LOAD_WEIGHTS_OUTER, issue_count=reduction_count), _pack_compiler_u8_rows(matrix, 16), f"load signed weight tile at column {column_start}", ‘ inside the function load_weights, which handles load weights.

The call advances the host-side job that tiles matrices and convolutions into validated accelerator commands and packed stream payloads.

Line 567: `_pack_compiler_u8_rows(matrix, 16),` This is continuation line 3 of the 5-line logical statement that begins at source line 565. Its exact fragment is '_pack_compiler_u8_rows(matrix, 16),'. The important operands are _pack_compiler_u8_rows: one output-row position processed by the tensor tile; matrix: the value named 'matrix' in this block. Read together, the complete operation is: This calls 'append_load' with ' tensor_command(Opcode.LOAD_WEIGHTS_OU issue_count=reduction_count), _pack_compiler_u8_rows(matrix, 16), f"load signed weight tile at column {column_start}", ' inside the function load_weights, which handles load weights. The call advances the host-side job that tiles matrices and convolutions into validated accelerator commands and packed stream payloads.

Line 568: `f"load signed weight tile at column {column_start}",` This is continuation line 4 of the 5-line logical statement that begins at source line 565. Its exact fragment is 'f"load signed weight tile at column {column_start}",'. The important operands are f: the value named 'f' in this block; load: the value named 'load' in this block; weight: a learned coefficient multiplied by an activation. Read together, the complete operation is: This calls 'append_load' with ' tensor_command(Opcode.LOAD_WEIGHTS_OUTER, issue_count=reduction_count), _pack_compiler_u8_rows(matrix, 16), f"load signed weight tile at column {column_start}", ' inside the function load_weights, which handles load weights. The call advances the host-side job that tiles matrices and convolutions into validated accelerator commands and packed stream payloads.

Line 569: `)` This is continuation line 5 of the 5-line logical statement that begins at source line 565. Its exact fragment is ')'. The expression is a literal or structural operator and has no hidden software state. Read together, the complete operation is: This calls 'append_load' with ' tensor_command(Opcode.LOAD_WEIGHTS_OUTER, issue_count=reduction_count), _pack_compiler_u8_rows(matrix, 16), f"load signed weight tile at column {column_start}", ' inside the function load_weights, which handles load weights. The call advances the host-side job that tiles matrices and convolutions into validated accelerator commands and packed stream payloads.

Line 571: `def append_compute(row_start: int, column_start: int) -> None:` This starts function append_compute. Its indented body performs append compute as part of the file that tiles matrices and convolutions into validated accelerator commands and packed stream payloads; it runs only when called.

Line 572: `tile_rows = min(ROW_TILE, rows - row_start)` This assigns 'min(ROW_TILE, rows - row_start)' to 'tile_rows ' in host memory. Here tile_rows means one output-row position processed by the tensor tile. The important operands are min: the value named 'min' in this block; ROW_TILE: one output-row position processed by the tensor tile; rows: one output-row position processed by the tensor tile. Context: the function append_compute, which handles append compute.

Line 573: `tile_columns = min(COLUMN_TILE, columns - column_start)` This assigns 'min(COLUMN_TILE, columns - column_start)' to 'tile_columns ' in host memory. Here tile_columns means one output-feature position processed in parallel. The important operands are min: the value named 'min' in this block; COLUMN_TILE: one output-feature position processed in parallel; columns: one output-feature position processed in parallel. Context: the function append_compute, which handles append compute.

Line 574: `instruction_index = len(instructions)` This assigns 'len(instructions)' to 'instruction_index ' in host memory. Here instruction_index means an integer selecting one tensor element, lane, bank, or state entry. The important operands are len: the value named 'len' in this block; instructions: the value named 'instructions' in this block. Context: the function append_compute, which handles append compute.

Line 575: `instructions.append(TensorInstruction(` This statement continues through source line 585; the explanation uses the complete expression rather than only the first visual fragment. This calls 'instructions.append' with 'TensorInstruction(tensor_command(compute_opcode, rows=tile_rows, columns=tile_columns, issue_count=reduction_count,), (), tile_rows * tile_columns, f"compute sparse C tile at ({row_start},{column_start})",)' inside the function append_compute, which handles append compute. The call advances the host-side job that tiles matrices and convolutions into validated accelerator commands and packed stream payloads.

Line 576: `tensor_command(` This is continuation line 2 of the 11-line logical statement that begins at source line 575. Its exact fragment is ‘tensor_command(‘. The important operands are tensor_command: the 128-bit instruction selecting an engine, shape, mode, and numeric parameters. Read together, the complete operation is: This calls ‘instructions.append‘ with ‘TensorInstruction(tensor_command(compute_opcode, rows=tile_rows, columns=tile_columns, issue_count=reduction_count,), (), tile_rows * tile_columns, f"compute sparse C tile at ({row_start},{column_start})",)‘ inside the function append_compute, which handles append compute. The call advances the host-side job that tiles matrices and convolutions into validated accelerator commands and packed stream payloads.

Line 577: `compute_opcode,` This is continuation line 3 of the 11-line logical statement that begins at source line 575. Its exact fragment is ‘compute_opcode,‘. compute. The call advances the host-side job that tiles matrices and convolutions into validated accelerator commands and packed stream payloads.

Line 583: `tile_rows * tile_columns,` This is continuation line 9 of the 11-line logical statement that begins at source line 575. Its exact fragment is ‘tile_rows * tile_columns,‘. The important operands are tile_rows: one output-row position processed by the tensor tile; tile_columns: one output-feature position processed in parallel. Read together, the complete operation is: This calls ‘instructions.append‘ with ‘TensorInstruction(tensor_command(compute_opcode, rows=tile_rows, columns=tile_columns, issue_count=reduction_count,), (), tile_rows * tile_columns, f"compute sparse C tile at ({row_start},{column_start})",)‘ inside the function append_compute, which handles append compute. The call advances the host-side job that tiles matrices and convolutions into validated accelerator commands and packed stream payloads.

Line 584: `f"compute sparse C tile at ({row_start},{column_start})",` This is continuation line 10 of the 11-line logical statement that begins at source line 575. Its exact fragment is ‘f"compute sparse C tile at ({row_start},{column_start})",‘. The important operands are f: the value named ’f’ in this block; compute: the value named ’compute’ in this block; sparse: the value named ’sparse’ in this block. Read together, the complete operation is: This calls ‘instructions.append‘ with ‘TensorInstruction(tensor_command(compute_opcode, rows=tile_rows, columns=tile_columns, issue_count=reduction_count,), (), tile_rows * tile_columns, f"compute sparse C tile at ({row_start},{column_start})",)‘ inside the function append_compute, which handles append compute. The call advances the host-side job that tiles matrices and convolutions into validated accelerator commands and packed stream payloads.

Line 585: `))` This is continuation line 11 of the 11-line logical statement that begins at source line 575. Its exact fragment is ‘))‘. The expression is a literal or structural operator and has no hidden software state. Read together, the complete operation is: This calls ‘instructions.append‘ with ‘TensorInstruction(tensor_command(compute_opcode, rows=tile_rows, columns=tile_columns, issue_count=reduction_count,), (), tile_rows * tile_columns, f"compute sparse C tile at ({row_start},{column_start})",)‘ inside the function append_compute, which handles append compute. The call advances the host-side job that tiles matrices and convolutions into validated accelerator commands and packed stream payloads.

Line 586: `bindings.append(ResultBinding(` This statement continues through source line 589; the explanation uses the complete expression rather than only the first visual fragment. This calls ‘bindings.append‘ with ‘ResultBinding(instruction_index, row_start, column_start, tile_rows, tile_columns, reduction_start, reduction_count,)‘ inside the function append_compute, which handles append compute. The call advances the host-side job that tiles matrices and convolutions into validated accelerator commands and packed stream payloads.

Line 587: `instruction_index, row_start, column_start, tile_rows, tile_columns,` This is continuation line 2 of the 4-line logical statement that begins at source line 586. Its exact fragment is ‘instruction_index, row_start, column_start, tile_rows, tile_columns,‘. The important operands are instruction_index: an integer selecting one tensor element, lane, bank, or state entry; row_start: one output-row position processed by the tensor tile; column_start: one output-feature position processed in parallel. Read together, the complete operation is: This calls ‘bindings.append‘ with ‘ResultBinding(instruction_index, row_start, column_start, tile_rows, tile_columns, reduction_start, reduction_count,)‘ inside the function append_compute, which handles append compute. The call advances the host-side job that tiles matrices and convolutions into validated accelerator commands and packed stream payloads.

Line 588: `reduction_start, reduction_count,` This is continuation line 3 of the 4-line logical statement that begins at source line 586. Its exact fragment is ‘reduction_start, reduction_count,‘. The important operands are reduction_start: the value named ’reduction start’ in this block; reduction_count: an integer count retained for control or measurable telemetry. Read together, the complete operation is: This calls ‘bindings.append‘ with ‘ResultBinding(instruction_index, row_start, column_start, tile_rows, tile_columns, reduction_start, reduction_count,)‘ inside the function append_compute, which handles append compute. The call advances the host-side job that tiles matrices and convolutions into validated accelerator commands and packed stream payloads.

Line 589: `))` This is continuation line 4 of the 4-line logical statement that begins at source line 586. Its exact fragment is ‘))‘. The expression is a literal or structural operator and has no hidden software state. Read together, the complete operation is: This calls ‘bindings.append‘ with ‘ResultBinding(instruction_index, row_start, column_start, tile_rows, tile_columns, reduction_start, reduction_count,)‘ inside the function append_compute, which handles append compute.

The call advances the host-side job that tiles matrices and convolutions into validated accelerator commands and packed stream payloads.

Line 591: `if selected == Dataflow.INPUT_BROADCAST:` This executes the following indented host-code branch only when 'selected == Dataflow.INPUT_BROADCAST' is true. The important operands are selected: the value named 'selected' in this block; Dataflow: the value named 'dataflow' in this block; INPUT_BROADCAST: the value named 'input broadcast' in this block. Context: the function compile_spike_gemm, which handles compile spike gemm.

Line 592: `for row_start in range(0, rows, ROW_TILE):` This iterates row_start over 'range(0, rows, ROW_TILE)'. Each iteration repeats the indented host operation, commonly once per layer, tile, timestep, or test case in the function compile_spike_gemm, which handles compile spike gemm.

Line 593: `load_activations(row_start)` This calls 'load_activations' with 'row_start' inside the function compile_spike_gemm, which handles compile spike gemm. The call advances the host-side job that tiles matrices and convolutions into validated accelerator commands and packed stream payloads.

Line 594: `for column_start in range(0, columns, COLUMN_TILE):` This iterates column_start over 'range(0, columns, COLUMN_TILE)'. Each iteration repeats the indented host operation, commonly once per layer, tile, timestep, or test case in the function compile_spike_gemm, which handles compile spike gemm.

Line 595: `load_weights(column_start)` This calls 'load_weights' with 'column_start' inside the function compile_spike_gemm, which handles compile spike gemm. The call advances the host-side job that tiles matrices and convolutions into validated accelerator commands and packed stream payloads.

Line 596: `append_compute(row_start, column_start)` This calls 'append_compute' with 'row_start, column_start' inside the function compile_spike_gemm, which handles compile spike gemm. The call advances the host-side job that tiles matrices and convolutions into validated accelerator commands and packed stream payloads.

Line 597: `else:` This begins the alternative host-code branch when the preceding condition was false, still inside the function compile_spike_gemm, which handles compile spike gemm.

Line 598: `for column_start in range(0, columns, COLUMN_TILE):` This iterates column_start over 'range(0, columns, COLUMN_TILE)'. Each iteration repeats the indented host operation, commonly once per layer, tile, timestep, or test case in the function compile_spike_gemm, which handles compile spike gemm.

Line 599: `load_weights(column_start)` This calls 'load_weights' with 'column_start' inside the function compile_spike_gemm, which handles compile spike gemm. The call advances the host-side job that tiles matrices and convolutions into validated accelerator commands and packed stream payloads.

Line 600: `for row_start in range(0, rows, ROW_TILE):` This iterates row_start over 'range(0, rows, ROW_TILE)'. Each iteration repeats the indented host operation, commonly once per layer, tile, timestep, or test case in the function compile_spike_gemm, which handles compile spike gemm.

Line 601: `load_activations(row_start)` This calls 'load_activations' with 'row_start' inside the function compile_spike_gemm, which handles compile spike gemm. The call advances the host-side job that tiles matrices and convolutions into validated accelerator commands and packed stream payloads.

Line 602: `append_compute(row_start, column_start)` This calls 'append_compute' with 'row_start, column_start' inside the function compile_spike_gemm, which handles compile spike gemm. The call advances the host-side job that tiles matrices and convolutions into validated accelerator commands and packed stream payloads.

Line 604: `spike_adds = int(np.count_nonzero(spike_i64)) * columns` This assigns ‘int(np.count_nonzero(spike_i64)) * columns‘ to ‘spike_adds ‘ in host memory. Here spike_adds means a binary event produced when a neuron crosses its threshold. The important operands are count_nonzero: the value named ’count nonzero’ in this block; spike_i64: a binary event produced when a neuron crosses its threshold; columns: one output-feature position processed in parallel. Context: the function compile_spike_gemm, which handles compile spike gemm.

Line 605: `return CompiledGemm(` This statement continues through source line 608; the explanation uses the complete expression rather than only the first visual fragment. This returns ‘CompiledGemm((rows, reduction, columns), 0, 0, tuple(instructions), tuple(bindings), bias_tuple, estimated_bytes, rows * reduction * columns, spike_adds,)‘ to the caller of the function compile_spike_gemm, which handles compile spike gemm, ending this invocation. The important operands are CompiledGemm: the value named ’compiled gemm’ in this block; rows: one output-row position processed by the tensor tile; reduction: the value named ’reduction’ in this block.

Line 606: `(rows, reduction, columns), 0, 0, tuple(instructions), tuple(bindings),` This is continuation line 2 of the 4-line logical statement that begins at source line 605. Its exact fragment is ‘(rows, reduction, columns), 0, 0, tuple(instructions), tuple(bindings),‘. The important operands are rows: one output-row position processed by the tensor tile; reduction: the value named ’reduction’ in this block; columns: one output-feature position processed in parallel. Read together, the complete operation is: This returns ‘CompiledGemm((rows, reduction, columns), 0, 0, tuple(instructions), tuple(bindings), bias_tuple, estimated_bytes, rows * reduction * columns, spike_adds,)‘ to the caller of the function compile_spike_gemm, which handles compile spike gemm, ending this invocation. The important operands are CompiledGemm: the value named ’compiled gemm’ in this block; rows: one output-row position processed by the tensor tile; reduction: the value named ’reduction’ in this block.

Line 607: `bias_tuple, estimated_bytes, rows * reduction * columns, spike_adds,` This is continuation line 3 of the 4-line logical statement that begins at source line 605. Its exact fragment is ‘bias_tuple, estimated_bytes, rows * reduction * columns, spike_adds,‘. The important operands are bias_tuple: an additive learned offset applied after accumulation; estimated_bytes: the value named ’estimated bytes’ in this block; rows: one output-row position processed by the tensor tile. Read together, the complete operation is: This returns ‘CompiledGemm((rows, reduction, columns), 0, 0, tuple(instructions), tuple(bindings), bias_tuple, estimated_bytes, rows * reduction * columns, spike_adds,)‘ to the caller of the function compile_spike_gemm, which handles compile spike gemm, ending this invocation. The important operands are CompiledGemm: the value named ’compiled gemm’ in this block; rows: one output-row position processed by the tensor tile; reduction: the value named ’reduction’ in this block.

Line 608: `)` This is continuation line 4 of the 4-line logical statement that begins at source line 605. Its exact fragment is ‘)‘. The expression is a literal or structural operator and has no hidden software state. Read together, the complete operation is: This returns ‘CompiledGemm((rows, reduction, columns), 0, 0, tuple(instructions), tuple(bindings), bias_tuple, estimated_bytes, rows * reduction * columns, spike_adds,)‘ to the caller of the function compile_spike_gemm, which handles compile spike gemm, ending this invocation. The important operands are CompiledGemm: the value named ’compiled gemm’ in this block; rows: one output-row position processed by the tensor tile; reduction: the value named ’reduction’ in this block.

Line 611: `def compile_u8_conv2d(` This starts function compile_u8_conv2d. Its indented body performs compile u8 conv2d as part of the file that tiles matrices and convolutions into validated accelerator commands and packed stream payloads; it runs only when called.

Line 612: `activations: np.ndarray | Sequence,` Inside the function compile_u8_conv2d, which handles compile u8 conv2d, this statement advances the host implementation that tiles matrices and convolutions into validated accelerator commands and packed stream payloads. The important operands are activations: an input feature value consumed by a neuron or multiply-accumulate operation; ndarray: the value named ’ndarray’ in this block; Sequence: the value named ’sequence’ in this block.

Line 613: `weights: np.ndarray | Sequence,` Inside the function compile_u8_conv2d, which handles compile u8 conv2d, this statement advances the host implementation that tiles matrices and convolutions into validated accelerator commands and packed stream payloads. The important operands are weights: a learned coefficient multiplied by an activation; ndarray: the value named ’ndarray’ in this block; Sequence: the value named ’sequence’ in this block.

Line 614: `*,` Inside the function compile_u8_conv2d, which handles compile u8 conv2d, this statement advances the host implementation that tiles matrices and convolutions into validated accelerator commands and packed stream payloads. The expression is a literal or structural operator and has no hidden software state.

Line 615: `activation_zero_point: int = 0,` This assigns ‘0,‘ to ‘activation_zero_point‘ in host memory. Here activation_zero_point means an input feature value consumed by a neuron or multiply-accumulate operation. The expression is a literal or structural operator and has no hidden software state. Context: the function compile_u8_conv2d, which handles compile u8 conv2d.

Line 616: `weight_zero_point: int = 0,` This assigns ‘0,‘ to ‘weight_zero_point‘ in host memory. Here weight_zero_point means a learned coefficient multiplied by an activation. The expression is a literal or structural operator and has no hidden software state. Context: the function compile_u8_conv2d, which handles compile u8 conv2d.

Line 617: `bias: Sequence[int] | np.ndarray | None = None,` This assigns ‘None,‘ to ‘bias‘ in host memory. Here bias means an additive learned offset applied after accumulation. The important operands are None: the value named 'none' in this block. Context: the function compile_u8_conv2d, which handles compile u8 conv2d.

Line 618: `stride: int | Sequence[int] = 1,` This assigns ‘1,‘ to ‘stride‘ in host memory. Here stride means the value named 'stride' in this block. The expression is a literal or structural operator and has no hidden software state. Context: the function compile_u8_conv2d, which handles compile u8 conv2d.

Line 619: `padding: int | Sequence[int] = 0,` This assigns ‘0,‘ to ‘padding‘ in host memory. Here padding means the value named 'padding' in this block. The expression is a literal or structural operator and has no hidden software state. Context: the function compile_u8_conv2d, which handles compile u8 conv2d.

Line 620: `dilation: int | Sequence[int] = 1,` This assigns ‘1,‘ to ‘dilation‘ in host memory. Here dilation means the value named 'dilation' in this block. The expression is a literal or structural operator and has no hidden software state. Context: the function compile_u8_conv2d, which handles compile u8 conv2d.

Line 621: `groups: int = 1,` This assigns ‘1,‘ to ‘groups‘ in host memory. Here groups means the value named 'groups' in this block. The expression is a literal or structural operator and has no hidden software state. Context: the function compile_u8_conv2d, which handles compile u8 conv2d.

Line 622: `dataflow: Dataflow | None = None,` This assigns ‘None,‘ to ‘dataflow‘ in host memory. Here dataflow means the value named 'dataflow' in this block. The important operands are None: the value named 'none' in this block. Context: the function compile_u8_conv2d, which handles compile u8 conv2d.

Line 623: `) -> CompiledConv2d:` Inside the function compile_u8_conv2d, which handles compile u8 conv2d, this statement advances the host implementation that tiles matrices and convolutions into validated accelerator commands and packed stream payloads. The important operands are CompiledConv2d: the value named 'compiled conv2d' in this block.

Line 624: `"""Lower an NCHW/OIHW asymmetric-uint8 convolution to tensor commands."""` This is executable documentation attached to the function compile_u8_conv2d, which handles compile u8 conv2d. It states the intended contract that tests and callers should enforce, but the text itself does not transform data or issue hardware work.

Line 625: `a = np.asarray(activations)` This assigns ‘np.asarray(activations)‘ to ‘a ‘ in host memory. Here a means the value named 'a' in this block. The important operands are asarray: the value named 'asarray' in this block; activations: an input feature value consumed by a neuron or multiply-accumulate operation. Context: the function compile_u8_conv2d, which handles compile u8 conv2d.

Line 626: `w = np.asarray(weights)` This assigns ‘np.asarray(weights)‘ to ‘w ‘ in host memory. Here w means the value named ’w’ in this block. The important operands are asarray: the value named ’asarray’ in this block; weights: a learned coefficient multiplied by an activation. Context: the function compile_u8_conv2d, which handles compile u8 conv2d.

Line 627: `if a.ndim != 4 or w.ndim != 4:` This executes the following indented host-code branch only when ‘a.ndim != 4 or w.ndim != 4‘ is true. The important operands are a: the value named ’a’ in this block; ndim: the value named ’ndim’ in this block; or: the value named ’or’ in this block. Context: the function compile_u8_conv2d, which handles compile u8 conv2d.

Line 628: `raise ValueError("convolution activations and weights must be NCHW and OIHW tensors")` This rejects an invalid state by raising ‘ValueError("convolution activations and weights must be NCHW and OIHW tensors")‘. Failing before DMA prevents malformed shapes or artifacts from silently becoming hardware results.

Line 629: `if not np.issubdtype(a.dtype, np.integer) or not np.issubdtype(w.dtype, np.integer):` This executes the following indented host-code branch only when ‘not np.issubdtype(a.dtype, np.integer) or not np.issubdtype(w.dtype, np.integer)‘ is true. The important operands are not: the value named ’not’ in this block; issubdtype: the value named ’issubdtype’ in this block; a: the value named ’a’ in this block. Context: the function compile_u8_conv2d, which handles compile u8 conv2d.

Line 630: `raise ValueError("convolution activations and weights must contain integers")` This rejects an invalid state by raising ‘ValueError("convolution activations and weights must contain integers")‘. Failing before DMA prevents malformed shapes or artifacts from silently becoming hardware results.

Line 631: `a_i64 = a.astype(np.int64)` This assigns ‘a.astype(np.int64)‘ to ‘a_i64 ‘ in host memory. Here a_i64 means the value named ’a i64’ in this block. The important operands are a: the value named ’a’ in this block; astype: the value named ’astype’ in this block; int64: the value named ’int64’ in this block. Context: the function compile_u8_conv2d, which handles compile u8 conv2d.

Line 632: `w_i64 = w.astype(np.int64)` This assigns ‘w.astype(np.int64)‘ to ‘w_i64 ‘ in host memory. Here w_i64 means the value named ’w i64’ in this block. The important operands are w: the value named ’w’ in this block; astype: the value named ’astype’ in this block; int64: the value named ’int64’ in this block. Context: the function compile_u8_conv2d, which handles compile u8 conv2d.

Line 633: `if np.any(a_i64 < 0) or np.any(a_i64 > 255):` This executes the following indented host-code branch only when ‘np.any(a_i64 $<$ 0) or np.any(a_i64 $>$ 255)‘ is true. The important operands are any: the value named ’any’ in this block; a_i64: the value named ’a i64’ in this block; or: the value named ’or’ in this block. Context: the function compile_u8_conv2d, which handles compile u8 conv2d.

Line 634: `raise ValueError("convolution activations must be in [0,255]")` This rejects an invalid state by raising ‘ValueError("convolution activations must be in [0,255]")‘. Failing before DMA prevents malformed shapes or artifacts from silently becoming hardware results.

Line 635: `if np.any(w_i64 < 0) or np.any(w_i64 > 255):` This executes the following indented host-code branch only when ‘np.any(w_i64 $<$ 0) or np.any(w_i64 $>$ 255)‘ is true. The important operands are any: the value named ’any’ in this block; w_i64: the value named ’w i64’ in this block; or: the value named ’or’ in this block. Context: the function compile_u8_conv2d, which handles compile u8 conv2d.

Line 636: `raise ValueError("convolution weights must be in [0,255]")` This rejects an invalid state by raising ‘ValueError("convolution weights must be in [0,255]")‘. Failing before DMA prevents malformed shapes or artifacts from silently becoming hardware results.

Line 637: `a_u8 = a_i64.astype(np.uint8)` This assigns ‘a_i64.astype(np.uint8)‘ to ‘a_u8 ‘ in host memory. Here a_u8 means the value named ’a u8’ in this block. The important operands are a_i64: the value named ’a i64’ in this block; astype: the value named ’astype’ in this block; uint8: the value named ’uint8’ in this block. Context: the function compile_u8_conv2d, which handles compile u8 conv2d.

Line 638: `w_u8 = w_i64.astype(np.uint8)` This assigns ‘w_i64.astype(np.uint8)‘ to ‘w_u8 ‘ in host memory. Here w_u8 means the value named ’w u8’ in this block. The important operands are w_i64: the value named ’w i64’ in this block; astype: the value named ’astype’ in this block; uint8: the value named ’uint8’ in this block. Context: the function compile_u8_conv2d, which handles compile u8 conv2d.

Line 639: `za = _u8("activation_zero_point", activation_zero_point)` This assigns ‘_u8("activation_zero_point", activation_zero_point)‘ to ‘za ‘ in host memory. Here za means the value named ’za’ in this block. The important operands are _u8: the value named ’u8’ in this block; activation_zero_point: an input feature value consumed by a neuron or multiply-accumulate operation. Context: the function compile_u8_conv2d, which handles compile u8 conv2d.

Line 640: `zb = _u8("weight_zero_point", weight_zero_point)` This assigns ‘_u8("weight_zero_point", weight_zero_point to ‘zb ‘ in host memory. Here zb means the value named ’zb’ in this block. The important operands are _u8: the value named ’u8’ in this block; weight_zero_point: a learned coefficient multiplied by an activation. Context: the function compile_u8_conv2d, which handles compile u8 conv2d.

Line 641: `stride_pair = _pair("stride", stride)` This assigns ‘_pair("stride", stride)‘ to ‘stride_pair ‘ in host memory. Here stride_pair means the value named ’stride pair’ in this block. The important operands are _pair: the value named ’pair’ in this block; stride: the value named ’stride’ in this block. Context: the function compile_u8_conv2d, which handles compile u8 conv2d.

Line 642: `padding_pair = _pair("padding", padding, allow_zero=True)` This assigns ‘_pair("padding", padding, allow_zero=True)‘ to ‘padding_pair ‘ in host memory. Here padding_pair means the value named ’padding pair’ in this block. The important operands are _pair: the value named ’pair’ in this block; padding: the value named ’padding’ in this block; allow_zero: the value named ’allow zero’ in this block. Context: the function compile_u8_conv2d, which handles compile u8 conv2d.

Line 643: `dilation_pair = _pair("dilation", dilation)` This assigns ‘_pair("dilation", dilation)‘ to ‘dilation_pair ‘ in host memory. Here dilation_pair means the value named ’dilation pair’ in this block. The important operands are _pair: the value named ’pair’ in this block; dilation: the value named ’dilation’ in this block. Context: the function compile_u8_conv2d, which handles compile u8 conv2d.

Line 645: `batch, input_channels, height, width = a_u8.shape` This assigns ‘a_u8.shape‘ to ‘batch, input_channels, height, width ‘ in host memory. Here batch means the value named ’batch’ in this block. The important operands are a_u8: the value named ’a u8’ in this block; shape: the value named ’shape’ in this block. Context: the function compile_u8_conv2d, which handles compile u8 conv2d.

Line 646: `output_channels, weight_channels, kernel_height, kernel_width = w_u8.shape` This assigns ‘w_u8.shape‘ to ‘output_channels, weight_channels, kernel_height, kernel_width ‘ in host memory. Here output_channels means the value named ’output channels’ in this block. The important operands are w_u8: the value named ’w u8’ in this block; shape: the value named ’shape’ in this block. Context: the function compile_u8_conv2d, which handles compile u8 conv2d.

Line 647: `group_count = int(groups)` This assigns ‘int(groups)‘ to ‘group_count ‘ in host memory. Here group_count means an integer count retained for control or measurable telemetry. The important operands are groups: the value named ’groups’ in this block. Context: the function compile_u8_conv2d, which handles compile u8 conv2d.

Line 648: `if group_count <= 0 or input_channels % group_count or output_channels % group_count:` This executes the following indented host-code branch only when ‘group_count <= 0 or input_channels % group_count or

output_channels % group_count‘ is true. The important operands are group_count: an integer count retained for control or measurable telemetry; or: the value named 'or' in this block; input_channels: the value named 'input channels' in this block. Context: the function compile_u8_conv2d, which handles compile u8 conv2d.

Line 649: `raise ValueError("groups must divide both input and output channels")` This rejects an invalid state by raising ‘ValueError("groups must divide both input and output channels")‘. Failing before DMA prevents malformed shapes or artifacts from silently becoming hardware results.

Line 650: `channels_per_group = input_channels // group_count` This assigns ‘input_channels // group_count‘ to ‘channels_per_group ‘ in host memory. Here channels_per_group means the value named 'channels per group' in this block. The important operands are input_channels: the value named 'input channels' in this block; group_count: an integer count retained for control or measurable telemetry. Context: the function compile_u8_conv2d, which handles compile u8 conv2d.

Line 651: `outputs_per_group = output_channels // group_count` This assigns ‘output_channels // group_count‘ to ‘outputs_per_group ‘ in host memory. Here outputs_per_group means the value named 'outputs per group' in this block. The important operands are output_channels: the value named 'output channels' in this block; group_count: an integer count retained for control or measurable telemetry. Context: the function compile_u8_conv2d, which handles compile u8 conv2d.

Line 652: `if weight_channels != channels_per_group:` This executes the following indented host-code branch only when ‘weight_channels != channels_per_group‘ is true. The important operands are weight_channels: a learned coefficient multiplied by an activation; channels_per_group: the value named 'channels per group' in this block. Context: the function compile_u8_conv2d, which handles compile u8 conv2d.

Line 653: `raise ValueError("OIHW weight input channels must equal input_channels/groups")` This rejects an invalid state by raising ‘ValueError("OIHW weight input channels must equal input_channels/groups")‘. Failing before DMA prevents malformed shapes or artifacts from silently becoming hardware results.

Line 654: `if kernel_height == 0 or kernel_width == 0:` This executes the following indented host-code branch only when ‘kernel_height == 0 or kernel_width == 0‘ is true. The important operands are kernel_height: the value named 'kernel height' in this block; or: the value named 'or' in this block; kernel_width: the value named 'kernel width' in this block. Context: the function compile_u8_conv2d, which handles compile u8 conv2d.

Line 655: `raise ValueError("convolution kernel dimensions must be non-zero")` This rejects an invalid state by raising ‘ValueError("convolution kernel dimensions must be non-zero")‘. Failing before DMA prevents malformed shapes or artifacts from silently becoming hardware results.

Line 656: `if bias is None:` This executes the following indented host-code branch only when ‘bias is None‘ is true. The important operands are bias: an additive learned offset applied after accumulation; is: the value named 'is' in this block; None: the value named 'none' in this block. Context: the function compile_u8_conv2d, which handles compile u8 conv2d.

Line 657: `bias_values = None` This assigns ‘None‘ to ‘bias_values ‘ in host memory. Here bias_values means an additive learned offset applied after accumulation. The important operands are None: the value named 'none' in this block. Context: the function compile_u8_conv2d, which handles compile u8 conv2d.

Line 658: `else:` This begins the alternative host-code branch when the preceding condition was false, still inside the function compile_u8_conv2d, which handles compile u8 conv2d.

Line 659: `bias_array = np.asarray(bias)` This assigns ‘np.asarray(bias)‘ to ‘bias_array ‘ in host memory. Here bias_array means an additive learned offset applied after accumulation. The important operands are asarray: the value named 'asarray' in this block; bias: an additive learned offset applied after accumulation. Context: the function compile_u8_conv2d, which handles compile u8 conv2d.

Line 660: `if bias_array.ndim != 1 or len(bias_array) != output_channels:` This executes the following indented host-code branch only when ‘bias_array.ndim != 1 or len(bias_array) != output_channels‘ is true. The important operands are bias_array: an additive learned offset applied after accumulation; ndim: the value named ’ndim’ in this block; or: the value named ’or’ in this block. Context: the function compile_u8_conv2d, which handles compile u8 conv2d.

Line 661: `raise ValueError("convolution bias must have one entry per output channel")` This rejects an invalid state by raising ‘ValueError("convolution bias must have one entry per output channel")‘. Failing before DMA prevents malformed shapes or artifacts from silently becoming hardware results.

Line 662: `if not np.issubdtype(bias_array.dtype, np.integer):` This executes the following indented host-code branch only when ‘not np.issubdtype(bias_array.dtype, np.integer)‘ is true. The important operands are not: the value named ’not’ in this block; issubdtype: the value named ’issubdtype’ in this block; bias_array: an additive learned offset applied after accumulation. Context: the function compile_u8_conv2d, which handles compile u8 conv2d.

Line 663: `raise ValueError("convolution bias must contain integers")` This rejects an invalid state by raising ‘ValueError("convolution bias must contain integers")‘. Failing before DMA prevents malformed shapes or artifacts from silently becoming hardware results.

Line 664: `bias_values = bias_array.astype(np.int64)` This assigns ‘bias_array.astype(np.int64)‘ to ‘bias_values ‘ in host memory. Here bias_values means an additive learned offset applied after accumulation. The important operands are bias_array: an additive learned offset applied after accumulation; astype: the value named ’astype’ in this block; int64: the value named ’int64’ in this block. Context: the function compile_u8_conv2d, which handles compile u8 conv2d.

Line 666: `programs: list[ConvGroupProgram] = []` This assigns ‘[]‘ to ‘programs‘ in host memory. Here programs means the value named ’programs’ in this block. The expression is a literal or structural operator and has no hidden software state. Context: the function compile_u8_conv2d, which handles compile u8 conv2d.

Line 667: `output_height = output_width = 0` This assigns ‘output_width = 0‘ to ‘output_height ‘ in host memory. Here output_height means the value named ’output height’ in this block. The important operands are output_width: the value named ’output width’ in this block. Context: the function compile_u8_conv2d, which handles compile u8 conv2d.

Line 668: `for group in range(group_count):` This iterates group over ‘range(group_count)‘. Each iteration repeats the indented host operation, commonly once per layer, tile, timestep, or test case in the function compile_u8_conv2d, which handles compile u8 conv2d.

Line 669: `input_start = group * channels_per_group` This assigns ‘group * channels_per_group‘ to ‘input_start ‘ in host memory. Here input_start means the value named ’input start’ in this block. The important operands are group: the value named ’group’ in this block; channels_per_group: the value named ’channels per group’ in this block. Context: the function compile_u8_conv2d, which handles compile u8 conv2d.

Line 670: `output_start = group * outputs_per_group` This assigns ‘group * outputs_per_group‘ to ‘output_start ‘ in host memory. Here output_start means the value named ’output start’ in this block. The important operands are group: the value named ’group’ in this block; outputs_per_group: the value named ’outputs per group’ in this block. Context: the function compile_u8_conv2d, which handles compile u8 conv2d.

Line 671: `columns, output_height, output_width = _im2col_nchw(` This statement continues through source line 675; the explanation uses the complete expression rather than only the first visual fragment. This assigns ‘_im2col_nchw(a_u8[:, input_start:input_start + channels_per_group], (kernel_height, kernel_width), stride_pair, padding_pair, dilation_pair, za,)‘ to ‘columns, output_height, output_width ‘ in host memory. Here columns means one output-feature position processed in parallel. The important operands are _im2col_nchw: the value named ’im2col nchw’ in this block; a_u8: the value named ’a u8’ in this block; input_start: the value named ’input start’ in this block. Context: the function compile_u8_conv2d, which handles compile u8 conv2d.

Line 672: `a_u8[:, input_start:input_start + channels_per_group],` This is continuation line 2 of the 5-line logical statement that begins at source line 671. Its exact fragment is 'a_u8[:, input_start:input_start + channels_per_group],'. The important operands are a_u8: the value named 'a u8' in this block; input_start: the value named 'input start' in this block; channels_per_group: the value named 'channels per group' in this block. Read together, the complete operation is: This assigns '_im2col_nchw(a_u8[:, input_start:input_start + channels_per_group], (kernel_height, kernel_width), stride_pair, padding_pair, dilation_pair, za,)' to 'columns, output_height, output_width ' in host memory. Here columns means one output-feature position processed in parallel. The important operands are _im2col_nchw: the value named 'im2col nchw' in this block; a_u8: the value named 'a u8' in this block; input_start: the value named 'input start' in this block. Context: the function compile_u8_conv2d, which handles compile u8 conv2d.

Line 673: `(kernel_height, kernel_width), stride_pair, padding_pair,` This is continuation line 3 of the 5-line logical statement that begins at source line 671. Its exact fragment is '(kernel_height, kernel_width), stride_pair, padding_pair,'. The important operands are kernel_height: the value named 'kernel height' in this block; kernel_width: the value named 'kernel width' in this block; stride_pair: the value named 'stride pair' in this block. Read together, the complete operation is: This assigns '_im2col_nchw(a_u8[:, input_start:input_start + channels_per_group], (kernel_height, kernel_width), stride_pair, padding_pair, dilation_pair, za,)' to 'columns, output_height, output_width ' in host memory. Here columns means one output-feature position processed in parallel. The important operands are _im2col_nchw: the value named 'im2col nchw' in this block; a_u8: the value named 'a u8' in this block; input_start: the value named 'input start' in this block. Context: the function compile_u8_conv2d, which handles compile u8 conv2d.

Line 674: `dilation_pair, za,` This is continuation line 4 of the 5-line logical statement that begins at source line 671. Its exact fragment is 'dilation_pair, za,'. The important operands are dilation_pair: the value named 'dilation pair' in this block; za: the value named 'za' in this block. Read together, the complete operation is: This assigns '_im2col_nchw(a_u8[:, input_start:input_start + channels_per_group], (kernel_height, kernel_width), stride_pair, padding_pair, dilation_pair, za,)' to 'columns, output_height, output_width ' in host memory. Here columns means one output-feature position processed in parallel. The important operands are _im2col_nchw: the value named 'im2col nchw' in this block; a_u8: the value named 'a u8' in this block; input_start: the value named 'input start' in this block. Context: the function compile_u8_conv2d, which handles compile u8 conv2d.

Line 675: `)` This is continuation line 5 of the 5-line logical statement that begins at source line 671. Its exact fragment is ')'. The expression is a literal or structural operator and has no hidden software state. Read together, the complete operation is: This assigns '_im2col_nchw(a_u8[:, input_start:input_start + channels_per_group], (kernel_height, kernel_width), stride_pair, padding_pair, dilation_pair, za,)' to 'columns, output_height, output_width ' in host memory. Here columns means one output-feature position processed in parallel. The important operands are _im2col_nchw: the value named 'im2col nchw' in this block; a_u8: the value named 'a u8' in this block; input_start: the value named 'input start' in this block. Context: the function compile_u8_conv2d, which handles compile u8 conv2d.

Line 676: `weight_matrix = w_u8[` This statement continues through source line 678; the explanation uses the complete expression rather than only the first visual fragment. This assigns 'w_u8[output_start:output_start + outputs_per_group].reshape(outputs_per_group, -1).T' to 'weight_matrix ' in host memory. Here weight_matrix means a learned coefficient multiplied by an activation. The important operands are w_u8: the value named 'w u8' in this block; output_start: the value named 'output start' in this block; outputs_per_group: the value named 'outputs per group' in this block. Context: the function compile_u8_conv2d, which handles compile u8 conv2d.

Line 677: `output_start:output_start + outputs_per_group` This is continuation line 2 of the 3-line logical statement that begins at source line 676. Its exact fragment is 'output_start:output_start + outputs_per_group'. The important operands are output_start: the value named 'output start' in this block; outputs_per_group: the value named 'outputs per group' in this block. Read together, the complete operation is: This assigns 'w_u8[output_start:output_start + outputs_per_group].reshape(outputs_per_group, -1).T' to 'weight_matrix ' in host memory. Here weight_matrix means a learned coefficient multiplied by an activation. The important operands are w_u8: the value named 'w u8' in this block; output_start: the value named 'output start' in this block; outputs_per_group: the value named 'outputs per group' in this block. Context: the function compile_u8_conv2d, which handles compile u8 conv2d.

Line 678: `].reshape(outputs_per_group, -1).T` This is continuation line 3 of the 3-line logical statement that begins at source line 676. Its exact fragment is '].reshape(outputs_per_group, -1).T'. The important operands are reshape: the value named 'reshape' in this block; outputs_per_group: the value named 'outputs per group' in this block; T: the

value named 't' in this block. Read together, the complete operation is: This assigns ‘w_u8[output_start:output_start + outputs_per_group].reshape(outputs_per_group, -1).T‘ to ‘weight_matrix ‘ in host memory. Here weight_matrix means a learned coefficient multiplied by an activation. The important operands are w_u8: the value named 'w u8' in this block; output_start: the value named 'output start' in this block; outputs_per_group: the value named 'outputs per group' in this block. Context: the function compile_u8_conv2d, which handles compile u8 conv2d.

Line 679: `group_bias = None if bias_values is None else bias_values[` This statement continues through source line 681; the explanation uses the complete expression rather than only the first visual fragment. This assigns ‘None if bias_values is None else bias_values[output_start:output_start + outputs_per_group]‘ to ‘group_bias ‘ in host memory. Here group_bias means an additive learned offset applied after accumulation. The important operands are None: the value named 'none' in this block; bias_values: an additive learned offset applied after accumulation; is: the value named 'is' in this block. Context: the function compile_u8_conv2d, which handles compile u8 conv2d.

Line 680: `output_start:output_start + outputs_per_group` This is continuation line 2 of the 3-line logical statement that begins at source line 679. Its exact fragment is ‘output_start:output_start + outputs_per_group‘. The important operands are output_start: the value named 'output start' in this block; outputs_per_group: the value named 'outputs per group' in this block. Read together, the complete operation is: This assigns ‘None if bias_values is None else bias_values[output_start:output_start + outputs_per_group]‘ to ‘group_bias ‘ in host memory. Here group_bias means an additive learned offset applied after accumulation. The important operands are None: the value named 'none' in this block; bias_values: an additive learned offset applied after accumulation; is: the value named 'is' in this block. Context: the function compile_u8_conv2d, which handles compile u8 conv2d.

Line 681: `]` This is continuation line 3 of the 3-line logical statement that begins at source line 679. Its exact fragment is ‘]‘. The expression is a literal or structural operator and has no hidden software state. Read together, the complete operation is: This assigns ‘None if bias_values is None else bias_values[output_start:output_start + outputs_per_group]‘ to ‘group_bias ‘ in host memory. Here group_bias means an additive learned offset applied after accumulation. The important operands are None: the value named 'none' in this block; bias_values: an additive learned offset applied after accumulation; is: the value named 'is' in this block. Context: the function compile_u8_conv2d, which handles compile u8 conv2d.

Line 682: `programs.append(ConvGroupProgram(` This statement continues through source line 693; the explanation uses the complete expression rather than only the first visual fragment. This calls ‘programs.append‘ with ‘ConvGroupProgram(output_start, outputs_per_group, compile_u8_gemm(columns, weight_matrix, activation_zero_point=za, weight_zero_point=zb, bias=group_bias, dataflow=dataflow,),)‘ inside the function compile_u8_conv2d, which handles compile u8 conv2d. The call advances the host-side job that tiles matrices and convolutions into validated accelerator commands and packed stream payloads.

Line 683: `output_start,` This is continuation line 2 of the 12-line logical statement that begins at source line 682. Its exact fragment is ‘output_start,‘. The important operands are output_start: the value named 'output start' in this block. Read together, the complete operation is: This calls ‘programs.append‘ with ‘ConvGroupProgram(output_start, outputs_per_group, compile_u8_gemm(columns, weight_matrix, activation_zero_point=za, weight_zero_point=zb, bias=group_bias, dataflow=dataflow,),)‘ inside the function compile_u8_conv2d, which handles compile u8 conv2d. The call advances the host-side job that tiles matrices and convolutions into validated accelerator commands and packed stream payloads.

Line 684: `outputs_per_group,` This is continuation line 3 of the 12-line logical statement that begins at source line 682. Its exact fragment is ‘outputs_per_group,‘. The important operands are outputs_per_group: the value named 'outputs per group' in this block. Read together, the complete operation is: This calls ‘programs.append‘ with ‘ConvGroupProgram(output_start, outputs_per_group, compile_u8_gemm(columns, weight_matrix, activation_zero_point=za, weight_zero_point=zb, bias=group_bias, dataflow=dataflow,),)‘ inside the function compile_u8_conv2d, which handles compile u8 conv2d. The call advances the host-side job that tiles matrices and convolutions into validated accelerator commands and packed stream payloads.

Line 685: `compile_u8_gemm(` This is continuation line 4 of the 12-line logical statement that begins at source line 682. Its exact fragment is ‘compile_u8_gemm(‘. The important operands are compile_u8_gemm: the value named 'compile

u8 gemm' in this block. Read together, the complete operation is: This calls 'programs.append' with 'ConvGroupProgram(output_start, outputs_per_group, compile_u8_gemm(columns, weight_matrix, activation_zero_point=za, weight_zero_point=zb, bias=group_bias, dataflow=dataflow,),)' inside the function compile_u8_conv2d, which handles compile u8 conv2d. The call advances the host-side job that tiles matrices and convolutions into validated accelerator commands and packed stream payloads.

Line 686: `columns,` This is continuation line 5 of the 12-line logical statement that begins at source line 682. Its exact fragment is 'columns,'. The important operands are columns: one output-feature position processed in parallel. Read together, the complete operation is: This calls 'programs.append' with 'ConvGroupProgram(output_start, outputs_per_group, compile_u8_gemm(columns, weight_matrix, activation_zero_point=za, weight_zero_point=zb, bias=group_bias, dataflow=dataflow,),)' inside the function compile_u8_conv2d, which handles compile u8 conv2d. The call advances the host-side job that tiles matrices and convolutions into validated accelerator commands and packed stream payloads.

Line 687: `weight_matrix,` This is continuation line 6 of the 12-line logical statement that begins at source line 682. Its exact fragment is 'weight_matrix,'. The important operands are weight_matrix: a learned coefficient multiplied by an activation. Read together, the complete operation is: This calls 'programs.append' with 'ConvGroupProgram(output_start, outputs_per_group, compile_u8_gemm(columns, weight_matrix, activation_zero_point=za, weight_zero_point=zb, bias=group_bias, dataflow=dataflow,),)' inside the function compile_u8_conv2d, which handles compile u8 conv2d. The call advances the host-side job that tiles matrices and convolutions into validated accelerator commands and packed stream payloads.

Line 688: `activation_zero_point=za,` This is continuation line 7 of the 12-line logical statement that begins at source line 682. Its exact fragment is 'activation_zero_point=za,'. The important operands are activation_zero_point: an input feature value consumed by a neuron or multiply-accumulate operation; za: the value named 'za' in this block. Read together, the complete operation is: This calls 'programs.append' with 'ConvGroupProgram(output_start, outputs_per_group, compile_u8_gemm(columns, weight_matrix, activation_zero_point=za, weight_zero_point=zb, bias=group_bias, dataflow=dataflow,),)' inside the function compile_u8_conv2d, which handles compile u8 conv2d. The call advances the host-side job that tiles matrices and convolutions into validated accelerator commands and packed stream payloads.

Line 689: `weight_zero_point=zb,` This is continuation line 8 of the 12-line logical statement that begins at source line 682. Its exact fragment is 'weight_zero_point=zb,'. The important operands are weight_zero_point: a learned coefficient multiplied by an activation; zb: the value named 'zb' in this block. Read together, the complete operation is: This calls 'programs.append' with 'ConvGroupProgram(output_start, outputs_per_group, compile_u8_gemm(columns, weight_matrix, activation_zero_point=za, weight_zero_point=zb, bias=group_bias, dataflow=dataflow,),)' inside the function compile_u8_conv2d, which handles compile u8 conv2d. The call advances the host-side job that tiles matrices and convolutions into validated accelerator commands and packed stream payloads.

Line 690: `bias=group_bias,` This is continuation line 9 of the 12-line logical statement that begins at source line 682. Its exact fragment is 'bias=group_bias,'. The important operands are bias: an additive learned offset applied after accumulation; group_bias: an additive learned offset applied after accumulation. Read together, the complete operation is: This calls 'programs.append' with 'ConvGroupProgram(output_start, outputs_per_group, compile_u8_gemm(columns, weight_matrix, activation_zero_point=za, weight_zero_point=zb, bias=group_bias, dataflow=dataflow,),)' inside the function compile_u8_conv2d, which handles compile u8 conv2d. The call advances the host-side job that tiles matrices and convolutions into validated accelerator commands and packed stream payloads.

Line 691: `dataflow=dataflow,` This is continuation line 10 of the 12-line logical statement that begins at source line 682. Its exact fragment is 'dataflow=dataflow,'. The important operands are dataflow: the value named 'dataflow' in this block. Read together, the complete operation is: This calls 'programs.append' with 'ConvGroupProgram(output_start, outputs_per_group, compile_u8_gemm(columns, weight_matrix, activation_zero_point=za, weight_zero_point=zb, bias=group_bias, dataflow=dataflow,),)' inside the function compile_u8_conv2d, which handles compile u8 conv2d. The call advances the host-side job that tiles matrices and convolutions into validated accelerator commands and packed stream payloads.

Line 692: `),` This is continuation line 11 of the 12-line logical statement that begins at source line 682. Its exact fragment is ‘),‘. The expression is a literal or structural operator and has no hidden software state. Read together, the complete operation is: This calls ‘programs.append‘ with ‘ConvGroupProgram(output_start, outputs_per_group, compile_u8_gemm(columns, weight_matrix, activation_zero_point=za, weight_zero_point=zb, bias=group_bias, dataflow=dataflow,),)‘ inside the function compile_u8_conv2d, which handles compile u8 conv2d. The call advances the host-side job that tiles matrices and convolutions into validated accelerator commands and packed stream payloads.

Line 693: `))` This is continuation line 12 of the 12-line logical statement that begins at source line 682. Its exact fragment is ‘))‘. The expression is a literal or structural operator and has no hidden software state. Read together, the complete operation is: This calls ‘programs.append‘ with ‘ConvGroupProgram(output_start, outputs_per_group, compile_u8_gemm(columns, weight_matrix, activation_zero_point=za, weight_zero_point=zb, bias=group_bias, dataflow=dataflow,),)‘ inside the function compile_u8_conv2d, which handles compile u8 conv2d. The call advances the host-side job that tiles matrices and convolutions into validated accelerator commands and packed stream payloads.

Line 694: `return CompiledConv2d(` This statement continues through source line 699; the explanation uses the complete expression rather than only the first visual fragment. This returns ‘CompiledConv2d((batch, input_channels, height, width), (batch, output_channels, output_height, output_width), (kernel_height, kernel_width), stride_pair, padding_pair, dilation_pair, group_count, tuple(programs),)‘ to the caller of the function compile_u8_conv2d, which handles compile u8 conv2d, ending this invocation. The important operands are CompiledConv2d: the value named ’compiled conv2d’ in this block; batch: the value named ’batch’ in this block; input_channels: the value named ’input channels’ in this block.

Line 695: `(batch, input_channels, height, width),` This is continuation line 2 of the 6-line logical statement that begins at source line 694. Its exact fragment is ‘(batch, input_channels, height, width),‘. The important operands are batch: the value named ’batch’ in this block; input_channels: the value named ’input channels’ in this block; height: the value named ’height’ in this block. Read together, the complete operation is: This returns ‘CompiledConv2d((batch, input_channels, height, width), (batch, output_channels, output_height, output_width), (kernel_height, kernel_width), stride_pair, padding_pair, dilation_pair, group_count, tuple(programs),)‘ to the caller of the function compile_u8_conv2d, which handles compile u8 conv2d, ending this invocation. The important operands are CompiledConv2d: the value named ’compiled conv2d’ in this block; batch: the value named ’batch’ in this block; input_channels: the value named ’input channels’ in this block.

Line 696: `(batch, output_channels, output_height, output_width),` This is continuation line 3 of the 6-line logical statement that begins at source line 694. Its exact fragment is ‘(batch, output_channels, output_height, output_width),‘. The important operands are batch: the value named ’batch’ in this block; output_channels: the value named ’output channels’ in this block; output_height: the value named ’output height’ in this block. Read together, the complete operation is: This returns ‘CompiledConv2d((batch, input_channels, height, width), (batch, output_channels, output_height, output_width), (kernel_height, kernel_width), stride_pair, padding_pair, dilation_pair, group_count, tuple(programs),)‘ to the caller of the function compile_u8_conv2d, which handles compile u8 conv2d, ending this invocation. The important operands are CompiledConv2d: the value named ’compiled conv2d’ in this block; batch: the value named ’batch’ in this block; input_channels: the value named ’input channels’ in this block.

Line 697: `(kernel_height, kernel_width), stride_pair, padding_pair, dilation_pair,` This is continuation line 4 of the 6-line logical statement that begins at source line 694. Its exact fragment is ‘(kernel_height, kernel_width), stride_pair, padding_pair, dilation_pair,‘. The important operands are kernel_height: the value named ’kernel height’ in this block; kernel_width: the value named ’kernel width’ in this block; stride_pair: the value named ’stride pair’ in this block. Read together, the complete operation is: This returns ‘CompiledConv2d((batch, input_channels, height, width), (batch, output_channels, output_height, output_width), (kernel_height, kernel_width), stride_pair, padding_pair, dilation_pair, group_count, tuple(programs),)‘ to the caller of the function compile_u8_conv2d, which handles compile u8 conv2d, ending this invocation. The important operands are CompiledConv2d: the value named ’compiled conv2d’ in this block; batch: the value named ’batch’ in this block; input_channels: the value named ’input channels’ in this block.

Line 698: `group_count, tuple(programs),` This is continuation line 5 of the 6-line logical statement that begins at source line 694. Its exact fragment is ‘group_count, tuple(programs),‘. The important operands are group_count: an integer count retained for control or measurable telemetry; tuple: the value named ’tuple’ in this block; programs: the value named ’programs’ in this block. Read together, the complete operation is: This returns ‘CompiledConv2d(

(batch, input_channels, height, width), (batch, output_channels, output_height, output_width), (kernel_height, kernel_width), stride_pair, padding_pair, dilation_pair, group_count, tuple(programs),)‘ to the caller of the function compile_u8_conv2d, which handles compile u8 conv2d, ending this invocation. The important operands are CompiledConv2d: the value named 'compiled conv2d' in this block; batch: the value named 'batch' in this block; input_channels: the value named 'input channels' in this block.

Line 699: `)` This is continuation line 6 of the 6-line logical statement that begins at source line 694. Its exact fragment is ‘)‘. The expression is a literal or structural operator and has no hidden software state. Read together, the complete operation is: This returns ‘CompiledConv2d((batch, input_channels, height, width), (batch, output_channels, output_height, output_width), (kernel_height, kernel_width), stride_pair, padding_pair, dilation_pair, group_count, tuple(programs),)‘ to the caller of the function compile_u8_conv2d, which handles compile u8 conv2d, ending this invocation. The important operands are CompiledConv2d: the value named 'compiled conv2d' in this block; batch: the value named 'batch' in this block; input_channels: the value named 'input channels' in this block.

Line 702: `def compile_spike_conv2d(` This starts function compile_spike_conv2d. Its indented body performs compile spike conv2d as part of the file that tiles matrices and convolutions into validated accelerator commands and packed stream payloads; it runs only when called.

Line 703: `spikes: np.ndarray | Sequence,` Inside the function compile_spike_conv2d, which handles compile spike conv2d, this statement advances the host implementation that tiles matrices and convolutions into validated accelerator commands and packed stream payloads. The important operands are spikes: a binary event produced when a neuron crosses its threshold; ndarray: the value named 'ndarray' in this block; Sequence: the value named 'sequence' in this block.

Line 704: `weights: np.ndarray | Sequence,` Inside the function compile_spike_conv2d, which handles compile spike conv2d, this statement advances the host implementation that tiles matrices and convolutions into validated accelerator commands and packed stream payloads. The important operands are weights: a learned coefficient multiplied by an activation; ndarray: the value named 'ndarray' in this block; Sequence: the value named 'sequence' in this block.

Line 705: `*,` Inside the function compile_spike_conv2d, which handles compile spike conv2d, this statement advances the host implementation that tiles matrices and convolutions into validated accelerator commands and packed stream payloads. The expression is a literal or structural operator and has no hidden software state.

Line 706: `ternary: bool = False,` This assigns ‘False,‘ to ‘ternary‘ in host memory. Here ternary means the value named 'ternary' in this block. The expression is a literal or structural operator and has no hidden software state. Context: the function compile_spike_conv2d, which handles compile spike conv2d.

Line 707: `bias: Sequence[int] | np.ndarray | None = None,` This assigns ‘None,‘ to ‘bias‘ in host memory. Here bias means an additive learned offset applied after accumulation. The important operands are None: the value named 'none' in this block. Context: the function compile_spike_conv2d, which handles compile spike conv2d.

Line 708: `stride: int | Sequence[int] = 1,` This assigns ‘1,‘ to ‘stride‘ in host memory. Here stride means the value named 'stride' in this block. The expression is a literal or structural operator and has no hidden software state. Context: the function compile_spike_conv2d, which handles compile spike conv2d.

Line 709: `padding: int | Sequence[int] = 0,` This assigns ‘0,‘ to ‘padding‘ in host memory. Here padding means the value named 'padding' in this block. The expression is a literal or structural operator and has no hidden software state. Context: the function compile_spike_conv2d, which handles compile spike conv2d.

Line 710: `dilation: int | Sequence[int] = 1,` This assigns ‘1,‘ to ‘dilation‘ in host memory. Here dilation means the value named 'dilation' in this block. The expression is a literal or structural operator and has no hidden software state. Context: the function compile_spike_conv2d, which handles compile spike conv2d.

Line 711: `groups: int = 1,` This assigns ‘1,‘ to ‘groups‘ in host memory. Here groups means the value named ’groups’ in this block. The expression is a literal or structural operator and has no hidden software state. Context: the function compile_spike_conv2d, which handles compile spike conv2d.

Line 712: `dataflow: Dataflow | None = None,` This assigns ‘None,‘ to ‘dataflow‘ in host memory. Here dataflow means the value named ’dataflow’ in this block. The important operands are None: the value named ’none’ in this block. Context: the function compile_spike_conv2d, which handles compile spike conv2d.

Line 713: `) -> CompiledConv2d:` Inside the function compile_spike_conv2d, which handles compile spike conv2d, this statement advances the host implementation that tiles matrices and convolutions into validated accelerator commands and packed stream payloads. The important operands are CompiledConv2d: the value named ’compiled conv2d’ in this block.

Line 714: `"""Lower grouped binary/ternary spike convolution to addition-only GEMMs."""` This is executable documentation attached to the function compile_spike_conv2d, which handles compile spike conv2d. It states the intended contract that tests and callers should enforce, but the text itself does not transform data or issue hardware work.

Line 715: `spike_array = np.asarray(spikes)` This assigns ‘np.asarray(spikes)‘ to ‘spike_array ‘ in host memory. Here spike_array means a binary event produced when a neuron crosses its threshold. The important operands are asarray: the value named ’asarray’ in this block; spikes: a binary event produced when a neuron crosses its threshold. Context: the function compile_spike_conv2d, which handles compile spike conv2d.

Line 716: `weight_array = np.asarray(weights)` This assigns ‘np.asarray(weights)‘ to ‘weight_array ‘ in host memory. Here weight_array means a learned coefficient multiplied by an activation. The important operands are asarray: the value named ’asarray’ in this block; weights: a learned coefficient multiplied by an activation. Context: the function compile_spike_conv2d, which handles compile spike conv2d.

Line 717: `if spike_array.ndim != 4 or weight_array.ndim != 4:` This executes the following indented host-code branch only when ‘spike_array.ndim != 4 or weight_array.ndim != 4‘ is true. The important operands are spike_array: a binary event produced when a neuron crosses its threshold; ndim: the value named ’ndim’ in this block; or: the value named ’or’ in this block. Context: the function compile_spike_conv2d, which handles compile spike conv2d.

Line 718: `raise ValueError("spike convolution requires NCHW activations and OIHW weights")` This rejects an invalid state by raising ‘ValueError("spike convolution requires NCHW activations and OIHW weights")‘. Failing before DMA prevents malformed shapes or artifacts from silently becoming hardware results.

Line 719: `if not np.issubdtype(spike_array.dtype, np.integer) or not np.issubdtype(weight_array.dtype, np.integer):` This executes the following indented host-code branch only when ‘not np.issubdtype(spike_array.dtype, np.integer) or not np.issubdtype(weight_array.dtype, np.integer)‘ is true. The important operands are not: the value named ’not’ in this block; issubdtype: the value named ’issubdtype’ in this block; spike_array: a binary event produced when a neuron crosses its threshold. Context: the function compile_spike_conv2d, which handles compile spike conv2d.

Line 720: `raise ValueError("spike convolution tensors must contain integers")` This rejects an invalid state by raising ‘ValueError("spike convolution tensors must contain integers")‘. Failing before DMA prevents malformed shapes or artifacts from silently becoming hardware results.

Line 721: `spike_i64 = spike_array.astype(np.int64)` This assigns ‘spike_array.astype(np.int64)‘ to ‘spike_i64 ‘ in host memory. Here spike_i64 means a binary event produced when a neuron crosses its threshold. The important operands are spike_array: a binary event produced when a neuron crosses its threshold; astype: the value named ’astype’ in this block; int64: the value named ’int64’ in this block. Context: the function compile_spike_conv2d, which handles compile spike conv2d.

Line 722: `weight_i64 = weight_array.astype(np.int64)` This assigns ‘weight_array.astype(np.int64)‘ to ‘weight_i64 ‘ in host memory. Here weight_i64 means a learned coefficient multiplied by an activation. The important operands are weight_array: a learned coefficient multiplied by an activation; astype: the value named ’astype’ in this block; int64: the value named ’int64’ in this block. Context: the function compile_spike_conv2d, which handles compile spike conv2d.

Line 723: `if not np.all(np.isin(spike_i64, (-1, 0, 1) if ternary else (0, 1))):` This executes the following indented host-code branch only when ‘not np.all(np.isin(spike_i64, (-1, 0, 1) if ternary else (0, 1)))‘ is true. The important operands are not: the value named ’not’ in this block; all: the value named ’all’ in this block; isin: the value named ’isin’ in this block. Context: the function compile_spike_conv2d, which handles compile spike conv2d.

Line 724: `raise ValueError("spike values do not match the selected binary/ternary mode")` This rejects an invalid state by raising ‘ValueError("spike values do not match the selected binary/ternary mode")‘. Failing before DMA prevents malformed shapes or artifacts from silently becoming hardware results.

Line 725: `if np.any(weight_i64 < -128) or np.any(weight_i64 > 127):` This executes the following indented host-code branch only when ‘np.any(weight_i64 < -128) or np.any(weight_i64 > 127)‘ is true. The important operands are any: the value named ’any’ in this block; weight_i64: a learned coefficient multiplied by an activation; or: the value named ’or’ in this block. Context: the function compile_spike_conv2d, which handles compile spike conv2d.

Line 726: `raise ValueError("spike convolution weights must be signed INT8")` This rejects an invalid state by raising ‘ValueError("spike convolution weights must be signed INT8")‘. Failing before DMA prevents malformed shapes or artifacts from silently becoming hardware results.

Line 727: `stride_pair = _pair("stride", stride)` This assigns ‘_pair("stride", stride)‘ to ‘stride_pair ‘ in host memory. Here stride_pair means the value named ’stride pair’ in this block. The important operands are _pair: the value named ’pair’ in this block; stride: the value named ’stride’ in this block. Context: the function compile_spike_conv2d, which handles compile spike conv2d.

Line 728: `padding_pair = _pair("padding", padding, allow_zero=True)` This assigns ‘_pair("padding", padding, allow_zero=True)‘ to ‘padding_pair ‘ in host memory. Here padding_pair means the value named ’padding pair’ in this block. The important operands are _pair: the value named ’pair’ in this block; padding: the value named ’padding’ in this block; allow_zero: the value named ’allow zero’ in this block. Context: the function compile_spike_conv2d, which handles compile spike conv2d.

Line 729: `dilation_pair = _pair("dilation", dilation)` This assigns ‘_pair("dilation", dilation)‘ to ‘dilation_pair ‘ in host memory. Here dilation_pair means the value named ’dilation pair’ in this block. The important operands are _pair: the value named ’pair’ in this block; dilation: the value named ’dilation’ in this block. Context: the function compile_spike_conv2d, which handles compile spike conv2d.

Line 730: `batch, input_channels, height, width = spike_i64.shape` This assigns ‘spike_i64.shape‘ to ‘batch, input_channels, height, width ‘ in host memory. Here batch means the value named ’batch’ in this block. The important operands are spike_i64: a binary event produced when a neuron crosses its threshold; shape: the value named ’shape’ in this block. Context: the function compile_spike_conv2d, which handles compile spike conv2d.

Line 731: `output_channels, weight_channels, kernel_height, kernel_width = weight_i64.shape` This assigns ‘weight_i64.shape‘ to ‘output_channels, weight_channels, kernel_height, kernel_width ‘ in host memory. Here output_channels means the value named ’output channels’ in this block. The important operands are weight_i64: a learned coefficient multiplied by an activation; shape: the value named ’shape’ in this block. Context: the function compile_spike_conv2d, which handles compile spike conv2d.

Line 732: `group_count = int(groups)` This assigns ‘int(groups)‘ to ‘group_count ‘ in host memory. Here group_count means an integer count retained for control or measurable telemetry. The important operands are groups: the value named ’groups’ in this block. Context: the function compile_spike_conv2d, which handles compile spike conv2d.

Line 733: `if group_count <= 0 or input_channels % group_count or output_channels % group_count:` This executes the following indented host-code branch only when ‘group_count <= 0 or input_channels % group_count or output_channels % group_count‘ is true. The important operands are group_count: an integer count retained for control or measurable telemetry; or: the value named ’or’ in this block; input_channels: the value named ’input channels’ in this block. Context: the function compile_spike_conv2d, which handles compile spike conv2d.

Line 734: `raise ValueError("groups must divide both input and output channels")` This rejects an invalid state by raising ‘ValueError("groups must divide both input and output channels")‘. Failing before DMA prevents malformed shapes or artifacts from silently becoming hardware results.

Line 735: `channels_per_group = input_channels // group_count` This assigns ‘input_channels // group_count‘ to ‘channels_per_group ‘ in host memory. Here channels_per_group means the value named ’channels per group’ in this block. The important operands are input_channels: the value named ’input channels’ in this block; group_count: an integer count retained for control or measurable telemetry. Context: the function compile_spike_conv2d, which handles compile spike conv2d.

Line 736: `outputs_per_group = output_channels // group_count` This assigns ‘output_channels // group_count‘ to ‘outputs_per_group ‘ in host memory. Here outputs_per_group means the value named ’outputs per group’ in this block. The important operands are output_channels: the value named ’output channels’ in this block; group_count: an integer count retained for control or measurable telemetry. Context: the function compile_spike_conv2d, which handles compile spike conv2d.

Line 737: `if weight_channels != channels_per_group:` This executes the following indented host-code branch only when ‘weight_channels != channels_per_group‘ is true. The important operands are weight_channels: a learned coefficient multiplied by an activation; channels_per_group: the value named ’channels per group’ in this block. Context: the function compile_spike_conv2d, which handles compile spike conv2d.

Line 738: `raise ValueError("OIHW weight input channels must equal input_channels/groups")` This rejects an invalid state by raising ‘ValueError("OIHW weight input channels must equal input_channels/groups")‘. Failing before DMA prevents malformed shapes or artifacts from silently becoming hardware results.

Line 739: `if bias is None:` This executes the following indented host-code branch only when ‘bias is None‘ is true. The important operands are bias: an additive learned offset applied after accumulation; is: the value named ’is’ in this block; None: the value named ’none’ in this block. Context: the function compile_spike_conv2d, which handles compile spike conv2d.

Line 740: `bias_values = None` This assigns ‘None‘ to ‘bias_values ‘ in host memory. Here bias_values means an additive learned offset applied after accumulation. The important operands are None: the value named ’none’ in this block. Context: the function compile_spike_conv2d, which handles compile spike conv2d.

Line 741: `else:` This begins the alternative host-code branch when the preceding condition was false, still inside the function compile_spike_conv2d, which handles compile spike conv2d.

Line 742: `bias_array = np.asarray(bias)` This assigns ‘np.asarray(bias)‘ to ‘bias_array ‘ in host memory. Here bias_array means an additive learned offset applied after accumulation. The important operands are asarray: the value named ’asarray’ in this block; bias: an additive learned offset applied after accumulation. Context: the function compile_spike_conv2d, which handles compile spike conv2d.

Line 743: `if bias_array.ndim != 1 or len(bias_array) != output_channels:` This executes the following indented host-code branch only when ‘bias_array.ndim != 1 or len(bias_array) != output_channels‘ is true. The important operands are bias_array: an additive learned offset applied after accumulation; ndim: the value named ’ndim’ in this block; or: the value named ’or’ in this block. Context: the function compile_spike_conv2d, which handles compile spike conv2d.

Line 744: `raise ValueError("spike convolution bias must have one entry per output channel")` This rejects an invalid state by raising ‘ValueError("spike convolution bias must have one entry per output channel")‘. Failing before DMA prevents malformed shapes or artifacts from silently becoming hardware results.

Line 745: `if not np.issubdtype(bias_array.dtype, np.integer):` This executes the following indented host-code branch only when ‘not np.issubdtype(bias_array.dtype, np.integer)‘ is true. The important operands are not: the value named ’not’ in this block; issubdtype: the value named ’issubdtype’ in this block; bias_array: an additive learned offset applied after accumulation. Context: the function compile_spike_conv2d, which handles compile spike conv2d.

Line 746: `raise ValueError("spike convolution bias must contain integers")` This rejects an invalid state by raising ‘ValueError("spike convolution bias must contain integers")‘. Failing before DMA prevents malformed shapes or artifacts from silently becoming hardware results.

Line 747: `bias_values = bias_array.astype(np.int64)` This assigns ‘bias_array.astype(np.int64)‘ to ‘bias_values ‘ in host memory. Here bias_values means an additive learned offset applied after accumulation. The important operands are bias_array: an additive learned offset applied after accumulation; astype: the value named ’astype’ in this block; int64: the value named ’int64’ in this block. Context: the function compile_spike_conv2d, which handles compile spike conv2d.

Line 749: `programs: list[ConvGroupProgram] = []` This assigns ‘[]‘ to ‘programs‘ in host memory. Here programs means the value named ’programs’ in this block. The expression is a literal or structural operator and has no hidden software state. Context: the function compile_spike_conv2d, which handles compile spike conv2d.

Line 750: `output_height = output_width = 0` This assigns ‘output_width = 0‘ to ‘output_height ‘ in host memory. Here output_height means the value named ’output height’ in this block. The important operands are output_width: the value named ’output width’ in this block. Context: the function compile_spike_conv2d, which handles compile spike conv2d.

Line 751: `for group in range(group_count):` This iterates group over ‘range(group_count)‘. Each iteration repeats the indented host operation, commonly once per layer, tile, timestep, or test case in the function compile_spike_conv2d, which handles compile spike conv2d.

Line 752: `input_start = group * channels_per_group` This assigns ‘group * channels_per_group‘ to ‘input_start ‘ in host memory. Here input_start means the value named ’input start’ in this block. The important operands are group: the value named ’group’ in this block; channels_per_group: the value named ’channels per group’ in this block. Context: the function compile_spike_conv2d, which handles compile spike conv2d.

Line 753: `output_start = group * outputs_per_group` This assigns ‘group * outputs_per_group‘ to ‘output_start ‘ in host memory. Here output_start means the value named ’output start’ in this block. The important operands are group: the value named ’group’ in this block; outputs_per_group: the value named ’outputs per group’ in this block. Context: the function compile_spike_conv2d, which handles compile spike conv2d.

Line 754: `columns, output_height, output_width = _im2col_nchw(` This statement continues through source line 758; the explanation uses the complete expression rather than only the first visual fragment. This assigns ‘_im2col_nchw(spike_i64[:, input_start:input_start + channels_per_group], (kernel_height, kernel_width), stride_pair, padding_pair, dilation_pair, 0,)‘ to ‘columns, output_height, output_width ‘ in host memory. Here columns means one output-feature position processed in parallel. The important operands are _im2col_nchw: the value named ’im2col nchw’ in this block; spike_i64: a binary event produced when a neuron crosses its threshold; input_start: the value named ’input start’ in this block. Context: the function compile_spike_conv2d, which handles compile spike conv2d.

Line 755: `spike_i64[:, input_start:input_start + channels_per_group],` This is continuation line 2 of the 5-line logical statement that begins at source line 754. Its exact fragment is ‘spike_i64[:, input_start:input_start + channels_per_group],‘. The important operands are spike_i64: a binary event produced when a neuron crosses its threshold; input_start: the value named ’input start’ in this block; channels_per_group: the value named ’channels per group’ in

this block. Read together, the complete operation is: This assigns '_im2col_nchw(spike_i64[:, input_start:input_start + channels_per_group], (kernel_height, kernel_width), stride_pair, padding_pair, dilation_pair, 0,)' to 'columns, output_height, output_width ' in host memory. Here columns means one output-feature position processed in parallel. The important operands are _im2col_nchw: the value named 'im2col nchw' in this block; spike_i64: a binary event produced when a neuron crosses its threshold; input_start: the value named 'input start' in this block. Context: the function compile_spike_conv2d, which handles compile spike conv2d.

Line 756: `(kernel_height, kernel_width), stride_pair, padding_pair,` This is continuation line 3 of the 5-line logical statement that begins at source line 754. Its exact fragment is '(kernel_height, kernel_width), stride_pair, padding_pair,'. The important operands are kernel_height: the value named 'kernel height' in this block; kernel_width: the value named 'kernel width' in this block; stride_pair: the value named 'stride pair' in this block. Read together, the complete operation is: This assigns '_im2col_nchw(spike_i64[:, input_start:input_start + channels_per_group], (kernel_height, kernel_width), stride_pair, padding_pair, dilation_pair, 0,)' to 'columns, output_height, output_width ' in host memory. Here columns means one output-feature position processed in parallel. The important operands are _im2col_nchw: the value named 'im2col nchw' in this block; spike_i64: a binary event produced when a neuron crosses its threshold; input_start: the value named 'input start' in this block. Context: the function compile_spike_conv2d, which handles compile spike conv2d.

Line 757: `dilation_pair, 0,` This is continuation line 4 of the 5-line logical statement that begins at source line 754. Its exact fragment is 'dilation_pair, 0,'. The important operands are dilation_pair: the value named 'dilation pair' in this block. Read together, the complete operation is: This assigns '_im2col_nchw(spike_i64[:, input_start:input_start + channels_per_group], (kernel_height, kernel_width), stride_pair, padding_pair, dilation_pair, 0,)' to 'columns, output_height, output_width ' in host memory. Here columns means one output-feature position processed in parallel. The important operands are _im2col_nchw: the value named 'im2col nchw' in this block; spike_i64: a binary event produced when a neuron crosses its threshold; input_start: the value named 'input start' in this block. Context: the function compile_spike_conv2d, which handles compile spike conv2d.

Line 758: `)` This is continuation line 5 of the 5-line logical statement that begins at source line 754. Its exact fragment is ')'. The expression is a literal or structural operator and has no hidden software state. Read together, the complete operation is: This assigns '_im2col_nchw(spike_i64[:, input_start:input_start + channels_per_group], (kernel_height, kernel_width), stride_pair, padding_pair, dilation_pair, 0,)' to 'columns, output_height, output_width ' in host memory. Here columns means one output-feature position processed in parallel. The important operands are _im2col_nchw: the value named 'im2col nchw' in this block; spike_i64: a binary event produced when a neuron crosses its threshold; input_start: the value named 'input start' in this block. Context: the function compile_spike_conv2d, which handles compile spike conv2d.

Line 759: `weight_matrix = weight_i64[` This statement continues through source line 761; the explanation uses the complete expression rather than only the first visual fragment. This assigns 'weight_i64[output_start:output_start + outputs_per_group].reshape(outputs_per_group, -1).T' to 'weight_matrix ' in host memory. Here weight_matrix means a learned coefficient multiplied by an activation. The important operands are weight_i64: a learned coefficient multiplied by an activation; output_start: the value named 'output start' in this block; outputs_per_group: the value named 'outputs per group' in this block. Context: the function compile_spike_conv2d, which handles compile spike conv2d.

Line 760: `output_start:output_start + outputs_per_group` This is continuation line 2 of the 3-line logical statement that begins at source line 759. Its exact fragment is 'output_start:output_start + outputs_per_group'. The important operands are output_start: the value named 'output start' in this block; outputs_per_group: the value named 'outputs per group' in this block. Read together, the complete operation is: This assigns 'weight_i64[output_start:output_start + outputs_per_group].reshape(outputs_per_group, -1).T' to 'weight_matrix ' in host memory. Here weight_matrix means a learned coefficient multiplied by an activation. The important operands are weight_i64: a learned coefficient multiplied by an activation; output_start: the value named 'output start' in this block; outputs_per_group: the value named 'outputs per group' in this block. Context: the function compile_spike_conv2d, which handles compile spike conv2d.

Line 761: `].reshape(outputs_per_group, -1).T` This is continuation line 3 of the 3-line logical statement that begins at source line 759. Its exact fragment is '].reshape(outputs_per_group, -1).T'. The important operands are

reshape: the value named 'reshape' in this block; outputs_per_group: the value named 'outputs per group' in this block; T: the value named 't' in this block. Read together, the complete operation is: This assigns ‘weight_i64[output_start:output_start + outputs_per_group].reshape(outputs_per_group, -1).T‘ to ‘weight_matrix ‘ in host memory. Here weight_matrix means a learned coefficient multiplied by an activation. The important operands are weight_i64: a learned coefficient multiplied by an activation; output_start: the value named 'output start' in this block; outputs_per_group: the value named 'outputs per group' in this block. Context: the function compile_spike_conv2d, which handles compile spike conv2d.

Line 762: `group_bias = None if bias_values is None else bias_values[` This statement continues through source line 764; the explanation uses the complete expression rather than only the first visual fragment. This assigns ‘None if bias_values is None else bias_values[output_start:output_start + outputs_per_group]‘ to ‘group_bias ‘ in host memory. Here group_bias means an additive learned offset applied after accumulation. The important operands are None: the value named 'none' in this block; bias_values: an additive learned offset applied after accumulation; is: the value named 'is' in this block. Context: the function compile_spike_conv2d, which handles compile spike conv2d.

Line 763: `output_start:output_start + outputs_per_group` This is continuation line 2 of the 3-line logical statement that begins at source line 762. Its exact fragment is ‘output_start:output_start + outputs_per_group‘. The important operands are output_start: the value named 'output start' in this block; outputs_per_group: the value named 'outputs per group' in this block. Read together, the complete operation is: This assigns ‘None if bias_values is None else bias_values[output_start:output_start + outputs_per_group]‘ to ‘group_bias ‘ in host memory. Here group_bias means an additive learned offset applied after accumulation. The important operands are None: the value named 'none' in this block; bias_values: an additive learned offset applied after accumulation; is: the value named 'is' in this block. Context: the function compile_spike_conv2d, which handles compile spike conv2d.

Line 764: `]` This is continuation line 3 of the 3-line logical statement that begins at source line 762. Its exact fragment is ‘]‘. The expression is a literal or structural operator and has no hidden software state. Read together, the complete operation is: This assigns ‘None if bias_values is None else bias_values[output_start:output_start + outputs_per_group]‘ to ‘group_bias ‘ in host memory. Here group_bias means an additive learned offset applied after accumulation. The important operands are None: the value named 'none' in this block; bias_values: an additive learned offset applied after accumulation; is: the value named 'is' in this block. Context: the function compile_spike_conv2d, which handles compile spike conv2d.

Line 765: `programs.append(ConvGroupProgram(` This statement continues through source line 775; the explanation uses the complete expression rather than only the first visual fragment. This calls ‘programs.append‘ with ‘ConvGroupProgram(output_start, outputs_per_group, compile_spike_gemm(columns, weight_matrix, ternary=ternary, bias=group_bias, dataflow=dataflow,),)‘ inside the function compile_spike_conv2d, which handles compile spike conv2d. The call advances the host-side job that tiles matrices and convolutions into validated accelerator commands and packed stream payloads.

Line 766: `output_start,` This is continuation line 2 of the 11-line logical statement that begins at source line 765. Its exact fragment is ‘output_start,‘. The important operands are output_start: the value named 'output start' in this block. Read together, the complete operation is: This calls ‘programs.append‘ with ‘ConvGroupProgram(output_start, outputs_per_group, compile_spike_gemm(columns, weight_matrix, ternary=ternary, bias=group_bias, dataflow=dataflow,),)‘ inside the function compile_spike_conv2d, which handles compile spike conv2d. The call advances the host-side job that tiles matrices and convolutions into validated accelerator commands and packed stream payloads.

Line 767: `outputs_per_group,` This is continuation line 3 of the 11-line logical statement that begins at source line 765. Its exact fragment is ‘outputs_per_group,‘. The important operands are outputs_per_group: the value named 'outputs per group' in this block. Read together, the complete operation is: This calls ‘programs.append‘ with ‘ConvGroupProgram(output_start, outputs_per_group, compile_spike_gemm(columns, weight_matrix, ternary=ternary, bias=group_bias, dataflow=dataflow,),)‘ inside the function compile_spike_conv2d, which handles compile spike conv2d. The call advances the host-side job that tiles matrices and convolutions into validated accelerator commands and packed stream payloads.

Line 768: `compile_spike_gemm(` This is continuation line 4 of the 11-line logical statement that begins at source line 765. Its exact fragment is 'compile_spike_gemm('. The important operands are compile_spike_gemm: a binary event produced when a neuron crosses its threshold. Read together, the complete operation is: This calls 'programs.append' with 'ConvGroupProgram(output_start, outputs_per_group, compile_spike_gemm(columns, weight_matrix, ternary=ternary, bias=group_bias, dataflow=dataflow,),)' inside the function compile_spike_conv2d, which handles compile spike conv2d. The call advances the host-side job that tiles matrices and convolutions into validated accelerator commands and packed stream payloads.

Line 769: `columns,` This is continuation line 5 of the 11-line logical statement that begins at source line 765. Its exact fragment is 'columns,'. The important operands are columns: one output-feature position processed in parallel. Read together, the complete operation is: This calls 'programs.append' with 'ConvGroupProgram(output_start, outputs_per_group, compile_spike_gemm(columns, weight_matrix, ternary=ternary, bias=group_bias, dataflow=dataflow,),)' inside the function compile_spike_conv2d, which handles compile spike conv2d. The call advances the host-side job that tiles matrices and convolutions into validated accelerator commands and packed stream payloads.

Line 770: `weight_matrix,` This is continuation line 6 of the 11-line logical statement that begins at source line 765. Its exact fragment is 'weight_matrix,'. The important operands are weight_matrix: a learned coefficient multiplied by an activation. Read together, the complete operation is: This calls 'programs.append' with 'ConvGroupProgram(output_start, outputs_per_group, compile_spike_gemm(columns, weight_matrix, ternary=ternary, bias=group_bias, dataflow=dataflow,),)' inside the function compile_spike_conv2d, which handles compile spike conv2d. The call advances the host-side job that tiles matrices and convolutions into validated accelerator commands and packed stream payloads.

Line 771: `ternary=ternary,` This is continuation line 7 of the 11-line logical statement that begins at source line 765. Its exact fragment is 'ternary=ternary,'. The important operands are ternary: the value named 'ternary' in this block. Read together, the complete operation is: This calls 'programs.append' with 'ConvGroupProgram(output_start, outputs_per_group, compile_spike_gemm(columns, weight_matrix, ternary=ternary, bias=group_bias, dataflow=dataflow,),)' inside the function compile_spike_conv2d, which handles compile spike conv2d. The call advances the host-side job that tiles matrices and convolutions into validated accelerator commands and packed stream payloads.

Line 772: `bias=group_bias,` This is continuation line 8 of the 11-line logical statement that begins at source line 765. Its exact fragment is 'bias=group_bias,'. The important operands are bias: an additive learned offset applied after accumulation; group_bias: an additive learned offset applied after accumulation. Read together, the complete operation is: This calls 'programs.append' with 'ConvGroupProgram(output_start, outputs_per_group, compile_spike_gemm(columns, weight_matrix, ternary=ternary, bias=group_bias, dataflow=dataflow,),)' inside the function compile_spike_conv2d, which handles compile spike conv2d. The call advances the host-side job that tiles matrices and convolutions into validated accelerator commands and packed stream payloads.

Line 773: `dataflow=dataflow,` This is continuation line 9 of the 11-line logical statement that begins at source line 765. Its exact fragment is 'dataflow=dataflow,'. The important operands are dataflow: the value named 'dataflow' in this block. Read together, the complete operation is: This calls 'programs.append' with 'ConvGroupProgram(output_start, outputs_per_group, compile_spike_gemm(columns, weight_matrix, ternary=ternary, bias=group_bias, dataflow=dataflow,),)' inside the function compile_spike_conv2d, which handles compile spike conv2d. The call advances the host-side job that tiles matrices and convolutions into validated accelerator commands and packed stream payloads.

Line 774: `),` This is continuation line 10 of the 11-line logical statement that begins at source line 765. Its exact fragment is '),'. The expression is a literal or structural operator and has no hidden software state. Read together, the complete operation is: This calls 'programs.append' with 'ConvGroupProgram(output_start, outputs_per_group, compile_spike_gemm(columns, weight_matrix, ternary=ternary, bias=group_bias, dataflow=dataflow,),)' inside the function compile_spike_conv2d, which handles compile spike conv2d. The call advances the host-side job that tiles matrices and convolutions into validated accelerator commands and packed stream payloads.

Line 775: `))` This is continuation line 11 of the 11-line logical statement that begins at source line 765. Its exact fragment is ‘))‘. The expression is a literal or structural operator and has no hidden software state. Read together, the complete operation is: This calls ‘programs.append‘ with ‘ConvGroupProgram(output_start, outputs_per_group, compile_spike_gemm(columns, weight_matrix, ternary=ternary, bias=group_bias, dataflow=dataflow,),)‘ inside the function compile_spike_conv2d, which handles compile spike conv2d. The call advances the host-side job that tiles matrices and convolutions into validated accelerator commands and packed stream payloads.

Line 776: `return CompiledConv2d(` This statement continues through source line 781; the explanation uses the complete expression rather than only the first visual fragment. This returns ‘CompiledConv2d((batch, input_channels, height, width), (batch, output_channels, output_height, output_width), (kernel_height, kernel_width), stride_pair, padding_pair, dilation_pair, group_count, tuple(programs),)‘ to the caller of the function compile_spike_conv2d, which handles compile spike conv2d, ending this invocation. The important operands are CompiledConv2d: the value named ’compiled conv2d’ in this block; batch: the value named ’batch’ in this block; input_channels: the value named ’input channels’ in this block.

Line 777: `(batch, input_channels, height, width),` This is continuation line 2 of the 6-line logical statement that begins at source line 776. Its exact fragment is ‘(batch, input_channels, height, width),‘. The important operands are batch: the value named ’batch’ in this block; input_channels: the value named ’input channels’ in this block; height: the value named ’height’ in this block. Read together, the complete operation is: This returns ‘CompiledConv2d((batch, input_channels, height, width), (batch, output_channels, output_height, output_width), (kernel_height, kernel_width), stride_pair, padding_pair, dilation_pair, group_count, tuple(programs),)‘ to the caller of the function compile_spike_conv2d, which handles compile spike conv2d, ending this invocation. The important operands are CompiledConv2d: the value named ’compiled conv2d’ in this block; batch: the value named ’batch’ in this block; input_channels: the value named ’input channels’ in this block.

Line 778: `(batch, output_channels, output_height, output_width),` This is continuation line 3 of the 6-line logical statement that begins at source line 776. Its exact fragment is ‘(batch, output_channels, output_height, output_width),‘. The important operands are batch: the value named ’batch’ in this block; output_channels: the value named ’output channels’ in this block; output_height: the value named ’output height’ in this block. Read together, the complete operation is: This returns ‘CompiledConv2d((batch, input_channels, height, width), (batch, output_channels, output_height, output_width), (kernel_height, kernel_width), stride_pair, padding_pair, dilation_pair, group_count, tuple(programs),)‘ to the caller of the function compile_spike_conv2d, which handles compile spike conv2d, ending this invocation. The important operands are CompiledConv2d: the value named ’compiled conv2d’ in this block; batch: the value named ’batch’ in this block; input_channels: the value named ’input channels’ in this block.

Line 779: `(kernel_height, kernel_width), stride_pair, padding_pair, dilation_pair,` This is continuation line 4 of the 6-line logical statement that begins at source line 776. Its exact fragment is ‘(kernel_height, kernel_width), stride_pair, padding_pair, dilation_pair,‘. The important operands are kernel_height: the value named ’kernel height’ in this block; kernel_width: the value named ’kernel width’ in this block; stride_pair: the value named ’stride pair’ in this block. Read together, the complete operation is: This returns ‘CompiledConv2d((batch, input_channels, height, width), (batch, output_channels, output_height, output_width), (kernel_height, kernel_width), stride_pair, padding_pair, dilation_pair, group_count, tuple(programs),)‘ to the caller of the function compile_spike_conv2d, which handles compile spike conv2d, ending this invocation. The important operands are CompiledConv2d: the value named ’compiled conv2d’ in this block; batch: the value named ’batch’ in this block; input_channels: the value named ’input channels’ in this block.

Line 780: `group_count, tuple(programs),` This is continuation line 5 of the 6-line logical statement that begins at source line 776. Its exact fragment is ‘group_count, tuple(programs),‘. The important operands are group_count: an integer count retained for control or measurable telemetry; tuple: the value named ’tuple’ in this block; programs: the value named ’programs’ in this block. Read together, the complete operation is: This returns ‘CompiledConv2d((batch, input_channels, height, width), (batch, output_channels, output_height, output_width), (kernel_height, kernel_width), stride_pair, padding_pair, dilation_pair, group_count, tuple(programs),)‘ to the caller of the function compile_spike_conv2d, which handles compile spike conv2d, ending this invocation. The important operands are CompiledConv2d: the value named ’compiled conv2d’ in this block; batch: the value named ’batch’ in this block; input_channels: the value named ’input channels’ in this block.

Line 781:) This is continuation line 6 of the 6-line logical statement that begins at source line 776. Its exact fragment is ‘)‘. The expression is a literal or structural operator and has no hidden software state. Read together, the complete operation is: This returns ‘CompiledConv2d((batch, input_channels, height, width), (batch, output_channels, output_height, output_width), (kernel_height, kernel_width), stride_pair, padding_pair, dilation_pair, group_count, tuple(programs),)‘ to the caller of the function compile_spike_conv2d, which handles compile spike conv2d, ending this invocation. 35 software/neuraedge_golden.py

Role in the complete system: implements independent mathematical reference models for every hardware arithmetic primitive.

35.1 Beginner architecture map

Dataflow responsibility This file's end-to-end responsibility is to implements independent mathematical reference models for every hardware arithmetic primitive.

Where it runs This is sequential host software. Python objects live in CPU memory; they become FPGA work only when the compiler packs a command or payload and the PYNQ driver transfers those bytes through AXI DMA or AXI-Lite.

Public structure Classes: Dataflow, ComputeMode, VectorOperation, DataflowDecision. Functions: encode_int8_as_uint8, decode_uint8_as_int8, packed_mac2_u8, gemm_u8_zero_point, direct_centered_gemm, active_outer_indices, active_dot8_indices, binary_weighted_gemm, ternary_weighted_gemm, alpha_xnor_similarity, log_int_softmax_q15, integer_layer_norm, lif_step, ternary_spike, saturate_signed, round_shift_signed, linear_backward_tile, quantize_flexible_scale, sgd_momentum_step, vector_alu, choose_dataflow, peak_dense_gops. Each function annotation below names its enclosing function so an array operation is tied to the model, compiler, driver, test, or report phase that uses it.

Numeric and failure boundary Shapes, signedness, byte order, scaling, and saturation are part of the hardware contract. Validation exceptions are functional safety checks: rejecting malformed input before DMA is different from silently clipping, reshaping, or continuing with an incompatible artifact.

35.3 Line annotations

Line 1: `"""Independent integer reference model for the NeuraEdge universal accelerator."""` This is executable documentation attached to the file whose role is to implements independent mathematical reference models for every hardware arithmetic primitive. It states the intended contract that tests and callers should enforce, but the text itself does not transform data or issue hardware work.

Line 3: `from __future__ import annotations` This imports the named Python API so the file whose role is to implements independent mathematical reference models for every hardware arithmetic primitive can use it explicitly. Imports execute on the host processor and create no FPGA hardware.

Line 5: `from dataclasses import dataclass` This imports the named Python API so the file whose role is to implements independent mathematical reference models for every hardware arithmetic primitive can use it explicitly. Imports execute on the host processor and create no FPGA hardware.

Line 6: `from enum import IntEnum` This imports the named Python API so the file whose role is to implements independent mathematical reference models for every hardware arithmetic primitive can use it explicitly. Imports execute on the host processor and create no FPGA hardware.

Line 7: `from math import ceil, frexp, isqrt` This imports the named Python API so the file whose role is to implements independent mathematical reference models for every hardware arithmetic primitive can use it explicitly. Imports execute on the host processor and create no FPGA hardware.

Line 9: `import numpy as np` This imports the named Python API so the file whose role is to implements independent mathematical reference models for every hardware arithmetic primitive can use it explicitly. Imports execute on the host processor and create no FPGA hardware.

Line 12: `class Dataflow(IntEnum):` This defines class Dataflow, which groups data and methods for dataflow. Instances exist in host memory and organize the flow that implements independent mathematical reference models for every hardware arithmetic primitive.

Line 13: `INPUT_BROADCAST = 0` This assigns ‘0‘ to ‘INPUT_BROADCAST ‘ in host memory. Here INPUT_BROADCAST means the value named ’input broadcast’ in this block. The expression is a literal or structural operator and has no hidden software state. Context: the class Dataflow, which handles dataflow.

Line 14: `WEIGHT_BROADCAST = 1` This assigns ‘1‘ to ‘WEIGHT_BROADCAST ‘ in host memory. Here WEIGHT_BROADCAST means a learned coefficient multiplied by an activation. The expression is a literal or structural operator and has no hidden software state. Context: the class Dataflow, which handles dataflow.

Line 17: `class ComputeMode(IntEnum):` This defines class ComputeMode, which groups data and methods for compute mode. Instances exist in host memory and organize the flow that implements independent mathematical reference models for every hardware arithmetic primitive.

Line 18: `DENSE_OUTER = 0` This assigns ‘0‘ to ‘DENSE_OUTER ‘ in host memory. Here DENSE_OUTER means the value named ’dense outer’ in this block. The expression is a literal or structural operator and has no hidden software state. Context: the class ComputeMode, which handles compute mode.

Line 19: `DENSE_DOT8 = 1` This assigns ‘1‘ to ‘DENSE_DOT8 ‘ in host memory. Here DENSE_DOT8 means the value named ’dense dot8’ in this block. The expression is a literal or structural operator and has no hidden software state. Context: the class ComputeMode, which handles compute mode.

Line 20: `BINARY_WEIGHTED = 2` This assigns ‘2‘ to ‘BINARY_WEIGHTED ‘ in host memory. Here BINARY_WEIGHTED means a learned coefficient multiplied by an activation. The expression is a literal or structural operator and has no hidden software state. Context: the class ComputeMode, which handles compute mode.

Line 21: `TERNARY_WEIGHTED = 3` This assigns ‘3‘ to ‘TERNARY_WEIGHTED ‘ in host memory. Here TERNARY_WEIGHTED means a learned coefficient multiplied by an activation. The expression is a literal or structural operator and has no hidden software state. Context: the class ComputeMode, which handles compute mode.

Line 24: `class VectorOperation(IntEnum):` This defines class VectorOperation, which groups data and methods for vector operation. Instances exist in host memory and organize the flow that implements independent mathematical reference models for every hardware arithmetic primitive.

Line 25: `ADD_SAT = 0` This assigns ‘0‘ to ‘ADD_SAT ‘ in host memory. Here ADD_SAT means the value named ’add sat’ in this block. The expression is a literal or structural operator and has no hidden software state. Context: the class VectorOperation, which handles vector operation.

Line 26: `RELU = 1` This assigns ‘1‘ to ‘RELU ‘ in host memory. Here RELU means the value named ’relu’ in this block. The expression is a literal or structural operator and has no hidden software state. Context: the class VectorOperation, which handles vector operation.

Line 27: `REQUANTIZE = 2` This assigns ‘2‘ to ‘REQUANTIZE ‘ in host memory. Here REQUANTIZE means the conversion of a wide accumulated result back into a bounded activation code. The expression is a literal or structural operator and has no hidden software state. Context: the class VectorOperation, which handles vector operation.

Line 28: `BINARY_SPIKE = 3` This assigns ‘3‘ to ‘BINARY_SPIKE ‘ in host memory. Here BINARY_SPIKE means a binary event produced when a neuron crosses its threshold. The expression is a literal or structural operator and has no hidden software state. Context: the class VectorOperation, which handles vector operation.

Line 29: `TERNARY_SPIKE = 4` This assigns ‘4‘ to ‘TERNARY_SPIKE ‘ in host memory. Here TERNARY_SPIKE means a binary event produced when a neuron crosses its threshold. The expression is a literal or structural operator and has no hidden software state. Context: the class VectorOperation, which handles vector operation.

Line 30: `SURROGATE_GRADIENT = 5` This assigns ‘5‘ to ‘SURROGATE_GRADIENT ‘ in host memory. Here SURROGATE_GRADIENT means the signed loss derivative used to update a learned parameter. The expression is a literal or structural operator and has no hidden software state. Context: the class VectorOperation, which handles vector operation.

Line 31: `MAXIMUM = 6` This assigns ‘6‘ to ‘MAXIMUM ‘ in host memory. Here MAXIMUM means the value named ’maximum’ in this block. The expression is a literal or structural operator and has no hidden software state. Context: the class VectorOperation, which handles vector operation.

Line 32: `MULTIPLY_Q15 = 7` This assigns ‘7‘ to ‘MULTIPLY_Q15 ‘ in host memory. Here MULTIPLY_Q15 means the value named ’multiply q15’ in this block. The expression is a literal or structural operator and has no hidden software state. Context: the class VectorOperation, which handles vector operation.

Line 33: `CLAMP = 8` This assigns ‘8‘ to ‘CLAMP ‘ in host memory. Here CLAMP means the value named ’clamp’ in this block. The expression is a literal or structural operator and has no hidden software state. Context: the class VectorOperation, which handles vector operation.

Line 34: `FLEX_REQUANTIZE = 9` This assigns ‘9‘ to ‘FLEX_REQUANTIZE ‘ in host memory. Here FLEX_REQUANTIZE means the conversion of a wide accumulated result back into a bounded activation code. The expression is a literal or structural operator and has no hidden software state. Context: the class VectorOperation, which handles vector operation.

Line 35: `SELECT_ZERO = 10` This assigns ‘10‘ to ‘SELECT_ZERO ‘ in host memory. Here SELECT_ZERO means the value named ’select zero’ in this block. The expression is a literal or structural operator and has no hidden software state. Context: the class VectorOperation, which handles vector operation.

Line 36: `SELECT_NONZERO = 11` This assigns ‘11‘ to ‘SELECT_NONZERO ‘ in host memory. Here SELECT_NONZERO means the value named ’select nonzero’ in this block. The expression is a literal or structural operator and has no hidden software state. Context: the class VectorOperation, which handles vector operation.

Line 37: `COMPARE_GE = 12` This assigns ‘12‘ to ‘COMPARE_GE ‘ in host memory. Here COMPARE_GE means the value named ’compare ge’ in this block. The expression is a literal or structural operator and has no hidden software state. Context: the class VectorOperation, which handles vector operation.

Line 40: `@dataclass(frozen=True)` This decorator changes how the following class or function is constructed. ‘@dataclass(frozen=True)‘ is applied at import time on the host and is part of the file whose role is to implements independent mathematical reference models for every hardware arithmetic primitive; it creates no FPGA circuit by itself.

Line 41: `class DataflowDecision:` This defines class DataflowDecision, which groups data and methods for dataflow decision. Instances exist in host memory and organize the flow that implements independent mathematical reference models for every hardware arithmetic primitive.

Line 42: `mode: Dataflow` Inside the class DataflowDecision, which handles dataflow decision, this statement advances the host implementation that implements independent mathematical reference models for every hardware arithmetic primitive. The important operands are mode: the value named ’mode’ in this block; Dataflow: the value named ’dataflow’ in this block.

Line 43: `input_broadcast_bytes: int` Inside the class DataflowDecision, which handles dataflow decision, this statement advances the host implementation that implements independent mathematical reference models for every hardware arithmetic primitive. The important operands are input_broadcast_bytes: the value named 'input broadcast bytes' in this block.

Line 44: `weight_broadcast_bytes: int` Inside the class DataflowDecision, which handles dataflow decision, this statement advances the host implementation that implements independent mathematical reference models for every hardware arithmetic primitive. The important operands are weight_broadcast_bytes: a learned coefficient multiplied by an activation.

Line 47: `def encode_int8_as_uint8(values: np.ndarray) -> np.ndarray:` This starts function encode_int8_as_uint8. Its indented body performs encode int8 as uint8 as part of the file that implements independent mathematical reference models for every hardware arithmetic primitive; it runs only when called.

Line 48: `"""Map signed INT8 bit patterns to the accelerator's unsigned arithmetic domain."""` This is executable documentation attached to the function encode_int8_as_uint8, which handles encode int8 as uint8. It states the intended contract that tests and callers should enforce, but the text itself does not transform data or issue hardware work.

Line 49: `signed = np.asarray(values, dtype=np.int16)` This assigns 'np.asarray(values, dtype=np.int16)' to 'signed ' in host memory. Here signed means the value named 'signed' in this block. The important operands are asarray: the value named 'asarray' in this block; values: the value named 'values' in this block; dtype: the value named 'dtype' in this block. Context: the function encode_int8_as_uint8, which handles encode int8 as uint8.

Line 50: `if np.any(signed < -128) or np.any(signed > 127):` This executes the following indented host-code branch only when 'np.any(signed < -128) or np.any(signed > 127)' is true. The important operands are any: the value named 'any' in this block; or: the value named 'or' in this block. Context: the function encode_int8_as_uint8, which handles encode int8 as uint8.

Line 51: `raise ValueError("signed INT8 values must be in [-128, 127]")` This rejects an invalid state by raising 'ValueError("signed INT8 values must be in [-128, 127]")'. Failing before DMA prevents malformed shapes or artifacts from silently becoming hardware results.

Line 52: `return (signed + 128).astype(np.uint8)` This returns '(signed + 128).astype(np.uint8)' to the caller of the function encode_int8_as_uint8, which handles encode int8 as uint8, ending this invocation. The important operands are astype: the value named 'astype' in this block; uint8: the value named 'uint8' in this block.

Line 55: `def decode_uint8_as_int8(values: np.ndarray) -> np.ndarray:` This starts function decode_uint8_as_int8. Its indented body performs decode uint8 as int8 as part of the file that implements independent mathematical reference models for every hardware arithmetic primitive; it runs only when called.

Line 56: `"""Undo encode_int8_as_uint8 without relying on implementation-defined casts."""` This is executable documentation attached to the function decode_uint8_as_int8, which handles decode uint8 as int8. It states the intended contract that tests and callers should enforce, but the text itself does not transform data or issue hardware work.

Line 57: `unsigned = np.asarray(values, dtype=np.int16)` This assigns 'np.asarray(values, dtype=np.int16)' to 'unsigned ' in host memory. Here unsigned means the value named 'unsigned' in this block. The important operands are asarray: the value named 'asarray' in this block; values: the value named 'values' in this block; dtype: the value named 'dtype' in this block. Context: the function decode_uint8_as_int8, which handles decode uint8 as int8.

Line 58: `if np.any(unsigned < 0) or np.any(unsigned > 255):` This executes the following indented host-code branch only when 'np.any(unsigned < 0) or np.any(unsigned > 255)' is true. The important operands are any: the value named 'any' in this block; or: the value named 'or' in this block. Context: the function decode_uint8_as_int8, which handles decode uint8 as int8.

Line 59: `raise ValueError("encoded values must be in [0, 255]")` This rejects an invalid state by raising ‘ValueError("encoded values must be in [0, 255]")‘. Failing before DMA prevents malformed shapes or artifacts from silently becoming hardware results.

Line 60: `return (unsigned - 128).astype(np.int16)` This returns ‘(unsigned - 128).astype(np.int16)‘ to the caller of the function decode_uint8_as_int8, which handles decode uint8 as int8, ending this invocation. The important operands are astype: the value named ’astype’ in this block; int16: the value named ’int16’ in this block.

Line 63: `def packed_mac2_u8(activation: int, weight_lo: int, weight_hi: int) -> tuple[int, int]:` This starts function packed_mac2_u8. Its indented body performs packed mac2 u8 as part of the file that implements independent mathematical reference models for every hardware arithmetic primitive; it runs only when called.

Line 64: `"""Bit-accurate model of neuraedge_mac2_u8, including its guard-bit packing."""` This is executable documentation attached to the function packed_mac2_u8, which handles packed mac2 u8. It states the intended contract that tests and callers should enforce, but the text itself does not transform data or issue hardware work.

Line 65: `for name, value in (("activation", activation), ("weight_lo", weight_lo), ("weight_hi", weight_hi)):` This iterates name, value over ‘(("activation", activation), ("weight_lo", weight_lo), ("weight_hi", weight_hi))‘. Each iteration repeats the indented host operation, commonly once per layer, tile, timestep, or test case in the function packed_mac2_u8, which handles packed mac2 u8.

Line 66: `if not 0 <= value <= 255:` This executes the following indented host-code branch only when ‘not 0 <= value <= 255‘ is true. The important operands are not: the value named ’not’ in this block; value: the value named ’value’ in this block. Context: the function packed_mac2_u8, which handles packed mac2 u8.

Line 67: `raise ValueError(f"{name} must be an unsigned byte")` This rejects an invalid state by raising ‘ValueError(f"{name} must be an unsigned byte")‘. Failing before DMA prevents malformed shapes or artifacts from silently becoming hardware results.

Line 68: `packed_weight = weight_lo | (weight_hi << 17)` This assigns ‘weight_lo | (weight_hi << 17)‘ to ‘packed_weight ‘ in host memory. Here packed_weight means a learned coefficient multiplied by an activation. The important operands are weight_lo: a learned coefficient multiplied by an activation; weight_hi: a learned coefficient multiplied by an activation. Context: the function packed_mac2_u8, which handles packed mac2 u8.

Line 69: `packed_product = packed_weight * activation` This assigns ‘packed_weight * activation‘ to ‘packed_product ‘ in host memory. Here packed_product means the value named ’packed product’ in this block. The important operands are packed_weight: a learned coefficient multiplied by an activation; activation: an input feature value consumed by a neuron or multiply-accumulate operation. Context: the function packed_mac2_u8, which handles packed mac2 u8.

Line 70: `return packed_product & 0xFFFF, (packed_product >> 17) & 0xFFFF` This returns ‘packed_product & 0xFFFF, (packed_product >> 17) & 0xFFFF‘ to the caller of the function packed_mac2_u8, which handles packed mac2 u8, ending this invocation. The important operands are packed_product: the value named ’packed product’ in this block.

Line 73: `def gemm_u8_zero_point(` This starts function gemm_u8_zero_point. Its indented body performs gemm u8 zero point as part of the file that implements independent mathematical reference models for every hardware arithmetic primitive; it runs only when called.

Line 74: `activations: np.ndarray,` Inside the function gemm_u8_zero_point, which handles gemm u8 zero point, this statement advances the host implementation that implements independent mathematical reference models for every hardware arithmetic primitive. The important operands are activations: an input feature value consumed by a neuron or multiply-accumulate operation; ndarray: the value named ’ndarray’ in this block.

Line 75: `weights: np.ndarray,` Inside the function gemm_u8_zero_point, which handles gemm u8 zero point, this statement advances the host implementation that implements independent mathematical reference models for every hardware arithmetic primitive. The important operands are weights: a learned coefficient multiplied by an activation; ndarray: the value named 'ndarray' in this block.

Line 76: `activation_zero_point: int,` Inside the function gemm_u8_zero_point, which handles gemm u8 zero point, this statement advances the host implementation that implements independent mathematical reference models for every hardware arithmetic primitive. The important operands are activation_zero_point: an input feature value consumed by a neuron or multiply-accumulate operation.

Line 77: `weight_zero_point: int,` Inside the function gemm_u8_zero_point, which handles gemm u8 zero point, this statement advances the host implementation that implements independent mathematical reference models for every hardware arithmetic primitive. The important operands are weight_zero_point: a learned coefficient multiplied by an activation.

Line 78: `bias: np.ndarray | None = None,` This assigns 'None,' to 'bias' in host memory. Here bias means an additive learned offset applied after accumulation. The important operands are None: the value named 'none' in this block. Context: the function gemm_u8_zero_point, which handles gemm u8 zero point.

Line 79: `) -> np.ndarray:` Inside the function gemm_u8_zero_point, which handles gemm u8 zero point, this statement advances the host implementation that implements independent mathematical reference models for every hardware arithmetic primitive. The important operands are ndarray: the value named 'ndarray' in this block.

Line 80: `"""Compute (A-Za)(B-Zb)+bias using the accelerator's raw-sum correction."""` This is executable documentation attached to the function gemm_u8_zero_point, which handles gemm u8 zero point. It states the intended contract that tests and callers should enforce, but the text itself does not transform data or issue hardware work.

Line 81: `a = np.asarray(activations, dtype=np.int64)` This assigns 'np.asarray(activations, dtype=np.int64)' to 'a ' in host memory. Here a means the value named 'a' in this block. The important operands are asarray: the value named 'asarray' in this block; activations: an input feature value consumed by a neuron or multiply-accumulate operation; dtype: the value named 'dtype' in this block. Context: the function gemm_u8_zero_point, which handles gemm u8 zero point.

Line 82: `b = np.asarray(weights, dtype=np.int64)` This assigns 'np.asarray(weights, dtype=np.int64)' to 'b ' in host memory. Here b means the value named 'b' in this block. The important operands are asarray: the value named 'asarray' in this block; weights: a learned coefficient multiplied by an activation; dtype: the value named 'dtype' in this block. Context: the function gemm_u8_zero_point, which handles gemm u8 zero point.

Line 83: `if a.ndim != 2 or b.ndim != 2 or a.shape[1] != b.shape[0]:` This executes the following indented host-code branch only when 'a.ndim != 2 or b.ndim != 2 or a.shape[1] != b.shape[0]' is true. The important operands are a: the value named 'a' in this block; ndim: the value named 'ndim' in this block; or: the value named 'or' in this block. Context: the function gemm_u8_zero_point, which handles gemm u8 zero point.

Line 84: `raise ValueError("expected A[M,K] and B[K,N]")` This rejects an invalid state by raising 'ValueError("expected A[M,K] and B[K,N]")'. Failing before DMA prevents malformed shapes or artifacts from silently becoming hardware results.

Line 85: `if np.any(a < 0) or np.any(a > 255) or np.any(b < 0) or np.any(b > 255):` This executes the following indented host-code branch only when 'np.any(a $<$ 0) or np.any(a $>$ 255) or np.any(b $<$ 0) or np.any(b $>$ 255)' is true. The important operands are any: the value named 'any' in this block; a: the value named 'a' in this block; or: the value named 'or' in this block. Context: the function gemm_u8_zero_point, which handles gemm u8 zero point.

Line 86: `raise ValueError("accelerator GEMM operands must be unsigned bytes")` This rejects an invalid state by raising 'ValueError("accelerator GEMM operands must be unsigned bytes")'. Failing before DMA prevents malformed shapes or artifacts from silently becoming hardware results.

Line 87: `if not 0 <= activation_zero_point <= 255 or not 0 <= weight_zero_point <= 255:` This executes the following indented host-code branch only when ‘not 0 <= activation_zero_point <= 255 or not 0 <= weight_zero_point <= 255‘ is true. The important operands are not: the value named ’not’ in this block; activation_zero_point: an input feature value consumed by a neuron or multiply-accumulate operation; or: the value named ’or’ in this block. Context: the function gemm_u8_zero_point, which handles gemm u8 zero point.

Line 88: `raise ValueError("zero points must be unsigned bytes")` This rejects an invalid state by raising ‘ValueError("zero points must be unsigned bytes")‘. Failing before DMA prevents malformed shapes or artifacts from silently becoming hardware results.

Line 90: `reduction = a.shape[1]` This assigns ‘a.shape[1]‘ to ‘reduction ‘ in host memory. Here reduction means the value named ’reduction’ in this block. The important operands are a: the value named ’a’ in this block; shape: the value named ’shape’ in this block. Context: the function gemm_u8_zero_point, which handles gemm u8 zero point.

Line 91: `raw = a @ b` This assigns ‘a @ b‘ to ‘raw ‘ in host memory. Here raw means the value named ’raw’ in this block. The important operands are a: the value named ’a’ in this block; b: the value named ’b’ in this block. Context: the function gemm_u8_zero_point, which handles gemm u8 zero point.

Line 92: `row_sum = a.sum(axis=1, keepdims=True)` This assigns ‘a.sum(axis=1, keepdims=True)‘ to ‘row_sum ‘ in host memory. Here row_sum means one output-row position processed by the tensor tile. The important operands are a: the value named ’a’ in this block; sum: the value named ’sum’ in this block; axis: the value named ’axis’ in this block. Context: the function gemm_u8_zero_point, which handles gemm u8 zero point.

Line 93: `column_sum = b.sum(axis=0, keepdims=True)` This assigns ‘b.sum(axis=0, keepdims=True)‘ to ‘column_sum ‘ in host memory. Here column_sum means one output-feature position processed in parallel. The important operands are b: the value named ’b’ in this block; sum: the value named ’sum’ in this block; axis: the value named ’axis’ in this block. Context: the function gemm_u8_zero_point, which handles gemm u8 zero point.

Line 94: `corrected = (` This statement continues through source line 99; the explanation uses the complete expression rather than only the first visual fragment. This assigns ‘(raw - weight_zero_point * row_sum - activation_zero_point * column_sum + reduction * activation_zero_point * weight_zero_point)‘ to ‘corrected ‘ in host memory. Here corrected means the value named ’corrected’ in this block. The important operands are raw: the value named ’raw’ in this block; weight_zero_point: a learned coefficient multiplied by an activation; row_sum: one output-row position processed by the tensor tile. Context: the function gemm_u8_zero_point, which handles gemm u8 zero point.

Line 95: `raw` This is continuation line 2 of the 6-line logical statement that begins at source line 94. Its exact fragment is ‘raw‘. The important operands are raw: the value named ’raw’ in this block. Read together, the complete operation is: This assigns ‘(raw - weight_zero_point * row_sum - activation_zero_point * column_sum + reduction * activation_zero_point * weight_zero_point)‘ to ‘corrected ‘ in host memory. Here corrected means the value named ’corrected’ in this block. The important operands are raw: the value named ’raw’ in this block; weight_zero_point: a learned coefficient multiplied by an activation; row_sum: one output-row position processed by the tensor tile. Context: the function gemm_u8_zero_point, which handles gemm u8 zero point.

Line 96: `- weight_zero_point * row_sum` This is continuation line 3 of the 6-line logical statement that begins at source line 94. Its exact fragment is ‘- weight_zero_point * row_sum‘. The important operands are weight_zero_point: a learned coefficient multiplied by an activation; row_sum: one output-row position processed by the tensor tile. Read together, the complete operation is: This assigns ‘(raw - weight_zero_point * row_sum - activation_zero_point * column_sum + reduction * activation_zero_point * weight_zero_point)‘ to ‘corrected ‘ in host memory. Here corrected means the value named ’corrected’ in this block. The important operands are raw: the value named ’raw’ in this block; weight_zero_point: a learned coefficient multiplied by an activation; row_sum: one output-row position processed by the tensor tile. Context: the function gemm_u8_zero_point, which handles gemm u8 zero point.

Line 97: `- activation_zero_point * column_sum` This is continuation line 4 of the 6-line logical statement that begins at source line 94. Its exact fragment is ‘- activation_zero_point * column_sum‘. The important operands are activation_zero_point: an input feature value consumed by a neuron or multiply-accumulate operation; column_sum:

one output-feature position processed in parallel. Read together, the complete operation is: This assigns ‘(raw - weight_zero_point * row_sum - activation_zero_point * column_sum + reduction * activation_zero_point * weight_zero_point)‘ to ‘corrected ‘ in host memory. Here corrected means the value named ’corrected’ in this block. The important operands are raw: the value named ’raw’ in this block; weight_zero_point: a learned coefficient multiplied by an activation; row_sum: one output-row position processed by the tensor tile. Context: the function gemm_u8_zero_point, which handles gemm u8 zero point.

Line 98: `+ reduction * activation_zero_point * weight_zero_point` This is continuation line 5 of the 6-line logical statement that begins at source line 94. Its exact fragment is ‘+ reduction * activation_zero_point * weight_zero_point‘. The important operands are reduction: the value named ’reduction’ in this block; activation_zero_point: an input feature value consumed by a neuron or multiply-accumulate operation; weight_zero_point: a learned coefficient multiplied by an activation. Read together, the complete operation is: This assigns ‘(raw - weight_zero_point * row_sum - activation_zero_point * column_sum + reduction * activation_zero_point * weight_zero_point)‘ to ‘corrected ‘ in host memory. Here corrected means the value named ’corrected’ in this block. The important operands are raw: the value named ’raw’ in this block; weight_zero_point: a learned coefficient multiplied by an activation; row_sum: one output-row position processed by the tensor tile. Context: the function gemm_u8_zero_point, which handles gemm u8 zero point.

Line 99: `)` This is continuation line 6 of the 6-line logical statement that begins at source line 94. Its exact fragment is ‘)‘. The expression is a literal or structural operator and has no hidden software state. Read together, the complete operation is: This assigns ‘(raw - weight_zero_point * row_sum - activation_zero_point * column_sum + reduction * activation_zero_point * weight_zero_point)‘ to ‘corrected ‘ in host memory. Here corrected means the value named ’corrected’ in this block. The important operands are raw: the value named ’raw’ in this block; weight_zero_point: a learned coefficient multiplied by an activation; row_sum: one output-row position processed by the tensor tile. Context: the function gemm_u8_zero_point, which handles gemm u8 zero point.

Line 100: `if bias is not None:` This executes the following indented host-code branch only when ‘bias is not None‘ is true. The important operands are bias: an additive learned offset applied after accumulation; is: the value named ’is’ in this block; not: the value named ’not’ in this block. Context: the function gemm_u8_zero_point, which handles gemm u8 zero point.

Line 101: `bias_array = np.asarray(bias, dtype=np.int64).reshape(1, -1)` This assigns ‘np.asarray(bias, dtype=np.int64 -1)‘ to ‘bias_array ‘ in host memory. Here bias_array means an additive learned offset applied after accumulation. The important operands are asarray: the value named ’asarray’ in this block; bias: an additive learned offset applied after accumulation; dtype: the value named ’dtype’ in this block. Context: the function gemm_u8_zero_point, which handles gemm u8 zero point.

Line 102: `if bias_array.shape[1] != b.shape[1]:` This executes the following indented host-code branch only when ‘bias_array.shape[1] != b.shape[1]‘ is true. The important operands are bias_array: an additive learned offset applied after accumulation; shape: the value named ’shape’ in this block; b: the value named ’b’ in this block. Context: the function gemm_u8_zero_point, which handles gemm u8 zero point.

Line 103: `raise ValueError("bias length must equal output columns")` This rejects an invalid state by raising ‘ValueError("bias length must equal output columns")‘. Failing before DMA prevents malformed shapes or artifacts from silently becoming hardware results.

Line 104: `corrected = corrected + bias_array` This assigns ‘corrected + bias_array‘ to ‘corrected ‘ in host memory. Here corrected means the value named ’corrected’ in this block. The important operands are corrected: the value named ’corrected’ in this block; bias_array: an additive learned offset applied after accumulation. Context: the function gemm_u8_zero_point, which handles gemm u8 zero point.

Line 105: `return corrected` This returns ‘corrected‘ to the caller of the function gemm_u8_zero_point, which handles gemm u8 zero point, ending this invocation. The important operands are corrected: the value named ’corrected’ in this block.

Line 108: `def direct_centered_gemm(` This starts function direct_centered_gemm. Its indented body performs direct centered gemm as part of the file that implements independent mathematical reference models for every hardware arithmetic primitive; it runs only when called.

Line 109: `activations: np.ndarray,` Inside the function direct_centered_gemm, which handles direct centered gemm, this statement advances the host implementation that implements independent mathematical reference models for every hardware arithmetic primitive. The important operands are activations: an input feature value consumed by a neuron or multiply-accumulate operation; ndarray: the value named 'ndarray' in this block.

Line 110: `weights: np.ndarray,` Inside the function direct_centered_gemm, which handles direct centered gemm, this statement advances the host implementation that implements independent mathematical reference models for every hardware arithmetic primitive. The important operands are weights: a learned coefficient multiplied by an activation; ndarray: the value named 'ndarray' in this block.

Line 111: `activation_zero_point: int,` Inside the function direct_centered_gemm, which handles direct centered gemm, this statement advances the host implementation that implements independent mathematical reference models for every hardware arithmetic primitive. The important operands are activation_zero_point: an input feature value consumed by a neuron or multiply-accumulate operation.

Line 112: `weight_zero_point: int,` Inside the function direct_centered_gemm, which handles direct centered gemm, this statement advances the host implementation that implements independent mathematical reference models for every hardware arithmetic primitive. The important operands are weight_zero_point: a learned coefficient multiplied by an activation.

Line 113: `bias: np.ndarray | None = None,` This assigns 'None,' to 'bias' in host memory. Here bias means an additive learned offset applied after accumulation. The important operands are None: the value named 'none' in this block. Context: the function direct_centered_gemm, which handles direct centered gemm.

Line 114: `) -> np.ndarray:` Inside the function direct_centered_gemm, which handles direct centered gemm, this statement advances the host implementation that implements independent mathematical reference models for every hardware arithmetic primitive. The important operands are ndarray: the value named 'ndarray' in this block.

Line 115: `"""Simple centered expression used only as an independent algebra oracle."""` This is executable documentation attached to the function direct_centered_gemm, which handles direct centered gemm. It states the intended contract that tests and callers should enforce, but the text itself does not transform data or issue hardware work.

Line 116: `a = np.asarray(activations, dtype=np.int64) - activation_zero_point` This assigns 'np.asarray(activations, dtype=np.int64) - activation_zero_point' to 'a ' in host memory. Here a means the value named 'a' in this block. The important operands are asarray: the value named 'asarray' in this block; activations: an input feature value consumed by a neuron or multiply-accumulate operation; dtype: the value named 'dtype' in this block. Context: the function direct_centered_gemm, which handles direct centered gemm.

Line 117: `b = np.asarray(weights, dtype=np.int64) - weight_zero_point` This assigns 'np.asarray(weights, dtype=np.int64) - weight_zero_point' to 'b ' in host memory. Here b means the value named 'b' in this block. The important operands are asarray: the value named 'asarray' in this block; weights: a learned coefficient multiplied by an activation; dtype: the value named 'dtype' in this block. Context: the function direct_centered_gemm, which handles direct centered gemm.

Line 118: `result = a @ b` This assigns 'a @ b' to 'result ' in host memory. Here result means the value named 'result' in this block. The important operands are a: the value named 'a' in this block; b: the value named 'b' in this block. Context: the function direct_centered_gemm, which handles direct centered gemm.

Line 119: `if bias is not None:` This executes the following indented host-code branch only when ‘bias is not None‘ is true. The important operands are bias: an additive learned offset applied after accumulation; is: the value named ’is’ in this block; not: the value named ’not’ in this block. Context: the function direct_centered_gemm, which handles direct centered gemm.

Line 120: `result = result + np.asarray(bias, dtype=np.int64).reshape(1, -1)` This assigns ‘result + np.asarray(bias, dtype=np.int64).reshape(1, -1)‘ to ‘result ‘ in host memory. Here result means the value named ’result’ in this block. The important operands are result: the value named ’result’ in this block; asarray: the value named ’asarray’ in this block; bias: an additive learned offset applied after accumulation. Context: the function direct_centered_gemm, which handles direct centered gemm.

Line 121: `return result` This returns ‘result‘ to the caller of the function direct_centered_gemm, which handles direct centered gemm, ending this invocation. The important operands are result: the value named ’result’ in this block.

Line 124: `def active_outer_indices(activations: np.ndarray, zero_point: int) -> np.ndarray:` This starts function active_outer_indices. Its indented body performs active outer indices as part of the file that implements independent mathematical reference models for every hardware arithmetic primitive; it runs only when called.

Line 125: `"""Return K indices where at least one row contains a non-zero activation."""` This is executable documentation attached to the function active_outer_indices, which handles active outer indices. It states the intended contract that tests and callers should enforce, but the text itself does not transform data or issue hardware work.

Line 126: `a = np.asarray(activations)` This assigns ‘np.asarray(activations)‘ to ‘a ‘ in host memory. Here a means the value named ’a’ in this block. The important operands are asarray: the value named ’asarray’ in this block; activations: an input feature value consumed by a neuron or multiply-accumulate operation. Context: the function active_outer_indices, which handles active outer indices.

Line 127: `if a.ndim != 2:` This executes the following indented host-code branch only when ‘a.ndim != 2‘ is true. The important operands are a: the value named ’a’ in this block; ndim: the value named ’ndim’ in this block. Context: the function active_outer_indices, which handles active outer indices.

Line 128: `raise ValueError("outer-mode activations must have shape [M,K]")` This rejects an invalid state by raising ‘ValueError("outer-mode activations must have shape [M,K]")‘. Failing before DMA prevents malformed shapes or artifacts from silently becoming hardware results.

Line 129: `return np.flatnonzero(np.any(a != zero_point, axis=0)).astype(np.int64)` This returns ‘np.flatnonzero(np.any(a != zero_point, axis=0)).astype(np.int64)‘ to the caller of the function active_outer_indices, which handles active outer indices, ending this invocation. The important operands are flatnonzero: the value named ’flatnonzero’ in this block; any: the value named ’any’ in this block; a: the value named ’a’ in this block.

Line 132: `def active_dot8_indices(activation_row: np.ndarray, zero_point: int) -> np.ndarray:` This starts function active_dot8_indices. Its indented body performs active dot8 indices as part of the file that implements independent mathematical reference models for every hardware arithmetic primitive; it runs only when called.

Line 133: `"""Return eight-element K chunks containing at least one non-zero activation."""` This is executable documentation attached to the function active_dot8_indices, which handles active dot8 indices. It states the intended contract that tests and callers should enforce, but the text itself does not transform data or issue hardware work.

Line 134: `row = np.asarray(activation_row).reshape(-1)` This assigns ‘np.asarray(activation_row).reshape(-1)‘ to ‘row ‘ in host memory. Here row means one output-row position processed by the tensor tile. The important operands are asarray: the value named ’asarray’ in this block; activation_row: an input feature value consumed by a neuron or multiply-accumulate operation; reshape: the value named ’reshape’ in this block. Context: the function active_dot8_indices, which handles active dot8 indices.

Line 135: `padded_length = ceil(row.size / 8) * 8` This assigns ‘ceil(row.size / 8) * 8‘ to ‘padded_length ‘ in host memory. Here padded_length means the value named ’padded length’ in this block. The important operands are ceil: the value named ’ceil’ in this block; row: one output-row position processed by the tensor tile; size: the value named ’size’ in this block. Context: the function active_dot8_indices, which handles active dot8 indices.

Line 136: `padded = np.full(padded_length, zero_point, dtype=row.dtype)` This assigns ‘np.full(padded_length, zero_point, dtype=row.dtype)‘ to ‘padded ‘ in host memory. Here padded means the value named ’padded’ in this block. The important operands are full: the value named ’full’ in this block; padded_length: the value named ’padded length’ in this block; zero_point: the integer code representing real numeric zero in affine quantization. Context: the function active_dot8_indices, which handles active dot8 indices.

Line 137: `padded[: row.size] = row` This assigns ‘row‘ to ‘padded[‘ in host memory. Here padded means the value named ’padded’ in this block. The important operands are row: one output-row position processed by the tensor tile. Context: the function active_dot8_indices, which handles active dot8 indices.

Line 138: `chunks = padded.reshape(-1, 8)` This assigns ‘padded.reshape(-1, 8)‘ to ‘chunks ‘ in host memory. Here chunks means the value named ’chunks’ in this block. The important operands are padded: the value named ’padded’ in this block; reshape: the value named ’reshape’ in this block. Context: the function active_dot8_indices, which handles active dot8 indices.

Line 139: `return np.flatnonzero(np.any(chunks != zero_point, axis=1)).astype(np.int64)` This returns ‘np.flatnonze != zero_point, axis=1)).astype(np.int64)‘ to the caller of the function active_dot8_indices, which handles active dot8 indices, ending this invocation. The important operands are flatnonzero: the value named ’flatnonzero’ in this block; any: the value named ’any’ in this block; chunks: the value named ’chunks’ in this block.

Line 142: `def binary_weighted_gemm(spikes: np.ndarray, weights: np.ndarray) -> np.ndarray:` This starts function binary_weighted_gemm. Its indented body performs binary weighted gemm as part of the file that implements independent mathematical reference models for every hardware arithmetic primitive; it runs only when called.

Line 143: `"""Addition-only matrix product for binary activations in {0,1}."""` This is executable documentation attached to the function binary_weighted_gemm, which handles binary weighted gemm. It states the intended contract that tests and callers should enforce, but the text itself does not transform data or issue hardware work.

Line 144: `x = np.asarray(spikes, dtype=np.int64)` This assigns ‘np.asarray(spikes, dtype=np.int64)‘ to ‘x ‘ in host memory. Here x means the value named ’x’ in this block. The important operands are asarray: the value named ’asarray’ in this block; spikes: a binary event produced when a neuron crosses its threshold; dtype: the value named ’dtype’ in this block. Context: the function binary_weighted_gemm, which handles binary weighted gemm.

Line 145: `w = np.asarray(weights, dtype=np.int64)` This assigns ‘np.asarray(weights, dtype=np.int64)‘ to ‘w ‘ in host memory. Here w means the value named ’w’ in this block. The important operands are asarray: the value named ’asarray’ in this block; weights: a learned coefficient multiplied by an activation; dtype: the value named ’dtype’ in this block. Context: the function binary_weighted_gemm, which handles binary weighted gemm.

Line 146: `if np.any((x != 0) & (x != 1)):` This executes the following indented host-code branch only when ‘np.any((x != 0) & (x != 1))‘ is true. The important operands are any: the value named ’any’ in this block; x: the value named ’x’ in this block. Context: the function binary_weighted_gemm, which handles binary weighted gemm.

Line 147: `raise ValueError("binary activations must contain only 0 and 1")` This rejects an invalid state by raising ‘ValueError("binary activations must contain only 0 and 1")‘. Failing before DMA prevents malformed shapes or artifacts from silently becoming hardware results.

Line 148: `return x @ w` This returns ‘x @ w‘ to the caller of the function binary_weighted_gemm, which handles binary weighted gemm, ending this invocation. The important operands are x: the value named ’x’ in this block; w: the value named ’w’ in this block.

Line 151: `def ternary_weighted_gemm(spikes: np.ndarray, weights: np.ndarray) -> np.ndarray:` This starts function ternary_weighted_gemm. Its indented body performs ternary weighted gemm as part of the file that implements independent mathematical reference models for every hardware arithmetic primitive; it runs only when called.

Line 152: `"""Addition/subtraction-only matrix product for activations in {-1,0,1}."""` This is executable documentation attached to the function ternary_weighted_gemm, which handles ternary weighted gemm. It states the intended contract that tests and callers should enforce, but the text itself does not transform data or issue hardware work.

Line 153: `x = np.asarray(spikes, dtype=np.int64)` This assigns 'np.asarray(spikes, dtype=np.int64)' to 'x ' in host memory. Here x means the value named 'x' in this block. The important operands are asarray: the value named 'asarray' in this block; spikes: a binary event produced when a neuron crosses its threshold; dtype: the value named 'dtype' in this block. Context: the function ternary_weighted_gemm, which handles ternary weighted gemm.

Line 154: `w = np.asarray(weights, dtype=np.int64)` This assigns 'np.asarray(weights, dtype=np.int64)' to 'w ' in host memory. Here w means the value named 'w' in this block. The important operands are asarray: the value named 'asarray' in this block; weights: a learned coefficient multiplied by an activation; dtype: the value named 'dtype' in this block. Context: the function ternary_weighted_gemm, which handles ternary weighted gemm.

Line 155: `if np.any((x < -1) | (x > 1)):` This executes the following indented host-code branch only when 'np.any((x < -1) | (x > 1))' is true. The important operands are any: the value named 'any' in this block; x: the value named 'x' in this block. Context: the function ternary_weighted_gemm, which handles ternary weighted gemm.

Line 156: `raise ValueError("ternary activations must be in {-1,0,1}")` This rejects an invalid state by raising 'ValueError("ternary activations must be in {-1,0,1}")'. Failing before DMA prevents malformed shapes or artifacts from silently becoming hardware results.

Line 157: `return x @ w` This returns 'x @ w' to the caller of the function ternary_weighted_gemm, which handles ternary weighted gemm, ending this invocation. The important operands are x: the value named 'x' in this block; w: the value named 'w' in this block.

Line 160: `def alpha_xnor_similarity(query: np.ndarray, key: np.ndarray, alpha_q8: int) -> np.ndarray:` This starts function alpha_xnor_similarity. Its indented body performs alpha xnor similarity as part of the file that implements independent mathematical reference models for every hardware arithmetic primitive; it runs only when called.

Line 161: `"""Equation 18 of Xiao et al. CVPR 2025, represented in unsigned Q8."""` This is executable documentation attached to the function alpha_xnor_similarity, which handles alpha xnor similarity. It states the intended contract that tests and callers should enforce, but the text itself does not transform data or issue hardware work.

Line 162: `q = np.asarray(query, dtype=np.uint8)` This assigns 'np.asarray(query, dtype=np.uint8)' to 'q ' in host memory. Here q means the value named 'q' in this block. The important operands are asarray: the value named 'asarray' in this block; query: the value named 'query' in this block; dtype: the value named 'dtype' in this block. Context: the function alpha_xnor_similarity, which handles alpha xnor similarity.

Line 163: `k = np.asarray(key, dtype=np.uint8)` This assigns 'np.asarray(key, dtype=np.uint8)' to 'k ' in host memory. Here k means the value named 'k' in this block. The important operands are asarray: the value named 'asarray' in this block; key: the value named 'key' in this block; dtype: the value named 'dtype' in this block. Context: the function alpha_xnor_similarity, which handles alpha xnor similarity.

Line 164: `if q.ndim != 2 or k.ndim != 2 or q.shape[1] != k.shape[1]:` This executes the following indented host-code branch only when 'q.ndim != 2 or k.ndim != 2 or q.shape[1] != k.shape[1]' is true. The important operands are q: the value named 'q' in this block; ndim: the value named 'ndim' in this block; or: the value named 'or' in this block. Context: the function alpha_xnor_similarity, which handles alpha xnor similarity.

Line 165: `raise ValueError("expected query[M,D] and key[N,D]")` This rejects an invalid state by raising ‘ValueError("expected query[M,D] and key[N,D]")‘. Failing before DMA prevents malformed shapes or artifacts from silently becoming hardware results.

Line 166: `if np.any(q > 1) or np.any(k > 1):` This executes the following indented host-code branch only when ‘np.any(q > 1) or np.any(k > 1)‘ is true. The important operands are any: the value named ’any’ in this block; q: the value named ’q’ in this block; or: the value named ’or’ in this block. Context: the function alpha_xnor_similarity, which handles alpha xnor similarity.

Line 167: `raise ValueError("alpha-XNOR inputs must be binary")` This rejects an invalid state by raising ‘ValueError("alph XNOR inputs must be binary")‘. Failing before DMA prevents malformed shapes or artifacts from silently becoming hardware results.

Line 168: `if not 0 <= alpha_q8 <= 256:` This executes the following indented host-code branch only when ‘not 0 <= alpha_q8 <= 256‘ is true. The important operands are not: the value named ’not’ in this block; alpha_q8: the programmable weight assigned to matching zero spikes in alpha-XNOR attention. Context: the function alpha_xnor_similarity, which handles alpha xnor similarity.

Line 169: `raise ValueError("alpha_q8 must represent a value in [0,1]")` This rejects an invalid state by raising ‘ValueError("alpha_q8 must represent a value in [0,1]")‘. Failing before DMA prevents malformed shapes or artifacts from silently becoming hardware results.

Line 170: `spike_matches = q.astype(np.int64) @ k.astype(np.int64).T` This assigns ‘q.astype(np.int64) @ k.astype(np.in to ‘spike_matches ‘ in host memory. Here spike_matches means a binary event produced when a neuron crosses its threshold. The important operands are q: the value named ’q’ in this block; astype: the value named ’astype’ in this block; int64: the value named ’int64’ in this block. Context: the function alpha_xnor_similarity, which handles alpha xnor similarity.

Line 171: `zero_matches = (1 - q.astype(np.int64)) @ (1 - k.astype(np.int64)).T` This assigns ‘(1 - q.astype(np.int64) @ (1 - k.astype(np.int64)).T‘ to ‘zero_matches ‘ in host memory. Here zero_matches means the value named ’zero matches’ in this block. The important operands are q: the value named ’q’ in this block; astype: the value named ’astype’ in this block; int64: the value named ’int64’ in this block. Context: the function alpha_xnor_similarity, which handles alpha xnor similarity.

Line 172: `return spike_matches * 256 + zero_matches * alpha_q8` This returns ‘spike_matches * 256 + zero_matches * alpha_q8‘ to the caller of the function alpha_xnor_similarity, which handles alpha xnor similarity, ending this invocation. The important operands are spike_matches: a binary event produced when a neuron crosses its threshold; zero_matches: the value named ’zero matches’ in this block; alpha_q8: the programmable weight assigned to matching zero spikes in alpha-XNOR attention.

Line 175: `def log_int_softmax_q15(scores: np.ndarray, difference_shift: int) -> np.ndarray:` This starts function log_int_softmax_q15. Its indented body performs log int softmax q15 as part of the file that implements independent mathematical reference models for every hardware arithmetic primitive; it runs only when called.

Line 176: `"""Power-of-two softmax with the Q31 reciprocal used by the RTL datapath."""` This is executable documentation attached to the function log_int_softmax_q15, which handles log int softmax q15. It states the intended contract that tests and callers should enforce, but the text itself does not transform data or issue hardware work.

Line 177: `x = np.asarray(scores, dtype=np.int64)` This assigns ‘np.asarray(scores, dtype=np.int64)‘ to ‘x ‘ in host memory. Here x means the value named ’x’ in this block. The important operands are asarray: the value named ’asarray’ in this block; scores: the value named ’scores’ in this block; dtype: the value named ’dtype’ in this block. Context: the function log_int_softmax_q15, which handles log int softmax q15.

Line 178: `if x.ndim != 1 or x.size == 0:` This executes the following indented host-code branch only when ‘x.ndim != 1 or x.size == 0‘ is true. The important operands are x: the value named ’x’ in this block; ndim: the value named ’ndim’ in this block; or: the value named ’or’ in this block. Context: the function log_int_softmax_q15, which handles log int softmax q15.

Line 179: `raise ValueError("scores must be a non-empty vector")` This rejects an invalid state by raising ‘ValueError("scores must be a non-empty vector")‘. Failing before DMA prevents malformed shapes or artifacts from silently becoming hardware results.

Line 180: `if not 0 <= difference_shift <= 31:` This executes the following indented host-code branch only when ‘not 0 <= difference_shift <= 31‘ is true. The important operands are not: the value named ’not’ in this block; difference_shift: the value named ’difference shift’ in this block. Context: the function log_int_softmax_q15, which handles log int softmax q15.

Line 181: `raise ValueError("difference_shift must be in [0,31]")` This rejects an invalid state by raising ‘ValueError("difference_shift must be in [0,31]")‘. Failing before DMA prevents malformed shapes or artifacts from silently becoming hardware results.

Line 182: `differences = x.max() - x` This assigns ‘x.max() - x‘ to ‘differences ‘ in host memory. Here differences means the value named ’differences’ in this block. The important operands are x: the value named ’x’ in this block; max: the value named ’max’ in this block. Context: the function log_int_softmax_q15, which handles log int softmax q15.

Line 183: `exponents = np.minimum(differences >> difference_shift, 15).astype(np.int64)` This assigns ‘np.minimum >> difference_shift, 15).astype(np.int64)‘ to ‘exponents ‘ in host memory. Here exponents means the value named ’exponents’ in this block. The important operands are minimum: the value named ’minimum’ in this block; differences: the value named ’differences’ in this block; difference_shift: the value named ’difference shift’ in this block. Context: the function log_int_softmax_q15, which handles log int softmax q15.

Line 184: `unnormalized = (1 << (15 - exponents)).astype(np.int64)` This assigns ‘(1 << (15 - exponents)).astype(np.int6 to ‘unnormalized ‘ in host memory. Here unnormalized means the value named ’unnormalized’ in this block. The important operands are exponents: the value named ’exponents’ in this block; astype: the value named ’astype’ in this block; int64: the value named ’int64’ in this block. Context: the function log_int_softmax_q15, which handles log int softmax q15.

Line 185: `denominator = int(unnormalized.sum())` This assigns ‘int(unnormalized.sum())‘ to ‘denominator ‘ in host memory. Here denominator means the value named ’denominator’ in this block. The important operands are unnormalized: the value named ’unnormalized’ in this block; sum: the value named ’sum’ in this block. Context: the function log_int_softmax_q15, which handles log int softmax q15.

Line 186: `reciprocal_q31 = ((1 << 31) - 1) // denominator` This assigns ‘((1 << 31) - 1) // denominator‘ to ‘reciprocal_q31 ‘ in host memory. Here reciprocal_q31 means the value named ’reciprocal q31’ in this block. The important operands are denominator: the value named ’denominator’ in this block. Context: the function log_int_softmax_q15, which handles log int softmax q15.

Line 187: `return round_shift_signed(unnormalized * reciprocal_q31, 16)` This returns ‘round_shift_signed(unnormaliz * reciprocal_q31, 16)‘ to the caller of the function log_int_softmax_q15, which handles log int softmax q15, ending this invocation. The important operands are round_shift_signed: the value named ’round shift signed’ in this block; unnormalized: the value named ’unnormalized’ in this block; reciprocal_q31: the value named ’reciprocal q31’ in this block.

Line 190: `def integer_layer_norm(` This starts function integer_layer_norm. Its indented body performs integer layer norm as part of the file that implements independent mathematical reference models for every hardware arithmetic primitive; it runs only when called.

Line 191: `values: np.ndarray,` Inside the function integer_layer_norm, which handles integer layer norm, this statement advances the host implementation that implements independent mathematical reference models for every hardware arithmetic primitive. The important operands are values: the value named 'values' in this block; ndarray: the value named 'ndarray' in this block.

Line 192: `gamma_q15: np.ndarray,` Inside the function integer_layer_norm, which handles integer layer norm, this statement advances the host implementation that implements independent mathematical reference models for every hardware arithmetic primitive. The important operands are gamma_q15: the learned multiplicative LayerNorm parameter; ndarray: the value named 'ndarray' in this block.

Line 193: `beta: np.ndarray,` Inside the function integer_layer_norm, which handles integer layer norm, this statement advances the host implementation that implements independent mathematical reference models for every hardware arithmetic primitive. The important operands are beta: the learned additive LayerNorm parameter; ndarray: the value named 'ndarray' in this block.

Line 194: `epsilon: int = 1,` This assigns '1,' to 'epsilon' in host memory. Here epsilon means the value named 'epsilon' in this block. The expression is a literal or structural operator and has no hidden software state. Context: the function integer_layer_norm, which handles integer layer norm.

Line 195: `) -> np.ndarray:` Inside the function integer_layer_norm, which handles integer layer norm, this statement advances the host implementation that implements independent mathematical reference models for every hardware arithmetic primitive. The important operands are ndarray: the value named 'ndarray' in this block.

Line 196: `"""I-ViT-style integer LayerNorm using sqrt and one shared Q31 reciprocal."""` This is executable documentation attached to the function integer_layer_norm, which handles integer layer norm. It states the intended contract that tests and callers should enforce, but the text itself does not transform data or issue hardware work.

Line 197: `x = np.asarray(values, dtype=np.int64).reshape(-1)` This assigns 'np.asarray(values, dtype=np.int64).reshape(-1)' to 'x ' in host memory. Here x means the value named 'x' in this block. The important operands are asarray: the value named 'asarray' in this block; values: the value named 'values' in this block; dtype: the value named 'dtype' in this block. Context: the function integer_layer_norm, which handles integer layer norm.

Line 198: `gamma = np.asarray(gamma_q15, dtype=np.int64).reshape(-1)` This assigns 'np.asarray(gamma_q15, dtype=np.int64).reshape(-1)' to 'gamma ' in host memory. Here gamma means the learned multiplicative LayerNorm parameter. The important operands are asarray: the value named 'asarray' in this block; gamma_q15: the learned multiplicative LayerNorm parameter; dtype: the value named 'dtype' in this block. Context: the function integer_layer_norm, which handles integer layer norm.

Line 199: `offset = np.asarray(beta, dtype=np.int64).reshape(-1)` This assigns 'np.asarray(beta, dtype=np.int64).reshape(-1)' to 'offset ' in host memory. Here offset means the value named 'offset' in this block. The important operands are asarray: the value named 'asarray' in this block; beta: the learned additive LayerNorm parameter; dtype: the value named 'dtype' in this block. Context: the function integer_layer_norm, which handles integer layer norm.

Line 200: `if x.size == 0 or gamma.size != x.size or offset.size != x.size:` This executes the following indented host-code branch only when 'x.size == 0 or gamma.size != x.size or offset.size != x.size' is true. The important operands are x: the value named 'x' in this block; size: the value named 'size' in this block; or: the value named 'or' in this block. Context: the function integer_layer_norm, which handles integer layer norm.

Line 201: `raise ValueError("values, gamma, and beta must be equally sized non-empty vectors")` This rejects an invalid state by raising 'ValueError("values, gamma, and beta must be equally sized non-empty vectors")'. Failing before DMA prevents malformed shapes or artifacts from silently becoming hardware results.

Line 202: `mean = int(x.sum() // x.size)` This assigns ‘int(x.sum() // x.size)‘ to ‘mean ‘ in host memory. Here mean means the arithmetic average used by normalization. The important operands are x: the value named ’x’ in this block; sum: the value named ’sum’ in this block; size: the value named ’size’ in this block. Context: the function integer_layer_norm, which handles integer layer norm.

Line 203: `centered = x - mean` This assigns ‘x - mean‘ to ‘centered ‘ in host memory. Here centered means the value named ’centered’ in this block. The important operands are x: the value named ’x’ in this block; mean: the arithmetic average used by normalization. Context: the function integer_layer_norm, which handles integer layer norm.

Line 204: `variance = int((centered * centered).sum() // x.size)` This assigns ‘int((centered * centered).sum() // x.size)‘ to ‘variance ‘ in host memory. Here variance means the average squared distance from the mean. The important operands are centered: the value named ’centered’ in this block; sum: the value named ’sum’ in this block; x: the value named ’x’ in this block. Context: the function integer_layer_norm, which handles integer layer norm.

Line 205: `sigma = max(1, isqrt(variance + epsilon))` This assigns ‘max(1, isqrt(variance + epsilon))‘ to ‘sigma ‘ in host memory. Here sigma means the value named ’sigma’ in this block. The important operands are max: the value named ’max’ in this block; isqrt: the value named ’isqrt’ in this block; variance: the average squared distance from the mean. Context: the function integer_layer_norm, which handles integer layer norm.

Line 206: `reciprocal_q31 = ((1 << 31) - 1) // sigma` This assigns ‘((1 << 31) - 1) // sigma‘ to ‘reciprocal_q31 ‘ in host memory. Here reciprocal_q31 means the value named ’reciprocal q31’ in this block. The important operands are sigma: the value named ’sigma’ in this block. Context: the function integer_layer_norm, which handles integer layer norm.

Line 207: `normalized = round_shift_signed(centered * reciprocal_q31, 31)` This assigns ‘round_shift_signed(centered * reciprocal_q31, 31)‘ to ‘normalized ‘ in host memory. Here normalized means the value named ’normalized’ in this block. The important operands are round_shift_signed: the value named ’round shift signed’ in this block; centered: the value named ’centered’ in this block; reciprocal_q31: the value named ’reciprocal q31’ in this block. Context: the function integer_layer_norm, which handles integer layer norm.

Line 208: `return round_shift_signed(normalized * gamma, 15) + offset` This returns ‘round_shift_signed(normalized * gamma, 15) + offset‘ to the caller of the function integer_layer_norm, which handles integer layer norm, ending this invocation. The important operands are round_shift_signed: the value named ’round shift signed’ in this block; normalized: the value named ’normalized’ in this block; gamma: the learned multiplicative LayerNorm parameter.

Line 211: `def lif_step(` This starts function lif_step. Its indented body performs lif step as part of the file that implements independent mathematical reference models for every hardware arithmetic primitive; it runs only when called.

Line 212: `membrane: np.ndarray,` Inside the function lif_step, which handles lif step, this statement advances the host implementation that implements independent mathematical reference models for every hardware arithmetic primitive. The important operands are membrane: the persistent LIF neuron state carrying charge between timesteps; ndarray: the value named ’ndarray’ in this block.

Line 213: `current: np.ndarray,` Inside the function lif_step, which handles lif step, this statement advances the host implementation that implements independent mathematical reference models for every hardware arithmetic primitive. The important operands are current: the value named ’current’ in this block; ndarray: the value named ’ndarray’ in this block.

Line 214: `leak_shift: int,` Inside the function lif_step, which handles lif step, this statement advances the host implementation that implements independent mathematical reference models for every hardware arithmetic primitive. The important operands are leak_shift: the retained fraction of prior membrane state.

Line 215: `threshold: int,` Inside the function lif_step, which handles lif step, this statement advances the host implementation that implements independent mathematical reference models for every hardware arithmetic primitive. The important operands are threshold: the membrane level at which a neuron emits a spike.

Line 216: `reset_value:  int = 0,` This assigns '0,' to 'reset_value' in host memory. Here reset_value means the value named 'reset value' in this block. The expression is a literal or structural operator and has no hidden software state. Context: the function lif_step, which handles lif step.

Line 217: `)  -> tuple[np.ndarray, np.ndarray]:` Inside the function lif_step, which handles lif step, this statement advances the host implementation that implements independent mathematical reference models for every hardware arithmetic primitive. The important operands are tuple: the value named 'tuple' in this block; ndarray: the value named 'ndarray' in this block.

Line 218: `"""One deterministic leaky-integrate-and-fire step."""` This is executable documentation attached to the function lif_step, which handles lif step. It states the intended contract that tests and callers should enforce, but the text itself does not transform data or issue hardware work.

Line 219: `v = np.asarray(membrane, dtype=np.int64)` This assigns 'np.asarray(membrane, dtype=np.int64)' to 'v ' in host memory. Here v means the value named 'v' in this block. The important operands are asarray: the value named 'asarray' in this block; membrane: the persistent LIF neuron state carrying charge between timesteps; dtype: the value named 'dtype' in this block. Context: the function lif_step, which handles lif step.

Line 220: `i = np.asarray(current, dtype=np.int64)` This assigns 'np.asarray(current, dtype=np.int64)' to 'i ' in host memory. Here i means the value named 'i' in this block. The important operands are asarray: the value named 'asarray' in this block; current: the value named 'current' in this block; dtype: the value named 'dtype' in this block. Context: the function lif_step, which handles lif step.

Line 221: `integrated = v - (v >> leak_shift) + i` This assigns 'v - (v >> leak_shift) + i' to 'integrated ' in host memory. Here integrated means the value named 'integrated' in this block. The important operands are v: the value named 'v' in this block; leak_shift: the retained fraction of prior membrane state; i: the value named 'i' in this block. Context: the function lif_step, which handles lif step.

Line 222: `spikes = integrated >= threshold` Inside the function lif_step, which handles lif step, this statement advances the host implementation that implements independent mathematical reference models for every hardware arithmetic primitive. The important operands are spikes: a binary event produced when a neuron crosses its threshold; integrated: the value named 'integrated' in this block; threshold: the membrane level at which a neuron emits a spike.

Line 223: `next_membrane = np.where(spikes, reset_value, integrated)` This assigns 'np.where(spikes, reset_value, integrated)' to 'next_membrane ' in host memory. Here next_membrane means the persistent LIF neuron state carrying charge between timesteps. The important operands are where: the value named 'where' in this block; spikes: a binary event produced when a neuron crosses its threshold; reset_value: the value named 'reset value' in this block. Context: the function lif_step, which handles lif step.

Line 224: `return next_membrane.astype(np.int64), spikes.astype(np.uint8)` This returns 'next_membrane.astype(np.in spikes.astype(np.uint8)' to the caller of the function lif_step, which handles lif step, ending this invocation. The important operands are next_membrane: the persistent LIF neuron state carrying charge between timesteps; astype: the value named 'astype' in this block; int64: the value named 'int64' in this block.

Line 227: `def ternary_spike(values:  np.ndarray, threshold:  int) -> np.ndarray:` This starts function ternary_spike. Its indented body performs ternary spike as part of the file that implements independent mathematical reference models for every hardware arithmetic primitive; it runs only when called.

Line 228: `"""Symmetric ternary firing rule used by the addition-only datapath."""` This is executable documentation attached to the function ternary_spike, which handles ternary spike. It states the intended contract that tests and callers should enforce, but the text itself does not transform data or issue hardware work.

Line 229: `x = np.asarray(values, dtype=np.int64)` This assigns ‘np.asarray(values, dtype=np.int64)‘ to ‘x ‘ in host memory. Here x means the value named ’x’ in this block. The important operands are asarray: the value named ’asarray’ in this block; values: the value named ’values’ in this block; dtype: the value named ’dtype’ in this block. Context: the function ternary_spike, which handles ternary spike.

Line 230: `return np.where(x >= threshold, 1, np.where(x <= -threshold, -1, 0)).astype(np.int8)` This returns ‘np.where(x >= threshold, 1, np.where(x <= -threshold, -1, 0)).astype(np.int8)‘ to the caller of the function ternary_spike, which handles ternary spike, ending this invocation. The important operands are where: the value named ’where’ in this block; x: the value named ’x’ in this block; threshold: the membrane level at which a neuron emits a spike.

Line 233: `def saturate_signed(values: np.ndarray | int, bits: int) -> np.ndarray:` This starts function saturate_signed. Its indented body performs saturate signed as part of the file that implements independent mathematical reference models for every hardware arithmetic primitive; it runs only when called.

Line 234: `"""Clamp integers to the exact range of a signed two's-complement field."""` This is executable documentation attached to the function saturate_signed, which handles saturate signed. It states the intended contract that tests and callers should enforce, but the text itself does not transform data or issue hardware work.

Line 235: `if bits < 2 or bits > 63:` This executes the following indented host-code branch only when ‘bits < 2 or bits > 63‘ is true. The important operands are bits: the value named ’bits’ in this block; or: the value named ’or’ in this block. Context: the function saturate_signed, which handles saturate signed.

Line 236: `raise ValueError("bits must be in [2,63]")` This rejects an invalid state by raising ‘ValueError("bits must be in [2,63]")‘. Failing before DMA prevents malformed shapes or artifacts from silently becoming hardware results.

Line 237: `array = np.asarray(values, dtype=np.int64)` This assigns ‘np.asarray(values, dtype=np.int64)‘ to ‘array ‘ in host memory. Here array means the value named ’array’ in this block. The important operands are asarray: the value named ’asarray’ in this block; values: the value named ’values’ in this block; dtype: the value named ’dtype’ in this block. Context: the function saturate_signed, which handles saturate signed.

Line 238: `minimum = -(1 << (bits - 1))` This assigns ‘-(1 << (bits - 1))‘ to ‘minimum ‘ in host memory. Here minimum means the value named ’minimum’ in this block. The important operands are bits: the value named ’bits’ in this block. Context: the function saturate_signed, which handles saturate signed.

Line 239: `maximum = (1 << (bits - 1)) - 1` This assigns ‘(1 << (bits - 1)) - 1‘ to ‘maximum ‘ in host memory. Here maximum means the value named ’maximum’ in this block. The important operands are bits: the value named ’bits’ in this block. Context: the function saturate_signed, which handles saturate signed.

Line 240: `return np.clip(array, minimum, maximum).astype(np.int64)` This returns ‘np.clip(array, minimum, maximum).astype(np.int64)‘ to the caller of the function saturate_signed, which handles saturate signed, ending this invocation. The important operands are clip: the value named ’clip’ in this block; array: the value named ’array’ in this block; minimum: the value named ’minimum’ in this block.

Line 243: `def round_shift_signed(values: np.ndarray | int, shift: int) -> np.ndarray:` This starts function round_shift_signed. Its indented body performs round shift signed as part of the file that implements independent mathematical reference models for every hardware arithmetic primitive; it runs only when called.

Line 244: `"""Round signed integers to nearest, with exact half cases away from zero."""` This is executable documentation attached to the function round_shift_signed, which handles round shift signed. It states the intended contract that tests and callers should enforce, but the text itself does not transform data or issue hardware work.

Line 245: `if not 0 <= shift <= 62:` This executes the following indented host-code branch only when ‘not 0 <= shift <= 62‘ is true. The important operands are not: the value named ’not’ in this block; shift: the value named ’shift’ in this block. Context: the function round_shift_signed, which handles round shift signed.

Line 246: `raise ValueError("shift must be in [0,62]")` This rejects an invalid state by raising ‘ValueError("shift must be in [0,62]")‘. Failing before DMA prevents malformed shapes or artifacts from silently becoming hardware results.

Line 247: `array = np.asarray(values, dtype=np.int64)` This assigns ‘np.asarray(values, dtype=np.int64)‘ to ‘array ‘ in host memory. Here array means the value named ’array’ in this block. The important operands are asarray: the value named ’asarray’ in this block; values: the value named ’values’ in this block; dtype: the value named ’dtype’ in this block. Context: the function round_shift_signed, which handles round shift signed.

Line 248: `if shift == 0:` This executes the following indented host-code branch only when ‘shift == 0‘ is true. The important operands are shift: the value named ’shift’ in this block. Context: the function round_shift_signed, which handles round shift signed.

Line 249: `return array.copy()` This returns ‘array.copy()‘ to the caller of the function round_shift_signed, which handles round shift signed, ending this invocation. The important operands are array: the value named ’array’ in this block; copy: the value named ’copy’ in this block.

Line 250: `magnitude = np.abs(array)` This assigns ‘np.abs(array)‘ to ‘magnitude ‘ in host memory. Here magnitude means the value named ’magnitude’ in this block. The important operands are abs: the value named ’abs’ in this block; array: the value named ’array’ in this block. Context: the function round_shift_signed, which handles round shift signed.

Line 251: `rounded = (magnitude + (1 << (shift - 1))) >> shift` This assigns ‘(magnitude + (1 << (shift - 1))) >> shift‘ to ‘rounded ‘ in host memory. Here rounded means the value named ’rounded’ in this block. The important operands are magnitude: the value named ’magnitude’ in this block; shift: the value named ’shift’ in this block. Context: the function round_shift_signed, which handles round shift signed.

Line 252: `return np.where(array < 0, -rounded, rounded).astype(np.int64)` This returns ‘np.where(array < 0, -rounded, rounded).astype(np.int64)‘ to the caller of the function round_shift_signed, which handles round shift signed, ending this invocation. The important operands are where: the value named ’where’ in this block; array: the value named ’array’ in this block; rounded: the value named ’rounded’ in this block.

Line 255: `def linear_backward_tile(` This starts function linear_backward_tile. Its indented body performs linear backward tile as part of the file that implements independent mathematical reference models for every hardware arithmetic primitive; it runs only when called.

Line 256: `activations: np.ndarray,` Inside the function linear_backward_tile, which handles linear backward tile, this statement advances the host implementation that implements independent mathematical reference models for every hardware arithmetic primitive. The important operands are activations: an input feature value consumed by a neuron or multiply-accumulate operation; ndarray: the value named ’ndarray’ in this block.

Line 257: `weights: np.ndarray,` Inside the function linear_backward_tile, which handles linear backward tile, this statement advances the host implementation that implements independent mathematical reference models for every hardware arithmetic primitive. The important operands are weights: a learned coefficient multiplied by an activation; ndarray: the value named ’ndarray’ in this block.

Line 258: `output_gradients: np.ndarray,` Inside the function linear_backward_tile, which handles linear backward tile, this statement advances the host implementation that implements independent mathematical reference models for every hardware arithmetic primitive. The important operands are output_gradients: the signed loss derivative used to update a learned parameter; ndarray: the value named ’ndarray’ in this block.

Line 259: `*,` Inside the function linear_backward_tile, which handles linear backward tile, this statement advances the host implementation that implements independent mathematical reference models for every hardware arithmetic primitive. The expression is a literal or structural operator and has no hidden software state.

Line 260: `input_gradient_shift: int = 0,` This assigns ‘0,‘ to ‘input_gradient_shift‘ in host memory. Here input_gradient_shift means the signed loss derivative used to update a learned parameter. The expression is a literal or structural operator and has no hidden software state. Context: the function linear_backward_tile, which handles linear backward tile.

Line 261: `weight_gradient_shift: int = 0,` This assigns ‘0,‘ to ‘weight_gradient_shift‘ in host memory. Here weight_gradient_shift means a learned coefficient multiplied by an activation. The expression is a literal or structural operator and has no hidden software state. Context: the function linear_backward_tile, which handles linear backward tile.

Line 262: `) -> tuple[np.ndarray, np.ndarray]:` Inside the function linear_backward_tile, which handles linear backward tile, this statement advances the host implementation that implements independent mathematical reference models for every hardware arithmetic primitive. The important operands are tuple: the value named ’tuple’ in this block; ndarray: the value named ’ndarray’ in this block.

Line 263: `"""Bit-exact reference for the signed RTL linear backward tile."""` This is executable documentation attached to the function linear_backward_tile, which handles linear backward tile. It states the intended contract that tests and callers should enforce, but the text itself does not transform data or issue hardware work.

Line 265: `x = np.asarray(activations, dtype=np.int64)` This assigns ‘np.asarray(activations, dtype=np.int64)‘ to ‘x ‘ in host memory. Here x means the value named ’x’ in this block. The important operands are asarray: the value named ’asarray’ in this block; activations: an input feature value consumed by a neuron or multiply-accumulate operation; dtype: the value named ’dtype’ in this block. Context: the function linear_backward_tile, which handles linear backward tile.

Line 266: `w = np.asarray(weights, dtype=np.int64)` This assigns ‘np.asarray(weights, dtype=np.int64)‘ to ‘w ‘ in host memory. Here w means the value named ’w’ in this block. The important operands are asarray: the value named ’asarray’ in this block; weights: a learned coefficient multiplied by an activation; dtype: the value named ’dtype’ in this block. Context: the function linear_backward_tile, which handles linear backward tile.

Line 267: `dy = np.asarray(output_gradients, dtype=np.int64)` This assigns ‘np.asarray(output_gradients, dtype=np.int64
to ‘dy ‘ in host memory. Here dy means the value named ’dy’ in this block. The important operands are asarray: the value named ’asarray’ in this block; output_gradients: the signed loss derivative used to update a learned parameter; dtype: the value named ’dtype’ in this block. Context: the function linear_backward_tile, which handles linear backward tile.

Line 268: `if x.ndim != 2 or w.ndim != 2 or dy.ndim != 2:` This executes the following indented host-code branch only when ‘x.ndim != 2 or w.ndim != 2 or dy.ndim != 2‘ is true. The important operands are x: the value named ’x’ in this block; ndim: the value named ’ndim’ in this block; or: the value named ’or’ in this block. Context: the function linear_backward_tile, which handles linear backward tile.

Line 269: `raise ValueError("linear backward operands must be two-dimensional")` This rejects an invalid state by raising ‘ValueError("linear backward operands must be two-dimensional")‘. Failing before DMA prevents malformed shapes or artifacts from silently becoming hardware results.

Line 270: `rows, input_features = x.shape` This assigns ‘x.shape‘ to ‘rows, input_features ‘ in host memory. Here rows means one output-row position processed by the tensor tile. The important operands are x: the value named ’x’ in this block; shape: the value named ’shape’ in this block. Context: the function linear_backward_tile, which handles linear backward tile.

Line 271: `weight_inputs, output_features = w.shape` This assigns ‘w.shape‘ to ‘weight_inputs, output_features ‘ in host memory. Here weight_inputs means a learned coefficient multiplied by an activation. The important operands are w: the value named ’w’ in this block; shape: the value named ’shape’ in this block. Context: the function linear_backward_tile, which handles linear backward tile.

Line 272: `if weight_inputs != input_features or dy.shape != (rows, output_features):` This executes the following indented host-code branch only when ‘weight_inputs != input_features or dy.shape != (rows, output_features)‘ is true. The important operands are weight_inputs: a learned coefficient multiplied by an activation; input_features: the value named ’input features’ in this block; or: the value named ’or’ in this block. Context: the function linear_backward_tile, which handles linear backward tile.

Line 273: `raise ValueError("linear backward matrix dimensions do not align")` This rejects an invalid state by raising ‘ValueError("linear backward matrix dimensions do not align")‘. Failing before DMA prevents malformed shapes or artifacts from silently becoming hardware results.

Line 274: `if not 1 <= rows <= 8 or not 1 <= input_features <= 8 or not 1 <= output_features <= 8:` This executes the following indented host-code branch only when ‘not 1 <= rows <= 8 or not 1 <= input_features <= 8 or not 1 <= output_features <= 8‘ is true. The important operands are not: the value named ’not’ in this block; rows: one output-row position processed by the tensor tile; or: the value named ’or’ in this block. Context: the function linear_backward_tile, which handles linear backward tile.

Line 275: `raise ValueError("linear backward tile dimensions must be in [1,8]")` This rejects an invalid state by raising ‘ValueError("linear backward tile dimensions must be in [1,8]")‘. Failing before DMA prevents malformed shapes or artifacts from silently becoming hardware results.

Line 276: `if np.any(x < -(1 << 15)) or np.any(x > (1 << 15) - 1):` This executes the following indented host-code branch only when ‘np.any(x < -(1 << 15)) or np.any(x > (1 << 15) - 1)‘ is true. The important operands are any: the value named ’any’ in this block; x: the value named ’x’ in this block; or: the value named ’or’ in this block. Context: the function linear_backward_tile, which handles linear backward tile.

Line 277: `raise ValueError("linear backward activations must fit signed 16-bit")` This rejects an invalid state by raising ‘ValueError("linear backward activations must fit signed 16-bit")‘. Failing before DMA prevents malformed shapes or artifacts from silently becoming hardware results.

Line 278: `if np.any(w < -(1 << 15)) or np.any(w > (1 << 15) - 1):` This executes the following indented host-code branch only when ‘np.any(w < -(1 << 15)) or np.any(w > (1 << 15) - 1)‘ is true. The important operands are any: the value named ’any’ in this block; w: the value named ’w’ in this block; or: the value named ’or’ in this block. Context: the function linear_backward_tile, which handles linear backward tile.

Line 279: `raise ValueError("linear backward weights must fit signed 16-bit")` This rejects an invalid state by raising ‘ValueError("linear backward weights must fit signed 16-bit")‘. Failing before DMA prevents malformed shapes or artifacts from silently becoming hardware results.

Line 280: `if np.any(dy < -(1 << 15)) or np.any(dy > (1 << 15) - 1):` This executes the following indented host-code branch only when ‘np.any(dy < -(1 << 15)) or np.any(dy > (1 << 15) - 1)‘ is true. The important operands are any: the value named ’any’ in this block; dy: the value named ’dy’ in this block; or: the value named ’or’ in this block. Context: the function linear_backward_tile, which handles linear backward tile.

Line 281: `raise ValueError("linear backward output gradients must fit signed 16-bit")` This rejects an invalid state by raising ‘ValueError("linear backward output gradients must fit signed 16-bit")‘. Failing before DMA prevents malformed shapes or artifacts from silently becoming hardware results.

Line 282: `if not 0 <= input_gradient_shift <= 31 or not 0 <= weight_gradient_shift <= 31:` This executes the following indented host-code branch only when ‘not 0 <= input_gradient_shift <= 31 or not 0 <= weight_gradient_shift <= 31‘ is true. The important operands are not: the value named ’not’ in this block; input_gradient_shift: the signed loss derivative used to update a learned parameter; or: the value named ’or’ in this block. Context: the function linear_backward_tile, which handles linear backward tile.

Line 283: `raise ValueError("linear backward shifts must be in [0,31]")` This rejects an invalid state by raising ‘ValueError("linear backward shifts must be in [0,31]")‘. Failing before DMA prevents malformed shapes or artifacts from silently becoming hardware results.

Line 285: `input_gradient = round_shift_signed(dy @ w.T, input_gradient_shift)` This assigns ‘round_shift_signed(dy @ w.T, input_gradient_shift)‘ to ‘input_gradient ‘ in host memory. Here input_gradient means the signed loss derivative used to update a learned parameter. The important operands are round_shift_signed: the value named ’round shift signed’ in this block; dy: the value named ’dy’ in this block; w: the value named ’w’ in this block. Context: the function linear_backward_tile, which handles linear backward tile.

Line 286: `weight_gradient = round_shift_signed(x.T @ dy, weight_gradient_shift)` This assigns ‘round_shift_signed(@ dy, weight_gradient_shift)‘ to ‘weight_gradient ‘ in host memory. Here weight_gradient means a learned coefficient multiplied by an activation. The important operands are round_shift_signed: the value named ’round shift signed’ in this block; x: the value named ’x’ in this block; T: the value named ’t’ in this block. Context: the function linear_backward_tile, which handles linear backward tile.

Line 287: `return saturate_signed(input_gradient, 32), saturate_signed(weight_gradient, 24)` This returns ‘saturate_signed(input_gradient, 32), saturate_signed(weight_gradient, 24)‘ to the caller of the function linear_backward_tile, which handles linear backward tile, ending this invocation. The important operands are saturate_signed: the value named ’saturate signed’ in this block; input_gradient: the signed loss derivative used to update a learned parameter; weight_gradient: a learned coefficient multiplied by an activation.

Line 290: `def quantize_flexible_scale(scale: float) -> tuple[int, int, float]:` This starts function quantize_flexible_scale. Its indented body performs quantize flexible scale as part of the file that implements independent mathematical reference models for every hardware arithmetic primitive; it runs only when called.

Line 291: `"""Encode a signed scale as Q15 mantissa and signed binary-point shift.` This is executable documentation attached to the function quantize_flexible_scale, which handles quantize flexible scale. It states the intended contract that tests and callers should enforce, but the text itself does not transform data or issue hardware work.

Line 293: `The flexible vector operation evaluates "x * multiplier / 2**(15+shift)".` Inside the function quantize_flexible_scale, which handles quantize flexible scale, this statement advances the host implementation that implements independent mathematical reference models for every hardware arithmetic primitive. The important operands are The: the value named ’the’ in this block; flexible: the value named ’flexible’ in this block; vector: the value named ’vector’ in this block.

Line 294: `Its signed five-bit shift covers [-15, 15], giving useful non-zero scale` Inside the function quantize_flexible_scale, which handles quantize flexible scale, this statement advances the host implementation that implements independent mathematical reference models for every hardware arithmetic primitive. The important operands are Its: the value named ’its’ in this block; five: the value named ’five’ in this block; bit: the value named ’bit’ in this block.

Line 295: `magnitudes from approximately 2^-16 through 2^15.` Inside the function quantize_flexible_scale, which handles quantize flexible scale, this statement advances the host implementation that implements independent mathematical reference models for every hardware arithmetic primitive. The important operands are magnitudes: the value named ’magnitudes’ in this block; from: the value named ’from’ in this block; approximately: the value named ’approximately’ in this block.

Line 296: `"""` This is executable documentation attached to the function quantize_flexible_scale, which handles quantize flexible scale. It states the intended contract that tests and callers should enforce, but the text itself does not transform data or issue hardware work.

Line 298: `if not np.isfinite(scale):` This executes the following indented host-code branch only when 'not np.isfinite(scale)' is true. The important operands are not: the value named 'not' in this block; isfinite: the value named 'isfinite' in this block; scale: the real-value spacing represented by one quantized integer step. Context: the function quantize_flexible_scale, which handles quantize flexible scale.

Line 299: `raise ValueError("scale must be finite")` This rejects an invalid state by raising 'ValueError("scale must be finite")'. Failing before DMA prevents malformed shapes or artifacts from silently becoming hardware results.

Line 300: `if scale == 0.0:` This executes the following indented host-code branch only when 'scale == 0.0' is true. The important operands are scale: the real-value spacing represented by one quantized integer step. Context: the function quantize_flexible_scale, which handles quantize flexible scale.

Line 301: `return 0, 0, 0.0` This returns '0, 0, 0.0' to the caller of the function quantize_flexible_scale, which handles quantize flexible scale, ending this invocation. The expression is a literal or structural operator and has no hidden software state.

Line 302: `mantissa, exponent = frexp(scale)` This assigns 'frexp(scale)' to 'mantissa, exponent ' in host memory. Here mantissa means the value named 'mantissa' in this block. The important operands are frexp: the value named 'frexp' in this block; scale: the real-value spacing represented by one quantized integer step. Context: the function quantize_flexible_scale, which handles quantize flexible scale.

Line 303: `multiplier = int(round(mantissa * (1 << 15)))` This assigns 'int(round(mantissa * (1 << 15)))' to 'multiplier ' in host memory. Here multiplier means the value named 'multiplier' in this block. The important operands are round: the value named 'round' in this block; mantissa: the value named 'mantissa' in this block. Context: the function quantize_flexible_scale, which handles quantize flexible scale.

Line 304: `if multiplier == (1 << 15):` This executes the following indented host-code branch only when 'multiplier == (1 << 15)' is true. The important operands are multiplier: the value named 'multiplier' in this block. Context: the function quantize_flexible_scale, which handles quantize flexible scale.

Line 305: `multiplier //= 2` Inside the function quantize_flexible_scale, which handles quantize flexible scale, this statement advances the host implementation that implements independent mathematical reference models for every hardware arithmetic primitive. The important operands are multiplier: the value named 'multiplier' in this block.

Line 306: `exponent += 1` Inside the function quantize_flexible_scale, which handles quantize flexible scale, this statement advances the host implementation that implements independent mathematical reference models for every hardware arithmetic primitive. The important operands are exponent: the value named 'exponent' in this block.

Line 307: `if multiplier < -(1 << 15) or multiplier > (1 << 15) - 1:` This executes the following indented host-code branch only when 'multiplier < -(1 << 15) or multiplier > (1 << 15) - 1' is true. The important operands are multiplier: the value named 'multiplier' in this block; or: the value named 'or' in this block. Context: the function quantize_flexible_scale, which handles quantize flexible scale.

Line 308: `raise ValueError("scale mantissa does not fit signed Q15")` This rejects an invalid state by raising 'ValueError("scale mantissa does not fit signed Q15")'. Failing before DMA prevents malformed shapes or artifacts from silently becoming hardware results.

Line 309: `shift = -exponent` This assigns '-exponent' to 'shift ' in host memory. Here shift means the value named 'shift' in this block. The important operands are exponent: the value named 'exponent' in this block. Context: the function quantize_flexible_scale, which handles quantize flexible scale.

Line 310: `if not -15 <= shift <= 15:` This executes the following indented host-code branch only when ‘not -15 <= shift <= 15‘ is true. The important operands are not: the value named ’not’ in this block; shift: the value named ’shift’ in this block. Context: the function quantize_flexible_scale, which handles quantize flexible scale.

Line 311: `raise ValueError("scale is outside the flexible requantizer range")` This rejects an invalid state by raising ‘ValueError("scale is outside the flexible requantizer range")‘. Failing before DMA prevents malformed shapes or artifacts from silently becoming hardware results.

Line 312: `represented = multiplier / float(1 << (15 + shift))` This assigns ‘multiplier / float(1 << (15 + shift))‘ to ‘represented ‘ in host memory. Here represented means the value named ’represented’ in this block. The important operands are multiplier: the value named ’multiplier’ in this block; float: the value named ’float’ in this block; shift: the value named ’shift’ in this block. Context: the function quantize_flexible_scale, which handles quantize flexible scale.

Line 313: `return multiplier, shift, represented` This returns ‘multiplier, shift, represented‘ to the caller of the function quantize_flexible_scale, which handles quantize flexible scale, ending this invocation. The important operands are multiplier: the value named ’multiplier’ in this block; shift: the value named ’shift’ in this block; represented: the value named ’represented’ in this block.

Line 316: `def sgd_momentum_step(` This starts function sgd_momentum_step. Its indented body performs sgd momentum step as part of the file that implements independent mathematical reference models for every hardware arithmetic primitive; it runs only when called.

Line 317: `weights: np.ndarray,` Inside the function sgd_momentum_step, which handles sgd momentum step, this statement advances the host implementation that implements independent mathematical reference models for every hardware arithmetic primitive. The important operands are weights: a learned coefficient multiplied by an activation; ndarray: the value named ’ndarray’ in this block.

Line 318: `gradients: np.ndarray,` Inside the function sgd_momentum_step, which handles sgd momentum step, this statement advances the host implementation that implements independent mathematical reference models for every hardware arithmetic primitive. The important operands are gradients: the signed loss derivative used to update a learned parameter; ndarray: the value named ’ndarray’ in this block.

Line 319: `velocities: np.ndarray,` Inside the function sgd_momentum_step, which handles sgd momentum step, this statement advances the host implementation that implements independent mathematical reference models for every hardware arithmetic primitive. The important operands are velocities: the value named ’velocities’ in this block; ndarray: the value named ’ndarray’ in this block.

Line 320: `learning_rate_q16: int,` Inside the function sgd_momentum_step, which handles sgd momentum step, this statement advances the host implementation that implements independent mathematical reference models for every hardware arithmetic primitive. The important operands are learning_rate_q16: the fixed-point multiplier controlling update magnitude.

Line 321: `momentum_q16: int,` Inside the function sgd_momentum_step, which handles sgd momentum step, this statement advances the host implementation that implements independent mathematical reference models for every hardware arithmetic primitive. The important operands are momentum_q16: the value named ’momentum q16’ in this block.

Line 322: `weight_decay_q16: int,` Inside the function sgd_momentum_step, which handles sgd momentum step, this statement advances the host implementation that implements independent mathematical reference models for every hardware arithmetic primitive. The important operands are weight_decay_q16: a learned coefficient multiplied by an activation.

Line 323: `update_right_shift:  int = 16,` This assigns '16,' to 'update_right_shift' in host memory. Here update_right_shift means the value named 'update right shift' in this block. The expression is a literal or structural operator and has no hidden software state. Context: the function sgd_momentum_step, which handles sgd momentum step.

Line 324: `)  -> tuple[np.ndarray, np.ndarray]:` Inside the function sgd_momentum_step, which handles sgd momentum step, this statement advances the host implementation that implements independent mathematical reference models for every hardware arithmetic primitive. The important operands are tuple: the value named 'tuple' in this block; ndarray: the value named 'ndarray' in this block.

Line 325: `"""Bit-exact SGDW update used by the fabric optimizer lanes."""` This is executable documentation attached to the function sgd_momentum_step, which handles sgd momentum step. It states the intended contract that tests and callers should enforce, but the text itself does not transform data or issue hardware work.

Line 326: `w = np.asarray(weights, dtype=np.int64)` This assigns 'np.asarray(weights, dtype=np.int64)' to 'w ' in host memory. Here w means the value named 'w' in this block. The important operands are asarray: the value named 'asarray' in this block; weights: a learned coefficient multiplied by an activation; dtype: the value named 'dtype' in this block. Context: the function sgd_momentum_step, which handles sgd momentum step.

Line 327: `g = np.asarray(gradients, dtype=np.int64)` This assigns 'np.asarray(gradients, dtype=np.int64)' to 'g ' in host memory. Here g means the value named 'g' in this block. The important operands are asarray: the value named 'asarray' in this block; gradients: the signed loss derivative used to update a learned parameter; dtype: the value named 'dtype' in this block. Context: the function sgd_momentum_step, which handles sgd momentum step.

Line 328: `v = np.asarray(velocities, dtype=np.int64)` This assigns 'np.asarray(velocities, dtype=np.int64)' to 'v ' in host memory. Here v means the value named 'v' in this block. The important operands are asarray: the value named 'asarray' in this block; velocities: the value named 'velocities' in this block; dtype: the value named 'dtype' in this block. Context: the function sgd_momentum_step, which handles sgd momentum step.

Line 329: `if w.shape != g.shape or w.shape != v.shape:` This executes the following indented host-code branch only when 'w.shape != g.shape or w.shape != v.shape' is true. The important operands are w: the value named 'w' in this block; shape: the value named 'shape' in this block; g: the value named 'g' in this block. Context: the function sgd_momentum_step, which handles sgd momentum step.

Line 330: `raise ValueError("weights, gradients, and velocities must have equal shapes")` This rejects an invalid state by raising 'ValueError("weights, gradients, and velocities must have equal shapes")'. Failing before DMA prevents malformed shapes or artifacts from silently becoming hardware results.

Line 331: `if not 0 <= learning_rate_q16 <= 131071:` This executes the following indented host-code branch only when 'not 0 <= learning_rate_q16 <= 131071' is true. The important operands are not: the value named 'not' in this block; learning_rate_q16: the fixed-point multiplier controlling update magnitude. Context: the function sgd_momentum_step, which handles sgd momentum step.

Line 332: `raise ValueError("learning_rate_q16 must be in [0,131071]")` This rejects an invalid state by raising 'ValueError("learning_rate_q16 must be in [0,131071]")'. Failing before DMA prevents malformed shapes or artifacts from silently becoming hardware results.

Line 333: `if not 0 <= momentum_q16 <= 65536 or not 0 <= weight_decay_q16 <= 65536:` This executes the following indented host-code branch only when 'not 0 <= momentum_q16 <= 65536 or not 0 <= weight_decay_q16 <= 65536' is true. The important operands are not: the value named 'not' in this block; momentum_q16: the value named 'momentum q16' in this block; or: the value named 'or' in this block. Context: the function sgd_momentum_step, which handles sgd momentum step.

Line 334: `raise ValueError("momentum and weight decay must be unsigned Q16 values")` This rejects an invalid state by raising ‘ValueError("momentum and weight decay must be unsigned Q16 values")‘. Failing before DMA prevents malformed shapes or artifacts from silently becoming hardware results.

Line 335: `if not 0 <= update_right_shift <= 31:` This executes the following indented host-code branch only when ‘not 0 <= update_right_shift <= 31‘ is true. The important operands are not: the value named ’not’ in this block; update_right_shift: the value named ’update right shift’ in this block. Context: the function sgd_momentum_step, which handles sgd momentum step.

Line 336: `raise ValueError("update_right_shift must be in [0,31]")` This rejects an invalid state by raising ‘ValueError("update_right_shift must be in [0,31]")‘. Failing before DMA prevents malformed shapes or artifacts from silently becoming hardware results.

Line 337: `momentum_term = round_shift_signed(v * momentum_q16, 16)` This assigns ‘round_shift_signed(v * momentum_q16, 16)‘ to ‘momentum_term ‘ in host memory. Here momentum_term means the value named ’momentum term’ in this block. The important operands are round_shift_signed: the value named ’round shift signed’ in this block; v: the value named ’v’ in this block; momentum_q16: the value named ’momentum q16’ in this block. Context: the function sgd_momentum_step, which handles sgd momentum step.

Line 338: `decay_term = round_shift_signed(w * weight_decay_q16, 16)` This assigns ‘round_shift_signed(w * weight_decay_q16, 16)‘ to ‘decay_term ‘ in host memory. Here decay_term means the value named ’decay term’ in this block. The important operands are round_shift_signed: the value named ’round shift signed’ in this block; w: the value named ’w’ in this block; weight_decay_q16: a learned coefficient multiplied by an activation. Context: the function sgd_momentum_step, which handles sgd momentum step.

Line 339: `next_velocity = saturate_signed(momentum_term + g, 24)` This assigns ‘saturate_signed(momentum_term + g, 24)‘ to ‘next_velocity ‘ in host memory. Here next_velocity means the momentum history retained by the SGD optimizer. The important operands are saturate_signed: the value named ’saturate signed’ in this block; momentum_term: the value named ’momentum term’ in this block; g: the value named ’g’ in this block. Context: the function sgd_momentum_step, which handles sgd momentum step.

Line 340: `update_direction = saturate_signed(next_velocity + decay_term, 24)` This assigns ‘saturate_signed(next_v + decay_term, 24)‘ to ‘update_direction ‘ in host memory. Here update_direction means the value named ’update direction’ in this block. The important operands are saturate_signed: the value named ’saturate signed’ in this block; next_velocity: the momentum history retained by the SGD optimizer; decay_term: the value named ’decay term’ in this block. Context: the function sgd_momentum_step, which handles sgd momentum step.

Line 341: `update = round_shift_signed(` This statement continues through source line 342; the explanation uses the complete expression rather than only the first visual fragment. This assigns ‘round_shift_signed(update_direction * learning_rate_q16, update_right_shift)‘ to ‘update ‘ in host memory. Here update means the value named ’update’ in this block. The important operands are round_shift_signed: the value named ’round shift signed’ in this block; update_direction: the value named ’update direction’ in this block; learning_rate_q16: the fixed-point multiplier controlling update magnitude. Context: the function sgd_momentum_step, which handles sgd momentum step.

Line 342: `update_direction * learning_rate_q16, update_right_shift)` This is continuation line 2 of the 2-line logical statement that begins at source line 341. Its exact fragment is ‘update_direction * learning_rate_q16, update_right_shift)‘. The important operands are update_direction: the value named ’update direction’ in this block; learning_rate_q16: the fixed-point multiplier controlling update magnitude; update_right_shift: the value named ’update right shift’ in this block. Read together, the complete operation is: This assigns ‘round_shift_signed(update_direction * learning_rate_q16, update_right_shift)‘ to ‘update ‘ in host memory. Here update means the value named ’update’ in this block. The important operands are round_shift_signed: the value named ’round shift signed’ in this block; update_direction: the value named ’update direction’ in this block; learning_rate_q16: the fixed-point multiplier controlling update magnitude. Context: the function sgd_momentum_step, which handles sgd momentum step.

Line 343: `next_weight = saturate_signed(w - update, 16)` This assigns ‘saturate_signed(w - update, 16)‘ to ‘next_weight ‘ in host memory. Here next_weight means a learned coefficient multiplied by an activation. The important operands are saturate_signed: the value named ’saturate signed’ in this block; w: the value named ’w’ in this block; update: the value named ’update’ in this block. Context: the function sgd_momentum_step, which handles sgd momentum step.

Line 344: `return next_weight, next_velocity` This returns ‘next_weight, next_velocity‘ to the caller of the function sgd_momentum_step, which handles sgd momentum step, ending this invocation. The important operands are next_weight: a learned coefficient multiplied by an activation; next_velocity: the momentum history retained by the SGD optimizer.

Line 347: `def vector_alu(` This starts function vector_alu. Its indented body performs vector alu as part of the file that implements independent mathematical reference models for every hardware arithmetic primitive; it runs only when called.

Line 348: `operation: VectorOperation,` Inside the function vector_alu, which handles vector alu, this statement advances the host implementation that implements independent mathematical reference models for every hardware arithmetic primitive. The important operands are operation: the value named ’operation’ in this block; VectorOperation: the value named ’vector operation’ in this block.

Line 349: `operand_a: np.ndarray,` Inside the function vector_alu, which handles vector alu, this statement advances the host implementation that implements independent mathematical reference models for every hardware arithmetic primitive. The important operands are operand_a: the value named ’operand a’ in this block; ndarray: the value named ’ndarray’ in this block.

Line 350: `operand_b: np.ndarray,` Inside the function vector_alu, which handles vector alu, this statement advances the host implementation that implements independent mathematical reference models for every hardware arithmetic primitive. The important operands are operand_b: the value named ’operand b’ in this block; ndarray: the value named ’ndarray’ in this block.

Line 351: `*,` Inside the function vector_alu, which handles vector alu, this statement advances the host implementation that implements independent mathematical reference models for every hardware arithmetic primitive. The expression is a literal or structural operator and has no hidden software state.

Line 352: `multiplier_q15: int = 0,` This assigns ‘0,‘ to ‘multiplier_q15‘ in host memory. Here multiplier_q15 means the value named ’multiplier q15’ in this block. The expression is a literal or structural operator and has no hidden software state. Context: the function vector_alu, which handles vector alu.

Line 353: `right_shift: int = 0,` This assigns ‘0,‘ to ‘right_shift‘ in host memory. Here right_shift means the value named ’right shift’ in this block. The expression is a literal or structural operator and has no hidden software state. Context: the function vector_alu, which handles vector alu.

Line 354: `output_zero_point: int = 0,` This assigns ‘0,‘ to ‘output_zero_point‘ in host memory. Here output_zero_point means the integer code representing real numeric zero in affine quantization. The expression is a literal or structural operator and has no hidden software state. Context: the function vector_alu, which handles vector alu.

Line 355: `threshold: int = 0,` This assigns ‘0,‘ to ‘threshold‘ in host memory. Here threshold means the membrane level at which a neuron emits a spike. The expression is a literal or structural operator and has no hidden software state. Context: the function vector_alu, which handles vector alu.

Line 356: `surrogate_window: int = 0,` This assigns ‘0,‘ to ‘surrogate_window‘ in host memory. Here surrogate_window means the value named ’surrogate window’ in this block. The expression is a literal or structural operator and has no hidden software state. Context: the function vector_alu, which handles vector alu.

Line 357: `clamp_minimum: int = -(1 << 31),` This assigns '-(1 << 31),' to 'clamp_minimum' in host memory. Here clamp_minimum means the value named 'clamp minimum' in this block. The expression is a literal or structural operator and has no hidden software state. Context: the function vector_alu, which handles vector alu.

Line 358: `clamp_maximum: int = (1 << 31) - 1,` This assigns '(1 << 31) - 1,' to 'clamp_maximum' in host memory. Here clamp_maximum means the value named 'clamp maximum' in this block. The expression is a literal or structural operator and has no hidden software state. Context: the function vector_alu, which handles vector alu.

Line 359: `) -> np.ndarray:` Inside the function vector_alu, which handles vector alu, this statement advances the host implementation that implements independent mathematical reference models for every hardware arithmetic primitive. The important operands are ndarray: the value named 'ndarray' in this block.

Line 360: `"""Reference for every operation in the eight-lane integer vector ALU."""` This is executable documentation attached to the function vector_alu, which handles vector alu. It states the intended contract that tests and callers should enforce, but the text itself does not transform data or issue hardware work.

Line 361: `a = np.asarray(operand_a, dtype=np.int64)` This assigns 'np.asarray(operand_a, dtype=np.int64)' to 'a ' in host memory. Here a means the value named 'a' in this block. The important operands are asarray: the value named 'asarray' in this block; operand_a: the value named 'operand a' in this block; dtype: the value named 'dtype' in this block. Context: the function vector_alu, which handles vector alu.

Line 362: `b = np.asarray(operand_b, dtype=np.int64)` This assigns 'np.asarray(operand_b, dtype=np.int64)' to 'b ' in host memory. Here b means the value named 'b' in this block. The important operands are asarray: the value named 'asarray' in this block; operand_b: the value named 'operand b' in this block; dtype: the value named 'dtype' in this block. Context: the function vector_alu, which handles vector alu.

Line 363: `if a.shape != b.shape:` This executes the following indented host-code branch only when 'a.shape != b.shape' is true. The important operands are a: the value named 'a' in this block; shape: the value named 'shape' in this block; b: the value named 'b' in this block. Context: the function vector_alu, which handles vector alu.

Line 364: `raise ValueError("operand vectors must have equal shapes")` This rejects an invalid state by raising 'ValueError("operand vectors must have equal shapes")'. Failing before DMA prevents malformed shapes or artifacts from silently becoming hardware results.

Line 365: `if operation == VectorOperation.FLEX_REQUANTIZE:` This executes the following indented host-code branch only when 'operation == VectorOperation.FLEX_REQUANTIZE' is true. The important operands are operation: the value named 'operation' in this block; VectorOperation: the value named 'vector operation' in this block; FLEX_REQUANTIZE: the conversion of a wide accumulated result back into a bounded activation code. Context: the function vector_alu, which handles vector alu.

Line 366: `if not -15 <= right_shift <= 15:` This executes the following indented host-code branch only when 'not -15 <= right_shift <= 15' is true. The important operands are not: the value named 'not' in this block; right_shift: the value named 'right shift' in this block. Context: the function vector_alu, which handles vector alu.

Line 367: `raise ValueError("flexible binary-point shift must be in [-15,15]")` This rejects an invalid state by raising 'ValueError("flexible binary-point shift must be in [-15,15]")'. Failing before DMA prevents malformed shapes or artifacts from silently becoming hardware results.

Line 368: `elif not 0 <= right_shift <= 31:` This executes the following indented host-code branch only when 'not 0 <= right_shift <= 31' is true. The important operands are not: the value named 'not' in this block; right_shift: the value named 'right shift' in this block. Context: the function vector_alu, which handles vector alu.

Line 369: `raise ValueError("right_shift must be in [0,31]")` This rejects an invalid state by raising ‘ValueError("right_shift must be in [0,31]")‘. Failing before DMA prevents malformed shapes or artifacts from silently becoming hardware results.

Line 370: `if clamp_minimum > clamp_maximum:` This executes the following indented host-code branch only when ‘clamp_minimum > clamp_maximum‘ is true. The important operands are clamp_minimum: the value named ’clamp minimum’ in this block; clamp_maximum: the value named ’clamp maximum’ in this block. Context: the function vector_alu, which handles vector alu.

Line 371: `raise ValueError("clamp_minimum must not exceed clamp_maximum")` This rejects an invalid state by raising ‘ValueError("clamp_minimum must not exceed clamp_maximum")‘. Failing before DMA prevents malformed shapes or artifacts from silently becoming hardware results.

Line 373: `if operation == VectorOperation.ADD_SAT:` This executes the following indented host-code branch only when ‘operation == VectorOperation.ADD_SAT‘ is true. The important operands are operation: the value named ’operation’ in this block; VectorOperation: the value named ’vector operation’ in this block; ADD_SAT: the value named ’add sat’ in this block. Context: the function vector_alu, which handles vector alu.

Line 374: `output = saturate_signed(a + b, 32)` This assigns ‘saturate_signed(a + b, 32)‘ to ‘output ‘ in host memory. Here output means the value named ’output’ in this block. The important operands are saturate_signed: the value named ’saturate signed’ in this block; a: the value named ’a’ in this block; b: the value named ’b’ in this block. Context: the function vector_alu, which handles vector alu.

Line 375: `elif operation == VectorOperation.RELU:` This executes the following indented host-code branch only when ‘operation == VectorOperation.RELU‘ is true. The important operands are operation: the value named ’operation’ in this block; VectorOperation: the value named ’vector operation’ in this block; RELU: the value named ’relu’ in this block. Context: the function vector_alu, which handles vector alu.

Line 376: `output = np.maximum(a, 0)` This assigns ‘np.maximum(a, 0)‘ to ‘output ‘ in host memory. Here output means the value named ’output’ in this block. The important operands are maximum: the value named ’maximum’ in this block; a: the value named ’a’ in this block. Context: the function vector_alu, which handles vector alu.

Line 377: `elif operation == VectorOperation.REQUANTIZE:` This executes the following indented host-code branch only when ‘operation == VectorOperation.REQUANTIZE‘ is true. The important operands are operation: the value named ’operation’ in this block; VectorOperation: the value named ’vector operation’ in this block; REQUANTIZE: the conversion of a wide accumulated result back into a bounded activation code. Context: the function vector_alu, which handles vector alu.

Line 378: `output = round_shift_signed(a * multiplier_q15, 15 + right_shift)` This assigns ‘round_shift_signed(a * multiplier_q15, 15 + right_shift)‘ to ‘output ‘ in host memory. Here output means the value named ’output’ in this block. The important operands are round_shift_signed: the value named ’round shift signed’ in this block; a: the value named ’a’ in this block; multiplier_q15: the value named ’multiplier q15’ in this block. Context: the function vector_alu, which handles vector alu.

Line 379: `output = np.clip(output + output_zero_point, clamp_minimum, clamp_maximum)` This assigns ‘np.clip(output + output_zero_point, clamp_minimum, clamp_maximum)‘ to ‘output ‘ in host memory. Here output means the value named ’output’ in this block. The important operands are clip: the value named ’clip’ in this block; output: the value named ’output’ in this block; output_zero_point: the integer code representing real numeric zero in affine quantization. Context: the function vector_alu, which handles vector alu.

Line 380: `elif operation == VectorOperation.FLEX_REQUANTIZE:` This executes the following indented host-code branch only when ‘operation == VectorOperation.FLEX_REQUANTIZE‘ is true. The important operands are operation: the value named ’operation’ in this block; VectorOperation: the value named ’vector operation’ in this block; FLEX_REQUANTIZE: the conversion of a wide accumulated result back into a bounded activation code. Context: the function vector_alu, which handles vector alu.

Line 381: `output = round_shift_signed(a * multiplier_q15, 15 + right_shift)` This assigns ‘round_shift_signed(a * multiplier_q15, 15 + right_shift)‘ to ‘output ‘ in host memory. Here output means the value named ’output’ in this block. The important operands are round_shift_signed: the value named ’round shift signed’ in this block; a: the value named ’a’ in this block; multiplier_q15: the value named ’multiplier q15’ in this block. Context: the function vector_alu, which handles vector alu.

Line 382: `output = np.clip(output + output_zero_point, clamp_minimum, clamp_maximum)` This assigns ‘np.clip(output + output_zero_point, clamp_minimum, clamp_maximum)‘ to ‘output ‘ in host memory. Here output means the value named ’output’ in this block. The important operands are clip: the value named ’clip’ in this block; output: the value named ’output’ in this block; output_zero_point: the integer code representing real numeric zero in affine quantization. Context: the function vector_alu, which handles vector alu.

Line 383: `elif operation == VectorOperation.BINARY_SPIKE:` This executes the following indented host-code branch only when ‘operation == VectorOperation.BINARY_SPIKE‘ is true. The important operands are operation: the value named ’operation’ in this block; VectorOperation: the value named ’vector operation’ in this block; BINARY_SPIKE: a binary event produced when a neuron crosses its threshold. Context: the function vector_alu, which handles vector alu.

Line 384: `output = (a >= threshold).astype(np.int64)` Inside the function vector_alu, which handles vector alu, this statement advances the host implementation that implements independent mathematical reference models for every hardware arithmetic primitive. The important operands are output: the value named ’output’ in this block; a: the value named ’a’ in this block; threshold: the membrane level at which a neuron emits a spike.

Line 385: `elif operation == VectorOperation.TERNARY_SPIKE:` This executes the following indented host-code branch only when ‘operation == VectorOperation.TERNARY_SPIKE‘ is true. The important operands are operation: the value named ’operation’ in this block; VectorOperation: the value named ’vector operation’ in this block; TERNARY_SPIKE: a binary event produced when a neuron crosses its threshold. Context: the function vector_alu, which handles vector alu.

Line 386: `output = np.where(a >= threshold, 1, np.where(a <= -threshold, -1, 0))` Inside the function vector_alu, which handles vector alu, this statement advances the host implementation that implements independent mathematical reference models for every hardware arithmetic primitive. The important operands are output: the value named ’output’ in this block; where: the value named ’where’ in this block; a: the value named ’a’ in this block.

Line 387: `elif operation == VectorOperation.SURROGATE_GRADIENT:` This executes the following indented host-code branch only when ‘operation == VectorOperation.SURROGATE_GRADIENT‘ is true. The important operands are operation: the value named ’operation’ in this block; VectorOperation: the value named ’vector operation’ in this block; SURROGATE_GRADIENT: the signed loss derivative used to update a learned parameter. Context: the function vector_alu, which handles vector alu.

Line 388: `output = np.where(np.abs(a - threshold) <= surrogate_window, b, 0)` Inside the function vector_alu, which handles vector alu, this statement advances the host implementation that implements independent mathematical reference models for every hardware arithmetic primitive. The important operands are output: the value named ’output’ in this block; where: the value named ’where’ in this block; abs: the value named ’abs’ in this block.

Line 389: `elif operation == VectorOperation.MAXIMUM:` This executes the following indented host-code branch only when ‘operation == VectorOperation.MAXIMUM‘ is true. The important operands are operation: the value named ’operation’ in this block; VectorOperation: the value named ’vector operation’ in this block; MAXIMUM: the value named ’maximum’ in this block. Context: the function vector_alu, which handles vector alu.

Line 390: `output = np.maximum(a, b)` This assigns ‘np.maximum(a, b)‘ to ‘output ‘ in host memory. Here output means the value named ’output’ in this block. The important operands are maximum: the value named ’maximum’ in this block; a: the value named ’a’ in this block; b: the value named ’b’ in this block. Context: the function vector_alu, which handles vector alu.

Line 391: `elif operation == VectorOperation.MULTIPLY_Q15:` This executes the following indented host-code branch only when ‘operation == VectorOperation.MULTIPLY_Q15‘ is true. The important operands are operation: the value named ’operation’ in this block; VectorOperation: the value named ’vector operation’ in this block; MULTIPLY_Q15: the value named ’multiply q15’ in this block. Context: the function vector_alu, which handles vector alu.

Line 392: `output = saturate_signed(round_shift_signed(a * b, 15), 32)` This assigns ‘saturate_signed(round_shift_sig * b, 15), 32)‘ to ‘output ‘ in host memory. Here output means the value named ’output’ in this block. The important operands are saturate_signed: the value named ’saturate signed’ in this block; round_shift_signed: the value named ’round shift signed’ in this block; a: the value named ’a’ in this block. Context: the function vector_alu, which handles vector alu.

Line 393: `elif operation == VectorOperation.CLAMP:` This executes the following indented host-code branch only when ‘operation == VectorOperation.CLAMP‘ is true. The important operands are operation: the value named ’operation’ in this block; VectorOperation: the value named ’vector operation’ in this block; CLAMP: the value named ’clamp’ in this block. Context: the function vector_alu, which handles vector alu.

Line 394: `output = np.clip(a, clamp_minimum, clamp_maximum)` This assigns ‘np.clip(a, clamp_minimum, clamp_maximum to ‘output ‘ in host memory. Here output means the value named ’output’ in this block. The important operands are clip: the value named ’clip’ in this block; a: the value named ’a’ in this block; clamp_minimum: the value named ’clamp minimum’ in this block. Context: the function vector_alu, which handles vector alu.

Line 395: `elif operation == VectorOperation.SELECT_ZERO:` This executes the following indented host-code branch only when ‘operation == VectorOperation.SELECT_ZERO‘ is true. The important operands are operation: the value named ’operation’ in this block; VectorOperation: the value named ’vector operation’ in this block; SELECT_ZERO: the value named ’select zero’ in this block. Context: the function vector_alu, which handles vector alu.

Line 396: `output = np.where(a == 0, b, 0)` Inside the function vector_alu, which handles vector alu, this statement advances the host implementation that implements independent mathematical reference models for every hardware arithmetic primitive. The important operands are output: the value named ’output’ in this block; where: the value named ’where’ in this block; a: the value named ’a’ in this block.

Line 397: `elif operation == VectorOperation.SELECT_NONZERO:` This executes the following indented host-code branch only when ‘operation == VectorOperation.SELECT_NONZERO‘ is true. The important operands are operation: the value named ’operation’ in this block; VectorOperation: the value named ’vector operation’ in this block; SELECT_NONZERO: the value named ’select nonzero’ in this block. Context: the function vector_alu, which handles vector alu.

Line 398: `output = np.where(a != 0, b, 0)` Inside the function vector_alu, which handles vector alu, this statement advances the host implementation that implements independent mathematical reference models for every hardware arithmetic primitive. The important operands are output: the value named ’output’ in this block; where: the value named ’where’ in this block; a: the value named ’a’ in this block.

Line 399: `elif operation == VectorOperation.COMPARE_GE:` This executes the following indented host-code branch only when ‘operation == VectorOperation.COMPARE_GE‘ is true. The important operands are operation: the value named ’operation’ in this block; VectorOperation: the value named ’vector operation’ in this block; COMPARE_GE: the value named ’compare ge’ in this block. Context: the function vector_alu, which handles vector alu.

Line 400: `output = (a >= b).astype(np.int64)` Inside the function vector_alu, which handles vector alu, this statement advances the host implementation that implements independent mathematical reference models for every hardware arithmetic primitive. The important operands are output: the value named ’output’ in this block; a: the value named ’a’ in this block; b: the value named ’b’ in this block.

Line 401: `else:` This begins the alternative host-code branch when the preceding condition was false, still inside the function vector_alu, which handles vector alu.

Line 402: `raise ValueError(f"unsupported vector operation {operation}")` This rejects an invalid state by raising ‘ValueError(f"unsupported vector operation {operation}")‘. Failing before DMA prevents malformed shapes or artifacts from silently becoming hardware results.

Line 403: `return np.asarray(output, dtype=np.int64)` This returns ‘np.asarray(output, dtype=np.int64)‘ to the caller of the function vector_alu, which handles vector alu, ending this invocation. The important operands are asarray: the value named ’asarray’ in this block; output: the value named ’output’ in this block; dtype: the value named ’dtype’ in this block.

Line 406: `def choose_dataflow(` This starts function choose_dataflow. Its indented body performs choose dataflow as part of the file that implements independent mathematical reference models for every hardware arithmetic primitive; it runs only when called.

Line 407: `rows: int,` Inside the function choose_dataflow, which handles choose dataflow, this statement advances the host implementation that implements independent mathematical reference models for every hardware arithmetic primitive. The important operands are rows: one output-row position processed by the tensor tile.

Line 408: `columns: int,` Inside the function choose_dataflow, which handles choose dataflow, this statement advances the host implementation that implements independent mathematical reference models for every hardware arithmetic primitive. The important operands are columns: one output-feature position processed in parallel.

Line 409: `reduction: int,` Inside the function choose_dataflow, which handles choose dataflow, this statement advances the host implementation that implements independent mathematical reference models for every hardware arithmetic primitive. The important operands are reduction: the value named ’reduction’ in this block.

Line 410: `row_tile: int = 8,` This assigns ‘8,‘ to ‘row_tile‘ in host memory. Here row_tile means one output-row position processed by the tensor tile. The expression is a literal or structural operator and has no hidden software state. Context: the function choose_dataflow, which handles choose dataflow.

Line 411: `column_tile: int = 16,` This assigns ‘16,‘ to ‘column_tile‘ in host memory. Here column_tile means one output-feature position processed in parallel. The expression is a literal or structural operator and has no hidden software state. Context: the function choose_dataflow, which handles choose dataflow.

Line 412: `) -> DataflowDecision:` Inside the function choose_dataflow, which handles choose dataflow, this statement advances the host implementation that implements independent mathematical reference models for every hardware arithmetic primitive. The important operands are DataflowDecision: the value named ’dataflow decision’ in this block.

Line 413: `"""Choose the traversal with fewer estimated operand bytes."""` This is executable documentation attached to the function choose_dataflow, which handles choose dataflow. It states the intended contract that tests and callers should enforce, but the text itself does not transform data or issue hardware work.

Line 414: `if min(rows, columns, reduction, row_tile, column_tile) <= 0:` This executes the following indented host-code branch only when ‘min(rows, columns, reduction, row_tile, column_tile) <= 0‘ is true. The important operands are min: the value named ’min’ in this block; rows: one output-row position processed by the tensor tile; columns: one output-feature position processed in parallel. Context: the function choose_dataflow, which handles choose dataflow.

Line 415: `raise ValueError("matrix and tile dimensions must be positive")` This rejects an invalid state by raising ‘ValueError("matrix and tile dimensions must be positive")‘. Failing before DMA prevents malformed shapes or artifacts from silently becoming hardware results.

Line 416: `row_tiles = ceil(rows / row_tile)` This assigns ‘ceil(rows / row_tile)‘ to ‘row_tiles ‘ in host memory. Here row_tiles means one output-row position processed by the tensor tile. The important operands are ceil: the value named ’ceil’ in this block; rows: one output-row position processed by the tensor tile; row_tile: one output-row position processed by the tensor tile. Context: the function choose_dataflow, which handles choose dataflow.

Line 417: `column_tiles = ceil(columns / column_tile)` This assigns ‘ceil(columns / column_tile)‘ to ‘column_tiles ‘ in host memory. Here column_tiles means one output-feature position processed in parallel. The important operands are ceil: the value named ’ceil’ in this block; columns: one output-feature position processed in parallel; column_tile: one output-feature position processed in parallel. Context: the function choose_dataflow, which handles choose dataflow.

Line 418: `input_tile_bytes = row_tile * reduction` This assigns ‘row_tile * reduction‘ to ‘input_tile_bytes ‘ in host memory. Here input_tile_bytes means the value named ’input tile bytes’ in this block. The important operands are row_tile: one output-row position processed by the tensor tile; reduction: the value named ’reduction’ in this block. Context: the function choose_dataflow, which handles choose dataflow.

Line 419: `weight_tile_bytes = column_tile * reduction` This assigns ‘column_tile * reduction‘ to ‘weight_tile_bytes ‘ in host memory. Here weight_tile_bytes means a learned coefficient multiplied by an activation. The important operands are column_tile: one output-feature position processed in parallel; reduction: the value named ’reduction’ in this block. Context: the function choose_dataflow, which handles choose dataflow.

Line 420: `input_broadcast_bytes = row_tiles * input_tile_bytes + row_tiles * column_tiles * weight_tile_bytes` This assigns ‘row_tiles * input_tile_bytes + row_tiles * column_tiles * weight_tile_bytes‘ to ‘input_broadcast_bytes ‘ in host memory. Here input_broadcast_bytes means the value named ’input broadcast bytes’ in this block. The important operands are row_tiles: one output-row position processed by the tensor tile; input_tile_bytes: the value named ’input tile bytes’ in this block; column_tiles: one output-feature position processed in parallel. Context: the function choose_dataflow, which handles choose dataflow.

Line 421: `weight_broadcast_bytes = column_tiles * weight_tile_bytes + column_tiles * row_tiles * input_tile_b` This assigns ‘column_tiles * weight_tile_bytes + column_tiles * row_tiles * input_tile_bytes‘ to ‘weight_broadcast_bytes ‘ in host memory. Here weight_broadcast_bytes means a learned coefficient multiplied by an activation. The important operands are column_tiles: one output-feature position processed in parallel; weight_tile_bytes: a learned coefficient multiplied by an activation; row_tiles: one output-row position processed by the tensor tile. Context: the function choose_dataflow, which handles choose dataflow.

Line 422: `mode = (` This statement continues through source line 426; the explanation uses the complete expression rather than only the first visual fragment. Inside the function choose_dataflow, which handles choose dataflow, this statement advances the host implementation that implements independent mathematical reference models for every hardware arithmetic primitive. The important operands are mode: the value named ’mode’ in this block; Dataflow: the value named ’dataflow’ in this block; INPUT_BROADCAST: the value named ’input broadcast’ in this block.

Line 423: `Dataflow.INPUT_BROADCAST` This is continuation line 2 of the 5-line logical statement that begins at source line 422. Its exact fragment is ‘Dataflow.INPUT_BROADCAST‘. The important operands are Dataflow: the value named ’dataflow’ in this block; INPUT_BROADCAST: the value named ’input broadcast’ in this block. Read together, the complete operation is: Inside the function choose_dataflow, which handles choose dataflow, this statement advances the host implementation that implements independent mathematical reference models for every hardware arithmetic primitive. The important operands are mode: the value named ’mode’ in this block; Dataflow: the value named ’dataflow’ in this block; INPUT_BROADCAST: the value named ’input broadcast’ in this block.

Line 424: `if input_broadcast_bytes <= weight_broadcast_bytes` This is continuation line 3 of the 5-line logical statement that begins at source line 422. Its exact fragment is ‘if input_broadcast_bytes <= weight_broadcast_bytes‘. The important operands are input_broadcast_bytes: the value named ’input broadcast bytes’ in this block; weight_broadcast_bytes a learned coefficient multiplied by an activation. Read together, the complete operation is: Inside the function choose_dataflow, which handles choose dataflow, this statement advances the host implementation that implements independent mathematical reference models for every hardware arithmetic primitive. The important operands are mode: the value named ’mode’ in this block; Dataflow: the value named ’dataflow’ in this block; INPUT_BROADCAST: the value named ’input broadcast’ in this block.

Line 425: `else Dataflow.WEIGHT_BROADCAST` This is continuation line 4 of the 5-line logical statement that begins at source line 422. Its exact fragment is ‘else Dataflow.WEIGHT_BROADCAST‘. The important operands are Dataflow: the value named ’dataflow’ in this block; WEIGHT_BROADCAST: a learned coefficient multiplied by an activation. Read together, the complete operation is: Inside the function choose_dataflow, which handles choose dataflow, this statement advances the host implementation that implements independent mathematical reference models for every hardware arithmetic primitive. The important operands are mode: the value named ’mode’ in this block; Dataflow: the value named ’dataflow’ in this block; INPUT_BROADCAST: the value named ’input broadcast’ in this block.

Line 426: `)` This is continuation line 5 of the 5-line logical statement that begins at source line 422. Its exact fragment is ‘)‘. The expression is a literal or structural operator and has no hidden software state. Read together, the complete operation is: Inside the function choose_dataflow, which handles choose dataflow, this statement advances the host implementation that implements independent mathematical reference models for every hardware arithmetic primitive. The important operands are mode: the value named ’mode’ in this block; Dataflow: the value named ’dataflow’ in this block; INPUT_BROADCAST: the value named ’input broadcast’ in this block.

Line 427: `return DataflowDecision(mode, input_broadcast_bytes, weight_broadcast_bytes)` This returns ‘DataflowDecision(mode, input_broadcast_bytes, weight_broadcast_bytes)‘ to the caller of the function choose_dataflow, which handles choose dataflow, ending this invocation. The important operands are DataflowDecision: the value named ’dataflow decision’ in this block; mode: the value named ’mode’ in this block; input_broadcast_bytes: the value named ’input broadcast bytes’ in this block.

Line 430: `def peak_dense_gops(clock_hz: float, packed_dsp_pairs: int) -> float:` This starts function peak_dense_gops. Its indented body performs peak dense gops as part of the file that implements independent mathematical reference models for every hardware arithmetic primitive; it runs only when called.

Line 431: `"""Two operations per MAC and two MACs per packed DSP pair."""` This is executable documentation attached to the function peak_dense_gops, which handles peak dense gops. It states the intended contract that tests and callers should enforce, but the text itself does not transform data or issue hardware work.

Line 432: `return clock_hz * packed_dsp_pairs * 2 * 2 / 1e9` This returns ‘clock_hz * packed_dsp_pairs * 2 * 2 / 1e9‘ to the caller of the function peak_dense_gops, which handles peak dense gops, ending this invocation. The important operands are clock_hz: the value named ’clock hz’ in this block; packed_dsp_pairs: the value named ’packed dsp pairs’ in this block.

36 software/neuraedge_protocol.py

Role in the complete system: defines command bit fields, descriptor records, packed streams, and result decoders.

36.1 Beginner architecture map

Dataflow responsibility This file is the bit-level contract shared with RTL. It packs each 128-bit command field, declares exact payload/result lengths, wraps records in descriptor headers, and decodes signed results so a software integer has the same bit meaning as FPGA wires.

Where it runs This is sequential host software. Python objects live in CPU memory; they become FPGA work only when the compiler packs a command or payload and the PYNQ driver transfers those bytes through AXI DMA or AXI-Lite.

Public structure Classes: Opcode, LutSuboperation, LinearGradientMode, StreamBeat, PackedStreamBeats, ProgramRecord, Command128. Functions: _unsigned, _signed_bits, _decode_signed, pack_descriptor_program, _put, clear_status_command, linear_backward_command, tensor_command, alpha_xnor_command, vector_command, layernorm_command, log_softmax_command, lif_command, sgd_command, lut_command, _finish_beats, pack_activation pack_outer_weight_beats, pack_dot8_weight_beats, pack_alpha_beats, pack_vector_beats, pack_layernorm_beats, pack_softmax_beats, pack_lif_beats. Each function annotation below names its enclosing function so an array operation is tied to the model, compiler, driver, test, or report phase that uses it.

Numeric and failure boundary Shapes, signedness, byte order, scaling, and saturation are part of the hardware contract. Validation exceptions are functional safety checks: rejecting malformed input before DMA is different from silently clipping, reshaping, or continuing with an incompatible artifact.

36.2 Complete source

```
"""Typed command and stream ABI for the NeuraEdge PYNQ accelerator.

The RTL command port is 128 bits wide and the data path is AXI4-Stream with
64-bit beats.  This module is deliberately independent of PYNQ and NumPy so it
can be used by fixture generators, desktop tests, and the board driver.
"""

Line 8: `from __future__ import annotations` This imports the named Python API so the file whose role is to defines command bit fields, descriptor records, packed streams, and result decoders can use it explicitly. Imports execute on the host processor and create no FPGA hardware.

Line 10: `from array import array` This imports the named Python API so the file whose role is to defines command bit fields, descriptor records, packed streams, and result decoders can use it explicitly. Imports execute on the host processor and create no FPGA hardware.

Line 11: `from dataclasses import dataclass` This imports the named Python API so the file whose role is to defines command bit fields, descriptor records, packed streams, and result decoders can use it explicitly. Imports execute on the host processor and create no FPGA hardware.

Line 12: `from enum import IntEnum` This imports the named Python API so the file whose role is to defines command bit fields, descriptor records, packed streams, and result decoders can use it explicitly. Imports execute on the host processor and create no FPGA hardware.

Line 13: `from sys import byteorder` This imports the named Python API so the file whose role is to defines command bit fields, descriptor records, packed streams, and result decoders can use it explicitly. Imports execute on the host processor and create no FPGA hardware.

Line 14: `from typing import Iterable, Iterator, Sequence, overload` This imports the named Python API so the file whose role is to defines command bit fields, descriptor records, packed streams, and result decoders can use it explicitly. Imports execute on the host processor and create no FPGA hardware.

Line 17: `class Opcode(IntEnum):` This defines class Opcode, which groups data and methods for opcode. Instances exist in host memory and organize the flow that defines command bit fields, descriptor records, packed streams, and result decoders.

Line 18: `TRAIN_LINEAR_BACKWARD = 0x0` This assigns ‘0x0‘ to ‘TRAIN_LINEAR_BACKWARD ‘ in host memory. Here TRAIN_LINEAR_BACKWARD means the value named ’train linear backward’ in this block. The expression is a literal or structural operator and has no hidden software state. Context: the class Opcode, which handles opcode.

Line 19: `LOAD_ACTIVATIONS = 0x1` This assigns ‘0x1‘ to ‘LOAD_ACTIVATIONS ‘ in host memory. Here LOAD_ACTIVATION means an input feature value consumed by a neuron or multiply-accumulate operation. The expression is a literal or structural operator and has no hidden software state. Context: the class Opcode, which handles opcode.

Line 20: `LOAD_WEIGHTS_OUTER = 0x2` This assigns ‘0x2‘ to ‘LOAD_WEIGHTS_OUTER ‘ in host memory. Here LOAD_WEIGHTS_OUTER means a learned coefficient multiplied by an activation. The expression is a literal or structural operator and has no hidden software state. Context: the class Opcode, which handles opcode.

Line 21: `LOAD_WEIGHTS_DOT8 = 0x3` This assigns ‘0x3‘ to ‘LOAD_WEIGHTS_DOT8 ‘ in host memory. Here LOAD_WEIGHTS_DOT8 means a learned coefficient multiplied by an activation. The expression is a literal or structural operator and has no hidden software state. Context: the class Opcode, which handles opcode.

Line 22: `COMPUTE_DENSE_OUTER = 0x4` This assigns ‘0x4‘ to ‘COMPUTE_DENSE_OUTER ‘ in host memory. Here COMPUTE_DENSE_OUTER means the value named ’compute dense outer’ in this block. The expression is a literal or structural operator and has no hidden software state. Context: the class Opcode, which handles opcode.

Line 23: `COMPUTE_DENSE_DOT8 = 0x5` This assigns ‘0x5‘ to ‘COMPUTE_DENSE_DOT8 ‘ in host memory. Here COMPUTE_DENSE_DOT8 means the value named ’compute dense dot8’ in this block. The expression is a literal or structural operator and has no hidden software state. Context: the class Opcode, which handles opcode.

Line 24: `COMPUTE_BINARY = 0x6` This assigns ‘0x6‘ to ‘COMPUTE_BINARY ‘ in host memory. Here COMPUTE_BINARY means the value named ’compute binary’ in this block. The expression is a literal or structural operator and has no hidden software state. Context: the class Opcode, which handles opcode.

Line 25: `COMPUTE_TERNARY = 0x7` This assigns ‘0x7‘ to ‘COMPUTE_TERNARY ‘ in host memory. Here COMPUTE_TERNARY means the value named ’compute ternary’ in this block. The expression is a literal or structural operator and has no hidden software state. Context: the class Opcode, which handles opcode.

Line 26: `ALPHA_XNOR = 0x8` This assigns ‘0x8‘ to ‘ALPHA_XNOR ‘ in host memory. Here ALPHA_XNOR means the programmable weight assigned to matching zero spikes in alpha-XNOR attention. The expression is a literal or structural operator and has no hidden software state. Context: the class Opcode, which handles opcode.

Line 27: `VECTOR_ALU = 0x9` This assigns ‘0x9‘ to ‘VECTOR_ALU ‘ in host memory. Here VECTOR_ALU means the value named ’vector alu’ in this block. The expression is a literal or structural operator and has no hidden software state. Context: the class Opcode, which handles opcode.

Line 28: `LAYERNORM = 0xA` This assigns ‘0xA‘ to ‘LAYERNORM ‘ in host memory. Here LAYERNORM means the value named ’layernorm’ in this block. The expression is a literal or structural operator and has no hidden software state. Context: the class Opcode, which handles opcode.

Line 29: `LOG_SOFTMAX = 0xB` This assigns ‘0xB‘ to ‘LOG_SOFTMAX ‘ in host memory. Here LOG_SOFTMAX means the value named ’log softmax’ in this block. The expression is a literal or structural operator and has no hidden software state. Context: the class Opcode, which handles opcode.

Line 30: `LIF_STEP = 0xC` This assigns ‘0xC‘ to ‘LIF_STEP ‘ in host memory. Here LIF_STEP means the value named ’lif step’ in this block. The expression is a literal or structural operator and has no hidden software state. Context: the class Opcode, which handles opcode.

Line 31: `SGD_UPDATE = 0xD` This assigns ‘0xD‘ to ‘SGD_UPDATE ‘ in host memory. Here SGD_UPDATE means the value named ’sgd update’ in this block. The expression is a literal or structural operator and has no hidden software state. Context: the class Opcode, which handles opcode.

Line 32: `ACTIVATION_LUT = 0xE` This assigns ‘0xE‘ to ‘ACTIVATION_LUT ‘ in host memory. Here ACTIVATION_LUT means an input feature value consumed by a neuron or multiply-accumulate operation. The expression is a literal or structural operator and has no hidden software state. Context: the class Opcode, which handles opcode.

Line 33: `CLEAR_STATUS = 0xF` This assigns ‘0xF‘ to ‘CLEAR_STATUS ‘ in host memory. Here CLEAR_STATUS means the value named ’clear status’ in this block. The expression is a literal or structural operator and has no hidden software state. Context: the class Opcode, which handles opcode.

Line 36: `class LutSuboperation(IntEnum):` This defines class LutSuboperation, which groups data and methods for lut suboperation. Instances exist in host memory and organize the flow that defines command bit fields, descriptor records, packed streams, and result decoders.

Line 37: `CLEAR = 0` This assigns ‘0‘ to ‘CLEAR ‘ in host memory. Here CLEAR means the value named ’clear’ in this block. The expression is a literal or structural operator and has no hidden software state. Context: the class LutSuboperation, which handles lut suboperation.

Line 38: `LOAD = 1` This assigns ‘1‘ to ‘LOAD ‘ in host memory. Here LOAD means the value named ’load’ in this block. The expression is a literal or structural operator and has no hidden software state. Context: the class LutSuboperation, which handles lut suboperation.

Line 39: `EVALUATE = 2` This assigns ‘2‘ to ‘EVALUATE ‘ in host memory. Here EVALUATE means the value named ’evaluate’ in this block. The expression is a literal or structural operator and has no hidden software state. Context: the class LutSuboperation, which handles lut suboperation.

Line 42: `class LinearGradientMode(IntEnum):` This defines class LinearGradientMode, which groups data and methods for linear gradient mode. Instances exist in host memory and organize the flow that defines command bit fields, descriptor records, packed streams, and result decoders.

Line 43: `BOTH = 0` This assigns ‘0‘ to ‘BOTH ‘ in host memory. Here BOTH means the value named ’both’ in this block. The expression is a literal or structural operator and has no hidden software state. Context: the class LinearGradientMode, which handles linear gradient mode.

Line 44: `INPUT = 1` This assigns ‘1‘ to ‘INPUT ‘ in host memory. Here INPUT means the value named ’input’ in this block. The expression is a literal or structural operator and has no hidden software state. Context: the class LinearGradientMode, which handles linear gradient mode.

Line 45: `WEIGHT = 2` This assigns ‘2‘ to ‘WEIGHT ‘ in host memory. Here WEIGHT means a learned coefficient multiplied by an activation. The expression is a literal or structural operator and has no hidden software state. Context: the class LinearGradientMode, which handles linear gradient mode.

Line 48: `@dataclass(frozen=True)` This decorator changes how the following class or function is constructed. ‘@dataclass(frozen=True)‘ is applied at import time on the host and is part of the file whose role is to defines command bit fields, descriptor records, packed streams, and result decoders; it creates no FPGA circuit by itself.

Line 49: `class StreamBeat:` This defines class StreamBeat, which groups data and methods for stream beat. Instances exist in host memory and organize the flow that defines command bit fields, descriptor records, packed streams, and result decoders.

Line 50: `data: int` Inside the class StreamBeat, which handles stream beat, this statement advances the host implementation that defines command bit fields, descriptor records, packed streams, and result decoders. The important operands are data: the value named ’data’ in this block.

Line 51: `last: bool = False` This assigns ‘False‘ to ‘last‘ in host memory. Here last means the AXI-Stream marker for the final beat of a packet or command payload. The expression is a literal or structural operator and has no hidden software state. Context: the class StreamBeat, which handles stream beat.

Line 53: `def __post_init__(self) -> None:` This starts function ___post_init___. Its indented body performs post init as part of the file that defines command bit fields, descriptor records, packed streams, and result decoders; it runs only when called.

Line 54: `_unsigned("stream data", self.data, 64)` This calls ‘_unsigned‘ with ‘"stream data", self.data, 64‘ inside the function ___post_init___, which handles post init. The call advances the host-side job that defines command bit fields, descriptor records, packed streams, and result decoders.

Line 57: `class PackedStreamBeats(Sequence[StreamBeat]):` This defines class PackedStreamBeats, which groups data and methods for packed stream beats. Instances exist in host memory and organize the flow that defines command bit fields, descriptor records, packed streams, and result decoders.

Line 58: `"""Compact 64-bit payload storage with the ordinary StreamBeat interface."""` This is executable documentation attached to the class PackedStreamBeats, which handles packed stream beats. It states the intended contract that tests and callers should enforce, but the text itself does not transform data or issue hardware work.

Line 60: `def __init__(self, words: Iterable[int] = ()) -> None:` This starts function ___init___. Its indented body performs init as part of the file that defines command bit fields, descriptor records, packed streams, and result decoders; it runs only when called.

Line 61: `self.words = array("Q", (_unsigned("stream word", word, 64) for word in words))` This assigns ‘array("Q", (_unsigned("stream word", word, 64) for word in words))‘ to ‘self.words ‘ in host memory. Here words means the value named ’words’ in this block. The important operands are array: the value named ’array’ in this block; Q: the value named ’q’ in this block; _unsigned: the value named ’unsigned’ in this block. Context: the function ___init___, which handles init.

Line 62: `if self.words.itemsize != 8:` This executes the following indented host-code branch only when ‘self.words.itemsize != 8‘ is true. The important operands are words: the value named ’words’ in this block; itemsize: the value named ’itemsize’ in this block. Context: the function ___init___, which handles init.

Line 63: `raise RuntimeError("platform unsigned long long is not 64 bits")` This rejects an invalid state by raising ‘RuntimeError("platform unsigned long long is not 64 bits")‘. Failing before DMA prevents malformed shapes or artifacts from silently becoming hardware results.

Line 65: `@classmethod` This decorator changes how the following class or function is constructed. ‘@classmethod‘ is applied at import time on the host and is part of the class PackedStreamBeats, which handles packed stream beats; it creates no FPGA circuit by itself.

Line 66: `def from_little_endian_bytes(cls, payload: bytes) -> "PackedStreamBeats":` This starts function from_little_endian_bytes. Its indented body performs from little endian bytes as part of the file that defines command bit fields, descriptor records, packed streams, and result decoders; it runs only when called.

Line 67: `if byteorder != "little":` This executes the following indented host-code branch only when ‘byteorder != "little"‘ is true. The important operands are byteorder: the value named ’byteorder’ in this block; little: the value named ’little’ in this block. Context: the function from_little_endian_bytes, which handles from little endian bytes.

Line 68: `raise RuntimeError("compact stream payloads require a little-endian host")` This rejects an invalid state by raising ‘RuntimeError("compact stream payloads require a little-endian host")‘. Failing before DMA prevents malformed shapes or artifacts from silently becoming hardware results.

Line 69: `if len(payload) % 8:` This executes the following indented host-code branch only when ‘len(payload) % 8‘ is true. The important operands are len: the value named ’len’ in this block; payload: stream data belonging to the current command. Context: the function from_little_endian_bytes, which handles from little endian bytes.

Line 70: `raise ValueError("packed stream byte length must be a multiple of eight")` This rejects an invalid state by raising ‘ValueError("packed stream byte length must be a multiple of eight")‘. Failing before DMA prevents malformed shapes or artifacts from silently becoming hardware results.

Line 71: `result = cls()` This assigns ‘cls()‘ to ‘result ‘ in host memory. Here result means the value named ’result’ in this block. The important operands are cls: the value named ’cls’ in this block. Context: the function from_little_endian_bytes, which handles from little endian bytes.

Line 72: `result.words.frombytes(payload)` This calls ‘result.words.frombytes‘ with ‘payload‘ inside the function from_little_endian_bytes, which handles from little endian bytes. The call advances the host-side job that defines command bit fields, descriptor records, packed streams, and result decoders.

Line 73: `return result` This returns ‘result‘ to the caller of the function from_little_endian_bytes, which handles from little endian bytes, ending this invocation. The important operands are result: the value named ’result’ in this block.

Line 75: `def __len__(self) -> int:` This starts function ___len___. Its indented body performs len as part of the file that defines command bit fields, descriptor records, packed streams, and result decoders; it runs only when called.

Line 76: `return len(self.words)` This returns ‘len(self.words)‘ to the caller of the function ___len___, which handles len, ending this invocation. The important operands are len: the value named ’len’ in this block; words: the value named ’words’ in this block.

Line 78: `@overload` This decorator changes how the following class or function is constructed. ‘@overload‘ is applied at import time on the host and is part of the class PackedStreamBeats, which handles packed stream beats; it creates no FPGA circuit by itself.

Line 79: `def __getitem__(self, index: int) -> StreamBeat: ...` This starts function ___getitem___. Its indented body performs getitem as part of the file that defines command bit fields, descriptor records, packed streams, and result decoders; it runs only when called.

Line 81: `@overload` This decorator changes how the following class or function is constructed. ‘@overload‘ is applied at import time on the host and is part of the class PackedStreamBeats, which handles packed stream beats; it creates no FPGA circuit by itself.

Line 82: `def __getitem__(self, index: slice) -> tuple[StreamBeat, ...]: ...` This starts function ___getitem___. Its indented body performs getitem as part of the file that defines command bit fields, descriptor records, packed streams, and result decoders; it runs only when called.

Line 84: `def __getitem__(self, index: int | slice) -> StreamBeat | tuple[StreamBeat, ...]:` This starts function ___getitem___. Its indented body performs getitem as part of the file that defines command bit fields, descriptor records, packed streams, and result decoders; it runs only when called.

Line 85: `if isinstance(index, slice):` This executes the following indented host-code branch only when ‘isinstance(index, slice)‘ is true. The important operands are isinstance: the value named ’isinstance’ in this block; index: an integer selecting one tensor element, lane, bank, or state entry; slice: the value named ’slice’ in this block. Context: the function ___getitem___, which handles getitem.

Line 86: `indices = range(*index.indices(len(self)))` This assigns ‘range(*index.indices(len(self)))‘ to ‘indices ‘ in host memory. Here indices means the value named ’indices’ in this block. The important operands are range: the value named ’range’ in this block; index: an integer selecting one tensor element, lane, bank, or state entry; indices: the value named ’indices’ in this block. Context: the function ___getitem___, which handles getitem.

Line 87: `return tuple(StreamBeat(self.words[item], item == len(self) - 1) for item in indices)` This returns ‘tuple(StreamBeat(self.words[item], item == len(self) - 1) for item in indices)‘ to the caller of the function ___getitem___, which handles getitem, ending this invocation. The important operands are tuple: the value named ’tuple’ in this block; StreamBeat: the value named ’stream beat’ in this block; words: the value named ’words’ in this block.

Line 88: `normalized = index + len(self) if index < 0 else index` This assigns ‘index + len(self) if index $<$ 0 else index‘ to ‘normalized ‘ in host memory. Here normalized means the value named ’normalized’ in this block. The important operands are index: an integer selecting one tensor element, lane, bank, or state entry; len: the value named ’len’ in this block. Context: the function ___getitem___, which handles getitem.

Line 89: `if not 0 <= normalized < len(self):` This executes the following indented host-code branch only when ‘not 0 $<=$ normalized $<$ len(self)‘ is true. The important operands are not: the value named ’not’ in this block; normalized: the value named ’normalized’ in this block; len: the value named ’len’ in this block. Context: the function ___getitem___, which handles getitem.

Line 90: `raise IndexError(index)` This rejects an invalid state by raising ‘IndexError(index)‘. Failing before DMA prevents malformed shapes or artifacts from silently becoming hardware results.

Line 91: `return StreamBeat(self.words[normalized], normalized == len(self) - 1)` This returns ‘StreamBeat(self.words[normalized], normalized == len(self) - 1)‘ to the caller of the function ___getitem___, which handles getitem, ending this invocation. The important operands are StreamBeat: the value named ’stream beat’ in this block; words: the value named ’words’ in this block; normalized: the value named ’normalized’ in this block.

Line 93: `def __iter__(self) -> Iterator[StreamBeat]:` This starts function ___iter___. Its indented body performs iter as part of the file that defines command bit fields, descriptor records, packed streams, and result decoders; it runs only when called.

Line 94: `final = len(self) - 1` This assigns ‘len(self) - 1‘ to ‘final ‘ in host memory. Here final means the value named ’final’ in this block. The important operands are len: the value named ’len’ in this block. Context: the function ___iter___, which handles iter.

Line 95: `return (StreamBeat(word, index == final) for index, word in enumerate(self.words))` This returns ‘(StreamBeat(word, index == final) for index, word in enumerate(self.words))‘ to the caller of the function ___iter___, which handles iter, ending this invocation. The important operands are StreamBeat: the value named ’stream beat’ in this block; word: the value named ’word’ in this block; index: an integer selecting one tensor element, lane, bank, or state entry.

Line 98: `@dataclass(frozen=True)` This decorator changes how the following class or function is constructed. ‘@dataclass(frozen=True)‘ is applied at import time on the host and is part of the file whose role is to defines command bit fields, descriptor records, packed streams, and result decoders; it creates no FPGA circuit by itself.

Line 99: `class ProgramRecord:` This defines class ProgramRecord, which groups data and methods for program record. Instances exist in host memory and organize the flow that defines command bit fields, descriptor records, packed streams, and result decoders.

Line 100: `"""One descriptor-program command and its stream contract."""` This is executable documentation attached to the class ProgramRecord, which handles program record. It states the intended contract that tests and callers should enforce, but the text itself does not transform data or issue hardware work.

Line 102: `command: Command128` Inside the class ProgramRecord, which handles program record, this statement advances the host implementation that defines command bit fields, descriptor records, packed streams, and result decoders. The important operands are command: the 128-bit instruction selecting an engine, shape, mode, and numeric parameters; Command128: the 128-bit instruction selecting an engine, shape, mode, and numeric parameters.

Line 103: `input_beats: Sequence[StreamBeat] = ()` This assigns ‘()‘ to ‘input_beats‘ in host memory. Here input_beats means the value named ’input beats’ in this block. The expression is a literal or structural operator and has no hidden software state. Context: the class ProgramRecord, which handles program record.

Line 104: `output_beats: int = 0` This assigns ‘0‘ to ‘output_beats‘ in host memory. Here output_beats means the value named ’output beats’ in this block. The expression is a literal or structural operator and has no hidden software state. Context: the class ProgramRecord, which handles program record.

Line 106: `def __post_init__(self) -> None:` This starts function ___post_init___. Its indented body performs post init as part of the file that defines command bit fields, descriptor records, packed streams, and result decoders; it runs only when called.

Line 107: `_unsigned("program output beat count", self.output_beats, 31)` This calls ‘_unsigned‘ with ‘"program output beat count", self.output_beats, 31‘ inside the function ___post_init___, which handles post init. The call advances the host-side job that defines command bit fields, descriptor records, packed streams, and result decoders.

Line 108: `_unsigned("program input beat count", len(self.input_beats), 32)` This calls '_unsigned' with '"program input beat count", len(self.input_beats), 32' inside the function ___post_init___, which handles post init. The call advances the host-side job that defines command bit fields, descriptor records, packed streams, and result decoders.

Line 109: `if not isinstance(self.input_beats, PackedStreamBeats):` This executes the following indented host-code branch only when 'not isinstance(self.input_beats, PackedStreamBeats)' is true. The important operands are not: the value named 'not' in this block; isinstance: the value named 'isinstance' in this block; input_beats: the value named 'input beats' in this block. Context: the function ___post_init___, which handles post init.

Line 110: `for index, beat in enumerate(self.input_beats):` This iterates index, beat over 'enumerate(self.input_beats)'. Each iteration repeats the indented host operation, commonly once per layer, tile, timestep, or test case in the function ___post_init___, which handles post init.

Line 111: `if beat.last != (index == len(self.input_beats) - 1):` This executes the following indented host-code branch only when 'beat.last != (index == len(self.input_beats) - 1)' is true. The important operands are beat: the value named 'beat' in this block; last: the AXI-Stream marker for the final beat of a packet or command payload; index: an integer selecting one tensor element, lane, bank, or state entry. Context: the function ___post_init___, which handles post init.

Line 112: `raise ValueError("record input TLAST must mark only its final payload beat")` This rejects an invalid state by raising 'ValueError("record input TLAST must mark only its final payload beat")'. Failing before DMA prevents malformed shapes or artifacts from silently becoming hardware results.

Line 115: `@dataclass(frozen=True)` This decorator changes how the following class or function is constructed. '@dataclass(frozen=True)' is applied at import time on the host and is part of the file whose role is to defines command bit fields, descriptor records, packed streams, and result decoders; it creates no FPGA circuit by itself.

Line 116: `class Command128:` This defines class Command128, which groups data and methods for command128. Instances exist in host memory and organize the flow that defines command bit fields, descriptor records, packed streams, and result decoders.

Line 117: `value: int` Inside the class Command128, which handles command128, this statement advances the host implementation that defines command bit fields, descriptor records, packed streams, and result decoders. The important operands are value: the value named 'value' in this block.

Line 119: `def __post_init__(self) -> None:` This starts function ___post_init___. Its indented body performs post init as part of the file that defines command bit fields, descriptor records, packed streams, and result decoders; it runs only when called.

Line 120: `_unsigned("command", self.value, 128)` This calls '_unsigned' with '"command", self.value, 128' inside the function ___post_init___, which handles post init. The call advances the host-side job that defines command bit fields, descriptor records, packed streams, and result decoders.

Line 122: `@property` This decorator changes how the following class or function is constructed. '@property' is applied at import time on the host and is part of the class Command128, which handles command128; it creates no FPGA circuit by itself.

Line 123: `def opcode(self) -> Opcode:` This starts function opcode. Its indented body performs opcode as part of the file that defines command bit fields, descriptor records, packed streams, and result decoders; it runs only when called.

Line 124: `return Opcode(self.value & 0xF)` This returns 'Opcode(self.value & 0xF)' to the caller of the function opcode, which handles opcode, ending this invocation. The important operands are Opcode: the value named 'opcode' in this block; value: the value named 'value' in this block.

Line 126: `@property` This decorator changes how the following class or function is constructed. ‘@property‘ is applied at import time on the host and is part of the class Command128, which handles command128; it creates no FPGA circuit by itself.

Line 127: `def words_le(self) -> tuple[int, int, int, int]:` This starts function words_le. Its indented body performs words le as part of the file that defines command bit fields, descriptor records, packed streams, and result decoders; it runs only when called.

Line 128: `return tuple((self.value >> (32 * index)) & 0xFFFFFFFF for index in range(4))` This returns ‘tuple((self.value >> (32 * index)) & 0xFFFFFFFF for index in range(4))‘ to the caller of the function words_le, which handles words le, ending this invocation. The important operands are tuple: the value named ’tuple’ in this block; value: the value named ’value’ in this block; index: an integer selecting one tensor element, lane, bank, or state entry.

Line 130: `@classmethod` This decorator changes how the following class or function is constructed. ‘@classmethod‘ is applied at import time on the host and is part of the class Command128, which handles command128; it creates no FPGA circuit by itself.

Line 131: `def from_words_le(cls, words: Sequence[int]) -> "Command128":` This starts function from_words_le. Its indented body performs from words le as part of the file that defines command bit fields, descriptor records, packed streams, and result decoders; it runs only when called.

Line 132: `if len(words) != 4:` This executes the following indented host-code branch only when ‘len(words) != 4‘ is true. The important operands are len: the value named ’len’ in this block; words: the value named ’words’ in this block. Context: the function from_words_le, which handles from words le.

Line 133: `raise ValueError("a command requires exactly four 32-bit words")` This rejects an invalid state by raising ‘ValueError("a command requires exactly four 32-bit words")‘. Failing before DMA prevents malformed shapes or artifacts from silently becoming hardware results.

Line 134: `value = 0` This assigns ‘0‘ to ‘value ‘ in host memory. Here value means the value named ’value’ in this block. The expression is a literal or structural operator and has no hidden software state. Context: the function from_words_le, which handles from words le.

Line 135: `for index, word in enumerate(words):` This iterates index, word over ‘enumerate(words)‘. Each iteration repeats the indented host operation, commonly once per layer, tile, timestep, or test case in the function from_words_le, which handles from words le.

Line 136: `value |= _unsigned(f"command word {index}", word, 32) << (32 * index)` Inside the function from_words_le which handles from words le, this statement advances the host implementation that defines command bit fields, descriptor records, packed streams, and result decoders. The important operands are value: the value named ’value’ in this block; _unsigned: the value named ’unsigned’ in this block; f: the value named ’f’ in this block.

Line 137: `return cls(value)` This returns ‘cls(value)‘ to the caller of the function from_words_le, which handles from words le, ending this invocation. The important operands are cls: the value named ’cls’ in this block; value: the value named ’value’ in this block.

Line 140: `def _unsigned(name: str, value: int, bits: int, maximum: int | None = None) -> int:` This starts function _unsigned. Its indented body performs unsigned as part of the file that defines command bit fields, descriptor records, packed streams, and result decoders; it runs only when called.

Line 141: `integer = int(value)` This assigns ‘int(value)‘ to ‘integer ‘ in host memory. Here integer means the value named ’integer’ in this block. The important operands are value: the value named ’value’ in this block. Context: the function _unsigned, which handles unsigned.

Line 142: `limit = (1 << bits) - 1 if maximum is None else maximum` This assigns ‘(1 << bits) - 1 if maximum is None else maximum‘ to ‘limit ‘ in host memory. Here limit means the value named ’limit’ in this block. The important operands are bits: the value named ’bits’ in this block; maximum: the value named ’maximum’ in this block; is: the value named ’is’ in this block. Context: the function _unsigned, which handles unsigned.

Line 143: `if integer < 0 or integer > limit:` This executes the following indented host-code branch only when ‘integer < 0 or integer > limit‘ is true. The important operands are integer: the value named ’integer’ in this block; or: the value named ’or’ in this block; limit: the value named ’limit’ in this block. Context: the function _unsigned, which handles unsigned.

Line 144: `raise ValueError(f"{name} must be in [0,{limit}]")` This rejects an invalid state by raising ‘ValueError(f"{name} must be in [0,{limit}]")‘. Failing before DMA prevents malformed shapes or artifacts from silently becoming hardware results.

Line 145: `return integer` This returns ‘integer‘ to the caller of the function _unsigned, which handles unsigned, ending this invocation. The important operands are integer: the value named ’integer’ in this block.

Line 148: `def _signed_bits(name: str, value: int, bits: int) -> int:` This starts function _signed_bits. Its indented body performs signed bits as part of the file that defines command bit fields, descriptor records, packed streams, and result decoders; it runs only when called.

Line 149: `integer = int(value)` This assigns ‘int(value)‘ to ‘integer ‘ in host memory. Here integer means the value named ’integer’ in this block. The important operands are value: the value named ’value’ in this block. Context: the function _signed_bits, which handles signed bits.

Line 150: `minimum = -(1 << (bits - 1))` This assigns ‘-(1 << (bits - 1))‘ to ‘minimum ‘ in host memory. Here minimum means the value named ’minimum’ in this block. The important operands are bits: the value named ’bits’ in this block. Context: the function _signed_bits, which handles signed bits.

Line 151: `maximum = (1 << (bits - 1)) - 1` This assigns ‘(1 << (bits - 1)) - 1‘ to ‘maximum ‘ in host memory. Here maximum means the value named ’maximum’ in this block. The important operands are bits: the value named ’bits’ in this block. Context: the function _signed_bits, which handles signed bits.

Line 152: `if integer < minimum or integer > maximum:` This executes the following indented host-code branch only when ‘integer < minimum or integer > maximum‘ is true. The important operands are integer: the value named ’integer’ in this block; minimum: the value named ’minimum’ in this block; or: the value named ’or’ in this block. Context: the function _signed_bits, which handles signed bits.

Line 153: `raise ValueError(f"{name} must be in [{minimum},{maximum}]")` This rejects an invalid state by raising ‘ValueError(f"{name} must be in [{minimum},{maximum}]")‘. Failing before DMA prevents malformed shapes or artifacts from silently becoming hardware results.

Line 154: `return integer & ((1 << bits) - 1)` This returns ‘integer & ((1 << bits) - 1)‘ to the caller of the function _signed_bits, which handles signed bits, ending this invocation. The important operands are integer: the value named ’integer’ in this block; bits: the value named ’bits’ in this block.

Line 157: `def _decode_signed(value: int, bits: int) -> int:` This starts function _decode_signed. Its indented body performs decode signed as part of the file that defines command bit fields, descriptor records, packed streams, and result decoders; it runs only when called.

Line 158: `masked = value & ((1 << bits) - 1)` This assigns ‘value & ((1 << bits) - 1)‘ to ‘masked ‘ in host memory. Here masked means the value named ’masked’ in this block. The important operands are value: the value named ’value’ in this block; bits: the value named ’bits’ in this block. Context: the function _decode_signed, which handles decode signed.

Line 159: `return masked - (1 << bits) if masked & (1 << (bits - 1)) else masked` This returns ‘masked - (1 << bits) if masked & (1 << (bits - 1)) else masked‘ to the caller of the function _decode_signed, which handles decode signed, ending this invocation. The important operands are masked: the value named ’masked’ in this block; bits: the value named ’bits’ in this block.

Line 162: `def pack_descriptor_program(` This starts function pack_descriptor_program. Its indented body performs pack descriptor program as part of the file that defines command bit fields, descriptor records, packed streams, and result decoders; it runs only when called.

Line 163: `records: Sequence[ProgramRecord],` Inside the function pack_descriptor_program, which handles pack descriptor program, this statement advances the host implementation that defines command bit fields, descriptor records, packed streams, and result decoders. The important operands are records: the number of descriptor records accepted since program start; Sequence: the value named ’sequence’ in this block; ProgramRecord: the value named ’program record’ in this block.

Line 164: `) -> tuple[tuple[StreamBeat, ...], int]:` Inside the function pack_descriptor_program, which handles pack descriptor program, this statement advances the host implementation that defines command bit fields, descriptor records, packed streams, and result decoders. The important operands are tuple: the value named ’tuple’ in this block; StreamBeat: the value named ’stream beat’ in this block.

Line 165: `"""Pack records into the descriptor sequencer’s single-DMA stream."""` This is executable documentation attached to the function pack_descriptor_program, which handles pack descriptor program. It states the intended contract that tests and callers should enforce, but the text itself does not transform data or issue hardware work.

Line 167: `if not records:` This executes the following indented host-code branch only when ‘not records‘ is true. The important operands are not: the value named ’not’ in this block; records: the number of descriptor records accepted since program start. Context: the function pack_descriptor_program, which handles pack descriptor program.

Line 168: `raise ValueError("a descriptor program must contain at least one record")` This rejects an invalid state by raising ‘ValueError("a descriptor program must contain at least one record")‘. Failing before DMA prevents malformed shapes or artifacts from silently becoming hardware results.

Line 169: `words: list[int] = []` This assigns ‘[]‘ to ‘words‘ in host memory. Here words means the value named ’words’ in this block. The expression is a literal or structural operator and has no hidden software state. Context: the function pack_descriptor_program, which handles pack descriptor program.

Line 170: `total_outputs = 0` This assigns ‘0‘ to ‘total_outputs ‘ in host memory. Here total_outputs means the value named ’total outputs’ in this block. The expression is a literal or structural operator and has no hidden software state. Context: the function pack_descriptor_program, which handles pack descriptor program.

Line 171: `for index, record in enumerate(records):` This iterates index, record over ‘enumerate(records)‘. Each iteration repeats the indented host operation, commonly once per layer, tile, timestep, or test case in the function pack_descriptor_program, which handles pack descriptor program.

Line 172: `final = index == len(records) - 1` Inside the function pack_descriptor_program, which handles pack descriptor program, this statement advances the host implementation that defines command bit fields, descriptor records, packed streams, and result decoders. The important operands are final: the value named ’final’ in this block; index: an integer selecting one tensor element, lane, bank, or state entry; len: the value named ’len’ in this block.

Line 173: `header = len(record.input_beats)` This assigns ‘len(record.input_beats)‘ to ‘header ‘ in host memory. Here header means the value named ’header’ in this block. The important operands are len: the value named ’len’ in this block; record: the value named ’record’ in this block; input_beats: the value named ’input beats’ in this block. Context: the function pack_descriptor_program, which handles pack descriptor program.

Line 174: `header |= record.output_beats << 32` Inside the function pack_descriptor_program, which handles pack descriptor program, this statement advances the host implementation that defines command bit fields, descriptor records, packed streams, and result decoders. The important operands are header: the value named 'header' in this block; record: the value named 'record' in this block; output_beats: the value named 'output beats' in this block.

Line 175: `header |= int(final) << 63` Inside the function pack_descriptor_program, which handles pack descriptor program, this statement advances the host implementation that defines command bit fields, descriptor records, packed streams, and result decoders. The important operands are header: the value named 'header' in this block; final: the value named 'final' in this block.

Line 176: `words.extend((` This statement continues through source line 180; the explanation uses the complete expression rather than only the first visual fragment. This calls ‘words.extend‘ with ‘(header, record.command.value & ((1 << 64) - 1), record.command.value >> 64,)‘ inside the function pack_descriptor_program, which handles pack descriptor program. The call advances the host-side job that defines command bit fields, descriptor records, packed streams, and result decoders.

Line 177: `header,` This is continuation line 2 of the 5-line logical statement that begins at source line 176. Its exact fragment is ‘header,‘. The important operands are header: the value named 'header' in this block. Read together, the complete operation is: This calls ‘words.extend‘ with ‘(header, record.command.value & ((1 << 64) - 1), record.command.value >> 64,)‘ inside the function pack_descriptor_program, which handles pack descriptor program. The call advances the host-side job that defines command bit fields, descriptor records, packed streams, and result decoders.

Line 178: `record.command.value & ((1 << 64) - 1),` This is continuation line 3 of the 5-line logical statement that begins at source line 176. Its exact fragment is ‘record.command.value & ((1 << 64) - 1),‘. The important operands are record: the value named 'record' in this block; command: the 128-bit instruction selecting an engine, shape, mode, and numeric parameters; value: the value named 'value' in this block. Read together, the complete operation is: This calls ‘words.extend‘ with ‘(header, record.command.value & ((1 << 64) - 1), record.command.value >> 64,)‘ inside the function pack_descriptor_program, which handles pack descriptor program. The call advances the host-side job that defines command bit fields, descriptor records, packed streams, and result decoders.

Line 179: `record.command.value >> 64,` This is continuation line 4 of the 5-line logical statement that begins at source line 176. Its exact fragment is ‘record.command.value >> 64,‘. The important operands are record: the value named 'record' in this block; command: the 128-bit instruction selecting an engine, shape, mode, and numeric parameters; value: the value named 'value' in this block. Read together, the complete operation is: This calls ‘words.extend‘ with ‘(header, record.command.value & ((1 << 64) - 1), record.command.value >> 64,)‘ inside the function pack_descriptor_program, which handles pack descriptor program. The call advances the host-side job that defines command bit fields, descriptor records, packed streams, and result decoders.

Line 180: `))` This is continuation line 5 of the 5-line logical statement that begins at source line 176. Its exact fragment is ‘))‘. The expression is a literal or structural operator and has no hidden software state. Read together, the complete operation is: This calls ‘words.extend‘ with ‘(header, record.command.value & ((1 << 64) - 1), record.command.value >> 64,)‘ inside the function pack_descriptor_program, which handles pack descriptor program. The call advances the host-side job that defines command bit fields, descriptor records, packed streams, and result decoders.

Line 181: `words.extend(beat.data for beat in record.input_beats)` This calls ‘words.extend‘ with ‘beat.data for beat in record.input_beats‘ inside the function pack_descriptor_program, which handles pack descriptor program. The call advances the host-side job that defines command bit fields, descriptor records, packed streams, and result decoders.

Line 182: `total_outputs += record.output_beats` Inside the function pack_descriptor_program, which handles pack descriptor program, this statement advances the host implementation that defines command bit fields, descriptor records, packed streams, and result decoders. The important operands are total_outputs: the value named 'total outputs' in this block; record: the value named 'record' in this block; output_beats: the value named 'output beats' in this block.

Line 183: `_unsigned("program total output beat count", total_outputs, 32)` This calls ‘_unsigned‘ with ‘"program total output beat count", total_outputs, 32‘ inside the function pack_descriptor_program, which handles pack descriptor program. The call advances the host-side job that defines command bit fields, descriptor records, packed streams, and result decoders.

Line 184: `beats = tuple(StreamBeat(word, item == len(words) - 1)` This statement continues through source line 185; the explanation uses the complete expression rather than only the first visual fragment. Inside the function pack_descriptor_program, which handles pack descriptor program, this statement advances the host implementation that defines command bit fields, descriptor records, packed streams, and result decoders. The important operands are beats: the value named ’beats’ in this block; tuple: the value named ’tuple’ in this block; StreamBeat: the value named ’stream beat’ in this block.

Line 185: `for item, word in enumerate(words))` This is continuation line 2 of the 2-line logical statement that begins at source line 184. Its exact fragment is ‘for item, word in enumerate(words))‘. The important operands are for: the value named ’for’ in this block; item: the value named ’item’ in this block; word: the value named ’word’ in this block. Read together, the complete operation is: Inside the function pack_descriptor_program, which handles pack descriptor program, this statement advances the host implementation that defines command bit fields, descriptor records, packed streams, and result decoders. The important operands are beats: the value named ’beats’ in this block; tuple: the value named ’tuple’ in this block; StreamBeat: the value named ’stream beat’ in this block.

Line 186: `return beats, total_outputs` This returns ‘beats, total_outputs‘ to the caller of the function pack_descriptor_prog which handles pack descriptor program, ending this invocation. The important operands are beats: the value named ’beats’ in this block; total_outputs: the value named ’total outputs’ in this block.

Line 189: `def _put(command: int, value: int, offset: int, bits: int) -> int:` This starts function _put. Its indented body performs put as part of the file that defines command bit fields, descriptor records, packed streams, and result decoders; it runs only when called.

Line 190: `return command | ((value & ((1 << bits) - 1)) << offset)` This returns ‘command | ((value & ((1 << bits) - 1)) << offset)‘ to the caller of the function _put, which handles put, ending this invocation. The important operands are command: the 128-bit instruction selecting an engine, shape, mode, and numeric parameters; value: the value named ’value’ in this block; bits: the value named ’bits’ in this block.

Line 193: `def clear_status_command() -> Command128:` This starts function clear_status_command. Its indented body performs clear status command as part of the file that defines command bit fields, descriptor records, packed streams, and result decoders; it runs only when called.

Line 194: `return Command128(int(Opcode.CLEAR_STATUS))` This returns ‘Command128(int(Opcode.CLEAR_STATUS))‘ to the caller of the function clear_status_command, which handles clear status command, ending this invocation. The important operands are Command128: the 128-bit instruction selecting an engine, shape, mode, and numeric parameters; Opcode: the value named ’opcode’ in this block; CLEAR_STATUS: the value named ’clear status’ in this block.

Line 197: `def linear_backward_command(` This starts function linear_backward_command. Its indented body performs linear backward command as part of the file that defines command bit fields, descriptor records, packed streams, and result decoders; it runs only when called.

Line 198: `rows: int,` Inside the function linear_backward_command, which handles linear backward command, this statement advances the host implementation that defines command bit fields, descriptor records, packed streams, and result decoders. The important operands are rows: one output-row position processed by the tensor tile.

Line 199: `input_features: int,` Inside the function linear_backward_command, which handles linear backward command, this statement advances the host implementation that defines command bit fields, descriptor records, packed streams, and result decoders. The important operands are input_features: the value named ’input features’ in this block.

Line 200: `output_features: int,` Inside the function linear_backward_command, which handles linear backward command, this statement advances the host implementation that defines command bit fields, descriptor records, packed streams, and result decoders. The important operands are output_features: the value named 'output features' in this block.

Line 201: `*,` Inside the function linear_backward_command, which handles linear backward command, this statement advances the host implementation that defines command bit fields, descriptor records, packed streams, and result decoders. The expression is a literal or structural operator and has no hidden software state.

Line 202: `input_gradient_shift: int = 0,` This assigns '0,' to 'input_gradient_shift' in host memory. Here input_gradient_shift means the signed loss derivative used to update a learned parameter. The expression is a literal or structural operator and has no hidden software state. Context: the function linear_backward_command, which handles linear backward command.

Line 203: `weight_gradient_shift: int = 0,` This assigns '0,' to 'weight_gradient_shift' in host memory. Here weight_gradient_shift means a learned coefficient multiplied by an activation. The expression is a literal or structural operator and has no hidden software state. Context: the function linear_backward_command, which handles linear backward command.

Line 204: `mode: LinearGradientMode = LinearGradientMode.BOTH,` This assigns 'LinearGradientMode.BOTH,' to 'mode' in host memory. Here mode means the value named 'mode' in this block. The important operands are LinearGradientMode: the signed loss derivative used to update a learned parameter; BOTH: the value named 'both' in this block. Context: the function linear_backward_command, which handles linear backward command.

Line 205: `accumulate: bool = False,` This assigns 'False,' to 'accumulate' in host memory. Here accumulate means the value named 'accumulate' in this block. The expression is a literal or structural operator and has no hidden software state. Context: the function linear_backward_command, which handles linear backward command.

Line 206: `suppress_output: bool = False,` This assigns 'False,' to 'suppress_output' in host memory. Here suppress_output means the value named 'suppress output' in this block. The expression is a literal or structural operator and has no hidden software state. Context: the function linear_backward_command, which handles linear backward command.

Line 207: `) -> Command128:` Inside the function linear_backward_command, which handles linear backward command, this statement advances the host implementation that defines command bit fields, descriptor records, packed streams, and result decoders. The important operands are Command128: the 128-bit instruction selecting an engine, shape, mode, and numeric parameters.

Line 208: `"""Configure one signed 8x8 linear-layer backward tile."""` This is executable documentation attached to the function linear_backward_command, which handles linear backward command. It states the intended contract that tests and callers should enforce, but the text itself does not transform data or issue hardware work.

Line 210: `row_count = _unsigned("rows", rows, 4, 8)` This assigns '_unsigned("rows", rows, 4, 8)' to 'row_count ' in host memory. Here row_count means one output-row position processed by the tensor tile. The important operands are _unsigned: the value named 'unsigned' in this block; rows: one output-row position processed by the tensor tile. Context: the function linear_backward_command, which handles linear backward command.

Line 211: `input_count = _unsigned("input_features", input_features, 4, 8)` This assigns '_unsigned("input_features" input_features, 4, 8)' to 'input_count ' in host memory. Here input_count means an integer count retained for control or measurable telemetry. The important operands are _unsigned: the value named 'unsigned' in this block; input_features: the value named 'input features' in this block. Context: the function linear_backward_command, which handles linear backward command.

Line 212: `output_count = _unsigned("output_features", output_features, 4, 8)` This assigns '_unsigned("output_feat output_features, 4, 8)' to 'output_count ' in host memory. Here output_count means an integer count retained for control or measurable telemetry. The important operands are _unsigned: the value named 'unsigned' in this block; output_features: the value named 'output features' in this block. Context: the function linear_backward_command, which handles linear backward command.

Line 213: `if row_count == 0 or input_count == 0 or output_count == 0:` This executes the following indented host-code branch only when 'row_count == 0 or input_count == 0 or output_count == 0' is true. The important operands are row_count: one output-row position processed by the tensor tile; or: the value named 'or' in this block; input_count: an integer count retained for control or measurable telemetry. Context: the function linear_backward_command, which handles linear backward command.

Line 214: `raise ValueError("linear backward dimensions must be non-zero")` This rejects an invalid state by raising 'ValueError("linear backward dimensions must be non-zero")'. Failing before DMA prevents malformed shapes or artifacts from silently becoming hardware results.

Line 215: `command = _put(int(Opcode.TRAIN_LINEAR_BACKWARD), row_count, 4, 4)` This assigns '_put(int(Opcode.TRAI row_count, 4, 4)' to 'command ' in host memory. Here command means the 128-bit instruction selecting an engine, shape, mode, and numeric parameters. The important operands are _put: the value named 'put' in this block; Opcode: the value named 'opcode' in this block; TRAIN_LINEAR_BACKWARD: the value named 'train linear backward' in this block. Context: the function linear_backward_command, which handles linear backward command.

Line 216: `command = _put(command, input_count, 8, 4)` This assigns '_put(command, input_count, 8, 4)' to 'command ' in host memory. Here command means the 128-bit instruction selecting an engine, shape, mode, and numeric parameters. The important operands are _put: the value named 'put' in this block; command: the 128-bit instruction selecting an engine, shape, mode, and numeric parameters; input_count: an integer count retained for control or measurable telemetry. Context: the function linear_backward_command, which handles linear backward command.

Line 217: `command = _put(command, output_count, 12, 4)` This assigns '_put(command, output_count, 12, 4)' to 'command ' in host memory. Here command means the 128-bit instruction selecting an engine, shape, mode, and numeric parameters. The important operands are _put: the value named 'put' in this block; command: the 128-bit instruction selecting an engine, shape, mode, and numeric parameters; output_count: an integer count retained for control or measurable telemetry. Context: the function linear_backward_command, which handles linear backward command.

Line 218: `command = _put(` This statement continues through source line 223; the explanation uses the complete expression rather than only the first visual fragment. This assigns '_put(command, _unsigned("input_gradient_shift", input_gradient_shift, 5), 16, 5,)' to 'command ' in host memory. Here command means the 128-bit instruction selecting an engine, shape, mode, and numeric parameters. The important operands are _put: the value named 'put' in this block; command: the 128-bit instruction selecting an engine, shape, mode, and numeric parameters; _unsigned: the value named 'unsigned' in this block. Context: the function linear_backward_command, which handles linear backward command.

Line 219: `command,` This is continuation line 2 of the 6-line logical statement that begins at source line 218. Its exact fragment is 'command,'. The important operands are command: the 128-bit instruction selecting an engine, shape, mode, and numeric parameters. Read together, the complete operation is: This assigns '_put(command, _unsigned("input_gradient_shift", input_gradient_shift, 5), 16, 5,)' to 'command ' in host memory. Here command means the 128-bit instruction selecting an engine, shape, mode, and numeric parameters. The important operands are _put: the value named 'put' in this block; command: the 128-bit instruction selecting an engine, shape, mode, and numeric parameters; _unsigned: the value named 'unsigned' in this block. Context: the function linear_backward_command, which handles linear backward command.

Line 220: `_unsigned("input_gradient_shift", input_gradient_shift, 5),` This is continuation line 3 of the 6-line logical statement that begins at source line 218. Its exact fragment is '_unsigned("input_gradient_shift", input_gradient_shift, 5),'. The important operands are _unsigned: the value named 'unsigned' in this block; input_gradient_shift:

the signed loss derivative used to update a learned parameter. Read together, the complete operation is: This assigns ‘_put(command, _unsigned("input_gradient_shift", input_gradient_shift, 5), 16, 5,)‘ to ‘command ‘ in host memory. Here command means the 128-bit instruction selecting an engine, shape, mode, and numeric parameters. The important operands are _put: the value named ’put’ in this block; command: the 128-bit instruction selecting an engine, shape, mode, and numeric parameters; _unsigned: the value named ’unsigned’ in this block. Context: the function linear_backward_command, which handles linear backward command.

Line 221: `16,` This is continuation line 4 of the 6-line logical statement that begins at source line 218. Its exact fragment is ‘16,‘. The expression is a literal or structural operator and has no hidden software state. Read together, the complete operation is: This assigns ‘_put(command, _unsigned("input_gradient_shift", input_gradient_shift, 5), 16, 5,)‘ to ‘command ‘ in host memory. Here command means the 128-bit instruction selecting an engine, shape, mode, and numeric parameters. The important operands are _put: the value named ’put’ in this block; command: the 128-bit instruction selecting an engine, shape, mode, and numeric parameters; _unsigned: the value named ’unsigned’ in this block. Context: the function linear_backward_command, which handles linear backward command.

Line 222: `5,` This is continuation line 5 of the 6-line logical statement that begins at source line 218. Its exact fragment is ‘5,‘. The expression is a literal or structural operator and has no hidden software state. Read together, the complete operation is: This assigns ‘_put(command, _unsigned("input_gradient_shift", input_gradient_shift, 5), 16, 5,)‘ to ‘command ‘ in host memory. Here command means the 128-bit instruction selecting an engine, shape, mode, and numeric parameters. The important operands are _put: the value named ’put’ in this block; command: the 128-bit instruction selecting an engine, shape, mode, and numeric parameters; _unsigned: the value named ’unsigned’ in this block. Context: the function linear_backward_command, which handles linear backward command.

Line 223: `)` This is continuation line 6 of the 6-line logical statement that begins at source line 218. Its exact fragment is ‘)‘. The expression is a literal or structural operator and has no hidden software state. Read together, the complete operation is: This assigns ‘_put(command, _unsigned("input_gradient_shift", input_gradient_shift, 5), 16, 5,)‘ to ‘command ‘ in host memory. Here command means the 128-bit instruction selecting an engine, shape, mode, and numeric parameters. The important operands are _put: the value named ’put’ in this block; command: the 128-bit instruction selecting an engine, shape, mode, and numeric parameters; _unsigned: the value named ’unsigned’ in this block. Context: the function linear_backward_command, which handles linear backward command.

Line 224: `command = _put(` This statement continues through source line 229; the explanation uses the complete expression rather than only the first visual fragment. This assigns ‘_put(command, _unsigned("weight_gradient_shift", weight_gradient_shift, 5), 21, 5,)‘ to ‘command ‘ in host memory. Here command means the 128-bit instruction selecting an engine, shape, mode, and numeric parameters. The important operands are _put: the value named ’put’ in this block; command: the 128-bit instruction selecting an engine, shape, mode, and numeric parameters; _unsigned: the value named ’unsigned’ in this block. Context: the function linear_backward_command, which handles linear backward command.

Line 225: `command,` This is continuation line 2 of the 6-line logical statement that begins at source line 224. Its exact fragment is ‘command,‘. The important operands are command: the 128-bit instruction selecting an engine, shape, mode, and numeric parameters. Read together, the complete operation is: This assigns ‘_put(command, _unsigned("weight_gradient_shift", weight_gradient_shift, 5), 21, 5,)‘ to ‘command ‘ in host memory. Here command means the 128-bit instruction selecting an engine, shape, mode, and numeric parameters. The important operands are _put: the value named ’put’ in this block; command: the 128-bit instruction selecting an engine, shape, mode, and numeric parameters; _unsigned: the value named ’unsigned’ in this block. Context: the function linear_backward_command, which handles linear backward command.

Line 226: `_unsigned("weight_gradient_shift", weight_gradient_shift, 5),` This is continuation line 3 of the 6-line logical statement that begins at source line 224. Its exact fragment is ‘_unsigned("weight_gradient_shift", weight_gradient_shift, 5),‘. The important operands are _unsigned: the value named ’unsigned’ in this block; weight_gradient_shift a learned coefficient multiplied by an activation. Read together, the complete operation is: This assigns ‘_put(command, _unsigned("weight_gradient_shift", weight_gradient_shift, 5), 21, 5,)‘ to ‘command ‘ in host memory. Here command means the 128-bit instruction selecting an engine, shape, mode, and numeric parameters. The important operands are _put: the value named ’put’ in this block; command: the 128-bit instruction selecting an engine, shape, mode, and numeric parameters; _unsigned: the value named ’unsigned’ in this block. Context: the function linear_backward_command, which handles linear backward command.

Line 227: `21,` This is continuation line 4 of the 6-line logical statement that begins at source line 224. Its exact fragment is ‘21,‘. The expression is a literal or structural operator and has no hidden software state. Read together, the complete operation is: This assigns ‘_put(command, _unsigned("weight_gradient_shift", weight_gradient_shift, 5), 21, 5,)‘ to ‘command ‘ in host memory. Here command means the 128-bit instruction selecting an engine, shape, mode, and numeric parameters. The important operands are _put: the value named ’put’ in this block; command: the 128-bit instruction selecting an engine, shape, mode, and numeric parameters; _unsigned: the value named ’unsigned’ in this block. Context: the function linear_backward_command, which handles linear backward command.

Line 228: `5,` This is continuation line 5 of the 6-line logical statement that begins at source line 224. Its exact fragment is ‘5,‘. The expression is a literal or structural operator and has no hidden software state. Read together, the complete operation is: This assigns ‘_put(command, _unsigned("weight_gradient_shift", weight_gradient_shift, 5), 21, 5,)‘ to ‘command ‘ in host memory. Here command means the 128-bit instruction selecting an engine, shape, mode, and numeric parameters. The important operands are _put: the value named ’put’ in this block; command: the 128-bit instruction selecting an engine, shape, mode, and numeric parameters; _unsigned: the value named ’unsigned’ in this block. Context: the function linear_backward_command, which handles linear backward command.

Line 229: `)` This is continuation line 6 of the 6-line logical statement that begins at source line 224. Its exact fragment is ‘)‘. The expression is a literal or structural operator and has no hidden software state. Read together, the complete operation is: This assigns ‘_put(command, _unsigned("weight_gradient_shift", weight_gradient_shift, 5), 21, 5,)‘ to ‘command ‘ in host memory. Here command means the 128-bit instruction selecting an engine, shape, mode, and numeric parameters. The important operands are _put: the value named ’put’ in this block; command: the 128-bit instruction selecting an engine, shape, mode, and numeric parameters; _unsigned: the value named ’unsigned’ in this block. Context: the function linear_backward_command, which handles linear backward command.

Line 230: `try:` This is explicit host-side failure handling inside the function linear_backward_command, which handles linear backward command; it ensures malformed artifacts, DMA errors, and tool failures are surfaced or cleaned up deterministically.

Line 231: `selected_mode = LinearGradientMode(mode)` This assigns ‘LinearGradientMode(mode)‘ to ‘selected_mode ‘ in host memory. Here selected_mode means the value named ’selected mode’ in this block. The important operands are LinearGradientMode: the signed loss derivative used to update a learned parameter; mode: the value named ’mode’ in this block. Context: the function linear_backward_command, which handles linear backward command.

Line 232: `except ValueError as error:` This is explicit host-side failure handling inside the function linear_backward_comma which handles linear backward command; it ensures malformed artifacts, DMA errors, and tool failures are surfaced or cleaned up deterministically.

Line 233: `raise ValueError("linear backward mode must be BOTH, INPUT, or WEIGHT") from error` This rejects an invalid state by raising ‘ValueError("linear backward mode must be BOTH, INPUT, or WEIGHT") from error‘. Failing before DMA prevents malformed shapes or artifacts from silently becoming hardware results.

Line 234: `command = _put(command, int(selected_mode), 26, 2)` This assigns ‘_put(command, int(selected_mode), 26, 2)‘ to ‘command ‘ in host memory. Here command means the 128-bit instruction selecting an engine, shape, mode, and numeric parameters. The important operands are _put: the value named ’put’ in this block; command: the 128-bit instruction selecting an engine, shape, mode, and numeric parameters; selected_mode: the value named ’selected mode’ in this block. Context: the function linear_backward_command, which handles linear backward command.

Line 235: `command = _put(command, int(bool(accumulate)), 28, 1)` This assigns ‘_put(command, int(bool(accumulate)), 28, 1)‘ to ‘command ‘ in host memory. Here command means the 128-bit instruction selecting an engine, shape, mode, and numeric parameters. The important operands are _put: the value named ’put’ in this block; command: the 128-bit instruction selecting an engine, shape, mode, and numeric parameters; bool: the value named ’bool’ in this block. Context: the function linear_backward_command, which handles linear backward command.

Line 236: `command = _put(command, int(bool(suppress_output)), 29, 1)` This assigns '_put(command, int(bool(suppress 29, 1)' to 'command ' in host memory. Here command means the 128-bit instruction selecting an engine, shape, mode, and numeric parameters. The important operands are _put: the value named 'put' in this block; command: the 128-bit instruction selecting an engine, shape, mode, and numeric parameters; bool: the value named 'bool' in this block. Context: the function linear_backward_command, which handles linear backward command.

Line 237: `return Command128(command)` This returns 'Command128(command)' to the caller of the function linear_backward_command, which handles linear backward command, ending this invocation. The important operands are Command128: the 128-bit instruction selecting an engine, shape, mode, and numeric parameters; command: the 128-bit instruction selecting an engine, shape, mode, and numeric parameters.

Line 240: `def tensor_command(` This starts function tensor_command. Its indented body performs tensor command as part of the file that defines command bit fields, descriptor records, packed streams, and result decoders; it runs only when called.

Line 241: `opcode: Opcode,` Inside the function tensor_command, which handles tensor command, this statement advances the host implementation that defines command bit fields, descriptor records, packed streams, and result decoders. The important operands are opcode: the value named 'opcode' in this block; Opcode: the value named 'opcode' in this block.

Line 242: `*,` Inside the function tensor_command, which handles tensor command, this statement advances the host implementation that defines command bit fields, descriptor records, packed streams, and result decoders. The expression is a literal or structural operator and has no hidden software state.

Line 243: `rows: int = 0,` This assigns '0,' to 'rows' in host memory. Here rows means one output-row position processed by the tensor tile. The expression is a literal or structural operator and has no hidden software state. Context: the function tensor_command, which handles tensor command.

Line 244: `columns: int = 0,` This assigns '0,' to 'columns' in host memory. Here columns means one output-feature position processed in parallel. The expression is a literal or structural operator and has no hidden software state. Context: the function tensor_command, which handles tensor command.

Line 245: `issue_count: int,` Inside the function tensor_command, which handles tensor command, this statement advances the host implementation that defines command bit fields, descriptor records, packed streams, and result decoders. The important operands are issue_count: an integer count retained for control or measurable telemetry.

Line 246: `activation_zero_point: int = 0,` This assigns '0,' to 'activation_zero_point' in host memory. Here activation_zero_point means an input feature value consumed by a neuron or multiply-accumulate operation. The expression is a literal or structural operator and has no hidden software state. Context: the function tensor_command, which handles tensor command.

Line 247: `weight_zero_point: int = 0,` This assigns '0,' to 'weight_zero_point' in host memory. Here weight_zero_point means a learned coefficient multiplied by an activation. The expression is a literal or structural operator and has no hidden software state. Context: the function tensor_command, which handles tensor command.

Line 248: `) -> Command128:` Inside the function tensor_command, which handles tensor command, this statement advances the host implementation that defines command bit fields, descriptor records, packed streams, and result decoders. The important operands are Command128: the 128-bit instruction selecting an engine, shape, mode, and numeric parameters.

Line 249: `tensor_opcodes = {` This statement continues through source line 257; the explanation uses the complete expression rather than only the first visual fragment. This assigns '{ Opcode.LOAD_ACTIVATIONS, Opcode.LOAD_WEIGHTS_OUTER, Opcode.LOAD_WEIGHTS_DOT8, Opcode.COMPUTE_DENSE_OUTER, Opcode.COMPUTE_DENSE_DOT8, Opcode.COMPUTE_BINARY, Opcode.COMPUTE_TERNARY, }' to 'tensor_opcodes

‘ in host memory. Here tensor_opcodes means the value named 'tensor opcodes' in this block. The important operands are Opcode: the value named 'opcode' in this block; LOAD_ACTIVATIONS: an input feature value consumed by a neuron or multiply-accumulate operation; LOAD_WEIGHTS_OUTER: a learned coefficient multiplied by an activation. Context: the function tensor_command, which handles tensor command.

Line 250: `Opcode.LOAD_ACTIVATIONS,` This is continuation line 2 of the 9-line logical statement that begins at source line 249. Its exact fragment is ‘Opcode.LOAD_ACTIVATIONS,‘. The important operands are Opcode: the value named 'opcode' in this block; LOAD_ACTIVATIONS: an input feature value consumed by a neuron or multiply-accumulate operation. Read together, the complete operation is: This assigns ‘{ Opcode.LOAD_ACTIVATIONS, Opcode.LOAD_WEIGHTS_OUTER, Opcode.LOAD_WEIGHTS_DOT8, Opcode.COMPUTE_DENSE_OUTER, Opcode.COMPUTE_DENSE_DOT8, Opcode.COMPUTE_BINARY, Opcode.COMPUTE_TERNARY, }‘ to ‘tensor_opcodes ‘ in host memory. Here tensor_opcodes means the value named 'tensor opcodes' in this block. The important operands are Opcode: the value named 'opcode' in this block; LOAD_ACTIVATIONS: an input feature value consumed by a neuron or multiply-accumulate operation; LOAD_WEIGHTS_OUTER: a learned coefficient multiplied by an activation. Context: the function tensor_command, which handles tensor command.

Line 251: `Opcode.LOAD_WEIGHTS_OUTER,` This is continuation line 3 of the 9-line logical statement that begins at source line 249. Its exact fragment is ‘Opcode.LOAD_WEIGHTS_OUTER,‘. The important operands are Opcode: the value named 'opcode' in this block; LOAD_WEIGHTS_OUTER: a learned coefficient multiplied by an activation. Read together, the complete operation is: This assigns ‘{ Opcode.LOAD_ACTIVATIONS, Opcode.LOAD_WEIGHTS_OUTER, Opcode.LOAD_WEIGHTS_DOT8, Opcode.COMPUTE_DENSE_OUTER, Opcode.COMPUTE_DENSE_DOT8, Opcode.COMPUTE_BINARY, Opcode.COMPUTE_TERNARY, }‘ to ‘tensor_opcodes ‘ in host memory. Here tensor_opcodes means the value named 'tensor opcodes' in this block. The important operands are Opcode: the value named 'opcode' in this block; LOAD_ACTIVATIONS: an input feature value consumed by a neuron or multiply-accumulate operation; LOAD_WEIGHTS_OUTER: a learned coefficient multiplied by an activation. Context: the function tensor_command, which handles tensor command.

Line 252: `Opcode.LOAD_WEIGHTS_DOT8,` This is continuation line 4 of the 9-line logical statement that begins at source line 249. Its exact fragment is ‘Opcode.LOAD_WEIGHTS_DOT8,‘. The important operands are Opcode: the value named 'opcode' in this block; LOAD_WEIGHTS_DOT8: a learned coefficient multiplied by an activation. Read together, the complete operation is: This assigns ‘{ Opcode.LOAD_ACTIVATIONS, Opcode.LOAD_WEIGHTS_OUTER, Opcode.LOAD_WEIGHTS_DOT8, Opcode.COMPUTE_DENSE_OUTER, Opcode.COMPUTE_DENSE_DOT8, Opcode.COMPUTE_BINARY, Opcode.COMPUTE_TERNARY, }‘ to ‘tensor_opcodes ‘ in host memory. Here tensor_opcodes means the value named 'tensor opcodes' in this block. The important operands are Opcode: the value named 'opcode' in this block; LOAD_ACTIVATIONS: an input feature value consumed by a neuron or multiply-accumulate operation; LOAD_WEIGHTS_OUTER: a learned coefficient multiplied by an activation. Context: the function tensor_command, which handles tensor command.

Line 253: `Opcode.COMPUTE_DENSE_OUTER,` This is continuation line 5 of the 9-line logical statement that begins at source line 249. Its exact fragment is ‘Opcode.COMPUTE_DENSE_OUTER,‘. The important operands are Opcode: the value named 'opcode' in this block; COMPUTE_DENSE_OUTER: the value named 'compute dense outer' in this block. Read together, the complete operation is: This assigns ‘{ Opcode.LOAD_ACTIVATIONS, Opcode.LOAD_WEIGHTS_OUTER, Opcode.LOAD_WEIGHTS_DOT8, Opcode.COMPUTE_DENSE_OUTER, Opcode.COMPUTE_DENSE_DOT8, Opcode.COMPUTE_BINARY, Opcode.COMPUTE_TERNARY, }‘ to ‘tensor_opcodes ‘ in host memory. Here tensor_opcodes means the value named 'tensor opcodes' in this block. The important operands are Opcode: the value named 'opcode' in this block; LOAD_ACTIVATIONS: an input feature value consumed by a neuron or multiply-accumulate operation; LOAD_WEIGHTS_OUTER: a learned coefficient multiplied by an activation. Context: the function tensor_command, which handles tensor command.

Line 254: `Opcode.COMPUTE_DENSE_DOT8,` This is continuation line 6 of the 9-line logical statement that begins at source line 249. Its exact fragment is ‘Opcode.COMPUTE_DENSE_DOT8,‘. The important operands are Opcode: the value named 'opcode' in this block; COMPUTE_DENSE_DOT8: the value named 'compute dense dot8' in this block. Read together, the complete operation is: This assigns ‘{ Opcode.LOAD_ACTIVATIONS, Opcode.LOAD_WEIGHTS_OUTER, Opcode.LOAD_WEIGHTS_DOT8, Opcode.COMPUTE_DENSE_OUTER, Opcode.COMPUTE_DENSE_DOT8, Opcode.COMPUTE_BINARY, Opcode.COMPUTE_TERNARY, }‘ to ‘tensor_opcodes ‘ in host memory. Here tensor_opcodes means the value named 'tensor opcodes' in this block. The important operands are Opcode: the value

named 'opcode' in this block; LOAD_ACTIVATIONS: an input feature value consumed by a neuron or multiply-accumulate operation; LOAD_WEIGHTS_OUTER: a learned coefficient multiplied by an activation. Context: the function tensor_command, which handles tensor command.

Line 255: `Opcode.COMPUTE_BINARY,` This is continuation line 7 of the 9-line logical statement that begins at source line 249. Its exact fragment is 'Opcode.COMPUTE_BINARY,'. The important operands are Opcode: the value named 'opcode' in this block; COMPUTE_BINARY: the value named 'compute binary' in this block. Read together, the complete operation is: This assigns '{ Opcode.LOAD_ACTIVATIONS, Opcode.LOAD_WEIGHTS_OUTER, Opcode.LOAD_WEIGHTS_DOT8, Opcode.COMPUTE_DENSE_OUTER, Opcode.COMPUTE_DENSE_DOT8, Opcode.COMPUTE_BINARY, Opcode.COMPUTE_TERNARY, }' to 'tensor_opcodes ' in host memory. Here tensor_opcodes means the value named 'tensor opcodes' in this block. The important operands are Opcode: the value named 'opcode' in this block; LOAD_ACTIVATIONS: an input feature value consumed by a neuron or multiply-accumulate operation; LOAD_WEIGHTS_OUTER: a learned coefficient multiplied by an activation. Context: the function tensor_command, which handles tensor command.

Line 256: `Opcode.COMPUTE_TERNARY,` This is continuation line 8 of the 9-line logical statement that begins at source line 249. Its exact fragment is 'Opcode.COMPUTE_TERNARY,'. The important operands are Opcode: the value named 'opcode' in this block; COMPUTE_TERNARY: the value named 'compute ternary' in this block. Read together, the complete operation is: This assigns '{ Opcode.LOAD_ACTIVATIONS, Opcode.LOAD_WEIGHTS_OUTER, Opcode.LOAD_WEIGHTS_DOT8, Opcode.COMPUTE_DENSE_OUTER, Opcode.COMPUTE_DENSE_DOT8, Opcode.COMPUTE_BINARY, Opcode.COMPUTE_TERNARY, }' to 'tensor_opcodes ' in host memory. Here tensor_opcodes means the value named 'tensor opcodes' in this block. The important operands are Opcode: the value named 'opcode' in this block; LOAD_ACTIVATIONS: an input feature value consumed by a neuron or multiply-accumulate operation; LOAD_WEIGHTS_OUTER: a learned coefficient multiplied by an activation. Context: the function tensor_command, which handles tensor command.

Line 257: `}` This is continuation line 9 of the 9-line logical statement that begins at source line 249. Its exact fragment is '}'. The expression is a literal or structural operator and has no hidden software state. Read together, the complete operation is: This assigns '{ Opcode.LOAD_ACTIVATIONS, Opcode.LOAD_WEIGHTS_OUTER, Opcode.LOAD_WEIGHTS_DOT8, Opcode.COMPUTE_DENSE_OUTER, Opcode.COMPUTE_DENSE_DOT8, Opcode.COMPUTE_BINARY, Opcode.COMPUTE_TERNARY, }' to 'tensor_opcodes ' in host memory. Here tensor_opcodes means the value named 'tensor opcodes' in this block. The important operands are Opcode: the value named 'opcode' in this block; LOAD_ACTIVATIONS: an input feature value consumed by a neuron or multiply-accumulate operation; LOAD_WEIGHTS_OUTER: a learned coefficient multiplied by an activation. Context: the function tensor_command, which handles tensor command.

Line 258: `if opcode not in tensor_opcodes:` This executes the following indented host-code branch only when 'opcode not in tensor_opcodes' is true. The important operands are opcode: the value named 'opcode' in this block; not: the value named 'not' in this block; in: the value named 'in' in this block. Context: the function tensor_command, which handles tensor command.

Line 259: `raise ValueError("tensor_command requires a tensor opcode")` This rejects an invalid state by raising 'ValueError("tensor_command requires a tensor opcode")'. Failing before DMA prevents malformed shapes or artifacts from silently becoming hardware results.

Line 260: `maximum_issues = 256 if opcode in {Opcode.LOAD_WEIGHTS_DOT8, Opcode.COMPUTE_DENSE_DOT8} else 2048` This assigns '256 if opcode in {Opcode.LOAD_WEIGHTS_DOT8, Opcode.COMPUTE_DENSE_DOT8} else 2048' to 'maximum_issues ' in host memory. Here maximum_issues means the value named 'maximum issues' in this block. The important operands are opcode: the value named 'opcode' in this block; in: the value named 'in' in this block; Opcode: the value named 'opcode' in this block. Context: the function tensor_command, which handles tensor command.

Line 261: `count = _unsigned("issue_count", issue_count, 12, maximum_issues)` This assigns '_unsigned("issue_count", issue_count, 12, maximum_issues)' to 'count ' in host memory. Here count means the value named 'count' in this block. The important operands are _unsigned: the value named 'unsigned' in this block; issue_count: an integer count retained

for control or measurable telemetry; maximum_issues: the value named 'maximum issues' in this block. Context: the function tensor_command, which handles tensor command.

Line 262: `if count == 0:` This executes the following indented host-code branch only when ‘count == 0‘ is true. The important operands are count: the value named 'count' in this block. Context: the function tensor_command, which handles tensor command.

Line 263: `raise ValueError("issue_count must be non-zero")` This rejects an invalid state by raising ‘ValueError("issue_count must be non-zero")‘. Failing before DMA prevents malformed shapes or artifacts from silently becoming hardware results.

Line 265: `compute = opcode in {` This statement continues through source line 270; the explanation uses the complete expression rather than only the first visual fragment. This assigns ‘opcode in { Opcode.COMPUTE_DENSE_OUTER, Opcode.COMPUTE_DENSE_DOT8, Opcode.COMPUTE_BINARY, Opcode.COMPUTE_TERNARY, }‘ to ‘compute ‘ in host memory. Here compute means the value named 'compute' in this block. The important operands are opcode: the value named 'opcode' in this block; in: the value named 'in' in this block; Opcode: the value named 'opcode' in this block. Context: the function tensor_command, which handles tensor command.

Line 266: `Opcode.COMPUTE_DENSE_OUTER,` This is continuation line 2 of the 6-line logical statement that begins at source line 265. Its exact fragment is ‘Opcode.COMPUTE_DENSE_OUTER,‘. The important operands are Opcode: the value named 'opcode' in this block; COMPUTE_DENSE_OUTER: the value named 'compute dense outer' in this block. Read together, the complete operation is: This assigns ‘opcode in { Opcode.COMPUTE_DENSE_OUTER, Opcode.COMPUTE_DENSE_DOT8, Opcode.COMPUTE_BINARY, Opcode.COMPUTE_TERNARY, }‘ to ‘compute ‘ in host memory. Here compute means the value named 'compute' in this block. The important operands are opcode: the value named 'opcode' in this block; in: the value named 'in' in this block; Opcode: the value named 'opcode' in this block. Context: the function tensor_command, which handles tensor command.

Line 267: `Opcode.COMPUTE_DENSE_DOT8,` This is continuation line 3 of the 6-line logical statement that begins at source line 265. Its exact fragment is ‘Opcode.COMPUTE_DENSE_DOT8,‘. The important operands are Opcode: the value named 'opcode' in this block; COMPUTE_DENSE_DOT8: the value named 'compute dense dot8' in this block. Read together, the complete operation is: This assigns ‘opcode in { Opcode.COMPUTE_DENSE_OUTER, Opcode.COMPUTE_DENSE_DOT8, Opcode.COMPUTE_BINARY, Opcode.COMPUTE_TERNARY, }‘ to ‘compute ‘ in host memory. Here compute means the value named 'compute' in this block. The important operands are opcode: the value named 'opcode' in this block; in: the value named 'in' in this block; Opcode: the value named 'opcode' in this block. Context: the function tensor_command, which handles tensor command.

Line 268: `Opcode.COMPUTE_BINARY,` This is continuation line 4 of the 6-line logical statement that begins at source line 265. Its exact fragment is ‘Opcode.COMPUTE_BINARY,‘. The important operands are Opcode: the value named 'opcode' in this block; COMPUTE_BINARY: the value named 'compute binary' in this block. Read together, the complete operation is: This assigns ‘opcode in { Opcode.COMPUTE_DENSE_OUTER, Opcode.COMPUTE_DENSE_DOT8, Opcode.COMPUTE_BINARY, Opcode.COMPUTE_TERNARY, }‘ to ‘compute ‘ in host memory. Here compute means the value named 'compute' in this block. The important operands are opcode: the value named 'opcode' in this block; in: the value named 'in' in this block; Opcode: the value named 'opcode' in this block. Context: the function tensor_command, which handles tensor command.

Line 269: `Opcode.COMPUTE_TERNARY,` This is continuation line 5 of the 6-line logical statement that begins at source line 265. Its exact fragment is ‘Opcode.COMPUTE_TERNARY,‘. The important operands are Opcode: the value named 'opcode' in this block; COMPUTE_TERNARY: the value named 'compute ternary' in this block. Read together, the complete operation is: This assigns ‘opcode in { Opcode.COMPUTE_DENSE_OUTER, Opcode.COMPUTE_DENSE_DOT8, Opcode.COMPUTE_BINARY, Opcode.COMPUTE_TERNARY, }‘ to ‘compute ‘ in host memory. Here compute means the value named 'compute' in this block. The important operands are opcode: the value named 'opcode' in this block; in: the value named 'in' in this block; Opcode: the value named 'opcode' in this block. Context: the function tensor_command, which handles tensor command.

Line 270: `}` This is continuation line 6 of the 6-line logical statement that begins at source line 265. Its exact fragment is '}'. The expression is a literal or structural operator and has no hidden software state. Read together, the complete operation is: This assigns 'opcode in { Opcode.COMPUTE_DENSE_OUTER, Opcode.COMPUTE_DENSE_DOT8, Opcode.COMPUTE_BINARY, Opcode.COMPUTE_TERNARY, }' to 'compute ' in host memory. Here compute means the value named 'compute' in this block. The important operands are opcode: the value named 'opcode' in this block; in: the value named 'in' in this block; Opcode: the value named 'opcode' in this block. Context: the function tensor_command, which handles tensor command.

Line 271: `if compute:` This executes the following indented host-code branch only when 'compute' is true. The important operands are compute: the value named 'compute' in this block. Context: the function tensor_command, which handles tensor command.

Line 272: `row_count = _unsigned("rows", rows, 4, 8)` This assigns '_unsigned("rows", rows, 4, 8)' to 'row_count ' in host memory. Here row_count means one output-row position processed by the tensor tile. The important operands are _unsigned: the value named 'unsigned' in this block; rows: one output-row position processed by the tensor tile. Context: the function tensor_command, which handles tensor command.

Line 273: `column_count = _unsigned("columns", columns, 6, 16)` This assigns '_unsigned("columns", columns, 6, 16)' to 'column_count ' in host memory. Here column_count means one output-feature position processed in parallel. The important operands are _unsigned: the value named 'unsigned' in this block; columns: one output-feature position processed in parallel. Context: the function tensor_command, which handles tensor command.

Line 274: `if row_count == 0 or column_count == 0:` This executes the following indented host-code branch only when 'row_count == 0 or column_count == 0' is true. The important operands are row_count: one output-row position processed by the tensor tile; or: the value named 'or' in this block; column_count: one output-feature position processed in parallel. Context: the function tensor_command, which handles tensor command.

Line 275: `raise ValueError("compute rows and columns must be non-zero")` This rejects an invalid state by raising 'ValueError("compute rows and columns must be non-zero")'. Failing before DMA prevents malformed shapes or artifacts from silently becoming hardware results.

Line 276: `if opcode == Opcode.COMPUTE_DENSE_DOT8 and row_count != 1:` This executes the following indented host-code branch only when 'opcode == Opcode.COMPUTE_DENSE_DOT8 and row_count != 1' is true. The important operands are opcode: the value named 'opcode' in this block; Opcode: the value named 'opcode' in this block; COMPUTE_DENSE_DOT8: the value named 'compute dense dot8' in this block. Context: the function tensor_command, which handles tensor command.

Line 277: `raise ValueError("dense Dot8 mode requires exactly one output row")` This rejects an invalid state by raising 'ValueError("dense Dot8 mode requires exactly one output row")'. Failing before DMA prevents malformed shapes or artifacts from silently becoming hardware results.

Line 278: `else:` This begins the alternative host-code branch when the preceding condition was false, still inside the function tensor_command, which handles tensor command.

Line 279: `row_count = _unsigned("rows", rows, 4, 8)` This assigns '_unsigned("rows", rows, 4, 8)' to 'row_count ' in host memory. Here row_count means one output-row position processed by the tensor tile. The important operands are _unsigned: the value named 'unsigned' in this block; rows: one output-row position processed by the tensor tile. Context: the function tensor_command, which handles tensor command.

Line 280: `column_count = _unsigned("columns", columns, 6, 16)` This assigns '_unsigned("columns", columns, 6, 16)' to 'column_count ' in host memory. Here column_count means one output-feature position processed in parallel. The important operands are _unsigned: the value named 'unsigned' in this block; columns: one output-feature position processed in parallel. Context: the function tensor_command, which handles tensor command.

Line 282: `command = int(opcode)` This assigns ‘int(opcode)‘ to ‘command ‘ in host memory. Here command means the 128-bit instruction selecting an engine, shape, mode, and numeric parameters. The important operands are opcode: the value named ’opcode’ in this block. Context: the function tensor_command, which handles tensor command.

Line 283: `command = _put(command, row_count, 4, 4)` This assigns ‘_put(command, row_count, 4, 4)‘ to ‘command ‘ in host memory. Here command means the 128-bit instruction selecting an engine, shape, mode, and numeric parameters. The important operands are _put: the value named ’put’ in this block; command: the 128-bit instruction selecting an engine, shape, mode, and numeric parameters; row_count: one output-row position processed by the tensor tile. Context: the function tensor_command, which handles tensor command.

Line 284: `command = _put(command, column_count, 8, 6)` This assigns ‘_put(command, column_count, 8, 6)‘ to ‘command ‘ in host memory. Here command means the 128-bit instruction selecting an engine, shape, mode, and numeric parameters. The important operands are _put: the value named ’put’ in this block; command: the 128-bit instruction selecting an engine, shape, mode, and numeric parameters; column_count: one output-feature position processed in parallel. Context: the function tensor_command, which handles tensor command.

Line 285: `command = _put(command, count, 14, 12)` This assigns ‘_put(command, count, 14, 12)‘ to ‘command ‘ in host memory. Here command means the 128-bit instruction selecting an engine, shape, mode, and numeric parameters. The important operands are _put: the value named ’put’ in this block; command: the 128-bit instruction selecting an engine, shape, mode, and numeric parameters; count: the value named ’count’ in this block. Context: the function tensor_command, which handles tensor command.

Line 286: `command = _put(command, _unsigned("activation_zero_point", activation_zero_point, 8), 26, 8)` This assigns ‘_put(command, _unsigned("activation_zero_point", activation_zero_point, 8), 26, 8)‘ to ‘command ‘ in host memory. Here command means the 128-bit instruction selecting an engine, shape, mode, and numeric parameters. The important operands are _put: the value named ’put’ in this block; command: the 128-bit instruction selecting an engine, shape, mode, and numeric parameters; _unsigned: the value named ’unsigned’ in this block. Context: the function tensor_command, which handles tensor command.

Line 287: `command = _put(command, _unsigned("weight_zero_point", weight_zero_point, 8), 34, 8)` This assigns ‘_put(command, _unsigned("weight_zero_point", weight_zero_point, 8), 34, 8)‘ to ‘command ‘ in host memory. Here command means the 128-bit instruction selecting an engine, shape, mode, and numeric parameters. The important operands are _put: the value named ’put’ in this block; command: the 128-bit instruction selecting an engine, shape, mode, and numeric parameters; _unsigned: the value named ’unsigned’ in this block. Context: the function tensor_command, which handles tensor command.

Line 288: `return Command128(command)` This returns ‘Command128(command)‘ to the caller of the function tensor_command, which handles tensor command, ending this invocation. The important operands are Command128: the 128-bit instruction selecting an engine, shape, mode, and numeric parameters; command: the 128-bit instruction selecting an engine, shape, mode, and numeric parameters.

Line 291: `def alpha_xnor_command(active_bits: int, alpha_q8: int) -> Command128:` This starts function alpha_xnor_command. Its indented body performs alpha xnor command as part of the file that defines command bit fields, descriptor records, packed streams, and result decoders; it runs only when called.

Line 292: `active = _unsigned("active_bits", active_bits, 9, 256)` This assigns ‘_unsigned("active_bits", active_bits, 9, 256)‘ to ‘active ‘ in host memory. Here active means the value named ’active’ in this block. The important operands are _unsigned: the value named ’unsigned’ in this block; active_bits: the value named ’active bits’ in this block. Context: the function alpha_xnor_command, which handles alpha xnor command.

Line 293: `alpha = _unsigned("alpha_q8", alpha_q8, 9, 256)` This assigns ‘_unsigned("alpha_q8", alpha_q8, 9, 256)‘ to ‘alpha ‘ in host memory. Here alpha means the programmable weight assigned to matching zero spikes in alpha-XNOR attention. The important operands are _unsigned: the value named ’unsigned’ in this block; alpha_q8: the programmable weight assigned to matching zero spikes in alpha-XNOR attention. Context: the function alpha_xnor_command, which handles alpha xnor command.

Line 294: `if active == 0:` This executes the following indented host-code branch only when ‘active == 0‘ is true. The important operands are active: the value named ’active’ in this block. Context: the function alpha_xnor_command, which handles alpha xnor command.

Line 295: `raise ValueError("active_bits must be non-zero")` This rejects an invalid state by raising ‘ValueError("active_bits must be non-zero")‘. Failing before DMA prevents malformed shapes or artifacts from silently becoming hardware results.

Line 296: `command = _put(int(Opcode.ALPHA_XNOR), active, 42, 9)` This assigns ‘_put(int(Opcode.ALPHA_XNOR), active, 42, 9)‘ to ‘command ‘ in host memory. Here command means the 128-bit instruction selecting an engine, shape, mode, and numeric parameters. The important operands are _put: the value named ’put’ in this block; Opcode: the value named ’opcode’ in this block; ALPHA_XNOR: the programmable weight assigned to matching zero spikes in alpha-XNOR attention. Context: the function alpha_xnor_command, which handles alpha xnor command.

Line 297: `command = _put(command, alpha, 51, 9)` This assigns ‘_put(command, alpha, 51, 9)‘ to ‘command ‘ in host memory. Here command means the 128-bit instruction selecting an engine, shape, mode, and numeric parameters. The important operands are _put: the value named ’put’ in this block; command: the 128-bit instruction selecting an engine, shape, mode, and numeric parameters; alpha: the programmable weight assigned to matching zero spikes in alpha-XNOR attention. Context: the function alpha_xnor_command, which handles alpha xnor command.

Line 298: `return Command128(command)` This returns ‘Command128(command)‘ to the caller of the function alpha_xnor_command, which handles alpha xnor command, ending this invocation. The important operands are Command128: the 128-bit instruction selecting an engine, shape, mode, and numeric parameters; command: the 128-bit instruction selecting an engine, shape, mode, and numeric parameters.

Line 301: `def vector_command(` This starts function vector_command. Its indented body performs vector command as part of the file that defines command bit fields, descriptor records, packed streams, and result decoders; it runs only when called.

Line 302: `operation: int,` Inside the function vector_command, which handles vector command, this statement advances the host implementation that defines command bit fields, descriptor records, packed streams, and result decoders. The important operands are operation: the value named ’operation’ in this block.

Line 303: `*,` Inside the function vector_command, which handles vector command, this statement advances the host implementation that defines command bit fields, descriptor records, packed streams, and result decoders. The expression is a literal or structural operator and has no hidden software state.

Line 304: `multiplier_q15: int = 0,` This assigns ‘0,‘ to ‘multiplier_q15‘ in host memory. Here multiplier_q15 means the value named ’multiplier q15’ in this block. The expression is a literal or structural operator and has no hidden software state. Context: the function vector_command, which handles vector command.

Line 305: `right_shift: int = 0,` This assigns ‘0,‘ to ‘right_shift‘ in host memory. Here right_shift means the value named ’right shift’ in this block. The expression is a literal or structural operator and has no hidden software state. Context: the function vector_command, which handles vector command.

Line 306: `output_zero_point: int = 0,` This assigns ‘0,‘ to ‘output_zero_point‘ in host memory. Here output_zero_point means the integer code representing real numeric zero in affine quantization. The expression is a literal or structural operator and has no hidden software state. Context: the function vector_command, which handles vector command.

Line 307: `threshold: int = 0,` This assigns ‘0,‘ to ‘threshold‘ in host memory. Here threshold means the membrane level at which a neuron emits a spike. The expression is a literal or structural operator and has no hidden software state. Context: the function vector_command, which handles vector command.

Line 308: `surrogate_window: int = 0,` This assigns ‘0,‘ to ‘surrogate_window‘ in host memory. Here surrogate_window means the value named ’surrogate window’ in this block. The expression is a literal or structural operator and has no hidden software state. Context: the function vector_command, which handles vector command.

Line 309: `) -> Command128:` Inside the function vector_command, which handles vector command, this statement advances the host implementation that defines command bit fields, descriptor records, packed streams, and result decoders. The important operands are Command128: the 128-bit instruction selecting an engine, shape, mode, and numeric parameters.

Line 310: `command = _put(int(Opcode.VECTOR_ALU), _unsigned("operation", operation, 4, 12), 4, 4)` This assigns ‘_put(int(Opcode.VECTOR_ALU), _unsigned("operation", operation, 4, 12), 4, 4)‘ to ‘command ‘ in host memory. Here command means the 128-bit instruction selecting an engine, shape, mode, and numeric parameters. The important operands are _put: the value named ’put’ in this block; Opcode: the value named ’opcode’ in this block; VECTOR_ALU: the value named ’vector alu’ in this block. Context: the function vector_command, which handles vector command.

Line 311: `command = _put(command, _signed_bits("multiplier_q15", multiplier_q15, 16), 8, 16)` This assigns ‘_put(command, _signed_bits("multiplier_q15", multiplier_q15, 16), 8, 16)‘ to ‘command ‘ in host memory. Here command means the 128-bit instruction selecting an engine, shape, mode, and numeric parameters. The important operands are _put: the value named ’put’ in this block; command: the 128-bit instruction selecting an engine, shape, mode, and numeric parameters; _signed_bits: the value named ’signed bits’ in this block. Context: the function vector_command, which handles vector command.

Line 312: `if operation == 9:` This executes the following indented host-code branch only when ‘operation == 9‘ is true. The important operands are operation: the value named ’operation’ in this block. Context: the function vector_command, which handles vector command.

Line 313: `if right_shift == -16:` This executes the following indented host-code branch only when ‘right_shift == -16‘ is true. The important operands are right_shift: the value named ’right shift’ in this block. Context: the function vector_command, which handles vector command.

Line 314: `raise ValueError("binary_point_shift must be in [-15,15]")` This rejects an invalid state by raising ‘ValueError("binary_point_shift must be in [-15,15]")‘. Failing before DMA prevents malformed shapes or artifacts from silently becoming hardware results.

Line 315: `shift_bits = _signed_bits("binary_point_shift", right_shift, 5)` This assigns ‘_signed_bits("binary_point right_shift, 5)‘ to ‘shift_bits ‘ in host memory. Here shift_bits means the value named ’shift bits’ in this block. The important operands are _signed_bits: the value named ’signed bits’ in this block; binary_point_shift: the value named ’binary point shift’ in this block; right_shift: the value named ’right shift’ in this block. Context: the function vector_command, which handles vector command.

Line 316: `else:` This begins the alternative host-code branch when the preceding condition was false, still inside the function vector_command, which handles vector command.

Line 317: `shift_bits = _unsigned("right_shift", right_shift, 5)` This assigns ‘_unsigned("right_shift", right_shift, 5)‘ to ‘shift_bits ‘ in host memory. Here shift_bits means the value named ’shift bits’ in this block. The important operands are _unsigned: the value named ’unsigned’ in this block; right_shift: the value named ’right shift’ in this block. Context: the function vector_command, which handles vector command.

Line 318: `command = _put(command, shift_bits, 24, 5)` This assigns ‘_put(command, shift_bits, 24, 5)‘ to ‘command ‘ in host memory. Here command means the 128-bit instruction selecting an engine, shape, mode, and numeric parameters. The important operands are _put: the value named ’put’ in this block; command: the 128-bit instruction selecting an engine, shape, mode, and numeric parameters; shift_bits: the value named ’shift bits’ in this block. Context: the function vector_command, which handles vector command.

Line 319: `command = _put(command, _signed_bits("output_zero_point", output_zero_point, 16), 29, 16)` This assigns ‘_put(command, _signed_bits("output_zero_point", output_zero_point, 16), 29, 16)‘ to ‘command ‘ in host memory. Here command means the 128-bit instruction selecting an engine, shape, mode, and numeric parameters. The important operands are _put: the value named ’put’ in this block; command: the 128-bit instruction selecting an engine, shape, mode, and numeric parameters; _signed_bits: the value named ’signed bits’ in this block. Context: the function vector_command, which handles vector command.

Line 320: `command = _put(command, _signed_bits("threshold", threshold, 32), 45, 32)` This assigns ‘_put(command, _signed_bits("threshold", threshold, 32), 45, 32)‘ to ‘command ‘ in host memory. Here command means the 128-bit instruction selecting an engine, shape, mode, and numeric parameters. The important operands are _put: the value named ’put’ in this block; command: the 128-bit instruction selecting an engine, shape, mode, and numeric parameters; _signed_bits: the value named ’signed bits’ in this block. Context: the function vector_command, which handles vector command.

Line 321: `command = _put(command, _unsigned("surrogate_window", surrogate_window, 32), 77, 32)` This assigns ‘_put(command, _unsigned("surrogate_window", surrogate_window, 32), 77, 32)‘ to ‘command ‘ in host memory. Here command means the 128-bit instruction selecting an engine, shape, mode, and numeric parameters. The important operands are _put: the value named ’put’ in this block; command: the 128-bit instruction selecting an engine, shape, mode, and numeric parameters; _unsigned: the value named ’unsigned’ in this block. Context: the function vector_command, which handles vector command.

Line 322: `return Command128(command)` This returns ‘Command128(command)‘ to the caller of the function vector_command, which handles vector command, ending this invocation. The important operands are Command128: the 128-bit instruction selecting an engine, shape, mode, and numeric parameters; command: the 128-bit instruction selecting an engine, shape, mode, and numeric parameters.

Line 325: `def layernorm_command(feature_count: int, epsilon: int = 1) -> Command128:` This starts function layernorm_command. Its indented body performs layernorm command as part of the file that defines command bit fields, descriptor records, packed streams, and result decoders; it runs only when called.

Line 326: `count = _unsigned("feature_count", feature_count, 12, 2048)` This assigns ‘_unsigned("feature_count", feature_count, 12, 2048)‘ to ‘count ‘ in host memory. Here count means the value named ’count’ in this block. The important operands are _unsigned: the value named ’unsigned’ in this block; feature_count: an integer count retained for control or measurable telemetry. Context: the function layernorm_command, which handles layernorm command.

Line 327: `if count == 0:` This executes the following indented host-code branch only when ‘count == 0‘ is true. The important operands are count: the value named ’count’ in this block. Context: the function layernorm_command, which handles layernorm command.

Line 328: `raise ValueError("feature_count must be non-zero")` This rejects an invalid state by raising ‘ValueError("feature_count must be non-zero")‘. Failing before DMA prevents malformed shapes or artifacts from silently becoming hardware results.

Line 329: `command = _put(int(Opcode.LAYERNORM), count, 4, 12)` This assigns ‘_put(int(Opcode.LAYERNORM), count, 4, 12)‘ to ‘command ‘ in host memory. Here command means the 128-bit instruction selecting an engine, shape, mode, and numeric parameters. The important operands are _put: the value named ’put’ in this block; Opcode: the value named ’opcode’ in this block; LAYERNORM: the value named ’layernorm’ in this block. Context: the function layernorm_command, which handles layernorm command.

Line 330: `command = _put(command, _unsigned("epsilon", epsilon, 32), 16, 32)` This assigns ‘_put(command, _unsigned("epsilon", epsilon, 32), 16, 32)‘ to ‘command ‘ in host memory. Here command means the 128-bit instruction selecting an engine, shape, mode, and numeric parameters. The important operands are _put: the value named ’put’ in this block; command: the 128-bit instruction selecting an engine, shape, mode, and numeric parameters; _unsigned: the value named ’unsigned’ in this block. Context: the function layernorm_command, which handles layernorm command.

Line 331: `return Command128(command)` This returns ‘Command128(command)‘ to the caller of the function layernorm_command, which handles layernorm command, ending this invocation. The important operands are Command128: the 128-bit instruction selecting an engine, shape, mode, and numeric parameters; command: the 128-bit instruction selecting an engine, shape, mode, and numeric parameters.

Line 334: `def log_softmax_command(item_count: int, difference_shift: int) -> Command128:` This starts function log_softmax_command. Its indented body performs log softmax command as part of the file that defines command bit fields, descriptor records, packed streams, and result decoders; it runs only when called.

Line 335: `count = _unsigned("item_count", item_count, 9, 256)` This assigns ‘_unsigned("item_count", item_count, 9, 256)‘ to ‘count ‘ in host memory. Here count means the value named ’count’ in this block. The important operands are _unsigned: the value named ’unsigned’ in this block; item_count: an integer count retained for control or measurable telemetry. Context: the function log_softmax_command, which handles log softmax command.

Line 336: `if count == 0:` This executes the following indented host-code branch only when ‘count == 0‘ is true. The important operands are count: the value named ’count’ in this block. Context: the function log_softmax_command, which handles log softmax command.

Line 337: `raise ValueError("item_count must be non-zero")` This rejects an invalid state by raising ‘ValueError("item_count must be non-zero")‘. Failing before DMA prevents malformed shapes or artifacts from silently becoming hardware results.

Line 338: `command = _put(int(Opcode.LOG_SOFTMAX), count, 4, 9)` This assigns ‘_put(int(Opcode.LOG_SOFTMAX), count, 4, 9)‘ to ‘command ‘ in host memory. Here command means the 128-bit instruction selecting an engine, shape, mode, and numeric parameters. The important operands are _put: the value named ’put’ in this block; Opcode: the value named ’opcode’ in this block; LOG_SOFTMAX: the value named ’log softmax’ in this block. Context: the function log_softmax_command, which handles log softmax command.

Line 339: `command = _put(command, _unsigned("difference_shift", difference_shift, 5), 13, 5)` This assigns ‘_put(command, _unsigned("difference_shift", difference_shift, 5), 13, 5)‘ to ‘command ‘ in host memory. Here command means the 128-bit instruction selecting an engine, shape, mode, and numeric parameters. The important operands are _put: the value named ’put’ in this block; command: the 128-bit instruction selecting an engine, shape, mode, and numeric parameters; _unsigned: the value named ’unsigned’ in this block. Context: the function log_softmax_command, which handles log softmax command.

Line 340: `return Command128(command)` This returns ‘Command128(command)‘ to the caller of the function log_softmax_comm which handles log softmax command, ending this invocation. The important operands are Command128: the 128-bit instruction selecting an engine, shape, mode, and numeric parameters; command: the 128-bit instruction selecting an engine, shape, mode, and numeric parameters.

Line 343: `def lif_command(` This starts function lif_command. Its indented body performs lif command as part of the file that defines command bit fields, descriptor records, packed streams, and result decoders; it runs only when called.

Line 344: `leak_shift: int,` Inside the function lif_command, which handles lif command, this statement advances the host implementation that defines command bit fields, descriptor records, packed streams, and result decoders. The important operands are leak_shift: the retained fraction of prior membrane state.

Line 345: `threshold: int,` Inside the function lif_command, which handles lif command, this statement advances the host implementation that defines command bit fields, descriptor records, packed streams, and result decoders. The important operands are threshold: the membrane level at which a neuron emits a spike.

Line 346: `reset_value: int,` Inside the function lif_command, which handles lif command, this statement advances the host implementation that defines command bit fields, descriptor records, packed streams, and result decoders. The important operands are reset_value: the value named ’reset value’ in this block.

Line 347: `*,` Inside the function lif_command, which handles lif command, this statement advances the host implementation that defines command bit fields, descriptor records, packed streams, and result decoders. The expression is a literal or structural operator and has no hidden software state.

Line 348: `clear_state: bool = False,` This assigns ‘False,‘ to ‘clear_state‘ in host memory. Here clear_state means the finite-state-machine phase retained in flip-flops. The expression is a literal or structural operator and has no hidden software state. Context: the function lif_command, which handles lif command.

Line 349: `trace_state: bool = False,` This assigns ‘False,‘ to ‘trace_state‘ in host memory. Here trace_state means the finite-state-machine phase retained in flip-flops. The expression is a literal or structural operator and has no hidden software state. Context: the function lif_command, which handles lif command.

Line 350: `) -> Command128:` Inside the function lif_command, which handles lif command, this statement advances the host implementation that defines command bit fields, descriptor records, packed streams, and result decoders. The important operands are Command128: the 128-bit instruction selecting an engine, shape, mode, and numeric parameters.

Line 351: `command = _put(int(Opcode.LIF_STEP), _unsigned("leak_shift", leak_shift, 5), 4, 5)` This assigns ‘_put(int(Opcode.LIF_STEP), _unsigned("leak_shift", leak_shift, 5), 4, 5)‘ to ‘command ‘ in host memory. Here command means the 128-bit instruction selecting an engine, shape, mode, and numeric parameters. The important operands are _put: the value named ’put’ in this block; Opcode: the value named ’opcode’ in this block; LIF_STEP: the value named ’lif step’ in this block. Context: the function lif_command, which handles lif command.

Line 352: `command = _put(command, _signed_bits("threshold", threshold, 24), 9, 24)` This assigns ‘_put(command, _signed_bits("threshold", threshold, 24), 9, 24)‘ to ‘command ‘ in host memory. Here command means the 128-bit instruction selecting an engine, shape, mode, and numeric parameters. The important operands are _put: the value named ’put’ in this block; command: the 128-bit instruction selecting an engine, shape, mode, and numeric parameters; _signed_bits: the value named ’signed bits’ in this block. Context: the function lif_command, which handles lif command.

Line 353: `command = _put(command, _signed_bits("reset_value", reset_value, 24), 33, 24)` This assigns ‘_put(command, _signed_bits("reset_value", reset_value, 24), 33, 24)‘ to ‘command ‘ in host memory. Here command means the 128-bit instruction selecting an engine, shape, mode, and numeric parameters. The important operands are _put: the value named ’put’ in this block; command: the 128-bit instruction selecting an engine, shape, mode, and numeric parameters; _signed_bits: the value named ’signed bits’ in this block. Context: the function lif_command, which handles lif command.

Line 354: `command = _put(command, int(bool(clear_state)), 57, 1)` This assigns ‘_put(command, int(bool(clear_state)) 57, 1)‘ to ‘command ‘ in host memory. Here command means the 128-bit instruction selecting an engine, shape, mode, and numeric parameters. The important operands are _put: the value named ’put’ in this block; command: the 128-bit instruction selecting an engine, shape, mode, and numeric parameters; bool: the value named ’bool’ in this block. Context: the function lif_command, which handles lif command.

Line 355: `command = _put(command, int(bool(trace_state)), 58, 1)` This assigns ‘_put(command, int(bool(trace_state)) 58, 1)‘ to ‘command ‘ in host memory. Here command means the 128-bit instruction selecting an engine, shape, mode, and numeric parameters. The important operands are _put: the value named ’put’ in this block; command: the 128-bit instruction selecting an engine, shape, mode, and numeric parameters; bool: the value named ’bool’ in this block. Context: the function lif_command, which handles lif command.

Line 356: `return Command128(command)` This returns ‘Command128(command)‘ to the caller of the function lif_command, which handles lif command, ending this invocation. The important operands are Command128: the 128-bit instruction selecting an engine, shape, mode, and numeric parameters; command: the 128-bit instruction selecting an engine, shape, mode, and numeric parameters.

Line 359: `def sgd_command(` This starts function sgd_command. Its indented body performs sgd command as part of the file that defines command bit fields, descriptor records, packed streams, and result decoders; it runs only when called.

Line 360: `learning_rate_q16: int,` Inside the function sgd_command, which handles sgd command, this statement advances the host implementation that defines command bit fields, descriptor records, packed streams, and result decoders. The important operands are learning_rate_q16: the fixed-point multiplier controlling update magnitude.

Line 361: `momentum_q16: int,` Inside the function sgd_command, which handles sgd command, this statement advances the host implementation that defines command bit fields, descriptor records, packed streams, and result decoders. The important operands are momentum_q16: the value named 'momentum q16' in this block.

Line 362: `weight_decay_q16: int,` Inside the function sgd_command, which handles sgd command, this statement advances the host implementation that defines command bit fields, descriptor records, packed streams, and result decoders. The important operands are weight_decay_q16: a learned coefficient multiplied by an activation.

Line 363: `*,` Inside the function sgd_command, which handles sgd command, this statement advances the host implementation that defines command bit fields, descriptor records, packed streams, and result decoders. The expression is a literal or structural operator and has no hidden software state.

Line 364: `update_right_shift: int = 16,` This assigns '16,' to 'update_right_shift' in host memory. Here update_right_shift means the value named 'update right shift' in this block. The expression is a literal or structural operator and has no hidden software state. Context: the function sgd_command, which handles sgd command.

Line 365: `) -> Command128:` Inside the function sgd_command, which handles sgd command, this statement advances the host implementation that defines command bit fields, descriptor records, packed streams, and result decoders. The important operands are Command128: the 128-bit instruction selecting an engine, shape, mode, and numeric parameters.

Line 366: `command = _put(int(Opcode.SGD_UPDATE), _unsigned("learning_rate_q16", learning_rate_q16, 18, 131071), 4, 18)` This assigns '_put(int(Opcode.SGD_UPDATE), _unsigned("learning_rate_q16", learning_rate_q16, 18, 131071), 4, 18)' to 'command ' in host memory. Here command means the 128-bit instruction selecting an engine, shape, mode, and numeric parameters. The important operands are _put: the value named 'put' in this block; Opcode: the value named 'opcode' in this block; SGD_UPDATE: the value named 'sgd update' in this block. Context: the function sgd_command, which handles sgd command.

Line 367: `command = _put(command, _unsigned("momentum_q16", momentum_q16, 17, 65536), 22, 17)` This assigns '_put(command, _unsigned("momentum_q16", momentum_q16, 17, 65536), 22, 17)' to 'command ' in host memory. Here command means the 128-bit instruction selecting an engine, shape, mode, and numeric parameters. The important operands are _put: the value named 'put' in this block; command: the 128-bit instruction selecting an engine, shape, mode, and numeric parameters; _unsigned: the value named 'unsigned' in this block. Context: the function sgd_command, which handles sgd command.

Line 368: `command = _put(command, _unsigned("weight_decay_q16", weight_decay_q16, 17, 65536), 39, 17)` This assigns '_put(command, _unsigned("weight_decay_q16", weight_decay_q16, 17, 65536), 39, 17)' to 'command ' in host memory. Here command means the 128-bit instruction selecting an engine, shape, mode, and numeric parameters. The important operands are _put: the value named 'put' in this block; command: the 128-bit instruction selecting an engine, shape, mode, and numeric parameters; _unsigned: the value named 'unsigned' in this block. Context: the function sgd_command, which handles sgd command.

Line 369: `command = _put(command, _unsigned("update_right_shift", update_right_shift, 5), 56, 5)` This assigns '_put(command, _unsigned("update_right_shift", update_right_shift, 5), 56, 5)' to 'command ' in host memory. Here command means the 128-bit instruction selecting an engine, shape, mode, and numeric parameters. The important operands are _put: the value named 'put' in this block; command: the 128-bit instruction selecting an engine,

shape, mode, and numeric parameters; _unsigned: the value named 'unsigned' in this block. Context: the function sgd_command, which handles sgd command.

Line 370: `return Command128(command)` This returns 'Command128(command)' to the caller of the function sgd_command, which handles sgd command, ending this invocation. The important operands are Command128: the 128-bit instruction selecting an engine, shape, mode, and numeric parameters; command: the 128-bit instruction selecting an engine, shape, mode, and numeric parameters.

Line 373: `def lut_command(suboperation: LutSuboperation, item_count: int = 0) -> Command128:` This starts function lut_command. Its indented body performs lut command as part of the file that defines command bit fields, descriptor records, packed streams, and result decoders; it runs only when called.

Line 374: `count = _unsigned("item_count", item_count, 12, 256)` This assigns '_unsigned("item_count", item_count, 12, 256)' to 'count ' in host memory. Here count means the value named 'count' in this block. The important operands are _unsigned: the value named 'unsigned' in this block; item_count: an integer count retained for control or measurable telemetry. Context: the function lut_command, which handles lut command.

Line 375: `if suboperation == LutSuboperation.LOAD and count == 0:` This executes the following indented host-code branch only when 'suboperation == LutSuboperation.LOAD and count == 0' is true. The important operands are suboperation: the value named 'suboperation' in this block; LutSuboperation: the value named 'lut suboperation' in this block; LOAD: the value named 'load' in this block. Context: the function lut_command, which handles lut command.

Line 376: `raise ValueError("LUT load requires at least one entry")` This rejects an invalid state by raising 'ValueError("LUT load requires at least one entry")'. Failing before DMA prevents malformed shapes or artifacts from silently becoming hardware results.

Line 377: `if suboperation == LutSuboperation.EVALUATE and count not in {0, 8}:` This executes the following indented host-code branch only when 'suboperation == LutSuboperation.EVALUATE and count not in {0, 8}' is true. The important operands are suboperation: the value named 'suboperation' in this block; LutSuboperation: the value named 'lut suboperation' in this block; EVALUATE: the value named 'evaluate' in this block. Context: the function lut_command, which handles lut command.

Line 378: `raise ValueError("LUT evaluate processes exactly eight indices")` This rejects an invalid state by raising 'ValueError("LUT evaluate processes exactly eight indices")'. Failing before DMA prevents malformed shapes or artifacts from silently becoming hardware results.

Line 379: `if suboperation == LutSuboperation.CLEAR and count != 0:` This executes the following indented host-code branch only when 'suboperation == LutSuboperation.CLEAR and count != 0' is true. The important operands are suboperation: the value named 'suboperation' in this block; LutSuboperation: the value named 'lut suboperation' in this block; CLEAR: the value named 'clear' in this block. Context: the function lut_command, which handles lut command.

Line 380: `raise ValueError("LUT clear does not accept stream items")` This rejects an invalid state by raising 'ValueError("LUT clear does not accept stream items")'. Failing before DMA prevents malformed shapes or artifacts from silently becoming hardware results.

Line 381: `command = _put(int(Opcode.ACTIVATION_LUT), int(suboperation), 4, 4)` This assigns '_put(int(Opcode.ACTI int(suboperation), 4, 4)' to 'command ' in host memory. Here command means the 128-bit instruction selecting an engine, shape, mode, and numeric parameters. The important operands are _put: the value named 'put' in this block; Opcode: the value named 'opcode' in this block; ACTIVATION_LUT: an input feature value consumed by a neuron or multiply-accumulate operation. Context: the function lut_command, which handles lut command.

Line 382: `command = _put(command, count, 8, 12)` This assigns '_put(command, count, 8, 12)' to 'command ' in host memory. Here command means the 128-bit instruction selecting an engine, shape, mode, and numeric parameters. The important operands are _put: the value named 'put' in this block; command: the 128-bit instruction selecting an engine, shape, mode, and numeric parameters; count: the value named 'count' in this block. Context: the function lut_command, which handles lut command.

Line 383: `return Command128(command)` This returns 'Command128(command)' to the caller of the function lut_command, which handles lut command, ending this invocation. The important operands are Command128: the 128-bit instruction selecting an engine, shape, mode, and numeric parameters; command: the 128-bit instruction selecting an engine, shape, mode, and numeric parameters.

Line 386: `def _finish_beats(words: Iterable[int]) -> PackedStreamBeats:` This starts function _finish_beats. Its indented body performs finish beats as part of the file that defines command bit fields, descriptor records, packed streams, and result decoders; it runs only when called.

Line 387: `return PackedStreamBeats(words)` This returns 'PackedStreamBeats(words)' to the caller of the function _finish_beats, which handles finish beats, ending this invocation. The important operands are PackedStreamBeats: the value named 'packed stream beats' in this block; words: the value named 'words' in this block.

Line 390: `def pack_activation_beats(vectors: Sequence[Sequence[int]]) -> PackedStreamBeats:` This starts function pack_activation_beats. Its indented body performs pack activation beats as part of the file that defines command bit fields, descriptor records, packed streams, and result decoders; it runs only when called.

Line 391: `words = []` This assigns '[]' to 'words ' in host memory. Here words means the value named 'words' in this block. The expression is a literal or structural operator and has no hidden software state. Context: the function pack_activation_beats, which handles pack activation beats.

Line 392: `for issue, vector in enumerate(vectors):` This iterates issue, vector over 'enumerate(vectors)'. Each iteration repeats the indented host operation, commonly once per layer, tile, timestep, or test case in the function pack_activation_beats, which handles pack activation beats.

Line 393: `if len(vector) != 8:` This executes the following indented host-code branch only when 'len(vector) != 8' is true. The important operands are len: the value named 'len' in this block; vector: the value named 'vector' in this block. Context: the function pack_activation_beats, which handles pack activation beats.

Line 394: `raise ValueError(f"activation issue {issue} must contain eight bytes")` This rejects an invalid state by raising 'ValueError(f"activation issue {issue} must contain eight bytes")'. Failing before DMA prevents malformed shapes or artifacts from silently becoming hardware results.

Line 395: `word = sum(_unsigned(f"activation[{issue},{lane}]", value, 8) << (8 * lane)` This statement continues through source line 396; the explanation uses the complete expression rather than only the first visual fragment. This assigns 'sum(_unsigned(f"activation[{issue},{lane}]", value, 8) << (8 * lane) for lane, value in enumerate(vector))' to 'word ' in host memory. Here word means the value named 'word' in this block. The important operands are sum: the value named 'sum' in this block; _unsigned: the value named 'unsigned' in this block; f: the value named 'f' in this block. Context: the function pack_activation_beats, which handles pack activation beats.

Line 396: `for lane, value in enumerate(vector))` This is continuation line 2 of the 2-line logical statement that begins at source line 395. Its exact fragment is 'for lane, value in enumerate(vector))'. The important operands are for: the value named 'for' in this block; lane: one parallel arithmetic element within a vector or tensor datapath; value: the value named 'value' in this block. Read together, the complete operation is: This assigns 'sum(_unsigned(f"activation[{issue},{lane}]", value, 8) << (8 * lane) for lane, value in enumerate(vector))' to 'word ' in host memory. Here word means the value named 'word' in this block. The important operands are sum: the value named 'sum' in this block; _unsigned: the value named 'unsigned' in this block; f: the value named 'f' in this block. Context: the function pack_activation_beats, which handles pack activation beats.

Line 397: `words.append(word)` This calls ‘words.append‘ with ‘word‘ inside the function pack_activation_beats, which handles pack activation beats. The call advances the host-side job that defines command bit fields, descriptor records, packed streams, and result decoders.

Line 398: `return _finish_beats(words)` This returns ‘_finish_beats(words)‘ to the caller of the function pack_activation_bea which handles pack activation beats, ending this invocation. The important operands are _finish_beats: the value named 'finish beats' in this block; words: the value named 'words' in this block.

Line 401: `def pack_outer_weight_beats(weights: Sequence[Sequence[int]]) -> PackedStreamBeats:` This starts function pack_outer_weight_beats. Its indented body performs pack outer weight beats as part of the file that defines command bit fields, descriptor records, packed streams, and result decoders; it runs only when called.

Line 402: `words = []` This assigns ‘[]‘ to ‘words ‘ in host memory. Here words means the value named 'words' in this block. The expression is a literal or structural operator and has no hidden software state. Context: the function pack_outer_weight_beats, which handles pack outer weight beats.

Line 403: `for issue, vector in enumerate(weights):` This iterates issue, vector over ‘enumerate(weights)‘. Each iteration repeats the indented host operation, commonly once per layer, tile, timestep, or test case in the function pack_outer_weight_beats, which handles pack outer weight beats.

Line 404: `if len(vector) != 16:` This executes the following indented host-code branch only when ‘len(vector) != 16‘ is true. The important operands are len: the value named 'len' in this block; vector: the value named 'vector' in this block. Context: the function pack_outer_weight_beats, which handles pack outer weight beats.

Line 405: `raise ValueError(f"outer weight issue {issue} must contain sixteen bytes")` This rejects an invalid state by raising ‘ValueError(f"outer weight issue {issue} must contain sixteen bytes")‘. Failing before DMA prevents malformed shapes or artifacts from silently becoming hardware results.

Line 406: `for half in range(2):` This iterates half over ‘range(2)‘. Each iteration repeats the indented host operation, commonly once per layer, tile, timestep, or test case in the function pack_outer_weight_beats, which handles pack outer weight beats.

Line 407: `words.append(sum(_unsigned(f"weight[{issue},{8 * half + lane}]", vector[8 * half + lane], 8)` This statement continues through source line 408; the explanation uses the complete expression rather than only the first visual fragment. This calls ‘words.append‘ with ‘sum(_unsigned(f"weight[{issue},{8 * half + lane}]", vector[8 * half + lane], 8) << (8 * lane) for lane in range(8))‘ inside the function pack_outer_weight_beats, which handles pack outer weight beats. The call advances the host-side job that defines command bit fields, descriptor records, packed streams, and result decoders.

Line 408: `<< (8 * lane) for lane in range(8)))` This is continuation line 2 of the 2-line logical statement that begins at source line 407. Its exact fragment is ‘<< (8 * lane) for lane in range(8)))‘. The important operands are lane: one parallel arithmetic element within a vector or tensor datapath; for: the value named 'for' in this block; in: the value named 'in' in this block. Read together, the complete operation is: This calls ‘words.append‘ with ‘sum(_unsigned(f"weight[{issue},{8 * half + lane}]", vector[8 * half + lane], 8) << (8 * lane) for lane in range(8))‘ inside the function pack_outer_weight_beats, which handles pack outer weight beats. The call advances the host-side job that defines command bit fields, descriptor records, packed streams, and result decoders.

Line 409: `return _finish_beats(words)` This returns ‘_finish_beats(words)‘ to the caller of the function pack_outer_weight_ which handles pack outer weight beats, ending this invocation. The important operands are _finish_beats: the value named 'finish beats' in this block; words: the value named 'words' in this block.

Line 412: `def pack_dot8_weight_beats(weights: Sequence[Sequence[Sequence[int]]]) -> PackedStreamBeats:` This starts function pack_dot8_weight_beats. Its indented body performs pack dot8 weight beats as part of the file that defines command bit fields, descriptor records, packed streams, and result decoders; it runs only when called.

Line 413: `words = []` This assigns '[]' to 'words ' in host memory. Here words means the value named 'words' in this block. The expression is a literal or structural operator and has no hidden software state. Context: the function pack_dot8_weight_beats, which handles pack dot8 weight beats.

Line 414: `for issue, matrix in enumerate(weights):` This iterates issue, matrix over 'enumerate(weights)'. Each iteration repeats the indented host operation, commonly once per layer, tile, timestep, or test case in the function pack_dot8_weight_beats, which handles pack dot8 weight beats.

Line 415: `if len(matrix) != 8 or any(len(row) != 16 for row in matrix):` This executes the following indented host-code branch only when 'len(matrix) != 8 or any(len(row) != 16 for row in matrix)' is true. The important operands are len: the value named 'len' in this block; matrix: the value named 'matrix' in this block; or: the value named 'or' in this block. Context: the function pack_dot8_weight_beats, which handles pack dot8 weight beats.

Line 416: `raise ValueError(f"Dot8 issue {issue} must have shape [8,16]")` This rejects an invalid state by raising 'ValueError(f"Dot8 issue {issue} must have shape [8,16]")'. Failing before DMA prevents malformed shapes or artifacts from silently becoming hardware results.

Line 417: `for reduction_lane, row in enumerate(matrix):` This iterates reduction_lane, row over 'enumerate(matrix)'. Each iteration repeats the indented host operation, commonly once per layer, tile, timestep, or test case in the function pack_dot8_weight_beats, which handles pack dot8 weight beats.

Line 418: `for half in range(2):` This iterates half over 'range(2)'. Each iteration repeats the indented host operation, commonly once per layer, tile, timestep, or test case in the function pack_dot8_weight_beats, which handles pack dot8 weight beats.

Line 419: `words.append(sum(_unsigned(` This statement continues through source line 421; the explanation uses the complete expression rather than only the first visual fragment. This calls 'words.append' with 'sum(_unsigned(f"dot8_weight[{issue},{reduction_lane},{8 * half + lane}]", row[8 * half + lane], 8) << (8 * lane) for lane in range(8))' inside the function pack_dot8_weight_beats, which handles pack dot8 weight beats. The call advances the host-side job that defines command bit fields, descriptor records, packed streams, and result decoders.

Line 420: `f"dot8_weight[{issue},{reduction_lane},{8 * half + lane}]",` This is continuation line 2 of the 3-line logical statement that begins at source line 419. Its exact fragment is 'f"dot8_weight[{issue},{reduction_lane},{8 * half + lane}]",'. The important operands are f: the value named 'f' in this block; dot8_weight: a learned coefficient multiplied by an activation; issue: the value named 'issue' in this block. Read together, the complete operation is: This calls 'words.append' with 'sum(_unsigned(f"dot8_weight[{issue},{reduction_lane},{8 * half + lane}]", row[8 * half + lane], 8) << (8 * lane) for lane in range(8))' inside the function pack_dot8_weight_beats, which handles pack dot8 weight beats. The call advances the host-side job that defines command bit fields, descriptor records, packed streams, and result decoders.

Line 421: `row[8 * half + lane], 8) << (8 * lane) for lane in range(8)))` This is continuation line 3 of the 3-line logical statement that begins at source line 419. Its exact fragment is 'row[8 * half + lane], 8) << (8 * lane) for lane in range(8)))'. The important operands are row: one output-row position processed by the tensor tile; half: the value named 'half' in this block; lane: one parallel arithmetic element within a vector or tensor datapath. Read together, the complete operation is: This calls 'words.append' with 'sum(_unsigned(f"dot8_weight[{issue},{reduction_lane},{8 * half + lane}]", row[8 * half + lane], 8) << (8 * lane) for lane in range(8))' inside the function pack_dot8_weight_beats, which handles pack dot8 weight beats. The call advances the host-side job that defines command bit fields, descriptor records, packed streams, and result decoders.

Line 422: `return _finish_beats(words)` This returns '_finish_beats(words)' to the caller of the function pack_dot8_weight_b which handles pack dot8 weight beats, ending this invocation. The important operands are _finish_beats: the value named 'finish beats' in this block; words: the value named 'words' in this block.

Line 425: `def pack_alpha_beats(query: Sequence[int], key: Sequence[int]) -> PackedStreamBeats:` This starts function pack_alpha_beats. Its indented body performs pack alpha beats as part of the file that defines command bit fields, descriptor records, packed streams, and result decoders; it runs only when called.

Line 426: `if len(query) != 256 or len(key) != 256:` This executes the following indented host-code branch only when ‘len(query) != 256 or len(key) != 256‘ is true. The important operands are len: the value named ’len’ in this block; query: the value named ’query’ in this block; or: the value named ’or’ in this block. Context: the function pack_alpha_beats, which handles pack alpha beats.

Line 427: `raise ValueError("alpha-XNOR query and key must each contain 256 bits")` This rejects an invalid state by raising ‘ValueError("alpha-XNOR query and key must each contain 256 bits")‘. Failing before DMA prevents malformed shapes or artifacts from silently becoming hardware results.

Line 428: `words = []` This assigns ‘[]‘ to ‘words ‘ in host memory. Here words means the value named ’words’ in this block. The expression is a literal or structural operator and has no hidden software state. Context: the function pack_alpha_beats, which handles pack alpha beats.

Line 429: `for vector_name, vector in (("query", query), ("key", key)):` This iterates vector_name, vector over ‘(("query", query), ("key", key))‘. Each iteration repeats the indented host operation, commonly once per layer, tile, timestep, or test case in the function pack_alpha_beats, which handles pack alpha beats.

Line 430: `for word_index in range(4):` This iterates word_index over ‘range(4)‘. Each iteration repeats the indented host operation, commonly once per layer, tile, timestep, or test case in the function pack_alpha_beats, which handles pack alpha beats.

Line 431: `word = 0` This assigns ‘0‘ to ‘word ‘ in host memory. Here word means the value named ’word’ in this block. The expression is a literal or structural operator and has no hidden software state. Context: the function pack_alpha_beats, which handles pack alpha beats.

Line 432: `for bit_index in range(64):` This iterates bit_index over ‘range(64)‘. Each iteration repeats the indented host operation, commonly once per layer, tile, timestep, or test case in the function pack_alpha_beats, which handles pack alpha beats.

Line 433: `bit = _unsigned(f"{vector_name} bit", vector[word_index * 64 + bit_index], 1)` This assigns ‘_unsigned(f"{vector_name} bit", vector[word_index * 64 + bit_index], 1)‘ to ‘bit ‘ in host memory. Here bit means the value named ’bit’ in this block. The important operands are _unsigned: the value named ’unsigned’ in this block; f: the value named ’f’ in this block; vector_name: the value named ’vector name’ in this block. Context: the function pack_alpha_beats, which handles pack alpha beats.

Line 434: `word |= bit << bit_index` Inside the function pack_alpha_beats, which handles pack alpha beats, this statement advances the host implementation that defines command bit fields, descriptor records, packed streams, and result decoders. The important operands are word: the value named ’word’ in this block; bit: the value named ’bit’ in this block; bit_index: an integer selecting one tensor element, lane, bank, or state entry.

Line 435: `words.append(word)` This calls ‘words.append‘ with ‘word‘ inside the function pack_alpha_beats, which handles pack alpha beats. The call advances the host-side job that defines command bit fields, descriptor records, packed streams, and result decoders.

Line 436: `return _finish_beats(words)` This returns ‘_finish_beats(words)‘ to the caller of the function pack_alpha_beats, which handles pack alpha beats, ending this invocation. The important operands are _finish_beats: the value named ’finish beats’ in this block; words: the value named ’words’ in this block.

Line 439: `def pack_vector_beats(` This starts function pack_vector_beats. Its indented body performs pack vector beats as part of the file that defines command bit fields, descriptor records, packed streams, and result decoders; it runs only when called.

Line 440: `operand_a: Sequence[int],` Inside the function pack_vector_beats, which handles pack vector beats, this statement advances the host implementation that defines command bit fields, descriptor records, packed streams, and result decoders. The important operands are operand_a: the value named 'operand a' in this block; Sequence: the value named 'sequence' in this block.

Line 441: `operand_b: Sequence[int],` Inside the function pack_vector_beats, which handles pack vector beats, this statement advances the host implementation that defines command bit fields, descriptor records, packed streams, and result decoders. The important operands are operand_b: the value named 'operand b' in this block; Sequence: the value named 'sequence' in this block.

Line 442: `*,` Inside the function pack_vector_beats, which handles pack vector beats, this statement advances the host implementation that defines command bit fields, descriptor records, packed streams, and result decoders. The expression is a literal or structural operator and has no hidden software state.

Line 443: `clamp_minimum: int = -(1 << 31),` This assigns '-(1 << 31),' to 'clamp_minimum' in host memory. Here clamp_minimum means the value named 'clamp minimum' in this block. The expression is a literal or structural operator and has no hidden software state. Context: the function pack_vector_beats, which handles pack vector beats.

Line 444: `clamp_maximum: int = (1 << 31) - 1,` This assigns '(1 << 31) - 1,' to 'clamp_maximum' in host memory. Here clamp_maximum means the value named 'clamp maximum' in this block. The expression is a literal or structural operator and has no hidden software state. Context: the function pack_vector_beats, which handles pack vector beats.

Line 445: `) -> PackedStreamBeats:` Inside the function pack_vector_beats, which handles pack vector beats, this statement advances the host implementation that defines command bit fields, descriptor records, packed streams, and result decoders. The important operands are PackedStreamBeats: the value named 'packed stream beats' in this block.

Line 446: `if len(operand_a) != 8 or len(operand_b) != 8:` This executes the following indented host-code branch only when 'len(operand_a) != 8 or len(operand_b) != 8' is true. The important operands are len: the value named 'len' in this block; operand_a: the value named 'operand a' in this block; or: the value named 'or' in this block. Context: the function pack_vector_beats, which handles pack vector beats.

Line 447: `raise ValueError("vector operands must each contain eight signed 32-bit lanes")` This rejects an invalid state by raising 'ValueError("vector operands must each contain eight signed 32-bit lanes")'. Failing before DMA prevents malformed shapes or artifacts from silently becoming hardware results.

Line 448: `words = [_signed_bits("clamp_minimum", clamp_minimum, 32)` This statement continues through source line 449; the explanation uses the complete expression rather than only the first visual fragment. This assigns '[_signed_bits("clamp_ clamp_minimum, 32) | (_signed_bits("clamp_maximum", clamp_maximum, 32) << 32)]' to 'words ' in host memory. Here words means the value named 'words' in this block. The important operands are _signed_bits: the value named 'signed bits' in this block; clamp_minimum: the value named 'clamp minimum' in this block; clamp_maximum: the value named 'clamp maximum' in this block. Context: the function pack_vector_beats, which handles pack vector beats.

Line 449: `| (_signed_bits("clamp_maximum", clamp_maximum, 32) << 32)]` This is continuation line 2 of the 2-line logical statement that begins at source line 448. Its exact fragment is '| (_signed_bits("clamp_maximum", clamp_maximum, 32) << 32)]'. The important operands are _signed_bits: the value named 'signed bits' in this block; clamp_maximum: the value named 'clamp maximum' in this block. Read together, the complete operation is: This assigns '[_signed_bits("clamp_minimum", clamp_minimum, 32) | (_signed_bits("clamp_maximum", clamp_maximum, 32) << 32)]' to 'words ' in host memory. Here words means the value named 'words' in this block. The important operands are _signed_bits: the value named 'signed bits' in this block; clamp_minimum: the value named 'clamp

minimum' in this block; clamp_maximum: the value named 'clamp maximum' in this block. Context: the function pack_vector_beats, which handles pack vector beats.

Line 450: `for name, operand in (("operand_a", operand_a), ("operand_b", operand_b)):` This iterates name, operand over '(("operand_a", operand_a), ("operand_b", operand_b))'. Each iteration repeats the indented host operation, commonly once per layer, tile, timestep, or test case in the function pack_vector_beats, which handles pack vector beats.

Line 451: `for lane in range(0, 8, 2):` This iterates lane over 'range(0, 8, 2)'. Each iteration repeats the indented host operation, commonly once per layer, tile, timestep, or test case in the function pack_vector_beats, which handles pack vector beats.

Line 452: `words.append(_signed_bits(f"{name}[{lane}]", operand[lane], 32)` This statement continues through source line 453; the explanation uses the complete expression rather than only the first visual fragment. This calls 'words.append' with '_signed_bits(f"{name}[{lane}]", operand[lane], 32) | (_signed_bits(f"{name}[{lane + 1}]", operand[lane + 1], 32) << 32)' inside the function pack_vector_beats, which handles pack vector beats. The call advances the host-side job that defines command bit fields, descriptor records, packed streams, and result decoders.

Line 453: `| (_signed_bits(f"{name}[{lane + 1}]", operand[lane + 1], 32) << 32))` This is continuation line 2 of the 2-line logical statement that begins at source line 452. Its exact fragment is '| (_signed_bits(f"{name}[{lane + 1}]", operand[lane + 1], 32) << 32))'. The important operands are _signed_bits: the value named 'signed bits' in this block; f: the value named 'f' in this block; name: the value named 'name' in this block. Read together, the complete operation is: This calls 'words.append' with '_signed_bits(f"{name}[{lane}]", operand[lane], 32) | (_signed_bits(f"{name}[{lane + 1}]", operand[lane + 1], 32) << 32)' inside the function pack_vector_beats, which handles pack vector beats. The call advances the host-side job that defines command bit fields, descriptor records, packed streams, and result decoders.

Line 454: `return _finish_beats(words)` This returns '_finish_beats(words)' to the caller of the function pack_vector_beats, which handles pack vector beats, ending this invocation. The important operands are _finish_beats: the value named 'finish beats' in this block; words: the value named 'words' in this block.

Line 457: `def pack_layernorm_beats(` This starts function pack_layernorm_beats. Its indented body performs pack layernorm beats as part of the file that defines command bit fields, descriptor records, packed streams, and result decoders; it runs only when called.

Line 458: `values: Sequence[int], gamma_q15: Sequence[int], beta: Sequence[int]` Inside the function pack_layernorm_beats, which handles pack layernorm beats, this statement advances the host implementation that defines command bit fields, descriptor records, packed streams, and result decoders. The important operands are values: the value named 'values' in this block; Sequence: the value named 'sequence' in this block; gamma_q15: the learned multiplicative LayerNorm parameter.

Line 459: `) -> PackedStreamBeats:` Inside the function pack_layernorm_beats, which handles pack layernorm beats, this statement advances the host implementation that defines command bit fields, descriptor records, packed streams, and result decoders. The important operands are PackedStreamBeats: the value named 'packed stream beats' in this block.

Line 460: `if not (len(values) == len(gamma_q15) == len(beta)) or len(values) == 0:` This executes the following indented host-code branch only when 'not (len(values) == len(gamma_q15) == len(beta)) or len(values) == 0' is true. The important operands are not: the value named 'not' in this block; len: the value named 'len' in this block; values: the value named 'values' in this block. Context: the function pack_layernorm_beats, which handles pack layernorm beats.

Line 461: `raise ValueError("LayerNorm value, gamma, and beta arrays must have equal non-zero length")` This rejects an invalid state by raising 'ValueError("LayerNorm value, gamma, and beta arrays must have equal non-zero length")'. Failing before DMA prevents malformed shapes or artifacts from silently becoming hardware results.

Line 462: `words = []` This assigns '[]' to 'words ' in host memory. Here words means the value named 'words' in this block. The expression is a literal or structural operator and has no hidden software state. Context: the function pack_layernorm_beats, which handles pack layernorm beats.

Line 463: `for index, (value, gamma, offset) in enumerate(zip(values, gamma_q15, beta)):` This iterates index, (value, gamma, offset) over 'enumerate(zip(values, gamma_q15, beta))'. Each iteration repeats the indented host operation, commonly once per layer, tile, timestep, or test case in the function pack_layernorm_beats, which handles pack layernorm beats.

Line 464: `beta_bits = _signed_bits(f"beta[{index}]", offset, 24)` This assigns '_signed_bits(f"beta[{index}]", offset, 24)' to 'beta_bits ' in host memory. Here beta_bits means the learned additive LayerNorm parameter. The important operands are _signed_bits: the value named 'signed bits' in this block; f: the value named 'f' in this block; beta: the learned additive LayerNorm parameter. Context: the function pack_layernorm_beats, which handles pack layernorm beats.

Line 465: `word0 = _signed_bits(f"value[{index}]", value, 24)` This assigns '_signed_bits(f"value[{index}]", value, 24)' to 'word0 ' in host memory. Here word0 means the value named 'word0' in this block. The important operands are _signed_bits: the value named 'signed bits' in this block; f: the value named 'f' in this block; value: the value named 'value' in this block. Context: the function pack_layernorm_beats, which handles pack layernorm beats.

Line 466: `word0 |= _signed_bits(f"gamma[{index}]", gamma, 24) << 24` Inside the function pack_layernorm_beats, which handles pack layernorm beats, this statement advances the host implementation that defines command bit fields, descriptor records, packed streams, and result decoders. The important operands are word0: the value named 'word0' in this block; _signed_bits: the value named 'signed bits' in this block; f: the value named 'f' in this block.

Line 467: `word0 |= (beta_bits & 0xFFFF) << 48` Inside the function pack_layernorm_beats, which handles pack layernorm beats, this statement advances the host implementation that defines command bit fields, descriptor records, packed streams, and result decoders. The important operands are word0: the value named 'word0' in this block; beta_bits: the learned additive LayerNorm parameter.

Line 468: `words.extend((word0, beta_bits >> 16))` This calls 'words.extend' with '(word0, beta_bits >> 16)' inside the function pack_layernorm_beats, which handles pack layernorm beats. The call advances the host-side job that defines command bit fields, descriptor records, packed streams, and result decoders.

Line 469: `return _finish_beats(words)` This returns '_finish_beats(words)' to the caller of the function pack_layernorm_bea which handles pack layernorm beats, ending this invocation. The important operands are _finish_beats: the value named 'finish beats' in this block; words: the value named 'words' in this block.

Line 472: `def pack_softmax_beats(scores: Sequence[int]) -> PackedStreamBeats:` This starts function pack_softmax_ Its indented body performs pack softmax beats as part of the file that defines command bit fields, descriptor records, packed streams, and result decoders; it runs only when called.

Line 473: `if not scores:` This executes the following indented host-code branch only when 'not scores' is true. The important operands are not: the value named 'not' in this block; scores: the value named 'scores' in this block. Context: the function pack_softmax_beats, which handles pack softmax beats.

Line 474: `raise ValueError("softmax requires at least one score")` This rejects an invalid state by raising 'ValueError("softmax requires at least one score")'. Failing before DMA prevents malformed shapes or artifacts from silently becoming hardware results.

Line 475: `return _finish_beats(_signed_bits(f"score[{index}]", score, 24)` This statement continues through source line 476; the explanation uses the complete expression rather than only the first visual fragment. This returns '_finish_beats(_signed_bits(f"score[{index}]", score, 24) for index, score in enumerate(scores))' to the caller of the function pack_softmax_beats, which handles pack softmax beats, ending this invocation. The important operands are

_finish_beats: the value named 'finish beats' in this block; _signed_bits: the value named 'signed bits' in this block; f: the value named 'f' in this block.

Line 476: `for index, score in enumerate(scores))` This is continuation line 2 of the 2-line logical statement that begins at source line 475. Its exact fragment is 'for index, score in enumerate(scores))'. The important operands are for: the value named 'for' in this block; index: an integer selecting one tensor element, lane, bank, or state entry; score: the value named 'score' in this block. Read together, the complete operation is: This returns '_finish_beats(_signed_bits(f"score[{index}]", score, 24) for index, score in enumerate(scores))' to the caller of the function pack_softmax_beats, which handles pack softmax beats, ending this invocation. The important operands are _finish_beats: the value named 'finish beats' in this block; _signed_bits: the value named 'signed bits' in this block; f: the value named 'f' in this block.

Line 479: `def pack_lif_beats(currents: Sequence[int]) -> PackedStreamBeats:` This starts function pack_lif_beats. Its indented body performs pack lif beats as part of the file that defines command bit fields, descriptor records, packed streams, and result decoders; it runs only when called.

Line 480: `if len(currents) != 32:` This executes the following indented host-code branch only when 'len(currents) != 32' is true. The important operands are len: the value named 'len' in this block; currents: the value named 'currents' in this block. Context: the function pack_lif_beats, which handles pack lif beats.

Line 481: `raise ValueError("LIF current vector must contain 32 signed 16-bit lanes")` This rejects an invalid state by raising 'ValueError("LIF current vector must contain 32 signed 16-bit lanes")'. Failing before DMA prevents malformed shapes or artifacts from silently becoming hardware results.

Line 482: `words = []` This assigns '[]' to 'words ' in host memory. Here words means the value named 'words' in this block. The expression is a literal or structural operator and has no hidden software state. Context: the function pack_lif_beats, which handles pack lif beats.

Line 483: `for lane in range(0, 32, 4):` This iterates lane over 'range(0, 32, 4)'. Each iteration repeats the indented host operation, commonly once per layer, tile, timestep, or test case in the function pack_lif_beats, which handles pack lif beats.

Line 484: `words.append(sum(_signed_bits(f"current[{lane + offset}]", currents[lane + offset], 16)` This statement continues through source line 485; the explanation uses the complete expression rather than only the first visual fragment. This calls 'words.append' with 'sum(_signed_bits(f"current[{lane + offset}]", currents[lane + offset], 16) << (16 * offset) for offset in range(4))' inside the function pack_lif_beats, which handles pack lif beats. The call advances the host-side job that defines command bit fields, descriptor records, packed streams, and result decoders.

Line 485: `<< (16 * offset) for offset in range(4)))` This is continuation line 2 of the 2-line logical statement that begins at source line 484. Its exact fragment is '<< (16 * offset) for offset in range(4)))'. The important operands are offset: the value named 'offset' in this block; for: the value named 'for' in this block; in: the value named 'in' in this block. Read together, the complete operation is: This calls 'words.append' with 'sum(_signed_bits(f"current[{lane + offset}]", currents[lane + offset], 16) << (16 * offset) for offset in range(4))' inside the function pack_lif_beats, which handles pack lif beats. The call advances the host-side job that defines command bit fields, descriptor records, packed streams, and result decoders.

Line 486: `return _finish_beats(words)` This returns '_finish_beats(words)' to the caller of the function pack_lif_beats, which handles pack lif beats, ending this invocation. The important operands are _finish_beats: the value named 'finish beats' in this block; words: the value named 'words' in this block.

Line 489: `def pack_optimizer_beats(` This starts function pack_optimizer_beats. Its indented body performs pack optimizer beats as part of the file that defines command bit fields, descriptor records, packed streams, and result decoders; it runs only when called.

Line 490: `weights: Sequence[int], gradients: Sequence[int], velocities: Sequence[int]` Inside the function pack_optimizer_beats, which handles pack optimizer beats, this statement advances the host implementation that defines command bit fields, descriptor records, packed streams, and result decoders. The important operands are weights: a learned coefficient multiplied by an activation; Sequence: the value named 'sequence' in this block; gradients: the signed loss derivative used to update a learned parameter.

Line 491: `) -> PackedStreamBeats:` Inside the function pack_optimizer_beats, which handles pack optimizer beats, this statement advances the host implementation that defines command bit fields, descriptor records, packed streams, and result decoders. The important operands are PackedStreamBeats: the value named 'packed stream beats' in this block.

Line 492: `if not (len(weights) == len(gradients) == len(velocities) == 8):` This executes the following indented host-code branch only when 'not (len(weights) == len(gradients) == len(velocities) == 8)' is true. The important operands are not: the value named 'not' in this block; len: the value named 'len' in this block; weights: a learned coefficient multiplied by an activation. Context: the function pack_optimizer_beats, which handles pack optimizer beats.

Line 493: `raise ValueError("optimizer vectors must each contain eight lanes")` This rejects an invalid state by raising 'ValueError("optimizer vectors must each contain eight lanes")'. Failing before DMA prevents malformed shapes or artifacts from silently becoming hardware results.

Line 494: `words = []` This assigns '[]' to 'words ' in host memory. Here words means the value named 'words' in this block. The expression is a literal or structural operator and has no hidden software state. Context: the function pack_optimizer_beats, which handles pack optimizer beats.

Line 495: `for lane in range(8):` This iterates lane over 'range(8)'. Each iteration repeats the indented host operation, commonly once per layer, tile, timestep, or test case in the function pack_optimizer_beats, which handles pack optimizer beats.

Line 496: `word = _signed_bits(f"weight[{lane}]", weights[lane], 16)` This assigns '_signed_bits(f"weight[{lane}]", weights[lane], 16)' to 'word ' in host memory. Here word means the value named 'word' in this block. The important operands are _signed_bits: the value named 'signed bits' in this block; f: the value named 'f' in this block; weight: a learned coefficient multiplied by an activation. Context: the function pack_optimizer_beats, which handles pack optimizer beats.

Line 497: `word |= _signed_bits(f"gradient[{lane}]", gradients[lane], 24) << 16` Inside the function pack_optimizer_
which handles pack optimizer beats, this statement advances the host implementation that defines command bit fields, descriptor records, packed streams, and result decoders. The important operands are word: the value named 'word' in this block; _signed_bits: the value named 'signed bits' in this block; f: the value named 'f' in this block.

Line 498: `word |= _signed_bits(f"velocity[{lane}]", velocities[lane], 24) << 40` Inside the function pack_optimize
which handles pack optimizer beats, this statement advances the host implementation that defines command bit fields, descriptor records, packed streams, and result decoders. The important operands are word: the value named 'word' in this block; _signed_bits: the value named 'signed bits' in this block; f: the value named 'f' in this block.

Line 499: `words.append(word)` This calls 'words.append' with 'word' inside the function pack_optimizer_beats, which handles pack optimizer beats. The call advances the host-side job that defines command bit fields, descriptor records, packed streams, and result decoders.

Line 500: `return _finish_beats(words)` This returns '_finish_beats(words)' to the caller of the function pack_optimizer_beat
which handles pack optimizer beats, ending this invocation. The important operands are _finish_beats: the value named 'finish beats' in this block; words: the value named 'words' in this block.

Line 503: `def pack_linear_backward_beats(` This starts function pack_linear_backward_beats. Its indented body performs pack linear backward beats as part of the file that defines command bit fields, descriptor records, packed streams, and result decoders; it runs only when called.

Line 504: `activations: Sequence[Sequence[int]],` Inside the function pack_linear_backward_beats, which handles pack linear backward beats, this statement advances the host implementation that defines command bit fields, descriptor records, packed streams, and result decoders. The important operands are activations: an input feature value consumed by a neuron or multiply-accumulate operation; Sequence: the value named 'sequence' in this block.

Line 505: `weights: Sequence[Sequence[int]],` Inside the function pack_linear_backward_beats, which handles pack linear backward beats, this statement advances the host implementation that defines command bit fields, descriptor records, packed streams, and result decoders. The important operands are weights: a learned coefficient multiplied by an activation; Sequence: the value named 'sequence' in this block.

Line 506: `output_gradients: Sequence[Sequence[int]],` Inside the function pack_linear_backward_beats, which handles pack linear backward beats, this statement advances the host implementation that defines command bit fields, descriptor records, packed streams, and result decoders. The important operands are output_gradients: the signed loss derivative used to update a learned parameter; Sequence: the value named 'sequence' in this block.

Line 507: `*,` Inside the function pack_linear_backward_beats, which handles pack linear backward beats, this statement advances the host implementation that defines command bit fields, descriptor records, packed streams, and result decoders. The expression is a literal or structural operator and has no hidden software state.

Line 508: `mode: LinearGradientMode = LinearGradientMode.BOTH,` This assigns 'LinearGradientMode.BOTH,' to 'mode' in host memory. Here mode means the value named 'mode' in this block. The important operands are LinearGradientMode: the signed loss derivative used to update a learned parameter; BOTH: the value named 'both' in this block. Context: the function pack_linear_backward_beats, which handles pack linear backward beats.

Line 509: `) -> PackedStreamBeats:` Inside the function pack_linear_backward_beats, which handles pack linear backward beats, this statement advances the host implementation that defines command bit fields, descriptor records, packed streams, and result decoders. The important operands are PackedStreamBeats: the value named 'packed stream beats' in this block.

Line 510: `"""Pack signed X, W, and dY matrices for one linear backward tile."""` This is executable documentation attached to the function pack_linear_backward_beats, which handles pack linear backward beats. It states the intended contract that tests and callers should enforce, but the text itself does not transform data or issue hardware work.

Line 512: `rows = len(activations)` This assigns 'len(activations)' to 'rows ' in host memory. Here rows means one output-row position processed by the tensor tile. The important operands are len: the value named 'len' in this block; activations: an input feature value consumed by a neuron or multiply-accumulate operation. Context: the function pack_linear_backward_beats, which handles pack linear backward beats.

Line 513: `input_features = len(weights)` This assigns 'len(weights)' to 'input_features ' in host memory. Here input_features means the value named 'input features' in this block. The important operands are len: the value named 'len' in this block; weights: a learned coefficient multiplied by an activation. Context: the function pack_linear_backward_beats, which handles pack linear backward beats.

Line 514: `output_features = len(weights[0]) if input_features else 0` This assigns 'len(weights[0]) if input_features else 0' to 'output_features ' in host memory. Here output_features means the value named 'output features' in this block. The important operands are len: the value named 'len' in this block; weights: a learned coefficient multiplied by an activation; input_features: the value named 'input features' in this block. Context: the function pack_linear_backward_beats, which handles pack linear backward beats.

Line 515: `if not 1 <= rows <= 8 or not 1 <= input_features <= 8 or not 1 <= output_features <= 8:` This executes the following indented host-code branch only when ‘not 1 <= rows <= 8 or not 1 <= input_features <= 8 or not 1 <= output_features <= 8‘ is true. The important operands are not: the value named ’not’ in this block; rows: one output-row position processed by the tensor tile; or: the value named ’or’ in this block. Context: the function pack_linear_backward_beats, which handles pack linear backward beats.

Line 516: `raise ValueError("linear backward tile dimensions must be in [1,8]")` This rejects an invalid state by raising ‘ValueError("linear backward tile dimensions must be in [1,8]")‘. Failing before DMA prevents malformed shapes or artifacts from silently becoming hardware results.

Line 517: `if any(len(row) != input_features for row in activations):` This executes the following indented host-code branch only when ‘any(len(row) != input_features for row in activations)‘ is true. The important operands are any: the value named ’any’ in this block; len: the value named ’len’ in this block; row: one output-row position processed by the tensor tile. Context: the function pack_linear_backward_beats, which handles pack linear backward beats.

Line 518: `raise ValueError("activation rows must match the weight input dimension")` This rejects an invalid state by raising ‘ValueError("activation rows must match the weight input dimension")‘. Failing before DMA prevents malformed shapes or artifacts from silently becoming hardware results.

Line 519: `if any(len(row) != output_features for row in weights):` This executes the following indented host-code branch only when ‘any(len(row) != output_features for row in weights)‘ is true. The important operands are any: the value named ’any’ in this block; len: the value named ’len’ in this block; row: one output-row position processed by the tensor tile. Context: the function pack_linear_backward_beats, which handles pack linear backward beats.

Line 520: `raise ValueError("weight rows must have one common output dimension")` This rejects an invalid state by raising ‘ValueError("weight rows must have one common output dimension")‘. Failing before DMA prevents malformed shapes or artifacts from silently becoming hardware results.

Line 521: `if len(output_gradients) != rows or any(` This line opens or closes a multi-line Python expression inside the function pack_linear_backward_beats, which handles pack linear backward beats; the neighboring lines supply its arguments or elements.

Line 522: `len(row) != output_features for row in output_gradients` Inside the function pack_linear_backward_beats, which handles pack linear backward beats, this statement advances the host implementation that defines command bit fields, descriptor records, packed streams, and result decoders. The important operands are len: the value named ’len’ in this block; row: one output-row position processed by the tensor tile; output_features: the value named ’output features’ in this block.

Line 523: `):` Inside the function pack_linear_backward_beats, which handles pack linear backward beats, this statement advances the host implementation that defines command bit fields, descriptor records, packed streams, and result decoders. The expression is a literal or structural operator and has no hidden software state.

Line 524: `raise ValueError("output gradients must have shape [rows, output_features]")` This rejects an invalid state by raising ‘ValueError("output gradients must have shape [rows, output_features]")‘. Failing before DMA prevents malformed shapes or artifacts from silently becoming hardware results.

Line 526: `try:` This is explicit host-side failure handling inside the function pack_linear_backward_beats, which handles pack linear backward beats; it ensures malformed artifacts, DMA errors, and tool failures are surfaced or cleaned up deterministically.

Line 527: `selected_mode = LinearGradientMode(mode)` This assigns ‘LinearGradientMode(mode)‘ to ‘selected_mode ‘ in host memory. Here selected_mode means the value named ’selected mode’ in this block. The important operands are LinearGradientMode: the signed loss derivative used to update a learned parameter; mode: the value named ’mode’ in this block. Context: the function pack_linear_backward_beats, which handles pack linear backward beats.

Line 528: `except ValueError as error:` This is explicit host-side failure handling inside the function pack_linear_backward_b which handles pack linear backward beats; it ensures malformed artifacts, DMA errors, and tool failures are surfaced or cleaned up deterministically.

Line 529: `raise ValueError("linear backward mode must be BOTH, INPUT, or WEIGHT") from error` This rejects an invalid state by raising 'ValueError("linear backward mode must be BOTH, INPUT, or WEIGHT") from error'. Failing before DMA prevents malformed shapes or artifacts from silently becoming hardware results.

Line 530: `words: list[int] = []` This assigns '[]' to 'words' in host memory. Here words means the value named 'words' in this block. The expression is a literal or structural operator and has no hidden software state. Context: the function pack_linear_backward_beats, which handles pack linear backward beats.

Line 531: `if selected_mode != LinearGradientMode.INPUT:` This executes the following indented host-code branch only when 'selected_mode != LinearGradientMode.INPUT' is true. The important operands are selected_mode: the value named 'selected mode' in this block; LinearGradientMode: the signed loss derivative used to update a learned parameter; INPUT: the value named 'input' in this block. Context: the function pack_linear_backward_beats, which handles pack linear backward beats.

Line 532: `for row_index, row in enumerate(activations):` This iterates row_index, row over 'enumerate(activations)'. Each iteration repeats the indented host operation, commonly once per layer, tile, timestep, or test case in the function pack_linear_backward_beats, which handles pack linear backward beats.

Line 533: `padded = list(row) + [0] * (8 - input_features)` This assigns 'list(row) + [0] * (8 - input_features)' to 'padded ' in host memory. Here padded means the value named 'padded' in this block. The important operands are list: the value named 'list' in this block; row: one output-row position processed by the tensor tile; input_features: the value named 'input features' in this block. Context: the function pack_linear_backward_beats, which handles pack linear backward beats.

Line 534: `for half in range(2):` This iterates half over 'range(2)'. Each iteration repeats the indented host operation, commonly once per layer, tile, timestep, or test case in the function pack_linear_backward_beats, which handles pack linear backward beats.

Line 535: `words.append(sum(` This statement continues through source line 542; the explanation uses the complete expression rather than only the first visual fragment. This calls 'words.append' with 'sum(_signed_bits(f"activation[{row_index},{ha * 4 + lane}]", padded[half * 4 + lane], 16,) << (16 * lane) for lane in range(4))' inside the function pack_linear_backward_beats, which handles pack linear backward beats. The call advances the host-side job that defines command bit fields, descriptor records, packed streams, and result decoders.

Line 536: `_signed_bits(` This is continuation line 2 of the 8-line logical statement that begins at source line 535. Its exact fragment is '_signed_bits('. The important operands are _signed_bits: the value named 'signed bits' in this block. Read together, the complete operation is: This calls 'words.append' with 'sum(_signed_bits(f"activation[{row_index},{half * 4 + lane}]", padded[half * 4 + lane], 16,) << (16 * lane) for lane in range(4))' inside the function pack_linear_backward_beats, which handles pack linear backward beats. The call advances the host-side job that defines command bit fields, descriptor records, packed streams, and result decoders.

Line 537: `f"activation[{row_index},{half * 4 + lane}]",` This is continuation line 3 of the 8-line logical statement that begins at source line 535. Its exact fragment is 'f"activation[{row_index},{half * 4 + lane}]",'. The important operands are f: the value named 'f' in this block; activation: an input feature value consumed by a neuron or multiply-accumulate operation; row_index: an integer selecting one tensor element, lane, bank, or state entry. Read together, the complete operation is: This calls 'words.append' with 'sum(_signed_bits(f"activation[{row_index},{half * 4 + lane}]", padded[half * 4 + lane], 16,) << (16 * lane) for lane in range(4))' inside the function pack_linear_backward_beats, which handles pack linear backward beats. The call advances the host-side job that defines command bit fields, descriptor records, packed streams, and result decoders.

Line 538: `padded[half * 4 + lane],` This is continuation line 4 of the 8-line logical statement that begins at source line 535. Its exact fragment is ‘padded[half * 4 + lane],‘. The important operands are padded: the value named ’padded’ in this block; half: the value named ’half’ in this block; lane: one parallel arithmetic element within a vector or tensor datapath. Read together, the complete operation is: This calls ‘words.append‘ with ‘sum(_signed_bits(f"activation[{row_index},{half * 4 + lane}]", padded[half * 4 + lane], 16,) << (16 * lane) for lane in range(4))‘ inside the function pack_linear_backward_beats, which handles pack linear backward beats. The call advances the host-side job that defines command bit fields, descriptor records, packed streams, and result decoders.

Line 539: `16,` This is continuation line 5 of the 8-line logical statement that begins at source line 535. Its exact fragment is ‘16,‘. The expression is a literal or structural operator and has no hidden software state. Read together, the complete operation is: This calls ‘words.append‘ with ‘sum(_signed_bits(f"activation[{row_index},{half * 4 + lane}]", padded[half * 4 + lane], 16,) << (16 * lane) for lane in range(4))‘ inside the function pack_linear_backward_beats, which handles pack linear backward beats. The call advances the host-side job that defines command bit fields, descriptor records, packed streams, and result decoders.

Line 540: `) << (16 * lane)` This is continuation line 6 of the 8-line logical statement that begins at source line 535. Its exact fragment is ‘) << (16 * lane)‘. The important operands are lane: one parallel arithmetic element within a vector or tensor datapath. Read together, the complete operation is: This calls ‘words.append‘ with ‘sum(_signed_bits(f"activation[{row_index},{half * 4 + lane}]", padded[half * 4 + lane], 16,) << (16 * lane) for lane in range(4))‘ inside the function pack_linear_backward_beats, which handles pack linear backward beats. The call advances the host-side job that defines command bit fields, descriptor records, packed streams, and result decoders.

Line 541: `for lane in range(4)` This is continuation line 7 of the 8-line logical statement that begins at source line 535. Its exact fragment is ‘for lane in range(4)‘. The important operands are for: the value named ’for’ in this block; lane: one parallel arithmetic element within a vector or tensor datapath; in: the value named ’in’ in this block. Read together, the complete operation is: This calls ‘words.append‘ with ‘sum(_signed_bits(f"activation[{row_index},{half * 4 + lane}]", padded[half * 4 + lane], 16,) << (16 * lane) for lane in range(4))‘ inside the function pack_linear_backward_beats, which handles pack linear backward beats. The call advances the host-side job that defines command bit fields, descriptor records, packed streams, and result decoders.

Line 542: `))` This is continuation line 8 of the 8-line logical statement that begins at source line 535. Its exact fragment is ‘))‘. The expression is a literal or structural operator and has no hidden software state. Read together, the complete operation is: This calls ‘words.append‘ with ‘sum(_signed_bits(f"activation[{row_index},{half * 4 + lane}]", padded[half * 4 + lane], 16,) << (16 * lane) for lane in range(4))‘ inside the function pack_linear_backward_beats, which handles pack linear backward beats. The call advances the host-side job that defines command bit fields, descriptor records, packed streams, and result decoders.

Line 543: `if selected_mode != LinearGradientMode.WEIGHT:` This executes the following indented host-code branch only when ‘selected_mode != LinearGradientMode.WEIGHT‘ is true. The important operands are selected_mode: the value named ’selected mode’ in this block; LinearGradientMode: the signed loss derivative used to update a learned parameter; WEIGHT: a learned coefficient multiplied by an activation. Context: the function pack_linear_backward_beats, which handles pack linear backward beats.

Line 544: `for row_index, row in enumerate(weights):` This iterates row_index, row over ‘enumerate(weights)‘. Each iteration repeats the indented host operation, commonly once per layer, tile, timestep, or test case in the function pack_linear_backward_beats, which handles pack linear backward beats.

Line 545: `padded = list(row) + [0] * (8 - output_features)` This assigns ‘list(row) + [0] * (8 - output_features)‘ to ‘padded ‘ in host memory. Here padded means the value named ’padded’ in this block. The important operands are list: the value named ’list’ in this block; row: one output-row position processed by the tensor tile; output_features: the value named ’output features’ in this block. Context: the function pack_linear_backward_beats, which handles pack linear backward beats.

Line 546: `for half in range(2):` This iterates half over ‘range(2)‘. Each iteration repeats the indented host operation, commonly once per layer, tile, timestep, or test case in the function pack_linear_backward_beats, which handles pack linear backward beats.

Line 547: `words.append(sum(` This statement continues through source line 554; the explanation uses the complete expression rather than only the first visual fragment. This calls ‘words.append‘ with ‘sum(_signed_bits(f"weight[{row_index},{half * 4 + lane}]", padded[half * 4 + lane], 16,) << (16 * lane) for lane in range(4))‘ inside the function pack_linear_backward_beats, which handles pack linear backward beats. The call advances the host-side job that defines command bit fields, descriptor records, packed streams, and result decoders.

Line 548: `_signed_bits(` This is continuation line 2 of the 8-line logical statement that begins at source line 547. Its exact fragment is ‘_signed_bits(‘. The important operands are _signed_bits: the value named ’signed bits’ in this block. Read together, the complete operation is: This calls ‘words.append‘ with ‘sum(_signed_bits(f"weight[{row_index},{half * 4 + lane}]", padded[half * 4 + lane], 16,) << (16 * lane) for lane in range(4))‘ inside the function pack_linear_backward_beats, which handles pack linear backward beats. The call advances the host-side job that defines command bit fields, descriptor records, packed streams, and result decoders.

Line 549: `f"weight[{row_index},{half * 4 + lane}]",` This is continuation line 3 of the 8-line logical statement that begins at source line 547. Its exact fragment is ‘f"weight[{row_index},{half * 4 + lane}]",‘. The important operands are f: the value named ’f’ in this block; weight: a learned coefficient multiplied by an activation; row_index: an integer selecting one tensor element, lane, bank, or state entry. Read together, the complete operation is: This calls ‘words.append‘ with ‘sum(_signed_bits(f"weight[{row_index},{half * 4 + lane}]", padded[half * 4 + lane], 16,) << (16 * lane) for lane in range(4))‘ inside the function pack_linear_backward_beats, which handles pack linear backward beats. The call advances the host-side job that defines command bit fields, descriptor records, packed streams, and result decoders.

Line 550: `padded[half * 4 + lane],` This is continuation line 4 of the 8-line logical statement that begins at source line 547. Its exact fragment is ‘padded[half * 4 + lane],‘. The important operands are padded: the value named ’padded’ in this block; half: the value named ’half’ in this block; lane: one parallel arithmetic element within a vector or tensor datapath. Read together, the complete operation is: This calls ‘words.append‘ with ‘sum(_signed_bits(f"weight[{row_index},{half * 4 + lane}]", padded[half * 4 + lane], 16,) << (16 * lane) for lane in range(4))‘ inside the function pack_linear_backward_beats, which handles pack linear backward beats. The call advances the host-side job that defines command bit fields, descriptor records, packed streams, and result decoders.

Line 551: `16,` This is continuation line 5 of the 8-line logical statement that begins at source line 547. Its exact fragment is ‘16,‘. The expression is a literal or structural operator and has no hidden software state. Read together, the complete operation is: This calls ‘words.append‘ with ‘sum(_signed_bits(f"weight[{row_index},{half * 4 + lane}]", padded[half * 4 + lane], 16,) << (16 * lane) for lane in range(4))‘ inside the function pack_linear_backward_beats, which handles pack linear backward beats. The call advances the host-side job that defines command bit fields, descriptor records, packed streams, and result decoders.

Line 552: `) << (16 * lane)` This is continuation line 6 of the 8-line logical statement that begins at source line 547. Its exact fragment is ‘) << (16 * lane)‘. The important operands are lane: one parallel arithmetic element within a vector or tensor datapath. Read together, the complete operation is: This calls ‘words.append‘ with ‘sum(_signed_bits(f"weight[{row_index},{half * 4 + lane}]", padded[half * 4 + lane], 16,) << (16 * lane) for lane in range(4))‘ inside the function pack_linear_backward_beats, which handles pack linear backward beats. The call advances the host-side job that defines command bit fields, descriptor records, packed streams, and result decoders.

Line 553: `for lane in range(4)` This is continuation line 7 of the 8-line logical statement that begins at source line 547. Its exact fragment is ‘for lane in range(4)‘. The important operands are for: the value named ’for’ in this block; lane: one parallel arithmetic element within a vector or tensor datapath; in: the value named ’in’ in this block. Read together, the complete operation is: This calls ‘words.append‘ with ‘sum(_signed_bits(f"weight[{row_index},{half * 4 + lane}]", padded[half * 4 + lane], 16,) << (16 * lane) for lane in range(4))‘ inside the function pack_linear_backward_beats, which handles pack linear backward beats. The call advances the host-side job that defines command bit fields, descriptor records, packed streams, and result decoders.

Line 554: `))` This is continuation line 8 of the 8-line logical statement that begins at source line 547. Its exact fragment is ‘))‘. The expression is a literal or structural operator and has no hidden software state. Read together, the complete operation is: This calls ‘words.append‘ with ‘sum(_signed_bits(f"weight[{row_index},{half * 4 + lane}]", padded[half * 4 + lane], 16,) << (16 * lane) for lane in range(4))‘ inside the function pack_linear_backward_beats, which handles

pack linear backward beats. The call advances the host-side job that defines command bit fields, descriptor records, packed streams, and result decoders.

Line 555: `for row_index, row in enumerate(output_gradients):` This iterates row_index, row over ‘enumerate(output_gradients)‘. Each iteration repeats the indented host operation, commonly once per layer, tile, timestep, or test case in the function pack_linear_backward_beats, which handles pack linear backward beats.

Line 556: `padded = list(row) + [0] * (8 - output_features)` This assigns ‘list(row) + [0] * (8 - output_features)‘ to ‘padded ‘ in host memory. Here padded means the value named ’padded’ in this block. The important operands are list: the value named ’list’ in this block; row: one output-row position processed by the tensor tile; output_features: the value named ’output features’ in this block. Context: the function pack_linear_backward_beats, which handles pack linear backward beats.

Line 557: `for half in range(2):` This iterates half over ‘range(2)‘. Each iteration repeats the indented host operation, commonly once per layer, tile, timestep, or test case in the function pack_linear_backward_beats, which handles pack linear backward beats.

Line 558: `words.append(sum(` This statement continues through source line 565; the explanation uses the complete expression rather than only the first visual fragment. This calls ‘words.append‘ with ‘sum(_signed_bits(f"output_gradient[{row_inde
* 4 + lane}]", padded[half * 4 + lane], 16,) << (16 * lane) for lane in range(4))‘ inside the function pack_linear_backward_beats, which handles pack linear backward beats. The call advances the host-side job that defines command bit fields, descriptor records, packed streams, and result decoders.

Line 559: `_signed_bits(` This is continuation line 2 of the 8-line logical statement that begins at source line 558. Its exact fragment is ‘_signed_bits(‘. The important operands are _signed_bits: the value named ’signed bits’ in this block. Read together, the complete operation is: This calls ‘words.append‘ with ‘sum(_signed_bits(f"output_gradient[{row_index},{half * 4 + lane}]", padded[half * 4 + lane], 16,) << (16 * lane) for lane in range(4))‘ inside the function pack_linear_backward_beats, which handles pack linear backward beats. The call advances the host-side job that defines command bit fields, descriptor records, packed streams, and result decoders.

Line 560: `f"output_gradient[{row_index},{half * 4 + lane}]",` This is continuation line 3 of the 8-line logical statement that begins at source line 558. Its exact fragment is ‘f"output_gradient[{row_index},{half * 4 + lane}]",‘. The important operands are f: the value named ’f’ in this block; output_gradient: the signed loss derivative used to update a learned parameter; row_index: an integer selecting one tensor element, lane, bank, or state entry. Read together, the complete operation is: This calls ‘words.append‘ with ‘sum(_signed_bits(f"output_gradient[{row_index},{half * 4 + lane}]", padded[half * 4 + lane], 16,) << (16 * lane) for lane in range(4))‘ inside the function pack_linear_backward_beats, which handles pack linear backward beats. The call advances the host-side job that defines command bit fields, descriptor records, packed streams, and result decoders.

Line 561: `padded[half * 4 + lane],` This is continuation line 4 of the 8-line logical statement that begins at source line 558. Its exact fragment is ‘padded[half * 4 + lane],‘. The important operands are padded: the value named ’padded’ in this block; half: the value named ’half’ in this block; lane: one parallel arithmetic element within a vector or tensor datapath. Read together, the complete operation is: This calls ‘words.append‘ with ‘sum(_signed_bits(f"output_gradient[{row_index},{half * 4 + lane}]", padded[half * 4 + lane], 16,) << (16 * lane) for lane in range(4))‘ inside the function pack_linear_backward_beats, which handles pack linear backward beats. The call advances the host-side job that defines command bit fields, descriptor records, packed streams, and result decoders.

Line 562: `16,` This is continuation line 5 of the 8-line logical statement that begins at source line 558. Its exact fragment is ‘16,‘. The expression is a literal or structural operator and has no hidden software state. Read together, the complete operation is: This calls ‘words.append‘ with ‘sum(_signed_bits(f"output_gradient[{row_index},{half * 4 + lane}]", padded[half * 4 + lane], 16,) << (16 * lane) for lane in range(4))‘ inside the function pack_linear_backward_beats, which handles pack linear backward beats. The call advances the host-side job that defines command bit fields, descriptor records, packed streams, and result decoders.

Line 563: `) << (16 * lane)` This is continuation line 6 of the 8-line logical statement that begins at source line 558. Its exact fragment is ‘) << (16 * lane)‘. The important operands are lane: one parallel arithmetic element within a vector or tensor datapath. Read together, the complete operation is: This calls ‘words.append‘ with ‘sum(_signed_bits(f"output_gradient[{row_index},{half * 4 + lane}]", padded[half * 4 + lane], 16,) << (16 * lane) for lane in range(4))‘ inside the function pack_linear_backward_beats, which handles pack linear backward beats. The call advances the host-side job that defines command bit fields, descriptor records, packed streams, and result decoders.

Line 564: `for lane in range(4)` This is continuation line 7 of the 8-line logical statement that begins at source line 558. Its exact fragment is ‘for lane in range(4)‘. The important operands are for: the value named ’for’ in this block; lane: one parallel arithmetic element within a vector or tensor datapath; in: the value named ’in’ in this block. Read together, the complete operation is: This calls ‘words.append‘ with ‘sum(_signed_bits(f"output_gradient[{row_index},{half * 4 + lane}]", padded[half * 4 + lane], 16,) << (16 * lane) for lane in range(4))‘ inside the function pack_linear_backward_beats, which handles pack linear backward beats. The call advances the host-side job that defines command bit fields, descriptor records, packed streams, and result decoders.

Line 565: `))` This is continuation line 8 of the 8-line logical statement that begins at source line 558. Its exact fragment is ‘))‘. The expression is a literal or structural operator and has no hidden software state. Read together, the complete operation is: This calls ‘words.append‘ with ‘sum(_signed_bits(f"output_gradient[{row_index},{half * 4 + lane}]", padded[half * 4 + lane], 16,) << (16 * lane) for lane in range(4))‘ inside the function pack_linear_backward_beats, which handles pack linear backward beats. The call advances the host-side job that defines command bit fields, descriptor records, packed streams, and result decoders.

Line 566: `return _finish_beats(words)` This returns ‘_finish_beats(words)‘ to the caller of the function pack_linear_backwar which handles pack linear backward beats, ending this invocation. The important operands are _finish_beats: the value named ’finish beats’ in this block; words: the value named ’words’ in this block.

Line 569: `def pack_lut_load_beats(entries: Sequence[tuple[int, int]]) -> PackedStreamBeats:` This starts function pack_lut_load_beats. Its indented body performs pack lut load beats as part of the file that defines command bit fields, descriptor records, packed streams, and result decoders; it runs only when called.

Line 570: `if not entries:` This executes the following indented host-code branch only when ‘not entries‘ is true. The important operands are not: the value named ’not’ in this block; entries: the value named ’entries’ in this block. Context: the function pack_lut_load_beats, which handles pack lut load beats.

Line 571: `raise ValueError("LUT load requires at least one entry")` This rejects an invalid state by raising ‘ValueError("LUT load requires at least one entry")‘. Failing before DMA prevents malformed shapes or artifacts from silently becoming hardware results.

Line 572: `words = []` This assigns ‘[]‘ to ‘words ‘ in host memory. Here words means the value named ’words’ in this block. The expression is a literal or structural operator and has no hidden software state. Context: the function pack_lut_load_beats, which handles pack lut load beats.

Line 573: `for index, (address, value) in enumerate(entries):` This iterates index, (address, value) over ‘enumerate(entries)‘. Each iteration repeats the indented host operation, commonly once per layer, tile, timestep, or test case in the function pack_lut_load_beats, which handles pack lut load beats.

Line 574: `words.append(_unsigned(f"LUT address {index}", address, 8)` This statement continues through source line 575; the explanation uses the complete expression rather than only the first visual fragment. This calls ‘words.append‘ with ‘_unsigned(f"LUT address {index}", address, 8) | (_signed_bits(f"LUT value {index}", value, 16) << 8)‘ inside the function pack_lut_load_beats, which handles pack lut load beats. The call advances the host-side job that defines command bit fields, descriptor records, packed streams, and result decoders.

Line 575: `| (_signed_bits(f"LUT value {index}", value, 16) << 8))` This is continuation line 2 of the 2-line logical statement that begins at source line 574. Its exact fragment is '| (_signed_bits(f"LUT value {index}", value, 16) << 8))'. The important operands are _signed_bits: the value named 'signed bits' in this block; f: the value named 'f' in this block; LUT: the value named 'lut' in this block. Read together, the complete operation is: This calls 'words.append' with '_unsigned(f"LUT address {index}", address, 8) | (_signed_bits(f"LUT value {index}", value, 16) << 8)' inside the function pack_lut_load_beats, which handles pack lut load beats. The call advances the host-side job that defines command bit fields, descriptor records, packed streams, and result decoders.

Line 576: `return _finish_beats(words)` This returns '_finish_beats(words)' to the caller of the function pack_lut_load_beats which handles pack lut load beats, ending this invocation. The important operands are _finish_beats: the value named 'finish beats' in this block; words: the value named 'words' in this block.

Line 579: `def pack_lut_eval_beat(indices: Sequence[int]) -> PackedStreamBeats:` This starts function pack_lut_eval_beat. Its indented body performs pack lut eval beat as part of the file that defines command bit fields, descriptor records, packed streams, and result decoders; it runs only when called.

Line 580: `if len(indices) != 8:` This executes the following indented host-code branch only when 'len(indices) != 8' is true. The important operands are len: the value named 'len' in this block; indices: the value named 'indices' in this block. Context: the function pack_lut_eval_beat, which handles pack lut eval beat.

Line 581: `raise ValueError("LUT evaluate requires exactly eight indices")` This rejects an invalid state by raising 'ValueError("LUT evaluate requires exactly eight indices")'. Failing before DMA prevents malformed shapes or artifacts from silently becoming hardware results.

Line 582: `word = sum(_unsigned(f"LUT index {lane}", value, 8) << (8 * lane)` This statement continues through source line 583; the explanation uses the complete expression rather than only the first visual fragment. This assigns 'sum(_unsigned(f"LUT index {lane}", value, 8) << (8 * lane) for lane, value in enumerate(indices))' to 'word ' in host memory. Here word means the value named 'word' in this block. The important operands are sum: the value named 'sum' in this block; _unsigned: the value named 'unsigned' in this block; f: the value named 'f' in this block. Context: the function pack_lut_eval_beat, which handles pack lut eval beat.

Line 583: `for lane, value in enumerate(indices))` This is continuation line 2 of the 2-line logical statement that begins at source line 582. Its exact fragment is 'for lane, value in enumerate(indices))'. The important operands are for: the value named 'for' in this block; lane: one parallel arithmetic element within a vector or tensor datapath; value: the value named 'value' in this block. Read together, the complete operation is: This assigns 'sum(_unsigned(f"LUT index {lane}", value, 8) << (8 * lane) for lane, value in enumerate(indices))' to 'word ' in host memory. Here word means the value named 'word' in this block. The important operands are sum: the value named 'sum' in this block; _unsigned: the value named 'unsigned' in this block; f: the value named 'f' in this block. Context: the function pack_lut_eval_beat, which handles pack lut eval beat.

Line 584: `return [StreamBeat(word, True)]` This returns '[StreamBeat(word, True)]' to the caller of the function pack_lut_eval_beat, which handles pack lut eval beat, ending this invocation. The important operands are StreamBeat: the value named 'stream beat' in this block; word: the value named 'word' in this block.

Line 587: `def unpack_tensor_result(word: int) -> tuple[int, int, int, bool]:` This starts function unpack_tensor_result. Its indented body performs unpack tensor result as part of the file that defines command bit fields, descriptor records, packed streams, and result decoders; it runs only when called.

Line 588: `value = _unsigned("tensor result word", word, 64)` This assigns '_unsigned("tensor result word", word, 64)' to 'value ' in host memory. Here value means the value named 'value' in this block. The important operands are _unsigned: the value named 'unsigned' in this block; tensor: the value named 'tensor' in this block; result: the value named 'result' in this block. Context: the function unpack_tensor_result, which handles unpack tensor result.

Line 589: `return (_decode_signed(value, 48), (value >> 48) & 0xF,` This statement continues through source line 590; the explanation uses the complete expression rather than only the first visual fragment. This returns ‘(_decode_signed(value, 48), (value >> 48) & 0xF, (value >> 52) & 0x3F, bool((value >> 58) & 1))‘ to the caller of the function unpack_tensor_result, which handles unpack tensor result, ending this invocation. The important operands are _decode_signed: the value named ’decode signed’ in this block; value: the value named ’value’ in this block; bool: the value named ’bool’ in this block.

Line 590: `(value >> 52) & 0x3F, bool((value >> 58) & 1))` This is continuation line 2 of the 2-line logical statement that begins at source line 589. Its exact fragment is ‘(value >> 52) & 0x3F, bool((value >> 58) & 1))‘. The important operands are value: the value named ’value’ in this block; bool: the value named ’bool’ in this block. Read together, the complete operation is: This returns ‘(_decode_signed(value, 48), (value >> 48) & 0xF, (value >> 52) & 0x3F, bool((value >> 58) & 1))‘ to the caller of the function unpack_tensor_result, which handles unpack tensor result, ending this invocation. The important operands are _decode_signed: the value named ’decode signed’ in this block; value: the value named ’value’ in this block; bool: the value named ’bool’ in this block.

Line 593: `def unpack_alpha_result(word: int) -> tuple[int, int, int]:` This starts function unpack_alpha_result. Its indented body performs unpack alpha result as part of the file that defines command bit fields, descriptor records, packed streams, and result decoders; it runs only when called.

Line 594: `value = _unsigned("alpha result word", word, 64)` This assigns ‘_unsigned("alpha result word", word, 64)‘ to ‘value ‘ in host memory. Here value means the value named ’value’ in this block. The important operands are _unsigned: the value named ’unsigned’ in this block; alpha: the programmable weight assigned to matching zero spikes in alpha-XNOR attention; result: the value named ’result’ in this block. Context: the function unpack_alpha_result, which handles unpack alpha result.

Line 595: `return value & 0x3FFFF, (value >> 18) & 0x1FF, (value >> 27) & 0x1FF` This returns ‘value & 0x3FFFF, (value >> 18) & 0x1FF, (value >> 27) & 0x1FF‘ to the caller of the function unpack_alpha_result, which handles unpack alpha result, ending this invocation. The important operands are value: the value named ’value’ in this block.

Line 598: `def unpack_vector_result(words: Sequence[int]) -> tuple[int, ...]:` This starts function unpack_vector_result. Its indented body performs unpack vector result as part of the file that defines command bit fields, descriptor records, packed streams, and result decoders; it runs only when called.

Line 599: `if len(words) != 4:` This executes the following indented host-code branch only when ‘len(words) != 4‘ is true. The important operands are len: the value named ’len’ in this block; words: the value named ’words’ in this block. Context: the function unpack_vector_result, which handles unpack vector result.

Line 600: `raise ValueError("vector result requires four words")` This rejects an invalid state by raising ‘ValueError("vector result requires four words")‘. Failing before DMA prevents malformed shapes or artifacts from silently becoming hardware results.

Line 601: `return tuple(_decode_signed(word >> shift, 32)` This statement continues through source line 602; the explanation uses the complete expression rather than only the first visual fragment. This returns ‘tuple(_decode_signed(word >> shift, 32) for word in words for shift in (0, 32))‘ to the caller of the function unpack_vector_result, which handles unpack vector result, ending this invocation. The important operands are tuple: the value named ’tuple’ in this block; _decode_signed: the value named ’decode signed’ in this block; word: the value named ’word’ in this block.

Line 602: `for word in words for shift in (0, 32))` This is continuation line 2 of the 2-line logical statement that begins at source line 601. Its exact fragment is ‘for word in words for shift in (0, 32))‘. The important operands are for: the value named ’for’ in this block; word: the value named ’word’ in this block; in: the value named ’in’ in this block. Read together, the complete operation is: This returns ‘tuple(_decode_signed(word >> shift, 32) for word in words for shift in (0, 32))‘ to the caller of the function unpack_vector_result, which handles unpack vector result, ending this invocation. The important operands are tuple: the value named ’tuple’ in this block; _decode_signed: the value named ’decode signed’ in this block; word: the value named ’word’ in this block.

Line 605: `def unpack_layernorm_result(word:  int) -> tuple[int, int, bool]:` This starts function unpack_layernorm
Its indented body performs unpack layernorm result as part of the file that defines command bit fields, descriptor records, packed streams, and result decoders; it runs only when called.

Line 606: `value = _unsigned("LayerNorm result word", word, 64)` This assigns '_unsigned("LayerNorm result word", word, 64)' to 'value ' in host memory. Here value means the value named 'value' in this block. The important operands are _unsigned: the value named 'unsigned' in this block; LayerNorm: the value named 'layer norm' in this block; result: the value named 'result' in this block. Context: the function unpack_layernorm_result, which handles unpack layernorm result.

Line 607: `return _decode_signed(value, 32), (value >> 32) & 0xFFF, bool((value >> 44) & 1)` This returns '_decode_signed(value, 32), (value >> 32) & 0xFFF, bool((value >> 44) & 1)' to the caller of the function unpack_layernorm_result, which handles unpack layernorm result, ending this invocation. The important operands are _decode_signed: the value named 'decode signed' in this block; value: the value named 'value' in this block; bool: the value named 'bool' in this block.

Line 610: `def unpack_softmax_result(word:  int) -> tuple[int, int, bool]:` This starts function unpack_softmax_res
Its indented body performs unpack softmax result as part of the file that defines command bit fields, descriptor records, packed streams, and result decoders; it runs only when called.

Line 611: `value = _unsigned("softmax result word", word, 64)` This assigns '_unsigned("softmax result word", word, 64)' to 'value ' in host memory. Here value means the value named 'value' in this block. The important operands are _unsigned: the value named 'unsigned' in this block; softmax: the value named 'softmax' in this block; result: the value named 'result' in this block. Context: the function unpack_softmax_result, which handles unpack softmax result.

Line 612: `return value & 0xFFFF, (value >> 16) & 0x1FF, bool((value >> 25) & 1)` This returns 'value & 0xFFFF, (value >> 16) & 0x1FF, bool((value >> 25) & 1)' to the caller of the function unpack_softmax_result, which handles unpack softmax result, ending this invocation. The important operands are value: the value named 'value' in this block; bool: the value named 'bool' in this block.

Line 615: `def unpack_lif_result(word:  int) -> tuple[int, int]:` This starts function unpack_lif_result. Its indented body performs unpack lif result as part of the file that defines command bit fields, descriptor records, packed streams, and result decoders; it runs only when called.

Line 616: `value = _unsigned("LIF result word", word, 64)` This assigns '_unsigned("LIF result word", word, 64)' to 'value ' in host memory. Here value means the value named 'value' in this block. The important operands are _unsigned: the value named 'unsigned' in this block; LIF: the value named 'lif' in this block; result: the value named 'result' in this block. Context: the function unpack_lif_result, which handles unpack lif result.

Line 617: `return value & 0xFFFFFFFF, value >> 32` This returns 'value & 0xFFFFFFFF, value >> 32' to the caller of the function unpack_lif_result, which handles unpack lif result, ending this invocation. The important operands are value: the value named 'value' in this block.

Line 620: `def unpack_lif_trace(words:  Sequence[int]) -> tuple[int, int, tuple[int, ...]]:` This starts function unpack_lif_trace. Its indented body performs unpack lif trace as part of the file that defines command bit fields, descriptor records, packed streams, and result decoders; it runs only when called.

Line 621: `"""Decode one traced LIF response:  metadata followed by 32 s24 membranes."""` This is executable documentation attached to the function unpack_lif_trace, which handles unpack lif trace. It states the intended contract that tests and callers should enforce, but the text itself does not transform data or issue hardware work.

Line 623: `if len(words) != 13:` This executes the following indented host-code branch only when 'len(words) != 13' is true. The important operands are len: the value named 'len' in this block; words: the value named 'words' in this block. Context: the function unpack_lif_trace, which handles unpack lif trace.

Line 624: `raise ValueError("a traced LIF result requires exactly thirteen words")` This rejects an invalid state by raising 'ValueError("a traced LIF result requires exactly thirteen words")'. Failing before DMA prevents malformed shapes or artifacts from silently becoming hardware results.

Line 625: `spikes, timestep = unpack_lif_result(words[0])` This assigns 'unpack_lif_result(words[0])' to 'spikes, timestep ' in host memory. Here spikes means a binary event produced when a neuron crosses its threshold. The important operands are unpack_lif_result: the value named 'unpack lif result' in this block; words: the value named 'words' in this block. Context: the function unpack_lif_trace, which handles unpack lif trace.

Line 626: `packed_membranes = 0` This assigns '0' to 'packed_membranes ' in host memory. Here packed_membranes means the persistent LIF neuron state carrying charge between timesteps. The expression is a literal or structural operator and has no hidden software state. Context: the function unpack_lif_trace, which handles unpack lif trace.

Line 627: `for index, word in enumerate(words[1:]):` This iterates index, word over 'enumerate(words[1:])'. Each iteration repeats the indented host operation, commonly once per layer, tile, timestep, or test case in the function unpack_lif_trace, which handles unpack lif trace.

Line 628: `packed_membranes |= _unsigned(f"LIF trace word {index}", word, 64) << (64 * index)` Inside the function unpack_lif_trace, which handles unpack lif trace, this statement advances the host implementation that defines command bit fields, descriptor records, packed streams, and result decoders. The important operands are packed_membranes: the persistent LIF neuron state carrying charge between timesteps; _unsigned: the value named 'unsigned' in this block; f: the value named 'f' in this block.

Line 629: `membranes = tuple(` This statement continues through source line 632; the explanation uses the complete expression rather than only the first visual fragment. This assigns 'tuple(_decode_signed(packed_membranes >> (24 * lane), 24) for lane in range(32))' to 'membranes ' in host memory. Here membranes means the persistent LIF neuron state carrying charge between timesteps. The important operands are tuple: the value named 'tuple' in this block; _decode_signed: the value named 'decode signed' in this block; packed_membranes: the persistent LIF neuron state carrying charge between timesteps. Context: the function unpack_lif_trace, which handles unpack lif trace.

Line 630: `_decode_signed(packed_membranes >> (24 * lane), 24)` This is continuation line 2 of the 4-line logical statement that begins at source line 629. Its exact fragment is '_decode_signed(packed_membranes >> (24 * lane), 24)'. The important operands are _decode_signed: the value named 'decode signed' in this block; packed_membranes: the persistent LIF neuron state carrying charge between timesteps; lane: one parallel arithmetic element within a vector or tensor datapath. Read together, the complete operation is: This assigns 'tuple(_decode_signed(packed_membranes >> (24 * lane), 24) for lane in range(32))' to 'membranes ' in host memory. Here membranes means the persistent LIF neuron state carrying charge between timesteps. The important operands are tuple: the value named 'tuple' in this block; _decode_signed: the value named 'decode signed' in this block; packed_membranes: the persistent LIF neuron state carrying charge between timesteps. Context: the function unpack_lif_trace, which handles unpack lif trace.

Line 631: `for lane in range(32)` This is continuation line 3 of the 4-line logical statement that begins at source line 629. Its exact fragment is 'for lane in range(32)'. The important operands are for: the value named 'for' in this block; lane: one parallel arithmetic element within a vector or tensor datapath; in: the value named 'in' in this block. Read together, the complete operation is: This assigns 'tuple(_decode_signed(packed_membranes >> (24 * lane), 24) for lane in range(32))' to 'membranes ' in host memory. Here membranes means the persistent LIF neuron state carrying charge between timesteps. The important operands are tuple: the value named 'tuple' in this block; _decode_signed: the value named 'decode signed' in this block; packed_membranes: the persistent LIF neuron state carrying charge between timesteps. Context: the function unpack_lif_trace, which handles unpack lif trace.

Line 632: `)` This is continuation line 4 of the 4-line logical statement that begins at source line 629. Its exact fragment is ')'. The expression is a literal or structural operator and has no hidden software state. Read together, the complete operation is: This assigns 'tuple(_decode_signed(packed_membranes >> (24 * lane), 24) for lane in range(32))' to 'membranes ' in host memory. Here membranes means the persistent LIF neuron state carrying charge between timesteps. The important operands are tuple: the value named 'tuple' in this block; _decode_signed: the value named 'decode signed' in this block; packed_membranes: the persistent LIF neuron state carrying charge between timesteps. Context: the function unpack_lif_trace, which handles unpack lif trace.

Line 633: `return spikes, timestep, membranes` This returns ‘spikes, timestep, membranes‘ to the caller of the function unpack_lif_trace, which handles unpack lif trace, ending this invocation. The important operands are spikes: a binary event produced when a neuron crosses its threshold; timestep: one discrete SNN update instant; membranes: the persistent LIF neuron state carrying charge between timesteps.

Line 636: `def unpack_optimizer_result(words: Sequence[int]) -> tuple[tuple[int, ...], tuple[int, ...]]:` This starts function unpack_optimizer_result. Its indented body performs unpack optimizer result as part of the file that defines command bit fields, descriptor records, packed streams, and result decoders; it runs only when called.

Line 637: `if len(words) != 8:` This executes the following indented host-code branch only when ‘len(words) != 8‘ is true. The important operands are len: the value named ’len’ in this block; words: the value named ’words’ in this block. Context: the function unpack_optimizer_result, which handles unpack optimizer result.

Line 638: `raise ValueError("optimizer result requires eight words")` This rejects an invalid state by raising ‘ValueError("optimizer result requires eight words")‘. Failing before DMA prevents malformed shapes or artifacts from silently becoming hardware results.

Line 639: `weights = tuple(_decode_signed(word, 16) for word in words)` This assigns ‘tuple(_decode_signed(word, 16) for word in words)‘ to ‘weights ‘ in host memory. Here weights means a learned coefficient multiplied by an activation. The important operands are tuple: the value named ’tuple’ in this block; _decode_signed: the value named ’decode signed’ in this block; word: the value named ’word’ in this block. Context: the function unpack_optimizer_result, which handles unpack optimizer result.

Line 640: `velocities = tuple(_decode_signed(word >> 16, 24) for word in words)` This assigns ‘tuple(_decode_signed >> 16, 24) for word in words)‘ to ‘velocities ‘ in host memory. Here velocities means the value named ’velocities’ in this block. The important operands are tuple: the value named ’tuple’ in this block; _decode_signed: the value named ’decode signed’ in this block; word: the value named ’word’ in this block. Context: the function unpack_optimizer_result, which handles unpack optimizer result.

Line 641: `return weights, velocities` This returns ‘weights, velocities‘ to the caller of the function unpack_optimizer_result, which handles unpack optimizer result, ending this invocation. The important operands are weights: a learned coefficient multiplied by an activation; velocities: the value named ’velocities’ in this block.

Line 644: `def unpack_linear_backward_result(` This starts function unpack_linear_backward_result. Its indented body performs unpack linear backward result as part of the file that defines command bit fields, descriptor records, packed streams, and result decoders; it runs only when called.

Line 645: `words: Sequence[int],` Inside the function unpack_linear_backward_result, which handles unpack linear backward result, this statement advances the host implementation that defines command bit fields, descriptor records, packed streams, and result decoders. The important operands are words: the value named ’words’ in this block; Sequence: the value named ’sequence’ in this block.

Line 646: `rows: int,` Inside the function unpack_linear_backward_result, which handles unpack linear backward result, this statement advances the host implementation that defines command bit fields, descriptor records, packed streams, and result decoders. The important operands are rows: one output-row position processed by the tensor tile.

Line 647: `input_features: int,` Inside the function unpack_linear_backward_result, which handles unpack linear backward result, this statement advances the host implementation that defines command bit fields, descriptor records, packed streams, and result decoders. The important operands are input_features: the value named ’input features’ in this block.

Line 648: `output_features: int,` Inside the function unpack_linear_backward_result, which handles unpack linear backward result, this statement advances the host implementation that defines command bit fields, descriptor records, packed streams, and result decoders. The important operands are output_features: the value named ’output features’ in this block.

Line 649: `*,` Inside the function unpack_linear_backward_result, which handles unpack linear backward result, this statement advances the host implementation that defines command bit fields, descriptor records, packed streams, and result decoders. The expression is a literal or structural operator and has no hidden software state.

Line 650: `mode: LinearGradientMode = LinearGradientMode.BOTH,` This assigns ‘LinearGradientMode.BOTH,‘ to ‘mode‘ in host memory. Here mode means the value named ’mode’ in this block. The important operands are LinearGradientMode: the signed loss derivative used to update a learned parameter; BOTH: the value named ’both’ in this block. Context: the function unpack_linear_backward_result, which handles unpack linear backward result.

Line 651: `) -> tuple[tuple[tuple[int, ...], ...], tuple[tuple[int, ...], ...]]:` Inside the function unpack_linear_backward_result, which handles unpack linear backward result, this statement advances the host implementation that defines command bit fields, descriptor records, packed streams, and result decoders. The important operands are tuple: the value named ’tuple’ in this block.

Line 652: `"""Decode padded s32 dX rows and packed s24 dW rows from the RTL."""` This is executable documentation attached to the function unpack_linear_backward_result, which handles unpack linear backward result. It states the intended contract that tests and callers should enforce, but the text itself does not transform data or issue hardware work.

Line 654: `if not 1 <= rows <= 8 or not 1 <= input_features <= 8 or not 1 <= output_features <= 8:` This executes the following indented host-code branch only when ‘not 1 <= rows <= 8 or not 1 <= input_features <= 8 or not 1 <= output_features <= 8‘ is true. The important operands are not: the value named ’not’ in this block; rows: one output-row position processed by the tensor tile; or: the value named ’or’ in this block. Context: the function unpack_linear_backward_result, which handles unpack linear backward result.

Line 655: `raise ValueError("linear backward tile dimensions must be in [1,8]")` This rejects an invalid state by raising ‘ValueError("linear backward tile dimensions must be in [1,8]")‘. Failing before DMA prevents malformed shapes or artifacts from silently becoming hardware results.

Line 656: `try:` This is explicit host-side failure handling inside the function unpack_linear_backward_result, which handles unpack linear backward result; it ensures malformed artifacts, DMA errors, and tool failures are surfaced or cleaned up deterministically.

Line 657: `selected_mode = LinearGradientMode(mode)` This assigns ‘LinearGradientMode(mode)‘ to ‘selected_mode ‘ in host memory. Here selected_mode means the value named ’selected mode’ in this block. The important operands are LinearGradientMode: the signed loss derivative used to update a learned parameter; mode: the value named ’mode’ in this block. Context: the function unpack_linear_backward_result, which handles unpack linear backward result.

Line 658: `except ValueError as error:` This is explicit host-side failure handling inside the function unpack_linear_backward which handles unpack linear backward result; it ensures malformed artifacts, DMA errors, and tool failures are surfaced or cleaned up deterministically.

Line 659: `raise ValueError("linear backward mode must be BOTH, INPUT, or WEIGHT") from error` This rejects an invalid state by raising ‘ValueError("linear backward mode must be BOTH, INPUT, or WEIGHT") from error‘. Failing before DMA prevents malformed shapes or artifacts from silently becoming hardware results.

Line 660: `expected_words = 0` This assigns ‘0‘ to ‘expected_words ‘ in host memory. Here expected_words means the value named ’expected words’ in this block. The expression is a literal or structural operator and has no hidden software state. Context: the function unpack_linear_backward_result, which handles unpack linear backward result.

Line 661: `if selected_mode != LinearGradientMode.WEIGHT:` This executes the following indented host-code branch only when ‘selected_mode != LinearGradientMode.WEIGHT‘ is true. The important operands are selected_mode: the value named ’selected mode’ in this block; LinearGradientMode: the signed loss derivative used to update a learned parameter; WEIGHT: a learned coefficient multiplied by an activation. Context: the function unpack_linear_backward_result, which handles unpack linear backward result.

Line 662: `expected_words += 4 * rows` Inside the function unpack_linear_backward_result, which handles unpack linear backward result, this statement advances the host implementation that defines command bit fields, descriptor records, packed streams, and result decoders. The important operands are expected_words: the value named 'expected words' in this block; rows: one output-row position processed by the tensor tile.

Line 663: `if selected_mode != LinearGradientMode.INPUT:` This executes the following indented host-code branch only when ‘selected_mode != LinearGradientMode.INPUT‘ is true. The important operands are selected_mode: the value named 'selected mode' in this block; LinearGradientMode: the signed loss derivative used to update a learned parameter; INPUT: the value named 'input' in this block. Context: the function unpack_linear_backward_result, which handles unpack linear backward result.

Line 664: `expected_words += 3 * input_features` Inside the function unpack_linear_backward_result, which handles unpack linear backward result, this statement advances the host implementation that defines command bit fields, descriptor records, packed streams, and result decoders. The important operands are expected_words: the value named 'expected words' in this block; input_features: the value named 'input features' in this block.

Line 665: `if len(words) != expected_words:` This executes the following indented host-code branch only when ‘len(words) != expected_words‘ is true. The important operands are len: the value named 'len' in this block; words: the value named 'words' in this block; expected_words: the value named 'expected words' in this block. Context: the function unpack_linear_backward_result, which handles unpack linear backward result.

Line 666: `raise ValueError(` This statement continues through source line 668; the explanation uses the complete expression rather than only the first visual fragment. This rejects an invalid state by raising ‘ValueError(f"linear backward result requires {expected_words} words; received {len(words)}")‘. Failing before DMA prevents malformed shapes or artifacts from silently becoming hardware results.

Line 667: `f"linear backward result requires {expected_words} words; received {len(words)}"` This is continuation line 2 of the 3-line logical statement that begins at source line 666. Its exact fragment is ‘f"linear backward result requires {expected_words} words; received {len(words)}"‘. The important operands are f: the value named 'f' in this block; linear: the value named 'linear' in this block; backward: the value named 'backward' in this block. Read together, the complete operation is: This rejects an invalid state by raising ‘ValueError(f"linear backward result requires {expected_words} words; received {len(words)}")‘. Failing before DMA prevents malformed shapes or artifacts from silently becoming hardware results.

Line 668: `)` This is continuation line 3 of the 3-line logical statement that begins at source line 666. Its exact fragment is ‘)‘. The expression is a literal or structural operator and has no hidden software state. Read together, the complete operation is: This rejects an invalid state by raising ‘ValueError(f"linear backward result requires {expected_words} words; received {len(words)}")‘. Failing before DMA prevents malformed shapes or artifacts from silently becoming hardware results.

Line 669: `input_gradients: list[tuple[int, ...]] = []` This assigns ‘[]‘ to ‘input_gradients‘ in host memory. Here input_gradients means the signed loss derivative used to update a learned parameter. The expression is a literal or structural operator and has no hidden software state. Context: the function unpack_linear_backward_result, which handles unpack linear backward result.

Line 670: `cursor = 0` This assigns ‘0‘ to ‘cursor ‘ in host memory. Here cursor means the value named 'cursor' in this block. The expression is a literal or structural operator and has no hidden software state. Context: the function unpack_linear_backward_result, which handles unpack linear backward result.

Line 671: `if selected_mode != LinearGradientMode.WEIGHT:` This executes the following indented host-code branch only when ‘selected_mode != LinearGradientMode.WEIGHT‘ is true. The important operands are selected_mode: the value named 'selected mode' in this block; LinearGradientMode: the signed loss derivative used to update a learned parameter; WEIGHT: a learned coefficient multiplied by an activation. Context: the function unpack_linear_backward_result, which handles unpack linear backward result.

Line 672: `for _ in range(rows):` This iterates _ over ‘range(rows)‘. Each iteration repeats the indented host operation, commonly once per layer, tile, timestep, or test case in the function unpack_linear_backward_result, which handles unpack linear backward result.

Line 673: `lanes = tuple(` This statement continues through source line 676; the explanation uses the complete expression rather than only the first visual fragment. This assigns ‘tuple(_decode_signed(words[cursor + lane // 2] >> (32 * (lane % 2)), 32) for lane in range(input_features))‘ to ‘lanes ‘ in host memory. Here lanes means one parallel arithmetic element within a vector or tensor datapath. The important operands are tuple: the value named ’tuple’ in this block; _decode_signed: the value named ’decode signed’ in this block; words: the value named ’words’ in this block. Context: the function unpack_linear_backward_result, which handles unpack linear backward result.

Line 674: `_decode_signed(words[cursor + lane // 2] >> (32 * (lane % 2)), 32)` This is continuation line 2 of the 4-line logical statement that begins at source line 673. Its exact fragment is ‘_decode_signed(words[cursor + lane // 2] >> (32 * (lane % 2)), 32)‘. The important operands are _decode_signed: the value named ’decode signed’ in this block; words: the value named ’words’ in this block; cursor: the value named ’cursor’ in this block. Read together, the complete operation is: This assigns ‘tuple(_decode_signed(words[cursor + lane // 2] >> (32 * (lane % 2)), 32) for lane in range(input_features))‘ to ‘lanes ‘ in host memory. Here lanes means one parallel arithmetic element within a vector or tensor datapath. The important operands are tuple: the value named ’tuple’ in this block; _decode_signed: the value named ’decode signed’ in this block; words: the value named ’words’ in this block. Context: the function unpack_linear_backward_result, which handles unpack linear backward result.

Line 675: `for lane in range(input_features)` This is continuation line 3 of the 4-line logical statement that begins at source line 673. Its exact fragment is ‘for lane in range(input_features)‘. The important operands are for: the value named ’for’ in this block; lane: one parallel arithmetic element within a vector or tensor datapath; in: the value named ’in’ in this block. Read together, the complete operation is: This assigns ‘tuple(_decode_signed(words[cursor + lane // 2] >> (32 * (lane % 2)), 32) for lane in range(input_features))‘ to ‘lanes ‘ in host memory. Here lanes means one parallel arithmetic element within a vector or tensor datapath. The important operands are tuple: the value named ’tuple’ in this block; _decode_signed: the value named ’decode signed’ in this block; words: the value named ’words’ in this block. Context: the function unpack_linear_backward_result, which handles unpack linear backward result.

Line 676: `)` This is continuation line 4 of the 4-line logical statement that begins at source line 673. Its exact fragment is ‘)‘. The expression is a literal or structural operator and has no hidden software state. Read together, the complete operation is: This assigns ‘tuple(_decode_signed(words[cursor + lane // 2] >> (32 * (lane % 2)), 32) for lane in range(input_features))‘ to ‘lanes ‘ in host memory. Here lanes means one parallel arithmetic element within a vector or tensor datapath. The important operands are tuple: the value named ’tuple’ in this block; _decode_signed: the value named ’decode signed’ in this block; words: the value named ’words’ in this block. Context: the function unpack_linear_backward_result, which handles unpack linear backward result.

Line 677: `input_gradients.append(lanes)` This calls ‘input_gradients.append‘ with ‘lanes‘ inside the function unpack_linear_backward_result, which handles unpack linear backward result. The call advances the host-side job that defines command bit fields, descriptor records, packed streams, and result decoders.

Line 678: `cursor += 4` Inside the function unpack_linear_backward_result, which handles unpack linear backward result, this statement advances the host implementation that defines command bit fields, descriptor records, packed streams, and result decoders. The important operands are cursor: the value named ’cursor’ in this block.

Line 679: `weight_gradients: list[tuple[int, ...]] = []` This assigns ‘[]‘ to ‘weight_gradients‘ in host memory. Here weight_gradients means a learned coefficient multiplied by an activation. The expression is a literal or structural operator and has no hidden software state. Context: the function unpack_linear_backward_result, which handles unpack linear backward result.

Line 680: `if selected_mode != LinearGradientMode.INPUT:` This executes the following indented host-code branch only when ‘selected_mode != LinearGradientMode.INPUT‘ is true. The important operands are selected_mode: the value named ’selected mode’ in this block; LinearGradientMode: the signed loss derivative used to update a learned parameter; INPUT: the value named ’input’ in this block. Context: the function unpack_linear_backward_result, which handles unpack linear backward result.

Line 681: `for _ in range(input_features):` This iterates _ over ‘range(input_features)‘. Each iteration repeats the indented host operation, commonly once per layer, tile, timestep, or test case in the function unpack_linear_backward_result, which handles unpack linear backward result.

Line 682: `packed = sum(words[cursor + index] << (64 * index) for index in range(3))` This assigns ‘sum(words[curso + index] << (64 * index) for index in range(3))‘ to ‘packed ‘ in host memory. Here packed means the value named ’packed’ in this block. The important operands are sum: the value named ’sum’ in this block; words: the value named ’words’ in this block; cursor: the value named ’cursor’ in this block. Context: the function unpack_linear_backward_result, which handles unpack linear backward result.

Line 683: `weight_gradients.append(tuple(` This statement continues through source line 686; the explanation uses the complete expression rather than only the first visual fragment. This calls ‘weight_gradients.append‘ with ‘tuple(_decode_signed(packed >> (24 * lane), 24) for lane in range(output_features))‘ inside the function unpack_linear_backward_result, which handles unpack linear backward result. The call advances the host-side job that defines command bit fields, descriptor records, packed streams, and result decoders.

Line 684: `_decode_signed(packed >> (24 * lane), 24)` This is continuation line 2 of the 4-line logical statement that begins at source line 683. Its exact fragment is ‘_decode_signed(packed >> (24 * lane), 24)‘. The important operands are _decode_signed: the value named ’decode signed’ in this block; packed: the value named ’packed’ in this block; lane: one parallel arithmetic element within a vector or tensor datapath. Read together, the complete operation is: This calls ‘weight_gradients.append‘ with ‘tuple(_decode_signed(packed >> (24 * lane), 24) for lane in range(output_features))‘ inside the function unpack_linear_backward_result, which handles unpack linear backward result. The call advances the host-side job that defines command bit fields, descriptor records, packed streams, and result decoders.

Line 685: `for lane in range(output_features)` This is continuation line 3 of the 4-line logical statement that begins at source line 683. Its exact fragment is ‘for lane in range(output_features)‘. The important operands are for: the value named ’for’ in this block; lane: one parallel arithmetic element within a vector or tensor datapath; in: the value named ’in’ in this block. Read together, the complete operation is: This calls ‘weight_gradients.append‘ with ‘tuple(_decode_signed(packed >> (24 * lane), 24) for lane in range(output_features))‘ inside the function unpack_linear_backward_result, which handles unpack linear backward result. The call advances the host-side job that defines command bit fields, descriptor records, packed streams, and result decoders.

Line 686: `))` This is continuation line 4 of the 4-line logical statement that begins at source line 683. Its exact fragment is ‘))‘. The expression is a literal or structural operator and has no hidden software state. Read together, the complete operation is: This calls ‘weight_gradients.append‘ with ‘tuple(_decode_signed(packed >> (24 * lane), 24) for lane in range(output_features))‘ inside the function unpack_linear_backward_result, which handles unpack linear backward result. The call advances the host-side job that defines command bit fields, descriptor records, packed streams, and result decoders.

Line 687: `cursor += 3` Inside the function unpack_linear_backward_result, which handles unpack linear backward result, this statement advances the host implementation that defines command bit fields, descriptor records, packed streams, and result decoders. The important operands are cursor: the value named ’cursor’ in this block.

Line 688: `return tuple(input_gradients), tuple(weight_gradients)` This returns ‘tuple(input_gradients), tuple(weight_gradients)‘ to the caller of the function unpack_linear_backward_result, which handles unpack linear backward result, ending this invocation. The important operands are tuple: the value named ’tuple’ in this block; input_gradients: the signed loss derivative used to update a learned parameter; weight_gradients: a learned coefficient multiplied by an activation.

Line 691: `def unpack_lut_result(words: Sequence[int]) -> tuple[int, ...]:` This starts function unpack_lut_result. Its indented body performs unpack lut result as part of the file that defines command bit fields, descriptor records, packed streams, and result decoders; it runs only when called.

Line 692: `if len(words) != 2:` This executes the following indented host-code branch only when ‘len(words) != 2‘ is true. The important operands are len: the value named ’len’ in this block; words: the value named ’words’ in this block. Context: the function unpack_lut_result, which handles unpack lut result.

Line 693: `raise ValueError("LUT result requires two words")` This rejects an invalid state by raising ‘ValueError("LUT result requires two words")‘. Failing before DMA prevents malformed shapes or artifacts from silently becoming hardware results.

Line 694: `return tuple(_decode_signed(word >> (16 * lane), 16)` This statement continues through source line 695; the explanation uses the complete expression rather than only the first visual fragment. This returns ‘tuple(_decode_signed(word >> (16 * lane), 16) for word in words for lane in range(4))‘ to the caller of the function unpack_lut_result, which handles unpack lut result, ending this invocation. The important operands are tuple: the value named ’tuple’ in this block; _decode_signed: the value named ’decode signed’ in this block; word: the value named ’word’ in this block.

Line 695: `for word in words for lane in range(4))` This is continuation line 2 of the 2-line logical statement that begins at source line 694. Its exact fragment is ‘for word in words for lane in range(4))‘. The important operands are for: the value named ’for’ in this block; word: the value named ’word’ in this block; in: the value named ’in’ in this block. Read together, the complete operation is: This returns ‘tuple(_decode_signed(word >> (16 * lane), 16) for word in words for lane in range(4))‘ to the caller of the function unpack_lut_result, which handles unpack lut result, ending this invocation. The important operands are tuple: the value named ’tuple’ in this block; _decode_signed: the value named ’decode signed’ in this block; word: the value named ’word’ in this block.

37 software/neuraedge_pynq.py

Role in the complete system: controls the overlay, AXI-Lite registers, DMA allocation, packet partitioning, errors, and telemetry.

37.1 Beginner architecture map

Dataflow responsibility The board driver loads the BIT/HWH overlay, allocates physically contiguous DMA buffers, writes AXI-Lite registers, arms receive before send, waits with timeouts, checks hardware errors, and returns telemetry beside result words.

Where it runs This is sequential host software. Python objects live in CPU memory; they become FPGA work only when the compiler packs a command or payload and the PYNQ driver transfers those bytes through AXI DMA or AXI-Lite.

Public structure Classes: RegisterMap, PerformanceSnapshot, NeuraEdgeHardwareError, NeuraEdgeTimeout, NeuraEdgeDriver. Functions: ___init___, from_bitfile, _check_identity, target_clock_hz, capabilities, status, _signed32, performance_snapshot, _control_value, clear_wrapper_status, _validate_input_beats, _release_buffer, _wait_dma_chan __wait_idle, execute, execute_program, _partition_program, _program_sizes, _fill_program_buffer, _execute_program_pa Each function annotation below names its enclosing function so an array operation is tied to the model, compiler, driver, test, or report phase that uses it.

Numeric and failure boundary Shapes, signedness, byte order, scaling, and saturation are part of the hardware contract. Validation exceptions are functional safety checks: rejecting malformed input before DMA is different from silently clipping, reshaping, or continuing with an incompatible artifact.

37.3 Line annotations

Line 1: `"""PYNQ DMA/MMIO driver for the complete NeuraEdge overlay."""` This is executable documentation attached to the file whose role is to controls the overlay, AXI-Lite registers, DMA allocation, packet partitioning, errors, and telemetry. It states the intended contract that tests and callers should enforce, but the text itself does not transform data or issue hardware work.

Line 3: `from __future__ import annotations` This imports the named Python API so the file whose role is to controls the overlay, AXI-Lite registers, DMA allocation, packet partitioning, errors, and telemetry can use it explicitly. Imports execute on the host processor and create no FPGA hardware.

Line 5: `from dataclasses import dataclass` This imports the named Python API so the file whose role is to controls the overlay, AXI-Lite registers, DMA allocation, packet partitioning, errors, and telemetry can use it explicitly. Imports execute on the host processor and create no FPGA hardware.

Line 6: `from pathlib import Path` This imports the named Python API so the file whose role is to controls the overlay, AXI-Lite registers, DMA allocation, packet partitioning, errors, and telemetry can use it explicitly. Imports execute on the host processor and create no FPGA hardware.

Line 7: `from time import monotonic, sleep` This imports the named Python API so the file whose role is to controls the overlay, AXI-Lite registers, DMA allocation, packet partitioning, errors, and telemetry can use it explicitly. Imports execute on the host processor and create no FPGA hardware.

Line 8: `from typing import Callable, Sequence` This imports the named Python API so the file whose role is to controls the overlay, AXI-Lite registers, DMA allocation, packet partitioning, errors, and telemetry can use it explicitly. Imports execute on the host processor and create no FPGA hardware.

Line 10: `import numpy as np` This imports the named Python API so the file whose role is to controls the overlay, AXI-Lite registers, DMA allocation, packet partitioning, errors, and telemetry can use it explicitly. Imports execute on the host processor and create no FPGA hardware.

Line 12: `from neuraedge_protocol import (` This statement continues through source line 17; the explanation uses the complete expression rather than only the first visual fragment. This imports the named Python API so the file whose role is to controls the overlay, AXI-Lite registers, DMA allocation, packet partitioning, errors, and telemetry can use it explicitly. Imports execute on the host processor and create no FPGA hardware.

Line 13: `Command128,` This is continuation line 2 of the 6-line logical statement that begins at source line 12. Its exact fragment is 'Command128,'. The important operands are Command128: the 128-bit instruction selecting an engine, shape, mode, and numeric parameters. Read together, the complete operation is: This imports the named Python API so the file whose role is to controls the overlay, AXI-Lite registers, DMA allocation, packet partitioning, errors, and telemetry can use it explicitly. Imports execute on the host processor and create no FPGA hardware.

Line 14: `PackedStreamBeats,` This is continuation line 3 of the 6-line logical statement that begins at source line 12. Its exact fragment is 'PackedStreamBeats,'. The important operands are PackedStreamBeats: the value named 'packed stream beats' in this block. Read together, the complete operation is: This imports the named Python API so the file whose role is to controls the overlay, AXI-Lite registers, DMA allocation, packet partitioning, errors, and telemetry can use it explicitly. Imports execute on the host processor and create no FPGA hardware.

Line 15: `ProgramRecord,` This is continuation line 4 of the 6-line logical statement that begins at source line 12. Its exact fragment is 'ProgramRecord,'. The important operands are ProgramRecord: the value named 'program record' in this block. Read together, the complete operation is: This imports the named Python API so the file whose role is to controls the overlay, AXI-Lite registers, DMA allocation, packet partitioning, errors, and telemetry can use it explicitly. Imports execute on the host processor and create no FPGA hardware.

Line 16: `StreamBeat,` This is continuation line 5 of the 6-line logical statement that begins at source line 12. Its exact fragment is 'StreamBeat,'. The important operands are StreamBeat: the value named 'stream beat' in this block. Read together, the complete operation is: This imports the named Python API so the file whose role is to controls the overlay, AXI-Lite registers, DMA allocation, packet partitioning, errors, and telemetry can use it explicitly. Imports execute on the host processor and create no FPGA hardware.

Line 17: `)` This is continuation line 6 of the 6-line logical statement that begins at source line 12. Its exact fragment is ')'. The expression is a literal or structural operator and has no hidden software state. Read together, the complete operation is: This imports the named Python API so the file whose role is to controls the overlay, AXI-Lite registers, DMA allocation, packet partitioning, errors, and telemetry can use it explicitly. Imports execute on the host processor and create no FPGA hardware.

Line 20: `@dataclass(frozen=True)` This decorator changes how the following class or function is constructed. '@dataclass(frozen=True)' is applied at import time on the host and is part of the file whose role is to controls the overlay, AXI-Lite registers, DMA allocation, packet partitioning, errors, and telemetry; it creates no FPGA circuit by itself.

Line 21: `class RegisterMap:` This defines class RegisterMap, which groups data and methods for register map. Instances exist in host memory and organize the flow that controls the overlay, AXI-Lite registers, DMA allocation, packet partitioning, errors, and telemetry.

Line 22: `control: int = 0x00` This assigns '0x00' to 'control' in host memory. Here control means the value named 'control' in this block. The expression is a literal or structural operator and has no hidden software state. Context: the class RegisterMap, which handles register map.

Line 23: `status: int = 0x04` This assigns '0x04' to 'status' in host memory. Here status means the value named 'status' in this block. The expression is a literal or structural operator and has no hidden software state. Context: the class RegisterMap, which handles register map.

Line 24: `active_opcode: int = 0x08` This assigns '0x08' to 'active_opcode' in host memory. Here active_opcode means the value named 'active opcode' in this block. The expression is a literal or structural operator and has no hidden software state. Context: the class RegisterMap, which handles register map.

Line 25: `command_count: int = 0x0C` This assigns ‘0x0C‘ to ‘command_count‘ in host memory. Here command_count means the 128-bit instruction selecting an engine, shape, mode, and numeric parameters. The expression is a literal or structural operator and has no hidden software state. Context: the class RegisterMap, which handles register map.

Line 26: `command0: int = 0x10` This assigns ‘0x10‘ to ‘command0‘ in host memory. Here command0 means the 128-bit instruction selecting an engine, shape, mode, and numeric parameters. The expression is a literal or structural operator and has no hidden software state. Context: the class RegisterMap, which handles register map.

Line 27: `input_beats: int = 0x20` This assigns ‘0x20‘ to ‘input_beats‘ in host memory. Here input_beats means the value named 'input beats' in this block. The expression is a literal or structural operator and has no hidden software state. Context: the class RegisterMap, which handles register map.

Line 28: `output_beats: int = 0x24` This assigns ‘0x24‘ to ‘output_beats‘ in host memory. Here output_beats means the value named 'output beats' in this block. The expression is a literal or structural operator and has no hidden software state. Context: the class RegisterMap, which handles register map.

Line 29: `target_clock: int = 0x28` This assigns ‘0x28‘ to ‘target_clock‘ in host memory. Here target_clock means the value named 'target clock' in this block. The expression is a literal or structural operator and has no hidden software state. Context: the class RegisterMap, which handles register map.

Line 30: `capabilities: int = 0x2C` This assigns ‘0x2C‘ to ‘capabilities‘ in host memory. Here capabilities means the value named 'capabilities' in this block. The expression is a literal or structural operator and has no hidden software state. Context: the class RegisterMap, which handles register map.

Line 31: `version: int = 0x30` This assigns ‘0x30‘ to ‘version‘ in host memory. Here version means the value named 'version' in this block. The expression is a literal or structural operator and has no hidden software state. Context: the class RegisterMap, which handles register map.

Line 32: `identity: int = 0x34` This assigns ‘0x34‘ to ‘identity‘ in host memory. Here identity means the value named 'identity' in this block. The expression is a literal or structural operator and has no hidden software state. Context: the class RegisterMap, which handles register map.

Line 33: `tensor_loaded: int = 0x38` This assigns ‘0x38‘ to ‘tensor_loaded‘ in host memory. Here tensor_loaded means the value named 'tensor loaded' in this block. The expression is a literal or structural operator and has no hidden software state. Context: the class RegisterMap, which handles register map.

Line 34: `tensor_active: int = 0x3C` This assigns ‘0x3C‘ to ‘tensor_active‘ in host memory. Here tensor_active means the value named 'tensor active' in this block. The expression is a literal or structural operator and has no hidden software state. Context: the class RegisterMap, which handles register map.

Line 35: `tensor_cycles: int = 0x40` This assigns ‘0x40‘ to ‘tensor_cycles‘ in host memory. Here tensor_cycles means the value named 'tensor cycles' in this block. The expression is a literal or structural operator and has no hidden software state. Context: the class RegisterMap, which handles register map.

Line 36: `tensor_skipped: int = 0x44` This assigns ‘0x44‘ to ‘tensor_skipped‘ in host memory. Here tensor_skipped means the value named 'tensor skipped' in this block. The expression is a literal or structural operator and has no hidden software state. Context: the class RegisterMap, which handles register map.

Line 37: `dense_macs_low: int = 0x48` This assigns ‘0x48‘ to ‘dense_macs_low‘ in host memory. Here dense_macs_low means a count of ordinary activation-times-weight operations actually issued. The expression is a literal or structural operator and has no hidden software state. Context: the class RegisterMap, which handles register map.

Line 38: `dense_macs_high: int = 0x4C` This assigns ‘0x4C‘ to ‘dense_macs_high‘ in host memory. Here dense_macs_high means a count of ordinary activation-times-weight operations actually issued. The expression is a literal or structural operator and has no hidden software state. Context: the class RegisterMap, which handles register map.

Line 39: `spike_adds_low: int = 0x50` This assigns ‘0x50‘ to ‘spike_adds_low‘ in host memory. Here spike_adds_low means a binary event produced when a neuron crosses its threshold. The expression is a literal or structural operator and has no hidden software state. Context: the class RegisterMap, which handles register map.

Line 40: `spike_adds_high: int = 0x54` This assigns ‘0x54‘ to ‘spike_adds_high‘ in host memory. Here spike_adds_high means a binary event produced when a neuron crosses its threshold. The expression is a literal or structural operator and has no hidden software state. Context: the class RegisterMap, which handles register map.

Line 41: `layernorm_cycles: int = 0x58` This assigns ‘0x58‘ to ‘layernorm_cycles‘ in host memory. Here layernorm_cycles means the value named ’layernorm cycles’ in this block. The expression is a literal or structural operator and has no hidden software state. Context: the class RegisterMap, which handles register map.

Line 42: `layernorm_mean: int = 0x5C` This assigns ‘0x5C‘ to ‘layernorm_mean‘ in host memory. Here layernorm_mean means the arithmetic average used by normalization. The expression is a literal or structural operator and has no hidden software state. Context: the class RegisterMap, which handles register map.

Line 43: `layernorm_variance: int = 0x60` This assigns ‘0x60‘ to ‘layernorm_variance‘ in host memory. Here layernorm_variance means the average squared distance from the mean. The expression is a literal or structural operator and has no hidden software state. Context: the class RegisterMap, which handles register map.

Line 44: `layernorm_sigma: int = 0x64` This assigns ‘0x64‘ to ‘layernorm_sigma‘ in host memory. Here layernorm_sigma means the value named ’layernorm sigma’ in this block. The expression is a literal or structural operator and has no hidden software state. Context: the class RegisterMap, which handles register map.

Line 45: `softmax_cycles: int = 0x68` This assigns ‘0x68‘ to ‘softmax_cycles‘ in host memory. Here softmax_cycles means the value named ’softmax cycles’ in this block. The expression is a literal or structural operator and has no hidden software state. Context: the class RegisterMap, which handles register map.

Line 46: `softmax_maximum: int = 0x6C` This assigns ‘0x6C‘ to ‘softmax_maximum‘ in host memory. Here softmax_maximum means the value named ’softmax maximum’ in this block. The expression is a literal or structural operator and has no hidden software state. Context: the class RegisterMap, which handles register map.

Line 47: `softmax_denominator: int = 0x70` This assigns ‘0x70‘ to ‘softmax_denominator‘ in host memory. Here softmax_denominator means the value named ’softmax denominator’ in this block. The expression is a literal or structural operator and has no hidden software state. Context: the class RegisterMap, which handles register map.

Line 48: `lif_spikes_low: int = 0x74` This assigns ‘0x74‘ to ‘lif_spikes_low‘ in host memory. Here lif_spikes_low means a binary event produced when a neuron crosses its threshold. The expression is a literal or structural operator and has no hidden software state. Context: the class RegisterMap, which handles register map.

Line 49: `lif_spikes_high: int = 0x78` This assigns ‘0x78‘ to ‘lif_spikes_high‘ in host memory. Here lif_spikes_high means a binary event produced when a neuron crosses its threshold. The expression is a literal or structural operator and has no hidden software state. Context: the class RegisterMap, which handles register map.

Line 50: `optimizer_updates: int = 0x7C` This assigns ‘0x7C‘ to ‘optimizer_updates‘ in host memory. Here optimizer_updates means the value named ’optimizer updates’ in this block. The expression is a literal or structural operator and has no hidden software state. Context: the class RegisterMap, which handles register map.

Line 51: `lut_entries: int = 0x80` This assigns ‘0x80‘ to ‘lut_entries‘ in host memory. Here lut_entries means the value named ’lut entries’ in this block. The expression is a literal or structural operator and has no hidden software state. Context: the class RegisterMap, which handles register map.

Line 52: `layernorm_reciprocal: int = 0x84` This assigns ‘0x84‘ to ‘layernorm_reciprocal‘ in host memory. Here layernorm_reciprocal means the value named ’layernorm reciprocal’ in this block. The expression is a literal or structural operator and has no hidden software state. Context: the class RegisterMap, which handles register map.

Line 53: `softmax_reciprocal: int = 0x88` This assigns ‘0x88‘ to ‘softmax_reciprocal‘ in host memory. Here softmax_reciprocal means the value named ’softmax reciprocal’ in this block. The expression is a literal or structural operator and has no hidden software state. Context: the class RegisterMap, which handles register map.

Line 54: `program_records: int = 0x8C` This assigns ‘0x8C‘ to ‘program_records‘ in host memory. Here program_records means the number of descriptor records accepted since program start. The expression is a literal or structural operator and has no hidden software state. Context: the class RegisterMap, which handles register map.

Line 55: `program_output_beats: int = 0x90` This assigns ‘0x90‘ to ‘program_output_beats‘ in host memory. Here program_output_beats means the value named ’program output beats’ in this block. The expression is a literal or structural operator and has no hidden software state. Context: the class RegisterMap, which handles register map.

Line 56: `training_tiles: int = 0x94` This assigns ‘0x94‘ to ‘training_tiles‘ in host memory. Here training_tiles means the value named ’training tiles’ in this block. The expression is a literal or structural operator and has no hidden software state. Context: the class RegisterMap, which handles register map.

Line 57: `training_cycles: int = 0x98` This assigns ‘0x98‘ to ‘training_cycles‘ in host memory. Here training_cycles means the value named ’training cycles’ in this block. The expression is a literal or structural operator and has no hidden software state. Context: the class RegisterMap, which handles register map.

Line 60: `@dataclass(frozen=True)` This decorator changes how the following class or function is constructed. ‘@dataclass(frozen=True)‘ is applied at import time on the host and is part of the file whose role is to controls the overlay, AXI-Lite registers, DMA allocation, packet partitioning, errors, and telemetry; it creates no FPGA circuit by itself.

Line 61: `class PerformanceSnapshot:` This defines class PerformanceSnapshot, which groups data and methods for performance snapshot. Instances exist in host memory and organize the flow that controls the overlay, AXI-Lite registers, DMA allocation, packet partitioning, errors, and telemetry.

Line 62: `tensor_loaded_activations: int` Inside the class PerformanceSnapshot, which handles performance snapshot, this statement advances the host implementation that controls the overlay, AXI-Lite registers, DMA allocation, packet partitioning, errors, and telemetry. The important operands are tensor_loaded_activations: an input feature value consumed by a neuron or multiply-accumulate operation.

Line 63: `tensor_loaded_weights: int` Inside the class PerformanceSnapshot, which handles performance snapshot, this statement advances the host implementation that controls the overlay, AXI-Lite registers, DMA allocation, packet partitioning, errors, and telemetry. The important operands are tensor_loaded_weights: a learned coefficient multiplied by an activation.

Line 64: `tensor_active_issues: int` Inside the class PerformanceSnapshot, which handles performance snapshot, this statement advances the host implementation that controls the overlay, AXI-Lite registers, DMA allocation, packet partitioning, errors, and telemetry. The important operands are tensor_active_issues: the value named ’tensor active issues’ in this block.

Line 65: `tensor_compute_cycles: int` Inside the class PerformanceSnapshot, which handles performance snapshot, this statement advances the host implementation that controls the overlay, AXI-Lite registers, DMA allocation, packet partitioning, errors, and telemetry. The important operands are tensor_compute_cycles: the value named 'tensor compute cycles' in this block.

Line 66: `tensor_skipped_issues: int` Inside the class PerformanceSnapshot, which handles performance snapshot, this statement advances the host implementation that controls the overlay, AXI-Lite registers, DMA allocation, packet partitioning, errors, and telemetry. The important operands are tensor_skipped_issues: the value named 'tensor skipped issues' in this block.

Line 67: `dense_macs: int` Inside the class PerformanceSnapshot, which handles performance snapshot, this statement advances the host implementation that controls the overlay, AXI-Lite registers, DMA allocation, packet partitioning, errors, and telemetry. The important operands are dense_macs: a count of ordinary activation-times-weight operations actually issued.

Line 68: `spike_adds: int` Inside the class PerformanceSnapshot, which handles performance snapshot, this statement advances the host implementation that controls the overlay, AXI-Lite registers, DMA allocation, packet partitioning, errors, and telemetry. The important operands are spike_adds: a binary event produced when a neuron crosses its threshold.

Line 69: `layernorm_cycles: int` Inside the class PerformanceSnapshot, which handles performance snapshot, this statement advances the host implementation that controls the overlay, AXI-Lite registers, DMA allocation, packet partitioning, errors, and telemetry. The important operands are layernorm_cycles: the value named 'layernorm cycles' in this block.

Line 70: `layernorm_mean: int` Inside the class PerformanceSnapshot, which handles performance snapshot, this statement advances the host implementation that controls the overlay, AXI-Lite registers, DMA allocation, packet partitioning, errors, and telemetry. The important operands are layernorm_mean: the arithmetic average used by normalization.

Line 71: `layernorm_variance: int` Inside the class PerformanceSnapshot, which handles performance snapshot, this statement advances the host implementation that controls the overlay, AXI-Lite registers, DMA allocation, packet partitioning, errors, and telemetry. The important operands are layernorm_variance: the average squared distance from the mean.

Line 72: `layernorm_sigma: int` Inside the class PerformanceSnapshot, which handles performance snapshot, this statement advances the host implementation that controls the overlay, AXI-Lite registers, DMA allocation, packet partitioning, errors, and telemetry. The important operands are layernorm_sigma: the value named 'layernorm sigma' in this block.

Line 73: `layernorm_reciprocal_q31: int` Inside the class PerformanceSnapshot, which handles performance snapshot, this statement advances the host implementation that controls the overlay, AXI-Lite registers, DMA allocation, packet partitioning, errors, and telemetry. The important operands are layernorm_reciprocal_q31: the value named 'layernorm reciprocal q31' in this block.

Line 74: `softmax_cycles: int` Inside the class PerformanceSnapshot, which handles performance snapshot, this statement advances the host implementation that controls the overlay, AXI-Lite registers, DMA allocation, packet partitioning, errors, and telemetry. The important operands are softmax_cycles: the value named 'softmax cycles' in this block.

Line 75: `softmax_maximum: int` Inside the class PerformanceSnapshot, which handles performance snapshot, this statement advances the host implementation that controls the overlay, AXI-Lite registers, DMA allocation, packet partitioning, errors, and telemetry. The important operands are softmax_maximum: the value named 'softmax maximum' in this block.

Line 76: `softmax_denominator: int` Inside the class PerformanceSnapshot, which handles performance snapshot, this statement advances the host implementation that controls the overlay, AXI-Lite registers, DMA allocation, packet partitioning, errors, and telemetry. The important operands are softmax_denominator: the value named 'softmax denominator' in this block.

Line 77: `softmax_reciprocal_q31: int` Inside the class PerformanceSnapshot, which handles performance snapshot, this statement advances the host implementation that controls the overlay, AXI-Lite registers, DMA allocation, packet partitioning, errors, and telemetry. The important operands are softmax_reciprocal_q31: the value named 'softmax reciprocal q31' in this block.

Line 78: `lif_total_spikes: int` Inside the class PerformanceSnapshot, which handles performance snapshot, this statement advances the host implementation that controls the overlay, AXI-Lite registers, DMA allocation, packet partitioning, errors, and telemetry. The important operands are lif_total_spikes: a binary event produced when a neuron crosses its threshold.

Line 79: `optimizer_updates: int` Inside the class PerformanceSnapshot, which handles performance snapshot, this statement advances the host implementation that controls the overlay, AXI-Lite registers, DMA allocation, packet partitioning, errors, and telemetry. The important operands are optimizer_updates: the value named 'optimizer updates' in this block.

Line 80: `lut_loaded_entries: int` Inside the class PerformanceSnapshot, which handles performance snapshot, this statement advances the host implementation that controls the overlay, AXI-Lite registers, DMA allocation, packet partitioning, errors, and telemetry. The important operands are lut_loaded_entries: the value named 'lut loaded entries' in this block.

Line 81: `training_tiles: int` Inside the class PerformanceSnapshot, which handles performance snapshot, this statement advances the host implementation that controls the overlay, AXI-Lite registers, DMA allocation, packet partitioning, errors, and telemetry. The important operands are training_tiles: the value named 'training tiles' in this block.

Line 82: `training_cycles: int` Inside the class PerformanceSnapshot, which handles performance snapshot, this statement advances the host implementation that controls the overlay, AXI-Lite registers, DMA allocation, packet partitioning, errors, and telemetry. The important operands are training_cycles: the value named 'training cycles' in this block.

Line 85: `class NeuraEdgeHardwareError(RuntimeError):` This defines class NeuraEdgeHardwareError, which groups data and methods for neura edge hardware error. Instances exist in host memory and organize the flow that controls the overlay, AXI-Lite registers, DMA allocation, packet partitioning, errors, and telemetry.

Line 86: `"""Raised when the RTL reports a sticky protocol or configuration error."""` This is executable documentation attached to the class NeuraEdgeHardwareError, which handles neura edge hardware error. It states the intended contract that tests and callers should enforce, but the text itself does not transform data or issue hardware work.

Line 89: `class NeuraEdgeTimeout(TimeoutError):` This defines class NeuraEdgeTimeout, which groups data and methods for neura edge timeout. Instances exist in host memory and organize the flow that controls the overlay, AXI-Lite registers, DMA allocation, packet partitioning, errors, and telemetry.

Line 90: `"""Raised when a DMA channel or accelerator command exceeds its deadline."""` This is executable documentation attached to the class NeuraEdgeTimeout, which handles neura edge timeout. It states the intended contract that tests and callers should enforce, but the text itself does not transform data or issue hardware work.

Line 93: `class NeuraEdgeDriver:` This defines class NeuraEdgeDriver, which groups data and methods for neura edge driver. Instances exist in host memory and organize the flow that controls the overlay, AXI-Lite registers, DMA allocation, packet partitioning, errors, and telemetry.

Line 94: `STATUS_BUSY = 1 << 0` This assigns ‘1 << 0‘ to ‘STATUS_BUSY ‘ in host memory. Here STATUS_BUSY means the value named ’status busy’ in this block. The expression is a literal or structural operator and has no hidden software state. Context: the class NeuraEdgeDriver, which handles neura edge driver.

Line 95: `STATUS_ERROR = 1 << 1` This assigns ‘1 << 1‘ to ‘STATUS_ERROR ‘ in host memory. Here STATUS_ERROR means the value named ’status error’ in this block. The expression is a literal or structural operator and has no hidden software state. Context: the class NeuraEdgeDriver, which handles neura edge driver.

Line 96: `STATUS_DONE = 1 << 2` This assigns ‘1 << 2‘ to ‘STATUS_DONE ‘ in host memory. Here STATUS_DONE means the value named ’status done’ in this block. The expression is a literal or structural operator and has no hidden software state. Context: the class NeuraEdgeDriver, which handles neura edge driver.

Line 97: `STATUS_PENDING = 1 << 3` This assigns ‘1 << 3‘ to ‘STATUS_PENDING ‘ in host memory. Here STATUS_PENDING means the value named ’status pending’ in this block. The expression is a literal or structural operator and has no hidden software state. Context: the class NeuraEdgeDriver, which handles neura edge driver.

Line 98: `STATUS_PROGRAM_ACTIVE = 1 << 5` This assigns ‘1 << 5‘ to ‘STATUS_PROGRAM_ACTIVE ‘ in host memory. Here STATUS_PROGRAM_ACTIVE means the value named ’status program active’ in this block. The expression is a literal or structural operator and has no hidden software state. Context: the class NeuraEdgeDriver, which handles neura edge driver.

Line 99: `EXPECTED_ID = 0x4E455552` This assigns ‘0x4E455552‘ to ‘EXPECTED_ID ‘ in host memory. Here EXPECTED_ID means the value named ’expected id’ in this block. The expression is a literal or structural operator and has no hidden software state. Context: the class NeuraEdgeDriver, which handles neura edge driver.

Line 100: `EXPECTED_ABI_MAJOR = 1` This assigns ‘1‘ to ‘EXPECTED_ABI_MAJOR ‘ in host memory. Here EXPECTED_ABI_MAJOR means the value named ’expected abi major’ in this block. The expression is a literal or structural operator and has no hidden software state. Context: the class NeuraEdgeDriver, which handles neura edge driver.

Line 101: `MAX_DMA_TRANSFER_BYTES = (1 << 26) - 1` This assigns ‘(1 << 26) - 1‘ to ‘MAX_DMA_TRANSFER_BYTES ‘ in host memory. Here MAX_DMA_TRANSFER_BYTES means the direct-memory-access engine moving contiguous buffers between DDR and FPGA logic. The expression is a literal or structural operator and has no hidden software state. Context: the class NeuraEdgeDriver, which handles neura edge driver.

Line 102: `PACK_COPY_WORDS = 1 << 16` This assigns ‘1 << 16‘ to ‘PACK_COPY_WORDS ‘ in host memory. Here PACK_COPY_WORDS means the value named ’pack copy words’ in this block. The expression is a literal or structural operator and has no hidden software state. Context: the class NeuraEdgeDriver, which handles neura edge driver.

Line 104: `def __init__(self, mmio, dma, allocator: Callable[..., object], *, interrupt_enable: bool = True):` This starts function ___init___. Its indented body performs init as part of the file that controls the overlay, AXI-Lite registers, DMA allocation, packet partitioning, errors, and telemetry; it runs only when called.

Line 105: `self.mmio = mmio` This assigns ‘mmio‘ to ‘self.mmio ‘ in host memory. Here mmio means the value named ’mmio’ in this block. The important operands are mmio: the value named ’mmio’ in this block. Context: the function ___init___, which handles init.

Line 106: `self.dma = dma` This assigns ‘dma‘ to ‘self.dma ‘ in host memory. Here dma means the direct-memory-access engine moving contiguous buffers between DDR and FPGA logic. The important operands are dma: the direct-memory-access engine moving contiguous buffers between DDR and FPGA logic. Context: the function ___init___, which handles init.

Line 107: `self.allocator = allocator` This assigns ‘allocator‘ to ‘self.allocator ‘ in host memory. Here allocator means the value named ’allocator’ in this block. The important operands are allocator: the value named ’allocator’ in this block. Context: the function ___init___, which handles init.

Line 108: `self.registers = RegisterMap()` This assigns ‘RegisterMap()‘ to ‘self.registers ‘ in host memory. Here registers means the value named ’registers’ in this block. The important operands are RegisterMap: the value named ’register map’ in this block. Context: the function ___init___, which handles init.

Line 109: `self.interrupt_enable = bool(interrupt_enable)` This assigns ‘bool(interrupt_enable)‘ to ‘self.interrupt_enable ‘ in host memory. Here interrupt_enable means the hardware notification that wakes software after completion or error. The important operands are bool: the value named ’bool’ in this block; interrupt_enable: the hardware notification that wakes software after completion or error. Context: the function ___init___, which handles init.

Line 110: `self._check_identity()` This calls ‘self._check_identity‘ with “ inside the function ___init___, which handles init. The call advances the host-side job that controls the overlay, AXI-Lite registers, DMA allocation, packet partitioning, errors, and telemetry.

Line 112: `@classmethod` This decorator changes how the following class or function is constructed. ‘@classmethod‘ is applied at import time on the host and is part of the class NeuraEdgeDriver, which handles neura edge driver; it creates no FPGA circuit by itself.

Line 113: `def from_bitfile(` This starts function from_bitfile. Its indented body performs from bitfile as part of the file that controls the overlay, AXI-Lite registers, DMA allocation, packet partitioning, errors, and telemetry; it runs only when called.

Line 114: `cls,` Inside the function from_bitfile, which handles from bitfile, this statement advances the host implementation that controls the overlay, AXI-Lite registers, DMA allocation, packet partitioning, errors, and telemetry. The important operands are cls: the value named ’cls’ in this block.

Line 115: `bitfile: str | Path,` Inside the function from_bitfile, which handles from bitfile, this statement advances the host implementation that controls the overlay, AXI-Lite registers, DMA allocation, packet partitioning, errors, and telemetry. The important operands are bitfile: the value named ’bitfile’ in this block; str: the value named ’str’ in this block; Path: the value named ’path’ in this block.

Line 116: `*,` Inside the function from_bitfile, which handles from bitfile, this statement advances the host implementation that controls the overlay, AXI-Lite registers, DMA allocation, packet partitioning, errors, and telemetry. The expression is a literal or structural operator and has no hidden software state.

Line 117: `download: bool = True,` This assigns ‘True,‘ to ‘download‘ in host memory. Here download means the value named ’download’ in this block. The expression is a literal or structural operator and has no hidden software state. Context: the function from_bitfile, which handles from bitfile.

Line 118: `accelerator_name: str = "accelerator",` This assigns ‘"accelerator",‘ to ‘accelerator_name‘ in host memory. Here accelerator_name means the value named ’accelerator name’ in this block. The important operands are accelerator: the value named ’accelerator’ in this block. Context: the function from_bitfile, which handles from bitfile.

Line 119: `dma_name: str = "dma",` This assigns ‘"dma",‘ to ‘dma_name‘ in host memory. Here dma_name means the direct-memory-access engine moving contiguous buffers between DDR and FPGA logic. The important operands are dma: the direct-memory-access engine moving contiguous buffers between DDR and FPGA logic. Context: the function from_bitfile, which handles from bitfile.

Line 120: `) -> "NeuraEdgeDriver":` Inside the function from_bitfile, which handles from bitfile, this statement advances the host implementation that controls the overlay, AXI-Lite registers, DMA allocation, packet partitioning, errors, and telemetry. The important operands are NeuraEdgeDriver: the value named ’neura edge driver’ in this block.

Line 121: `try:` This is explicit host-side failure handling inside the function from_bitfile, which handles from bitfile; it ensures malformed artifacts, DMA errors, and tool failures are surfaced or cleaned up deterministically.

Line 122: `from pynq import Overlay, allocate` This imports the named Python API so the function from_bitfile, which handles from bitfile can use it explicitly. Imports execute on the host processor and create no FPGA hardware.

Line 123: `except ImportError as error:` This is explicit host-side failure handling inside the function from_bitfile, which handles from bitfile; it ensures malformed artifacts, DMA errors, and tool failures are surfaced or cleaned up deterministically.

Line 124: `raise RuntimeError("the pynq package is required on the PYNQ-Z2 board") from error` This rejects an invalid state by raising ‘RuntimeError("the pynq package is required on the PYNQ-Z2 board") from error‘. Failing before DMA prevents malformed shapes or artifacts from silently becoming hardware results.

Line 126: `overlay = Overlay(str(Path(bitfile)), download=download)` This assigns ‘Overlay(str(Path(bitfile)), download=download)‘ to ‘overlay ‘ in host memory. Here overlay means the value named ’overlay’ in this block. The important operands are Overlay: the value named ’overlay’ in this block; str: the value named ’str’ in this block; Path: the value named ’path’ in this block. Context: the function from_bitfile, which handles from bitfile.

Line 127: `accelerator = getattr(overlay, accelerator_name)` This assigns ‘getattr(overlay, accelerator_name)‘ to ‘accelerator ‘ in host memory. Here accelerator means the value named ’accelerator’ in this block. The important operands are getattr: the value named ’getattr’ in this block; overlay: the value named ’overlay’ in this block; accelerator_name: the value named ’accelerator name’ in this block. Context: the function from_bitfile, which handles from bitfile.

Line 128: `dma = getattr(overlay, dma_name)` This assigns ‘getattr(overlay, dma_name)‘ to ‘dma ‘ in host memory. Here dma means the direct-memory-access engine moving contiguous buffers between DDR and FPGA logic. The important operands are getattr: the value named ’getattr’ in this block; overlay: the value named ’overlay’ in this block; dma_name: the direct-memory-access engine moving contiguous buffers between DDR and FPGA logic. Context: the function from_bitfile, which handles from bitfile.

Line 129: `driver = cls(accelerator.mmio, dma, allocate)` This assigns ‘cls(accelerator.mmio, dma, allocate)‘ to ‘driver ‘ in host memory. Here driver means the value named ’driver’ in this block. The important operands are cls: the value named ’cls’ in this block; accelerator: the value named ’accelerator’ in this block; mmio: the value named ’mmio’ in this block. Context: the function from_bitfile, which handles from bitfile.

Line 130: `driver.overlay = overlay` This assigns ‘overlay‘ to ‘driver.overlay ‘ in host memory. Here overlay means the value named ’overlay’ in this block. The important operands are overlay: the value named ’overlay’ in this block. Context: the function from_bitfile, which handles from bitfile.

Line 131: `return driver` This returns ‘driver‘ to the caller of the function from_bitfile, which handles from bitfile, ending this invocation. The important operands are driver: the value named ’driver’ in this block.

Line 133: `def _check_identity(self) -> None:` This starts function _check_identity. Its indented body performs check identity as part of the file that controls the overlay, AXI-Lite registers, DMA allocation, packet partitioning, errors, and telemetry; it runs only when called.

Line 134: `identity = int(self.mmio.read(self.registers.identity))` This assigns ‘int(self.mmio.read(self.registers.identit
to ‘identity ‘ in host memory. Here identity means the value named ’identity’ in this block. The important operands are mmio: the value named ’mmio’ in this block; read: the value named ’read’ in this block; registers: the value named ’registers’ in this block. Context: the function _check_identity, which handles check identity.

Line 135: `version = int(self.mmio.read(self.registers.version))` This assigns ‘int(self.mmio.read(self.registers.version))’ to ‘version ‘ in host memory. Here version means the value named ’version’ in this block. The important operands are mmio: the value named ’mmio’ in this block; read: the value named ’read’ in this block; registers: the value named ’registers’ in this block. Context: the function _check_identity, which handles check identity.

Line 136: `if identity != self.EXPECTED_ID:` This executes the following indented host-code branch only when ‘identity != self.EXPECTED_ID‘ is true. The important operands are identity: the value named ’identity’ in this block; EXPECTED_ID: the value named ’expected id’ in this block. Context: the function _check_identity, which handles check identity.

Line 137: `raise NeuraEdgeHardwareError(` This statement continues through source line 139; the explanation uses the complete expression rather than only the first visual fragment. This rejects an invalid state by raising ‘NeuraEdgeHardwareError(f"unexpected accelerator identity 0x{identity:08x}; expected 0x{self.EXPECTED_ID:08x}")‘. Failing before DMA prevents malformed shapes or artifacts from silently becoming hardware results.

Line 138: `f"unexpected accelerator identity 0x{identity:08x}; expected 0x{self.EXPECTED_ID:08x}"` This is continuation line 2 of the 3-line logical statement that begins at source line 137. Its exact fragment is ‘f"unexpected accelerator identity 0x{identity:08x}; expected 0x{self.EXPECTED_ID:08x}"‘. The important operands are f: the value named ’f’ in this block; unexpected: the value named ’unexpected’ in this block; accelerator: the value named ’accelerator’ in this block. Read together, the complete operation is: This rejects an invalid state by raising ‘NeuraEdgeHardwareError(f"unexpected accelerator identity 0x{identity:08x}; expected 0x{self.EXPECTED_ID:08x}")‘. Failing before DMA prevents malformed shapes or artifacts from silently becoming hardware results.

Line 139: `)` This is continuation line 3 of the 3-line logical statement that begins at source line 137. Its exact fragment is ‘)‘. The expression is a literal or structural operator and has no hidden software state. Read together, the complete operation is: This rejects an invalid state by raising ‘NeuraEdgeHardwareError(f"unexpected accelerator identity 0x{identity:08x}; expected 0x{self.EXPECTED_ID:08x}")‘. Failing before DMA prevents malformed shapes or artifacts from silently becoming hardware results.

Line 140: `if version >> 16 != self.EXPECTED_ABI_MAJOR:` This executes the following indented host-code branch only when ‘version >> 16 != self.EXPECTED_ABI_MAJOR‘ is true. The important operands are version: the value named ’version’ in this block; EXPECTED_ABI_MAJOR: the value named ’expected abi major’ in this block. Context: the function _check_identity, which handles check identity.

Line 141: `raise NeuraEdgeHardwareError(` This statement continues through source line 143; the explanation uses the complete expression rather than only the first visual fragment. This rejects an invalid state by raising ‘NeuraEdgeHardwareError(f"unsupported accelerator ABI 0x{version:08x}; expected major {self.EXPECTED_ABI_MAJOR}")‘. Failing before DMA prevents malformed shapes or artifacts from silently becoming hardware results.

Line 142: `f"unsupported accelerator ABI 0x{version:08x}; expected major {self.EXPECTED_ABI_MAJOR}"` This is continuation line 2 of the 3-line logical statement that begins at source line 141. Its exact fragment is ‘f"unsupported accelerator ABI 0x{version:08x}; expected major {self.EXPECTED_ABI_MAJOR}"‘. The important operands are f: the value named ’f’ in this block; unsupported: the value named ’unsupported’ in this block; accelerator: the value named ’accelerator’ in this block. Read together, the complete operation is: This rejects an invalid state by raising ‘NeuraEdgeHardwareError(f"unsupported accelerator ABI 0x{version:08x}; expected major {self.EXPECTED_ABI_MAJOR}")‘. Failing before DMA prevents malformed shapes or artifacts from silently becoming hardware results.

Line 143: `)` This is continuation line 3 of the 3-line logical statement that begins at source line 141. Its exact fragment is ‘)‘. The expression is a literal or structural operator and has no hidden software state. Read together, the complete operation is: This rejects an invalid state by raising ‘NeuraEdgeHardwareError(f"unsupported accelerator ABI 0x{version:08x}; expected major {self.EXPECTED_ABI_MAJOR}")‘. Failing before DMA prevents malformed shapes or artifacts from silently becoming hardware results.

Line 145: `@property` This decorator changes how the following class or function is constructed. ‘@property‘ is applied at import time on the host and is part of the class NeuraEdgeDriver, which handles neura edge driver; it creates no FPGA circuit by itself.

Line 146: `def target_clock_hz(self) -> int:` This starts function target_clock_hz. Its indented body performs target clock hz as part of the file that controls the overlay, AXI-Lite registers, DMA allocation, packet partitioning, errors, and telemetry; it runs only when called.

Line 147: `return int(self.mmio.read(self.registers.target_clock))` This returns ‘int(self.mmio.read(self.registers.target to the caller of the function target_clock_hz, which handles target clock hz, ending this invocation. The important operands are mmio: the value named ’mmio’ in this block; read: the value named ’read’ in this block; registers: the value named ’registers’ in this block.

Line 149: `@property` This decorator changes how the following class or function is constructed. ‘@property‘ is applied at import time on the host and is part of the class NeuraEdgeDriver, which handles neura edge driver; it creates no FPGA circuit by itself.

Line 150: `def capabilities(self) -> int:` This starts function capabilities. Its indented body performs capabilities as part of the file that controls the overlay, AXI-Lite registers, DMA allocation, packet partitioning, errors, and telemetry; it runs only when called.

Line 151: `return int(self.mmio.read(self.registers.capabilities))` This returns ‘int(self.mmio.read(self.registers.capab to the caller of the function capabilities, which handles capabilities, ending this invocation. The important operands are mmio: the value named ’mmio’ in this block; read: the value named ’read’ in this block; registers: the value named ’registers’ in this block.

Line 153: `def status(self) -> int:` This starts function status. Its indented body performs status as part of the file that controls the overlay, AXI-Lite registers, DMA allocation, packet partitioning, errors, and telemetry; it runs only when called.

Line 154: `return int(self.mmio.read(self.registers.status))` This returns ‘int(self.mmio.read(self.registers.status))‘ to the caller of the function status, which handles status, ending this invocation. The important operands are mmio: the value named ’mmio’ in this block; read: the value named ’read’ in this block; registers: the value named ’registers’ in this block.

Line 156: `@staticmethod` This decorator changes how the following class or function is constructed. ‘@staticmethod‘ is applied at import time on the host and is part of the class NeuraEdgeDriver, which handles neura edge driver; it creates no FPGA circuit by itself.

Line 157: `def _signed32(value: int) -> int:` This starts function _signed32. Its indented body performs signed32 as part of the file that controls the overlay, AXI-Lite registers, DMA allocation, packet partitioning, errors, and telemetry; it runs only when called.

Line 158: `masked = int(value) & 0xFFFFFFFF` This assigns ‘int(value) & 0xFFFFFFFF‘ to ‘masked ‘ in host memory. Here masked means the value named ’masked’ in this block. The important operands are value: the value named ’value’ in this block. Context: the function _signed32, which handles signed32.

Line 159: `return masked - (1 << 32) if masked & (1 << 31) else masked` This returns ‘masked - (1 << 32) if masked & (1 << 31) else masked‘ to the caller of the function _signed32, which handles signed32, ending this invocation. The important operands are masked: the value named ’masked’ in this block.

Line 161: `def performance_snapshot(self) -> PerformanceSnapshot:` This starts function performance_snapshot. Its indented body performs performance snapshot as part of the file that controls the overlay, AXI-Lite registers, DMA allocation, packet partitioning, errors, and telemetry; it runs only when called.

Line 162: `"""Read one coherent-enough diagnostic snapshot while the core is idle."""` This is executable documentation attached to the function performance_snapshot, which handles performance snapshot. It states the intended contract that tests and callers should enforce, but the text itself does not transform data or issue hardware work.

Line 163: `if self.status() & (self.STATUS_BUSY | self.STATUS_PENDING):` This executes the following indented host-code branch only when 'self.status() & (self.STATUS_BUSY | self.STATUS_PENDING)' is true. The important operands are status: the value named 'status' in this block; STATUS_BUSY: the value named 'status busy' in this block; STATUS_PENDING: the value named 'status pending' in this block. Context: the function performance_snapshot, which handles performance snapshot.
